ABSTRACT BOOK

WORLD CONFERENCE ON LUNG HEALTH 2025 OF THE INTERNATIONAL UNION AGAINST TUBERCULOSIS AND LUNG DISEASE (THE UNION)

COPENHAGEN, DENMARK
18 – 21 NOVEMBER 2025

The Research Institute of Tuberculosis,
Japan Anti-Tuberculosis Association

Since its foundation in 1939, the mission of the Research Institute of Tuberculosis, Japan Anti-Tuberculosis Association (RIT/JATA) has been to contribute to domestic and global tuberculosis control by conducting various studies in broad fields, including basic science to clinical/epidemiological studies, providing technical support for national and local governments, public health centres, and medical facilities, as well as performing activities for international cooperation and collaboration.

Our Vision

A world where no one suffers from tuberculosis

Our Mission

Our mission is to eliminate TB suffering through the development and implementation of comprehensive TB control strategies.

The International Journal of Tuberculosis and Lung Disease

SUPPLEMENT 1

VOLUME 29 NUMBER 11 NOVEMBER 2025

The Union would like to thank the Research Institute of Tuberculosis, Japan Anti-Tuberculosis Association (RIT/JATA) for their support in publishing the Abstract Book for The Union World Conference on Lung Health.

SYMPOSIA

TUESDAY, 18 NOVEMBER 2025

S1 SY01-110-01 The Lancet Global Health Commission on medical oxygen security

S2 SY02-120-02 Expanding access to molecular testing for TB: Evidence, scope, and impact of specimen pooling strategies

S4 SY03-130-03 The urgent need for pragmatic clinical trials for new TB regimens: Considerations for design and conduct

S5 SY04-140-04 Innovative financing for TB programmes: Maximising resources in line with ambitious targets

S6 SY05-150-05 Drug-drug interactions in TB management: What every clinician should know

WEDNESDAY, 19 NOVEMBER 2025

S8 SY06-160-06 Progress towards a PAN-TB regimen: Insights from the PAN-TB collaboration's XBQS phase 2b/c Trial

S9 SY07-170-07 Aligning priorities: Integrating TB and maternal health for better outcomes

S11 SY08-180-08 Crossing borders: Addressing TB in migrant and refugee populations

S12 SY09-190-09 How to improve trials and development, and ensure uptake, of innovations to prevent, diagnose, and treat TB

S13 SY10-200-10 Uniting voices for equitable TB care in Europe: Advancing people-centred diagnosis and treatment

S15 SY11-210-11 Generating evidence: A call to action for the optimal inclusion of pregnant and lactating women in TB clinical research

S16 SY12-220-12 How can asymptomatic TB help the development and global impact of new TB vaccines?

S18 SY13-230-13 Innovative TB screening and diagnosis at healthcare facilities to find the missed millions: Evidence from four high-burden TB countries

S19 SY14-240-14 Delivering multi-drug-resistant TB services in war and complex emergencies: A joint symposium with IOM, MSF, The Union, and WHO

THURSDAY, 20 NOVEMBER 2025

S21 SY15-250-15 The paediatric TB meningitis SURE trial: What have we learnt?

S22 SY16-260-16 CAD-supported chest radiography for TB screening and diagnosis in children as well as young adolescents: Key advances and remaining gaps

S24 SY17-270-17 Tomorrow is here: Innovative financing for the future of TB funding

S25 SY18-280-18 Optimising TB screening as a critical gateway to TB care: Recent advances in available and emerging tools and technologies

S27 SY19-290-19 Emerging data in maternal and infant TB

S28 SY20-300-20 Impact of recent and expected reductions in international donor funding for TB prevention and care

S30 SY21-310-21 Investment case: Why community engagement is critical to ending TB

S31 SY22-320-22 Charting the course of post-TB lung health and well-being: Advances and opportunities in the field

S32 SY23-330-23 Beyond explanatory phase III adult trials: Innovative TB treatment trials for effectiveness in programmatic settings and inclusion of priority populations

S34 SY24-340-24 Unveiling TB narratives: The power of storytelling

S35 SY25-350-25 Implementation research to prepare for the introduction of new TB vaccines for adults and adolescents

FRIDAY, 21 NOVEMBER 2025

S36 SY26-360-26 A world without TB must not be a world without ethics: The AI dilemma

S37 SY27-370-27 Bridging the gap: Accelerating development and approval of priority formulations for children with TB

S39 SY28-380-28 Global political and financial shifts: Impact on TB communities and a collective action response

S40 SY29-390-29 Addressing TB in migrant populations: Challenges, evidence, and strategies for action

S42 SY30-400-30 Accelerating the introduction of new sample types and near point of care platforms to close gaps in TB diagnosis

S43 SY31-410-31 It takes a village: Advancing late-stage TB vaccine trials in adults and adolescents through global collaboration

S44 SY32-420-32 Ensuring global access to shorter, better regimens for multi-drug-resistant/rifampicin-resistant TB for children, adolescents and pregnant women

S46 SY33-430-33 Lymph node TB: Identifying priorities, challenges, and finding better treatments faster

S47 SY34-440-34 Generating social science evidence alongside TB trials: Opportunities and impacts

S49 SY35-450-35 TB in an era of arctic self-determination

S50 SY36-460-36 Scaling-up community-wide TB screening irrespective of symptoms: Recognising and overcoming the barriers

S52 SY37-470-37 A forgotten population: Finding TB and disparities within prisons

ABSTRACT PRESENTATIONS

TUESDAY, 18 NOVEMBER 2025

ORAL ABSTRACT SESSIONS

S53 OA01 Forgotten lungs: Emerging from the shadow of TB, silicosis, and NTM

S59 OA02 Life after TB

S66 OA03 Innovations in assessing TB transmission across different settings

S73 OA04 TB and co-morbidities

S81 OA05 It takes a village: Improving prevention and detection of TB among children

SHORT ORAL ABSTRACT SESSIONS

S87 SOA01 Maternal, child, and adolescent TB care: Prevention, diagnosis and treatment

S94 SOA02 Eyes on the Unseen: Leveraging data, tech, and community in finding the missing people with TB

MODERATED E-POSTER SESSIONS

S102 EP01 Next-gen technology for TB: Bridging the gaps in surveillance, diagnosis, and treatment

S108 EP02 Diagnostic networks in TB: Optimisation through innovation

S114 EP03 Childhood TB: Prevention and treatment for drug-susceptible and resistant TB

S120 EP04 Strenghtening laboratory systems for TB management

S126 EP05 Childhood TB: Diagnosis and case-finding

S132 EP06 Pregnancy: M. tuberculosis infection, TB diagnosis and treatment

S139 EP07 Measuring what matters: Prevalance, adherence and the human dimensions of TB care

S147 EP08 TB treatment risks uncovered: Tackling adverse drug events and drug interactions

S153 EP09 Training & education to end TB

WEDNESDAY, 19 NOVEMBER 2025

ORAL ABSTRACT SESSIONS

S161 OA06 Genotypic and phenotypic resistance testing for TB

S167 OA07 Diagnosing and treating drug-resistant TB

S175 OA08 Preventing TB by addressing the gap

S181 OA09 Finding TB in key vulnerable populations

S187 OA10 Just the two of us: The continuum of maternal and early childhood TB

S193 OA11 Life after TB: Priorities and opportunities in post-TB health and wellbeing

S201 OA12 Navigating TB therapy: Side effects, adverse events and tolerability

S208 OA13 Optimising community-based TB screening and finding people with TB

S214 OA14 Predicting TB: New disease, reinfection and relapse

S220 OA15 Differentiated service delivery in precarious conditions

SHORT ORAL ABSTRACT SESSIONS

S226 SOA03 Refining the performance of computer-assisted TB diagnostics

S233 SOA04 Innovative programmatic approaches to eliminate TB

S240 SOA05 Surveillance in the digital age

S248 SOA06 Window of opportunity: Integrated service delivery for co-morbidities

S254 SOA07 Managing drug-resistant TB in the 21st century: Data, diagnostics and delivery

MODERATED E-POSTER SESSIONS

S262 EP10 Enhanced TB detection: Integrating digital radiography with other tools

S267 EP11 From mines to clinics, securing lung health in high-risk occupations

S271 EP12 Leveraging AI across the TB care cascade: From hotspot detection to treatment success

S278 EP13 Electrifying TB: Using digital tools across the care cascade

S284 EP14 Enhancing TB diagnosis and case finding among children

S290 EP15 Prevent to end: Catalysing implementation of TB preventive treatment

S294 EP16 Finding the missing people with TB: Lessons learned from and across Nigeria

S301 EP17 Improving diagnostic yield for TB: Methods and innovations

S307 EP18 PLHIV - the continuum of TB care (prevention, diagnosis, treatment and post-treatment)

S312 EP19 Adult lung - burden and care of lung conditions

S319 EP20 Messaging that matters: Effective communication for TB elimination

S325 EP21 TB contact screening across the age spectrum

S331 EP22 The challenge of extrapulmonary TB

S336 EP23 Unravelling Progress: The fallout of donor funding and accountability

S340 EP24 Frontiers in immunology and biomarkers - infection, disease risk and treatment monitoring

S346 EP25 Community wide systematic screening: Programmatic considerations

S351 EP26 Finding the missing millions: A focus on key populations

S356 EP27 Cracking the code on TB surveillance

THURSDAY, 20 NOVEMBER 2025

ORAL ABSTRACT SESSIONS

S362 OA16 Reaching the hard-to-reach: Increasing access and uptake

S368 OA17 TB screening and finding TB in marginalised populations

S373 OA18 Building sustainable systems and workforce

S378 OA19 It's all about the money: Optimising TB care

S385 OA20 Prevalence surveys (TB disease and M. TB infection) and transmission studies

S391 OA21 Breaking the TB poverty cycle: Tackling inequality, financial burden and policy gaps for people-powered solutions

S397 OA22 Understanding the impact of case finding modalities: From the facility to the population

S403 OA23 Prevention, diagnosis, and treatment for people living with HIV

S410 OA24 Sustainability in demand: Feasibility, acceptability, cost effectiveness, and TB care approaches

SHORT ORAL ABSTRACT SESSIONS

S417 SOA08 New TB diagnostics in the pipeline

S424 SOA09 Communities at the centre: Driving TB awareness, support, and science

S431 SOA10 Reducing risk for close contacts of people with TB: Find, treat, prevent

S438 SOA11 Bridging gaps in TB care: AI solutions for high-risk populations

S445 SOA12 Making it work for us: Community-led programme design

S453 SOA13 Feeding recovery, fueling hope: Nutrition's central role in TB elimination

MODERATED E-POSTER SESSIONS

S463 EP28 Advances in diagnosis, epidemiology and management of non-tuberculous mycobacterial disease

S467 EP29 Breaking the cycle of M. tuberculosis infection

S473 EP30 Economic evaluations to improve TB care

S479 EP31 Everyone exposed deserves a chance: Contact investigation as a gateway to prevention

S484 EP32 Building capacity in systems and people to deliver person-centred care

S490 EP33 Characterising the drivers and impacts of TB-related stigma across different contexts

S496 EP34 Advanced tools and strategies to enhance detection

S502 EP35 Integrating systems to improve TB care outcomes

S508 EP36 TB and comorbidities including mental health

S514 EP37 Beyond the cure: Addressing TB sequelae, relapse and reinfection in long-term health

S518 EP38 Uniting forces: Collaborative strategies and policies driving TB progress

S523 EP39 Engaging private sector to innovate finding TB

S530 EP40 Burning planet, broken systems: Addressing TB at the crossroads of climate inequality

S536 EP41 What do you need? Innovation to realise the delivery of person-centred care

S543 EP42 Innovating TB care: Triage, technology, mobility and workforce solutions for better outcomes

S548 EP43 Diabetes and ageing in TB: Breaking barriers to better care

S553 EP44 Harnessing Innovation: AI, breathomics, and data science for the future of TB detection, prevention and care

S558 EP45 Innovating multi-sectoral engagement to improve TB care

FRIDAY, 21 NOVEMBER 2025

ORAL ABSTRACT SESSIONS

S565 OA25 Enhancing TB detection and diagnostics in public and private settings

S572 OA26 Advancing TB care: Innovations in drugs, vaccines, diagnostics and treatment

S580 OA27 Institutional hotspots: Addressing TB transmission in hospitals and prisons

S587 OA28 Lung health in children and adolescents

S593 OA29 Equity at the doorstep: Community health workers for lung health

S598 OA30 Environmental determinants of lung health: From fossil fuel to filter tips

S604 OA31 Informing evidence-based TB policies

S611 OA32 Person-centred quality care for all

S617 OA33 The future of TB screening: Integrating AI, economic modelling, and community-based approaches

S623 OA34 From households to health systems: Innovations, ethics, and integration in TB prevention and contact care

S630 OA35 Tiny-people, big challenges: Emerging diagnostics for paediatric TB

SHORT ORAL ABSTRACT SESSIONS

S637 SOA14 A taste for something new: Innovative sampling for mycobacterial testing

S644 SOA15 Zero deaths? Hope dims with funding cuts

S652 SOA16 Geospatial analytics and mapping for TB prevention, detection and care

S658 SOA17 Innovations and insights in tobacco control: From community action to policy reform

MODERATED E-POSTER SESSIONS

S663 EP46 Asymptomatic TB - reports from the field

S669 EP47 Enhancing TB care: Innovations in drug therapy, pharmacokinetics and treatment strategies

S675 EP48 Surveillance of drug-resistant TB

S682 EP49 Journeys through TB: Stories of hope, resilience and recovery

S688 EP50 Sick because they are poor: Undernutrition poverty and the TB crisis

S693 EP51 Finding those missing: Responding to differentiated screening need

S698 EP52 Preventing and finding TB in children and household contacts

S703 EP53 Mobilising communities: The heartbeat of TB response

S708 EP54 Understanding tobacco use in a changing world: Insight on policy, risk and communication

S713 EP55 Novel diagnostics and treatment monitoring methods

S719 EP56 From policy to practice: Strategic alignment to fight TB

S725 EP57 Rapid diagnostic and resistance testing

S730 EP58 Outcomes of drug-resistant TB

S736 EP59 Digital and AI-driven approaches to integrated TB and respiratory health management

S743 EP60 Innovations in TB Modelling for vaccination, diagnosis and treatment

S747 EP61 Bold actions advancing TB elimination

S752 EP62 M. tuberculosis infection and preventive treatment

S758 EP63 TB uncovered: Advocacy and awareness in action

LATE-BREAKER PRESENTATIONS

TUESDAY 18 NOVEMBER 2025

S764 LB01 RIT/JATA Student Late Breaker Session on Lung Health

WEDNESDAY 19 NOVEMBER 2025

S773 LB02 The Union/CDC Late-Breaker Session - Clinical Trial Advances in TB: HIV Co-Infection, Pediatric Meningitis, and New Drugs

COMMUNITY CONNECT SESSIONS

S943 CCS001 Community-driven TB stigma reduction initiatives in high- burden TB settings: Lessons learned

S944 CCS002 Catalysing community power: Driving demand and accountability in drug-resistant TB care

S945 CCS003 Lives on hold: The impact of the TB funding crisis from global to grassroot

S946 CCS004 Community pharmacists as enablers of equitable TB care and referral in India

S947 CCS005 From Awareness to Ownership: Institutionalizing Community Capacity to End TB

S948 CCS006 Understanding the principles, building blocks and priority investment areas to realise stronger and sustainable community systems to end TB: Launching a new Stop TB Partnership Community Support Package

S949 CCS007 „There'll be dragons": Untangling stigma and discrimination

S950 CCS008 Trust, tools and TB: Community-led solutions for local challenges

S951 CCS010 Reaching the hardest to reach populations: Results from prioritised TB key and vulnerable population size estimations in 12 countries

S952 CCS011 Communities first: Building responsive systems for a TB-free future

S953 CCS012 Leveraging AI and lung health innovation to reach the unreached

S954 CCS013 Youth-led initiatives and using technology to drive access to better TB service and treatments

S955 CCS014 Power, policy and people: Mobilising political will and resources to end TB

S956 CCS015 Integrating gender-related knowledge into the national medical training curriculum and healthcare workplace practices

S957 CCS016 Climate, conflict and care: Building TB programme resilience in an era of instability

S958 CCS017 Engaging lawmakers and judges in Anglophone Africa to promote accountability, access to justice and rights-based laws in the TB response

S959 CCS018 Advocating integration: Civil society's role in transforming health systems for UHC

S960 CCS019 From fragility to force: Community resilience and leadership amid TB funding shifts

S961 CCS021 Empowering communities: Our children should not die of TB!

S962 CCS022 From research conceptualisation to scientific publication: A community actor's journey with TB research

S963 CCS023 Generating community demand for the best available treatments and comprehensive packages of care for drug-resistant tuberculosis

S964 CCS024 Art, AI-enabled X-rays and partnerships in the fight against TB

MANUSCRIPTS AND CORRESPONDENCE
Director of Publications: Hugh Blackbourn Editorial Coordinator: Rasha Jerandi Technical Editor: Irene Roy E-mail: journal@theunion.org

EDITORIAL OFFICE
The International Union Against Tuberculosis and Lung Disease (The Union) 2, rue Jean Lantier, 75001 Paris, France
e-mail: journal@theunion.org website: www.theunion.org

AIMS AND SCOPE
The International Journal of Tuberculosis and Lung Disease is an official journal of The Union. The Journal's main aim is the continuing education of physicians and other health personnel, and the dissemination of the most up-to-date information in the feld of TB and lung health. It publishes original articles and commissioned reviews not only on the clinical and biological and epidemiological aspects, but also on community aspects: fundamental research and assessment of field projects and action programmes for TB control and the promotion of lung health. The Journal welcomes articles submitted on all aspects of lung health, including cost-benefit analysis, legislation, epidemiology, intervention studies and health systems research.

DISCLAIMER
Any opinions expressed, or policies advocated, do not necessarily reflect those of The Union.

SUBSCRIPTION INFORMATION
The International Journal of Tuberculosis and Lung Disease is published monthly by The Union. For subscription information, please contact: subscription@theunion.org

INSTRUCTIONS TO AUTHORS
Instructions on manuscript submission can be obtained from the Union website www.theunion.org.

ADVERTISING SALES
Contact journal@theunion.org

EXCESS PAGE CHARGES
All articles over length will be subject to an excess page charge (see Instructions to authors and website).

FULL TEXT VERSION ONLINE
The full text of the Journal is published online as of Volume 1, 1997. Free access to back issues.
Address: www.theunion.org or www.ingentaconnect.com

INDEXING AND ABSTRACTING SERVICES
The Journal is indexed and/or abstracted in the following media: PubMed/Medline, CLOCKSS, Current Contents/Clinical Medicine, Excerpta Medica/EMBASE, the Global Health and CAB Abstracts databases, Index Medicus, Google Scholar, ISI Alerting Services, LOCKSS, the Science Citation Index, SciSearch and the SIIC databases.

SYMPOSIA

SY01-110-01 The Lancet Global Health Commission on medical oxygen security

Chair: Rebecca Nantanda, Makerere University Lung Institute, College of Health Sciences Makerere University, Kampala, Uganda
Chair: Carina King, Karolinska Institutet, Stockholm, Sweden

The Lancet Global Health Commission on Medical Oxygen Security was published in February 2025 with the first estimates of the number of patients needing medical oxygen by region and type of need (acute, surgical, long-term, and COVID), and the quantities needed. The report also estimated the size of the access gaps for pulse oximetry and medical oxygen and the cost of filling the gaps by region. The Commission produced new tools for governments and global health agencies, including 10 oxygen coverage indicators, a scorecard to measure national progress, 20 areas for innovation, and priorities for future research. The Commission's 52 recommendations call for measurable actions for specific stakeholders.
This session will communicate the findings of the Commission and engage the audience the implementation of the recommendations to save lives now and prepare for the next pandemic.

The Lancet Global Health Commission on Medical Oxygen Security: Findings and recommendations

C King,[1] [1]Karolinska Institutet, Stockholm, Sweden.
e-mail: carina.king@ki.se

The presentation will address the major findings and recommendations from the Lancet Global Health Oxygen Commission, and describe the new tools developed to help health facilities, governments, and global health agencies measure progress to universal access to pulse oximetry and medical oxygen. These tools include oxygen coverage indicators, a national scorecard, and priority areas for oxygen innovation and research.
The presentation will engage the audience in the specific actions required to implement the Commission's recommendations and how they can contribute to transforming access to oxygen - a neglected area of lung health affecting many infectious and chronic respiratory conditions.

The vital role of pulse oximetry as the gateway to safe, effective, and appropriate medical oxygen services

E McCollum,[1] [1]Johns Hopkins University School of Medicine, Baltimore, United States.
e-mail: emccoll3@jhmi.edu

The presentation will provide a thorough exploration of the findings and recommendations of the Lancet Global Health Oxygen Commission relating to pulse oximetry. The Commission found that pulse oximetry was done in only 19% of people presenting to general hospitals in LMICs, and almost never done at primary health-care facilities, and that this lack of access was the fundamental barrier to safe, effective, and appropriate medical oxygen services.
The presentation will also discuss other critical issues, including the accuracy of pulse oximeters on darker skin tones and in infants and young children.

Long-term oxygen therapy for people with chronic needs: Addressing a neglected and rapidly growing population

N Navuluri,[1] [1]Duke University School of Medicine, Durham, United States.
e-mail: neelima.navuluri@duke.edu

The large and growing number of individuals needing long-term oxygen therapy to manage chronic lung conditions will continue to place great demands on health systems, especially those in low- and middle-income countries (LMICs). Lack of data, especially from LMICs,

hampered efforts by the Lancet Global Health Commission to examine barriers to oxygen access for this group and recommend remedial action.
This presentation will describe the Commission's findings with respect to patients needing long-term oxygen therapy and discuss emerging research to better understand how to meet the long-term oxygen needs of patients with chronic conditions.

Oxygen for essential emergency and critical care, including during pandemics and other health emergencies

T Baker,[1] [1]Muhimbili University of Health and Allied Sciences, Dar es Salaam, Tanzania.
e-mail: tim.baker@ki.se

The massive need for medical oxygen to treat critically ill patients and for surgery was documented by the Lancet Global Health Oxygen Commission alongside large gaps in access in low-resource settings; gaps which grew exponentially during COVID-19 and led to many health systems running out of oxygen.
This presentation will explore current trends in essential emergency and critical care and how oxygen access be guaranteed in low-resource health facilities. Recent research from The African Critical Illness Outcomes Study (ACIOS): a point prevalence study of critical illness in 22 nations in Africa, will also be presented.

Closing pulse oximetry and medical oxygen access gaps across Africa: What will it take?

R Nantanda,[1] [1]Makerere University Lung Institute, College of Health Sciences Makerere University, Kampala, Uganda.
e-mail: rnantanda@gmail.com

The Lancet Global Health Oxygen Commission highlighted the widest gaps in access to pulse oximetry and medical oxygen across Africa,with nine in every ten patients needing oxygen for acute care unable to access it.
This presentation will explore the specific barriers to pulse oximetry and oxygen coverage across the continent and discuss strategies to close the gaps. Emerging research on the burden of conditions requiring oxygen among children and adults in Africa will be discussed.

SY02-120-02 Expanding access to molecular testing for TB: Evidence, scope, and impact of specimen pooling strategies

Chair: Jacob Creswell, Stop TB, Geneva, Switzerland
Chair: Mohammed Yassin, Global Fund to fight AIDS, Tuberculosis and Malaria, Geneva, Switzerland

In 2023, less than half of people with TB received an initial rapid molecular diagnostic (RMD) test. Specimen pooling can expand access to RMD, combating high costs, supply limitations, and funding constraints. With TB and infectious diseases expertise, pooling is set for WHO guidelines evaluation. This symposium highlights innovative use of specimen pooling in TB diagnosis, particularly focusing on experiences from Bangladesh, Brazil, Cameroon, Kenya, Malawi, Nigeria, and Vietnam. Presentations will cover a range of insights from the operational feasibility and acceptability of pooling sputum samples, to the experiences and outcomes of implementing these strategies in programmatic settings.
Two presentations will share the latest evidence on accuracy of pooling from a large implementation study and from a systematic review. The discussions will also navigate the potential risks, future opportunities, and necessary considerations for scaling up pooling in TB diagnostics worldwide.

Increasing access to rapid molecular detection of TB with pooled testing of specimens from multiple individuals in Cameroon

V Donkeng Donfack,[1] [1]Centre Pasteur du Cameroun, Yaounde, Cameroon.
e-mail: donkeng@pasteur-yaounde.org

In Cameroon, pooled testing has been used as a strategy to increase access to rapid molecular diagnostics since 2020. Specimens from more than 80,000 people have been tested using this approach, as part of TB REACH activities and also in routine testing. Approximately twice as many people have been able to access a rapid molecular test with pooled testing as compared to individual testing.
We will describe results to date, as well as the perspectives of laboratory personnel, clinicians, and decision makers on the use of pooled testing for TB in this setting.

Evaluating the feasibility and acceptability of pooled testing for TB screening: A qualitative study across seven high-burden, low- and middle-income countries

V Iem,[1] [1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom.
e-mail: vibol.iem@lstmed.ac.uk

Pooled testing, where multiple samples are combined and tested with a single test, was explored across seven high-TB burden countries to assess its acceptability and feasibility for TB screening. Data were collected through key informant interviews and focus group discussions with healthcare workers, people with TB, and stakeholders. Participants expressed mixed views.
While some saw pooling as cost-effective and practical in resource-limited settings, others raised concerns about operational complexity, accuracy, and delays. Feasibility depended on training, infrastructure, and workflow alignment. Acceptability was influenced by clarity of procedures and confidence in results. With proper support, pooled testing could enhance TB screening.

Testing more for less: evidence on pooling specimens for molecular testing at healthcare facilities and by active case finding in communities across seven high-burden countries

T Garg,[1] [1]Stop TB Partnership, Geneva, Switzerland.
e-mail: tusharg@stoptb.org

Specimen pooling can expand access to rapid, molecular diagnostics and overcome persistent challenges posed by high costs and supply-chain limitations.
We present results from the Start4All study which recruited individuals at primary and secondary level facilities, and through active case finding (ACF) in Bangladesh, Brazil, Cameroon, Kenya, Malawi, Nigeria, and Vietnam.

Mass testing, smarter strategies: The case for sputum pooling for TB prevention and care among vulnerable populations

B Duarte,[1] [1]Institute of Research in Priority Populations (IRPP), Salvador, Brazil.
e-mail: beatriz.duarte@monsterinitiative.com

This presentation explores the potential of pooled sputum testing as a cost-effective and scalable strategy for tuberculosis (TB) diagnosis in vulnerable populations. We present the results of a systematic review and meta-analysis evaluating the diagnostic accuracy, efficiency, and limitations of pooling strategies.
In parallel, we share findings from a real-world mass screening initiative conducted in a high-burden, underserved setting of Brazil. By combining global evidence with field experience, this talk highlights the feasibility and impact of pooled testing in resource-limited contexts, offering practical insights into implementation and policy development for more equitable TB control.

SY03-130-03 The urgent need for pragmatic clinical trials for new TB regimens: Considerations for design and conduct

Chair: Christian Lienhardt, French Institute for Research on Sustainable Development (IRD), Montpellier, France
Chair: Gavin Churchyard, The Aurum Institute, Isando, South Africa

Pragmatic trials bridge the gap between controlled clinical trials and real-world application. These trials assess how regimens proven efficacious in highly controlled, explanatory settings perform in diverse clinical environments, while retaining randomization as the gold standard tool for evidence generation. By evaluating the relevance and scalability of these regimens (or variations thereof) across diverse settings and populations, pragmatic trials play a major role in informing strong recommendations in international and national guidelines and drive broader adoption.
The objective of this session is to establish the rationale for pragmatic TB trials, explore practical considerations for their design and execution, and present case studies of ongoing and planned trials.
Join us to discover how pragmatic trials are transforming TB treatment and shaping the future of global health!

Pragmatic trials and streamlined trials: What are they and why do we need them in TB?

S Schumacher,[1] [1]World Health Organization, Geneva, Switzerland.
e-mail: schumachers@who.int

Pragmatic, streamlined trials have demonstrated their value in generating large-scale, high-quality evidence rapidly and at relatively low cost in the context of COVID-19 and other diseases. In this session, Dr. Schumacher will outline the defining features of this trial approach and explain its strong potential for evaluating both existing and novel tuberculosis treatments. He will also examine the limitations of the current evidence base supporting TB treatment guidelines and discuss how pragmatic trials—aligned with recently released WHO 'Guidance on evidence generation'—can support more robust and actionable global recommendations.

Maximising both internal *and* external validity: Practical design considerations for pragmatic TB trials

P Phillips,[1] [1]University of California San Francisco, San Francisco, United States.
e-mail: patrick.phillips@ucsf.edu

There is a false perception that clinical trials with high internal validity must sacrifice generalizability (external validity) and operational research studies that prioritize pragmatic generalizability necessarily lack rigor.
In this talk, Dr. Phillips will talk about design and conduct considerations for pragmatic TB trials that maximize both internal and external validity, presenting options and highlighting advantages and limitations. Dr. Phillips will use the PRECIS-2 tool as a framework for discussion.

A pragmatic trial of high-dose rifampicin in India

G Narendran,[1] [1]National Institute for Research in Tuberculosis, ICMR, Chennai, India.
e-mail: gopalannaren@yahoo.co.in

In this talk, Dr. Narendran will present the pragmatic trial for high-dose rifampicin regimens for the treatment of TB that will be conducted in India. Dr. Narendran will present data on relevant results from recent high-dose rifampicin trials in India and worldwide, describing the rationale and key design and conduct aspects for the forthcoming trial.

The 4MOR trial: Evaluating HPMZ in a pragmatic cluster-randomised trial

S. Wasserman[1] [1]St Georges University London / University of Cape Town, London, United Kingdom.
e-mail: swasserm@sgul.ac.uk

In this talk, Dr Wasserman will present the pragmatic cluster-randomized trial for a four-month rifapentine-moxifloxacin regimen for the treatment of TB (4MOR) that will be conducted in South Africa and Zimbabwe.
Dr. Wasserman will present relevant recent data, describe the rationale and key design and conduct aspects for the forthcoming hybrid effectiveness-implementation trial.

Panel discussion on pragmatic TB trials: Charting the way forward

P Discussion,[1] [1]Mixed, Mixed, Switzerland.
e-mail: schumachers@who.int

We will finish the session with a panel discussion including chairs, speakers, and experts from the field. The panel will add additional perspectives on pragmatic TB trials, commenting on the future and taking questions from the floor.
Additional experts include Oxana Rucsineanu, co-chair of the Global TB CAB; Dr. Francesca Conradie, a pragmatic trialist from the University of Witwatersrand; Dr. Sean Wasserman who is leading a pragmatic trial to be conducted across four countries; and Dr. Wenhong Zhang who runs a pragmatic clinical trials platform for TB treatment in China.

SY04-140-04 Innovative financing for TB programmes: Maximising resources in line with ambitious targets

Chair: Lucica Ditiu, Stop TB Partnership, Switzerland
Chair: Yogan Pillay, Gates Foundation, South Africa

In light of the sharp decline in traditional Development Assistance for Health (DAH), this session will explore the options for generating sufficient financing for TB prevention and care, consistent with eliminating TB at country level while increasing national self-reliance and resilience. It will explore prospects for increasing domestic funding and the roles to be played by Multilateral Development Banks (MDB), the Global Fund, private or corporate philanthropy, and innovative debt-for-health arrangements. Speakers will draw on recent experiences in Nigeria, Indonesia, India and other countries to explore lessons and identify practical opportunities for innovative financing models.

The Global Fund perspective on sustaining financing for TB elimination at the country level

E Wandwalo,[1] [1]The Global Fund to Fight HIV, TB and Malaria, Geneva, Switzerland.
e-mail: eliud.wandwalo@theglobalfund.org

Faced with the prospect of severely constrained resources in GC8, how will the Global Fund leverage its budgets to maximize available funding for TB in high-burden countries?
The presentation will outline changes to the Global Fund's policies and practices with respect to matching funds requirements, eligibility transition, innovative financing approaches, and partnership with private philanthropy and multilateral development banks.

The role of multilateral development banks in financing for TB elimination at the country level

P Harimurti,[1] [1]World Bank, Indonesia.
e-mail: pharimurti@worldbank.org

In recent years, based on demand from client countries, most Multilateral Development Banks have tended to focus on system-wide health investments. This presentation will discuss the challenges and opportunities for leveraging such investments to drive TB-specific outcomes. It will also discuss lessons learned from recent TB-specific operations by the World Bank in Southern Africa, India and Indonesia, and the prospects for further such investments in high-burden countries facing a reduction in offi-

cial TB grants. The presentation will discuss opportunities for innovative financing, including buy-downs to enable high burden TB countries to implement high impact interventions at scale.

The potential role of debt-for-health transactions in financing for TB elimination at the country level

R Hurley,[1] [1]South Africa.
e-mail: raphael.hurley@gmail.com

This presentation will review the experience, strengths and limitations of traditional bilateral debt-for-health transactions for TB. It will describe the key features of the new generation of "trilateral" debt swaps on commercial claims, which generated close to US$ 1 billion of funding mainly for nature conservation in the last quarter of 2024 alone, and discuss the challenges and opportunities for TB programs to possibly benefit from this new mechanism.

The role of private and corporate philanthropy and investments in financing for TB elimination at the country level

E Dawodu,[1] [1]Anadach Consulting, Lagos, Nigeria.
e-mail: eosifodawodu@anadach.com

This presentation will discuss opportunities and challenges in raising funds for TB programs from domestic corporate and private philanthropic sources. It will review progress and lessons learned in Nigeria, where in July 2024 private sector partners pledged to raise $25m for TB as a match to the Federal Ministry of Health, and place this experience in the context of similar efforts in South Africa, India and elsewhere. It will assess the scope and the constraints to emerging innovative models of private financing.

Lessons from Indonesia's experience with mobilisation of domestic resources for TB

L Andalusia,[1] [1]Ministry of Health of the Republic Indonesia, Indonesia.
e-mail: lucia.randalusia@kemkes.go.id

Governments of TB High-Burden Countries are responding to cuts in international funding for TB programs by mobilizing increased domestic resources in the context of their own fiscal constraints. TB is among the top health priorities of the Government of Indonesia.
This presentation will review lessons from Indonesia's experience in mobilizing increased budgets for TB, including from sub-national governments, social health insurance, debt swaps and the private sector.

SY05-150-05 Drug-drug interactions in TB management: What every clinician should know

Chair: David Burger, RadboudUMC, Nijmegen, The Netherlands, Nijmegen, Netherlands

Management of drug-drug interactions (DDIs) in patients with tuberculosis (TB) is an important aspect of the clinical management of these patients worldwide. Rifampicin is without doubt the agent that causes most DDIs with a variety of co-administered agents, but for instance isoniazid and bedaquiline are also not without DDI issues.
Clinical decision support systems generate many DDI signals, but it is difficult for clinicians to judge which signals are clinically relevant, resulting in 'alert fatigue'. In some settings, clinical decision support systems may not be present and clinicians rely on publicly available (on-line) sources of DDI information. Many DDI sources are generic and not specifically built for TB patients, and not always take into account the complexity of TB treatment.
In this Symposium, we aim to give clinicians and pharmacists more guidance to optimize DDI management in patients with TB.

INSTI-based cART + HRZE for people with TB/HIV infection: New data changing policy

K Dooley,[1] [1]Vanderbilt University School of Medicine, Nashville, United States.
e-mail: kelly.e.dooley@vumc.org

The presentation on INSTI-based combination antiretroviral therapy (cART) in TB/HIV-infected patients highlights the efficacy and safety of integrase strand transfer inhibitors (INSTIs) in managing co-infection. It discusses the challenges of treating patients with both tuberculosis (TB) and HIV, including drug interactions and the impact on treatment adherence.
The presentation presents clinical trial data demonstrating that INSTI-based regimens can achieve viral suppression while minimizing adverse effects. Additionally, it emphasizes the importance of early diagnosis and integrated care approaches to improve patient outcomes in this vulnerable population, advocating for further research to optimize treatment strategies.

QTc-interval prolongation in people on bedaquiline and other TB drugs: A perfect storm or a tempest in a teacup?

I Monedero-Recuero,[1] [1]The Union / Action Damien, Vilanova i la Geltrú, Spain.
e-mail: monederoi@hotmail.com

The introduction of novel and repurposed anti-tuberculosis (TB) drugs, including bedaquiline, delamanid, and fluoroquinolones, raised significant concerns about QTc interval prolongation and the risk of life-threatening arrhythmias. A 2018 critical review concluded that the risk of inadequately managed drug-resistant TB (DR-TB) far outweighed the risk of arrhythmias.
This pioneering study established the clinical relevance of QTc prolongation, identified key risk factors, and proposed mitigation strategies. Subsequent research has reinforced these findings, leading to the use of three QTc-prolonging drugs in the current DR-TB standard of care. While severe cardiac events remain rare, careful assessment is essential for certain high-risk patients.

TB and diabetes mellitus: Drug-drug interactions in two colliding epidemics

R Rovina,[1] [1]Universitas Padjadjaran, Bandung, Bandung, Indonesia.
e-mail: rovina.ruslami@unpad.ac.id

The presentation on tuberculosis (TB) and diabetes mellitus explores the complex interplay between these two epidemics and their drug-drug interactions. It highlights how diabetes can exacerbate TB outcomes, complicating treatment regimens. The discussion includes the pharmacokinetic and pharmacodynamic interactions between antidiabetic medications and anti-TB drugs, which may affect efficacy and safety.
The presentation emphasizes the need for careful monitoring and individualized treatment plans to manage both conditions effectively. It advocates for integrated healthcare strategies that address the dual burden of TB and diabetes, aiming to improve patient adherence and overall health outcomes in affected populations.

Depression and TB: Double trouble?

R Aarnoutse,[1] [1]Radboudumc, Nijmegen, Netherlands.
e-mail: rob.aarnoutse@radboudumc.nl

Depression and tuberculosis (TB) create a complex health challenge, often referred to as a "syndemic" due to their synergistic effects. Depression is prevalent among TB patients, exacerbating morbidity, mortality, and drug resistance, while also increasing the risk of TB reactivation and transmission. The bidirectional relationship between these conditions is influenced by biological factors such as immune response dysregulation and psychosocial factors like stigma and treatment non-adherence.
Addressing this syndemic requires integrated care approaches that combine mental health and TB treatment to improve patient outcomes and support global TB elimination efforts.

SY06-160-06 Progress towards a PAN-TB regimen: Insights from the PAN-TB collaboration's XBQS phase 2b/c Trial

Chair: David Holtzman, Gates Medical Research Institute, Cambridge, United States
Chair: Morounfolu Olugbosi, TB Alliance, Sandton, South Africa

New treatment options are urgently needed to simplify treatments for people with TB and health systems delivering their care. The PAN-TB Collaboration focuses on developing new, shorter regimens that treat drug-sensitive and drug-resistant TB (pan-TB). The PAN-TB trial is a two-stage, Phase 2b/c randomized controlled trial launched in July 2023 evaluating bedaquiline, quabodepistat, and sutezolid with delamanid or pretomanid. The trial introduced important innovations:
Staged design to assess treatment-shortening potential in a stepwise manner
Incorporation of typical Phase 3 endpoints (unfavorable outcome and durable cure utilizing whole genome sequencing) into Phase 2
A person-centered approach to TB care
Evaluation of multiple exploratory lab-based and clinical biomarkers
The symposium's overall objective is to contribute to the TB regimen development community's efforts to develop new TB drugs and regimens by presenting the final PAN-TB trial results and key learnings from the innovations implemented. Trial data will be available by Q3-2025.

When things don't PAN out: Results from the PAN-TB randomised controlled, treatment-shortening clinical trial

R Dawson,[1] [1]University of Cape Town Lung Institute, Mowbray, South Africa.
e-mail: rodney.dawson@uct.ac.za

The PAN-TB trial evaluated two investigational regimens (bedaquiline, quabodepistat, and sutezolid with delamanid [DBQS] or pretomanid [PBQS]) for their treatment-shortening potential. The trial's two-stage design planned to evaluate treatment durations of 4 months in Stage 1 followed by further reduction to 2-4 months in Stage 2. The trial was stopped early after enrolling 73% of Stage 1 participants based on insufficient efficacy observed in DBQS and PBQS arms to achieve the target regimen duration of =3 months.
This presentation will report final efficacy and safety outcomes from the trial, including end-of-treatment and 12-month unfavorable outcomes and sputum culture conversion.

Use and impact of whole genome sequencing to determine outcomes in the PAN-TB trial

K Stinson,[1] [1]Bill & Melinda Gates Medical Research Institute, Atlanta, United States.
e-mail: Kelly.stinson@gatesmri.org

Use of whole genome sequencing (WGS) to classify post-treatment Mtb strains as same or different from baseline is a rapidly evolving field that has more recently been adopted in assessing outcomes of TB treatment trials. WGS was used in the PAN-TB trial to assess end-of-treatment and 12-month unfavorable outcomes by categorizing microbiologic failures as relapses or re-infections.
This presentation will report on the WGS classification of relapse or re-infection for participants with =1 Mtb-positive sputum culture(s) at 4 months of treatment or later in all arms and a description of evolution of intra-participant strains during and after cessation of treatment.

Implementing a person-centered approach to TB care in the PAN-TB trial via a holistic treatment support model including video-supported treatment

M Gler,[1] [1]TB HIV Innovations and Clinical Research Foundation, Silang, Cavite, Philippines.
e-mail: msgler@tbhivicr.org.ph

People with TB enrolled in treatment-shortening trials face potentially heightened risk of poor treatment outcomes given the yet unproven efficacy and safety of investigational regimens. Ensuring they are the center of care and treatment provided within these trials is paramount. The PAN-TB trial implemented a holistic person-centered treatment support model to ensure this, including provision of a treatment support worker, use of a secure smartphone video app for documenting medication ingestions, and nutrition support among others.
This presentation will describe the trial's model and present participant-level adherence data and feedback on the app-based video-supported treatment from participants and trial staff.

In pursuit of non-culture-based TB treatment response biomarkers: Results from novel biomarker assays in the PAN-TB trial

N Frahm,[1] [1]Gates Medical Research Institute, Cambridge, United States.
e-mail: nicole.frahm@gatesmri.org

Sputum-based culture assays remain the gold standard microbiologic test for evaluating new TB drugs and regimens despite their many limitations. Numerous biomarkers, both sputum-based and non-sputum-based, are currently being investigated for their ability to measure a drug or regimen's bactericidal and/or sterilizing ability against Mtb or the impact of treatment on the host response against Mtb.
This presentation will share results from the PAN-TB trial's evaluation of multiple treatment response biomarkers, including sputum-based (mycobacterial load assay [MBLA], lipoarabinomannan [LAM], GeneXpert Ultra, and ribosomal RNA synthesis ratio [RS ratio]) and non-sputum-based (host transcriptomics, C-reactive protein) assays.

Protecting participants and preserving endpoints in treatment-shortening trials: Experience implementing a stop-treatment-and-watch framework in the PAN-TB trial

S Staples,[1] [1]THINK, Durban, South Africa.
e-mail: s.staples@think.org.za

Participants in TB trials evaluating investigational treatment-shortening regimens face potentially heightened risk of poor treatment outcomes given the regimens' yet unproven efficacy and safety. Simultaneously, trial investigators may introduce bias against investigational regimens when an open-label design is required due to inherent blinding challenges.
This presentation will describe the Stop-Treatment-and-Watch (STrAW) framework in the PAN-TB trial which was implemented to balance these important risks by protecting participants and supporting investigators. The framework consisted of an external concilium providing real-time review of potential unfavorable outcomes and delivering participant-level treatment monitoring reports to investigators. Data on concilium utilization will be presented.

SY07-170-07 Aligning priorities: Integrating TB and maternal health for better outcomes

Chair: Chidimma Okoye, Catholic Caritas Foundation of Nigeria, Abak, Nigeria
Chair: Beatrice Wangari Kirubi, Stop TB Partnership, Geneva, Switzerland

This symposium explores innovative and context-specific approaches to integrate tuberculosis (TB) screening, diagnosis, and care into maternal, newborn, and reproductive health services. With growing recognition of the vulnerability of pregnant and postpartum women to TB, especially in high-burden and underserved settings, this session highlights operational models and field experiences from Papua New Guinea, India, and Afghanistan, and broader research needs and gaps.
Presentations will examine strategies to leverage antenatal and postnatal platforms for TB detection, engage community health workers to improve referral and treatment outcomes and apply digital tools such as AI-assisted chest X-ray screening. Discussions will focus on the feasibility, acceptability, and effectiveness of integrating TB care within existing maternal and child health services, including challenges around stigma, resource constraints, and system readiness. The session will also identify persistent gaps in evidence and delivery systems while outlining key priorities for future research, innovation, and scale-up in TB-maternal health integration.

TB and pregnancy; what we don't know and need to know

H Cox,[1] [1]Burnet Institute, Melbourne, Australia.
e-mail: helen.cox@uct.ac.za

While the World Health Organization highlighted the increased risk of TB in pregnancy for the first time in 2023, estimates of the burden of disease in this important population are lacking. TB is estimated to contribute to 6-15% of maternal mortality and contributes to poor perinatal outcomes. Yet, there are few examples of integration of TB screening into antenatal care services and limited evidence to support effective TB management during pregnancy. This presentation will discuss important research priorities to address these gaps.

Integrating Tuberculosis Care into Maternal and Newborn Health Services in Papua New Guinea

A Vasiliu,[1] [1]Baylor College of Medicine, Houston, United States.
e-mail: anca.vasiliu@bcm.edu

This presentation highlights challenges and success of integrating tuberculosis (TB) screening and treatment into maternal, newborn, and child health services. Implemented at Port Moresby General Hospital, the initiative links peri-partum women and their families to TB care using innovative tools like AI-assisted chest X-rays and hospital-based screening.
With over 12,000 maternal screening points and a 1.7% TB detection rate, the project highlights the importance of embedded TB care on improving early diagnosis and treatment initiation among pregnant and post-partum women in high-burden settings.

Connecting Care: Home Visits & Screenings, Transforming TB & Pregnancy in India

K Taluja,[1] [1]Innovators in Health, Samastipur, India.
e-mail: doc.kajaltaluja.93@gmail.com

In rural Bihar‘s underserved communities, ASHA workers are vital in reaching pregnant women in Bihar‘s remote and marginalized areas for TB screening. By addressing myths and connecting presumed symptomatic pregnant women to public health systems for diagnosis, they enable focused antenatal care, institutional delivery, and successful TB treatment during regular home-visits leading to improved maternal health.

Addressing the challenge of Tuberculosis among clients seeking maternal and reproductive health services in Afghanistan

G Qader,[1] [1]Organization for Research, Evaluation and Afghanistan Development (OREAD) and Care of Afghan Families (CAF), Kabul, Afghanistan.
e-mail: gqader@gmail.com

In Afghanistan’s fragile health system, maternal and child health (MCH) services served as strategic entry points for TB screening among women, who bear a disproportionate burden of disease. Through the TB REACH Wave 10 project, TB screening was integrated into antenatal, delivery, postnatal, family planning, immunization, and nutrition services. Over individuals with 1,300 TB were diagnosed—including bacteriologically confirmed and clinically diagnosed cases—with nearly 90% completing treatment. By leveraging routine MCH visits and engaging frontline providers, the project demonstrated the feasibility and impact of integrating TB services into reproductive health platforms in resource-constrained, high-burden settings.

SY08-180-08 Crossing borders: Addressing TB in migrant and refugee populations

Chair: Tereza Kasaeva, WHO Global Tuberculosis Programme, Switzerland

Human migration and displacement are social determinants of the tuberculosis (TB) epidemic. Globally, about 1 billion (or one in eight) people have migrated or have been forcibly displaced. Migrants, refugees, asylum seekers, and internally displaced persons are at significantly higher risk of developing TB due to overlapping social, structural or biomedical determinants and risk factors, including limited access to health care and poor living conditions. In 2024, WHO, in collaboration with the World Innovation Summit for Health, Qatar Foundation, published a technical report focused on combating TB in refugees and migrants. The report proposes ten key policy options to address TB among refugees and migrants.
This symposium will provide an overview of the policy options and will feature cross border and country focused examples on best practices with regards to TB prevention and care among migrant and refugee populations.

Innovative solutions for the elimination of TB among migrants and refugees

K Viney,[1] [1]World Health Organization, Geneva, Switzerland.
e-mail: vineyk@who.int

Refugees, migrants, and other displaced people are disproportionately vulnerable to TB. The World Health Organization in collaboration with the World Innovation Summit for Health, Qatar Foundation, have outlined innovative solutions and policy options to address TB in migrants, refugees and internally displaced persons in their 2024 report: "Innovative solutions for the elimination of tuberculosis among migrants and refugees"
The report outlines ten key policy options to effectively prevent and address TB among these groups, which will be the feature of this presentation and when adopted are expected to contribute towards improved health and well-being of refugees and migrants.

TB and drug-resistant TB in migrants and conflict-displaced populations: The experience of the MSF-TB project in Poland, responding to the Ukrainian crisis

J Ladomirska,[1] [1]Medecins Sans Frontieres, Den Haag, Netherlands.
e-mail: msfocb-poland-medco@brussels.msf.org

The presentation will address the context of MSF's intervention in Poland in response to the Ukrainian crisis, highlighting key activities, challenges, and achievements. Focus will be on barriers faced by Ukrainian refugees in seeking and adhering to TB care, and MSF's response. It will showcase the catalytic effect of operational and advocacy activities conducted in collaboration with key stakeholders, as well as remaining challenges in access to TB medicines, the person-centered model of care, and implementation of WHO recommendations.

Addressing cross-border TB burden: IOM experience in regular migration pathways

A Klosovskiy,[1] [1]International Organization for Migration, Geneva, Switzerland.
e-mail: aklosovsky@iom.int

Addressing TB has never been easy, doing that in migrant populations crossing borders is a major challenge requiring close collaboration between all relevant stakeholders and, of course, empowering migrants themselves. Key factors include fast and efficient diagnosis of TB during the migration process, preventing TB resistance, ensuring health education, good electronic documentation, cross-border information sharing and continuity of care. IOM Health Assessment Programming is uniquely positioned to facilitate the required connections and will be presenting key recommendations and best practices developed in this area.

From Risk to Resilience: Collective Action to End TB in Humanitarian Settings

A Kahindo Maina,[1] [1]Switzerland.
e-mail: mainaa@unhcr.org

TB is both preventable and curable, yet it continues to take lives among refugees and other displaced populations who face barriers to access and continuity of care. UNHCR's upcoming Global Public Health Strategy (2026-2030) calls for inclusion in national systems, catalytic partnerships, sustainable financing, community resilience and safeguarding essential services throughout all phases of displacement. UNHCR works with governments, WHO, and partners to close TB care gaps, ensur-

ing continuity across borders, building resilient health systems, multisectoral approach and advancing global TB elimination while protecting the most vulnerable.

The Need for Rights-Based Responses on TB in Migrant and Refugee Populations

T Kunor,[1] [1]United States.
e-mail: tenzinkunor@gmail.com

As a TB survivor born in a Tibetan resettlement camp in India, Tenzin offers affected community narratives to this discussion on TB among migrant and refugee populations. Building on the 2024 WHO/WISH report, Tenzin will highlight civil society perspectives on the ten proposed policy options, emphasizing the need for barrier-free access to TB care, social protections, and community engagement. Civil society and affected communities are key in translating policy into practice, ensuring accountability, and addressing stigma and legal barriers.

SY09-190-09 How to improve trials and development, and ensure uptake, of innovations to prevent, diagnose, and treat TB

Chair: Ani Herna Sari, Rekat Peduli Indonesia Foundation, Indonesia
Chair: Anneke C. Hesseling, Desmond Tutu TB Centre, Stellenbosch University, Cape Town, South Africa

Major advances in preventive therapy, treatment for active DS- and MDR/RR-TB have emerged through clinical trials in recent years. These innovations have been codified in marketing authorizations and/or WHO endorsements. Major evidence gaps persist, however, which constrain uptake generally and in priority populations.
This symposium will highlight common gaps in clinical development and their consequences. Speakers will discuss omnipresent tensions between research expediency and production of high-certainty, comprehensive evidence, frameworks to weigh priorities, and alternative strategies that can be deployed to fill these gaps.

When are uncontrolled trials in TB scientifically and ethically justified: Borrowing wisdom from early AIDS clinical trials

C Mitnick,[1] [1]Harvard Medical School, Boston, United States.
e-mail: carole_mitnick@hms.harvard.edu

In a 1989 paper, Byar and colleagues established five conditions for the use of uncontrolled trials for HIV. A number of recently completed trials have changed global standards of care for TB and multidrug/rifampin-resistant TB. Trials have used a variety of strategies for comparison, ranging from no or an external, historical comparator to a fixed or evolving internally controlled comparator regimen(s). With new trials imminent, it is timely to reconsider the role of uncontrolled trials in TB treatment research, guided by the five conditions from Byar et al, current ethical standards (Helsinki, CIOMS), and new WHO Guidelines for Evidence Generation.

Toward earlier inclusion of pregnant and breastfeeding women in TB treatment trials

S Verkuijl,[1] [1]World Health Organization, Geneva, Switzerland.
e-mail: verkuijls@who.int

The World Health Assembly Resolution WHA75.8 (May 2022), calls for transforming clinical trial practices, including for underrepresented populations. Pregnant and postpartum women have an increased risk of developing TB compared to the general population, however, pregnant women have historically been excluded from TB trials.

To address this, the WHO Global Programme on Tuberculosis and Lung health initiated a consensus-building process on optimal inclusion of pregnant and lactating women in TB trials, culminating in a consensus meeting in early 2025.
This presentation summarizes the consensus process and the resulting consensus statement and call to action.

Continuity of care among TB treatment trial participants whose study treatment is discontinued

M Gler,[1] [1]TB HIV Innovations and Clinical Research Foundation, Silang, Cavite, Philippines.
e-mail: msgler@tbhivicr.org.ph

Participation in TB clinical trials requires adherence to study protocol and regimen. Deviation from those standards, however, is sometimes required in a participant's best interest, notably for poor treatment response or treatment-limiting toxicity. Some trials are discontinued prematurely.
Two recent examples are (TB-PRACTECAL) stopped for efficacy and (PAN-TB) for futility relative to the study objective. Regardless of the reason, participants whose study treatment is prematurely interrupted typically require additional treatment in the local context.
How should these risks be communicated to participants?
How should participants of clinical trials be monitored when study treatment?
What are the responsibilities of sponsors and sites?

Best practices for paediatric investigational plans in TB drug/regimen development

P Howell,[1] [1]Clinical HIV Research Unit, Wits Health Consortium, University of the Witwatersrand, Johannesburg, South Africa.
e-mail: phowell@witshealth.co.za

This presentation will outline best practices for paediatric investigational plans (PIPs) in TB drug and regimen development, highlighting current challenges such as delayed initiation, fragmented and stand-alone studies, limited site capacity and suboptimal trial design.
Drawing on insights from the CHEETA project, it will explore strategic solutions to optimise paediatric trial design, accelerate access to novel treatments, and ensure regulatory readiness across development stages.

SY10-200-10 Uniting voices for equitable TB care in Europe: Advancing people-centred diagnosis and treatment

Chair: Ilaria Motta, University College London (UCL), Medecines Sans Frontieres (MSF), London, United Kingdom
Chair: Senia Rosales-Klintz, European Centre for Disease Prevention and Control, Sweden

Access to timely diagnosis and effective treatment in the European Union, European Economic Area (EU/EEA) and the United Kingdom (UK) remains challenging due to disparities in healthcare systems, high costs of newer TB medicines, and restrictive regulatory policies. Vulnerable populations—such as migrants, children, and those with multidrug-resistant TB—face even greater barriers, including delays in diagnosis, limited treatment options, and inadequate social support.
Additionally, bureaucratic hurdles and lack of patient-centred approaches often leave those affected feeling unheard and underserved. This symposium targets clinicians, policymakers and advocates and will discuss the general landscape for TB care in the EU/EEA and the UK, with insights to access to medicines and diagnostics and exploring possible solutions via examples from countries. A final call to action will be articulated to reinforce the adoption and integration of a patient-centred approach within tuberculosis care frameworks.

Regional landscape of TB care in the European Region

A Yedilbayev,[1] [1]World Health Organization, Switzerland.
e-mail: yedilbayeva@who.int

The first talk will give an overview of TB care landscape across the European Region, highlighting key trends, challenges, and opportunities for action. While TB incidence is declining overall, significant disparities persist, especially amid the current humanitarian crisis in Europe, in access to timely diagnosis, WHO-recommended treatment and care for vulnerable populations, including migrants and those with drug-resistant TB.
The session will underscore the importance of equity-focused, people-centred approaches and stronger regional collaboration. United action and sustained advocacy are needed to expand access to high-quality TB services and accelerate progress toward global and regional targets to end TB across Europe.

From innovation to implementation: Access challenges for TB diagnostics in the European Region

F Saluzzo,[1] [1]IRCCS San Raffaele Scientific Institute, Milan, Milan, Italy.
e-mail: saluzzo.francesca@hsr.it

This presentation examines the challenges and priorities in achieving equitable access to TB diagnostics across the EU/EEA and the UK. Despite the increased availability of advanced tools for TB detection, drug resistance testing, and genomic surveillance, their use is inconsistent and key and vulnerable populations often face limited diagnostic options due to funding gaps and fragmented policies.
The talk will highlight the importance of cross-border collaboration in monitoring TB and MDR-TB transmission, discussing the role of the European Reference Laboratory Network for TB, coordinated by the ECDC. The session will propose actions to close the diagnostic-access gap and maximise public health impact across Europe.

Access to TB medicines in the European Region: Challenges and potential solutions

F Jouberton,[1] [1]Médecins Sans Frontières, Geneva, Switzerland.
e-mail: fabienne.jouberton@geneva.msf.org

Access to TB medicines in the EU/EEA and the UK remains challenging due to lack of registration or commercialisation, and high costs of newer or repurposed drugs. While quality-assured generics are available globally, their absence in the EU/EEA and the UK hinders implementation of WHO treatment guidelines and limits patient access to optimal care.
This presentation will outline the key barriers and explore potential solutions, such as streamlining regulatory pathways, reducing costs, and fostering collaboration with manufacturers and policymakers. The goal is to improve access, ensure equity, and align TB care in the EU/EEA and the UK with international standards.

Fostering availability of age-appropriate formulations for children with TB to tackle the worrying surge in paediatric TB in the EU/EEA

T Masini,[1] [1]World Health Organization, Geneva, Switzerland.
e-mail: tmasini@who.int

Age-appropriate fixed-dose formulations for children with TB have been available since 2015 and implemented in over 120 countries. However, due to lack of registration at the European Medicines Agency, they are not available in EU/EEA countries. This leads to the use of crushed adult formulations with the wrong drug ratio or suboptimal formulations, negatively impacting adherence and treatment outcomes.
The presentation will provide an overview about strategies used by European countries to import these formulations as well as other initiatives ongoing to improve access.

From awareness to action: Mobilising advocacy for accessible TB medications in the European Region

P Sommerfeld,[1] [1]TB Europe Coalition, London, United Kingdom.
e-mail: paul_sommerfeld@tbcoalition.eu

Building on the previous discussion, this talk will summarize the key actions countries can take to improve access to newer TB medications in low-burden regions like the EU/EEA, and the UK, where non-registration delays treatment. We will emphasize the need for streamlined regulatory processes and flexible approval mechanisms, such as conditional marketing authorization, to ensure timely access to life-saving drugs, especially for drug-resistant TB.
The session will call on regulatory bodies, governments, and pharmaceutical companies to collaborate and take urgent steps to break down barriers, ensuring equitable access to TB treatments across all regions.

SY11-210-11 Generating evidence: A call to action for the optimal inclusion of pregnant and lactating women in TB clinical research

Chair: Kerri Viney, World Health Organization, Geneva, Switzerland
Chair: Yael Hirsch-Moverman, Columbia University, New York, United States

TB contributes 6–15% of all maternal mortality. TB in pregnancy and postpartum is associated with adverse maternal and perinatal outcomes. Pregnant and lactating women have largely been excluded from TB clinical trials, resulting in a lack of access to the most effective therapeutic regimens. Most newer TB regimens are therefore not used during pregnancy or occasionally used without supporting data. Pregnant and lactating women have also been excluded from all previous and current TB vaccine trials. The WHO Global Programme on Tuberculosis and Lung Health initiated a consensus-building process on the earlier and optimal inclusion of pregnant and lactating women in TB therapeutic and vaccine trials. Evidence reviews were conducted to address gaps in data and knowledge and inform this process.
This symposium will deliver the latest TB estimates among pregnant and lactating women and disseminate new evidence generated from the WHO commissioned reviews for the 2025 Consensus process.

A pressing need: Reaching consensus on how to advance the early and optimal inclusion of pregnant and lactating women in TB clinical research

S Verkuijl,[1] [1]World Health Organization, Geneva, Switzerland.
e-mail: verkuijls@who.int

Pregnant and lactating women are at high risk of developing TB, which is associated with increased risk of maternal and perinatal morbidity and mortality. Historically, pregnant and lactating women have been excluded from TB trials and thus cannot benefit from the latest innovations to prevent and manage TB.
A consensus-building process on inclusion of pregnant and lactating women in TB trials was initiated in 2023/2024. Five working groups (preclinical, therapeutics, vaccines, maternal TB surveillance, advocacy) were established. A consensus meeting was conducted in February 2025. This presentation summarizes the consensus process and the resulting consensus statement and call to action.

Hot off the press: The latest estimates of TB in pregnant and lactating women

P Dodd,[1] [1]University of Sheffield, Sheffield, United Kingdom.
e-mail: p.j.dodd@sheffield.ac.uk

Tuberculosis risk is elevated during pregnancy and postpartum, contributing to adverse maternal, fetal, and infant outcomes. However, limited evidence and widespread underreporting obscure the true burden of tuberculosis in these populations. To address this gap, we synthesized data from WHO's age- and sex-disaggregated tuberculosis estimates, UN population and fertility data, UNAIDS HIV indicators, and findings from our systematic review and meta-analysis of tuberculosis incidence rate ratios during pregnancy and postpartum.
By integrating these data sources, we generated tuberculosis burden estimates (by HIV status) at country, regional, and global levels, offering new clarity on tuberculosis risks in this priority group.

Hot stuff: Systematic review on TB and pregnancy

L Chaisson,[1] [1]University of California, San Francisco, San Francisco, United States.
e-mail: lelia.chaisson@ucsf.edu

This presentation will review results of a systematic review on TB and pregnancy undertaken to inform the consensus process for the optimal inclusion of pregnant and lactating women in TB clinical research. Questions evaluated in the review include understanding how pregnancy-related immune changes affect testing for TB infection; risks of TB infection and disease among pregnant and lactating women; diagnostic accuracy of TB screening tools in pregnancy; safety of TB preventive treatment regimens in pregnant and lactating women; TB treatment outcomes among pregnant and lactating women; and incidence of adverse infant outcomes for pregnant and lactating women receiving TB treatment.

Turning up the heat: Pregnant and lactating women have been excluded from TB clinical trials for far too long

S Meehan,[1] [1]Stellenbosch University, Cape Town, South Africa.
e-mail: sueannm@sun.ac.za

To support the work of the global consensus process, we collated a systematic inventory of clinical trials conducted in the past 10 years or planned on TB treatment, TB prevention, and TB vaccines. We reviewed the trials and determined whether they included/excluded pregnant and lactating women. We also conducted in-depth inter-

views with 18 globally representative TB clinical trialists and sponsors, which explored barriers and facilitators to optimal inclusion of pregnant and lactating women in TB clinical trials.
This presentation will highlight findings from the systematic inventory and interviews and present strategies for earlier inclusion of this population in clinical trials.

Invisible mothers: Closing the data gap in maternal TB monitoring

T Housen,[1] [1]Solidarity in Health, Canberra, Australia.
e-mail: tambri.housen@solidarityinhealth.com

This landscape analysis highlights critical gaps in maternal TB surveillance and funding. Despite increased risks during pregnancy and the postpartum period, data on TB in this population remain sparse.
The report identifies structural barriers—including siloed health systems and limited integration with maternal and child health programs—and proposes strategic solutions like sentinel surveillance, data linkage, and leveraging existing registries. It calls for strengthening data collection on maternal TB, pilot programs in high-burden countries, and stronger cross-program collaboration.
Enhanced surveillance is key to improved maternal outcomes and attracting sustainable, multisectoral funding to address this under-recognized public health issue.

SY12-220-12 How can asymptomatic TB help the development and global impact of new TB vaccines?

Chair: Rhea Lobo, Stop TB Community Delegation, Australia
Chair: Richard White, London School of Hygiene and Tropical Medicine, London, United Kingdom

Our objective is to discuss how asymptomatic TB could help the development and global impact of new TB vaccines.
New TB vaccine trial results are due soon. At least 50% of prevalent TB is asymptomatic, and asymptomatic TB is likely important for TB infection transmission, but there are crucial asymptomatic TB unknows.
We present a community perspective on why asymptomatic TB and new TB vaccines matter to TB care/prevention, present a state of the art summary on asymptomatic TB and new TB vaccines, present a framework to determine if/how we could use asymptomatic TB to accelerate new TB vaccine development by reducing trial size/cost, present new modelling results that suggest whether new TB vaccines prevent asymptomatic TB may be crucial for global impact, and, present new evidence on the critical gaps we need to fill on asymptomatic TB to accelerate vaccine trials and maximise global impact of new TB vaccines.

A community perspective on why asymptomatic TB and new TB vaccines matter to global TB care and prevention

B Kumar,[1] [1]Global Coalition of TB Advocates, New Delhi, India.
e-mail: blessi.k@gmail.com

The presentation will focus on two things: the time before we have new TB vaccines, when asymptomatic TB needs to be found and treated. 'All TB is TB!' I will also state that new TB vaccines are essential, and should be designed to prevent all forms of TB, particularly given recent global funding cuts. For too long, the TB-affected communities and TB survivors have waited for a vaccine.
Finally, I will describe how communities can continue to advocate for a new TB vaccine and support the awareness and implementation at the community level.

Why asymptomatic TB could accelerate TB vaccine development, and what do we know?

G Churchyard,[1] [1]The Aurum Institute, Isando, South Africa.
e-mail: gchurchyard@auruminstitute.org

In this talk, I will present what we do know and don't know about asymptomatic TB, give an update on TB vaccine trials, particularly with regard to asymptomatic TB, and how we could measure impact on asymptomatic TB, including which vaccine trials are doing so.

How could we fill the remaining asymptomatic TB knowledge gaps, to know if we can use aTB to accelerate vaccine trials?

P Dewan,[1] [1]Gates Foundation, Seattle, United States.
e-mail: puneet.dewan@gatesfoundation.org

In this talk, I will present a summary of how we get the data we need to use asymptomatic TB to accelerate vaccine trials and maximise the global impact of new TB vaccines. These will range from observational to interventional studies, with the advantages and disadvantages highlighted. I will also present a summary of what data we know are currently being collected, and what are the critical remaining gaps are. This should lead to concerted global action to fill these gaps.

New modelling results suggest that the ability of new TB vaccines to prevent asymptomatic TB may be key to their global impact

R Clark,[1] [1]London School of Hygiene and Tropical Medicine, London, United Kingdom.
e-mail: rebecca.clark@lshtm.ac.uk

Our evolving understanding of the natural history of TB changes the way we think about new TB vaccines, and specifically about how the vaccine mechanism of action interacts with underlying TB stages.
In this talk, I will share new modelling analysis that suggests that whether new TB vaccines prevent asymptomatic TB may be critical to the global impact of new TB vaccines. Therefore, it is essential to measure the impact of new TB vaccines against asymptomatic TB.

What potential regulatory considerations may arise in TB vaccine clinical trials that incorporate asymptomatic TB as a study endpoint?

H Rees,[1] [1]Wits RHI, South Africa.
e-mail: hrees@wrhi.ac.za

I will present a framework to help determine if/how we could use asymptomatic TB to accelerate new TB vaccine development by reducing the size/cost of TB vaccine trials, including a potential regulatory perspective. What regulators might think about a asymptomatic TB trial endpoint will be critical. I will bring insights from my knowledge of the regulation process to this discussion - how regulators work, what evidence they are likely to need to consider a change in licensure endpoint, and other information from this perspective that would be useful for TB vaccine trialists and TB epidemiologists to know.

SY13-230-13 Innovative TB screening and diagnosis at healthcare facilities to find the missed millions: Evidence from four high-burden TB countries

Chair: Cecily Miller, World Health Organization , Geneva, Switzerland
Chair: Monde Muyoyeta, Centre for Infectious Diseases Research in Zambia, Zambia (CIDRZ), Lusaka, Zambia

Lack of access to TB screening, diagnosis and linkage to care is a key contributor to TB morbidity and mortality with 25% of people with TB being "missed" globally.
Start4All is a seven-country UNITAID-funded project aiming to address this by evaluating novel point-of-care TB screening and diagnostic combinations, including in lowest level healthcare facilities.
By March 2025, Start4All had recruited 15,000 adult participants, who kindly provided: two spontaneous sputa, capillary blood, urine, and a chest x-ray (CXR). Tests performed included CXR computer aided detection (CAD), pooled molecular sputum testing, C-Reactive Protein, and urinary lateral-flow assay; all evaluated against microbiological reference standards (individual sputum molecular test and/or culture).
Here, we present an overview of the performance of tests and test combinations implemented at primary healthcare facilities and district hospitals in Nigeria, Malawi, Kenya, and Brazil; and consider the challenges, successes, and lessons learnt locally to facilitate future implementation and potential scale-up.

The Start4All Project: Enhancing TB diagnosis and linkage to care across seven high-burden countries

T Wingfield,[1] [1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom.
e-mail: tom.wingfield@lstmed.ac.uk

Start4All is evaluating innovative TB screening and diagnostic test combinations to enhance linkage to care, particularly in primary healthcare and community settings, and amongst underserved groups. Screening tests include C-reactive protein (CRP), chest x-ray with computer aided detection (CAD), urinary LAM, and pooled sputum testing. By March 2025, Start4All had recruited >15,000 participants (including ~1,000 children, 1-14 years) from Bangladesh, Brazil, Cameroon, Kenya, Malawi, Nigeria, and Viet Nam.
This session will share real-world case studies, community engagement learnings, and key findings on the effectiveness, cost-effectiveness, feasibility, acceptability and scalability of TB screening and diagnostic algorithms to find the "missed millions".

Identifying optimal TB screening and diagnostic strategies at the frontline in Malawi

C Kwanjo Banda,[1] [1]Malawi Liverpool Wellcome Programme, Blantyre, Malawi.
e-mail: ckwanjobanda@mlw.mw

In a mixed-methods cross-sectional study, we evaluated the performance of: C-reactive protein (CRP), computer-aided X-ray diagnosis, pooled sample Xpert Ultra testing, and urine lipoarabinomannan (LAM) testing and investigated whether test combinations had the potential to increase the proportion of people diagnosed with bacteriologically-confirmed TB among adults seeking primary healthcare services at three health facilities in Blantyre, Malawi.
We used trained research nurses to deliver the point of care tests (CRP and LAM) and ministry of health personnel at the facilities to conduct the X-rays and Xpert ultra tests. Here, we present the results of the 574 participants with presumptive TB.

Innovations in point-of-care TB screening and diagnosis at healthcare facilities to find the missed millions: implementation evidence from Nigeria

G Bahuyak,[1] [1]Bingham University, Nasarawa, Nigeria.
e-mail: graciousbahuyak@gmail.com

By March 2025, Zankli Research Centre, Nigeria, implementing partner on Start4All, had recruited 1,703 adult participants who provided two spontaneous sputum samples, capillary blood, urine, and a chest X-ray (CXR). Tests conducted included computer-aided detection (CAD) on CXR, pooled Xpert MTB/RIF testing, C-reactive protein, and a urinary lateral-flow assay, alongside microbiological reference standards.
Here, we share an overview of implementation at two primary healthcare facilities and a district hospital in Nigeria, highlighting operational experiences, challenges addressed, successes achieved, and lessons learnt to inform future deployment and potential scale-up.

Lessons from the field on implementation and evaluation of novel TB screening and diagnostic tests in primary healthcare facilities in Brazil

V Santos,[1] [1]Federal University of Sergipe, Lagarto, Brazil.
e-mail: victorsan@academico.ufs.br

As part of the Unitaid-funded Start4All project, 306 adults aged 15 years and above with presumptive TB were recruited, predominantly from primary healthcare facilities in two sites, Maceio and Aracaju, Brazil. All participants provided sputum, urine, capillary blood, and a chest x-ray (CXR). We then evaluated the performance of screening tests including computer-aided detection (CAD) CXR, urinary lipoarabinomannan (LAM), and pooled testing of sputum by Xpert Ultra, against individual Xpert Ultra and mycobacterial culture of sputum. Here we present practical lessons learnt about introducing new screening and diagnostic tests at primary healthcare level and consider policy and practice implications.

Real-world challenges and successes of expanding novel TB screening and diagnostic tests in the health system in Kenya

S Wandiga,[1] [1]Kenya Medical Research Institute (KEMRI), Kisumu, Kenya.
e-mail: stevequanza@gmail.com

START4ALL Kenya sites recruited 799 adults (15 years+) with presumptive TB, of whom 46% (367/799) were HIV positive, over seven months between 2024 and 2025, Implemented by the Kenyan Medical Research Institute, the sites relied on strong partnerships with the Ministry of Health and County Governments. Challenges included changes in public healthcare grading of sites that reduced client attendance and seasonal variations in healthcare seeking. Successes included radiography being introduced for the first time in Rabuor Sub-county Hospital, supporting referrals from nearby centres; and adaptability and strong local collaboration with public health bodies to facilitate policy and practice change.

SY14-240-14 Delivering multi-drug-resistant TB services in war and complex emergencies: A joint symposium with IOM, MSF, The Union, and WHO

Chair: Medea Gegia, WHO HQ, Geneva, Switzerland
Chair: Anita Mesic, Médecins Sans Frontières, Amsterdam, Netherlands

Nearly 300 million people live in countries affected by war or complex emergencies (CE), where antimicrobial resistance (AMR) is an emerging concern. Modern conflicts are increasingly prolonged and frequent, severely disrupting health systems and compromising tuberculosis (TB) care. War and postwar conditions may accelerate TB drug resistance due to fragmented healthcare access, treatment interruptions, and increased vulnerable populations. Given the global rise in CE, there is an urgent need to analyze existing evidence to improve multidrug-resistant TB (MDR-TB) management in these settings. However, published research on this topic remains scarce.
This symposium explores the role of conflict in driving AMR, particularly drug-resistant TB, and the challenges of providing continuous care. It brings together field experts from NGOs, key institutional stakeholders, and funders to discuss innovative strategies for MDR-TB management in fragile settings, aiming to strengthen response mechanisms and ensure treatment continuity despite healthcare system disruptions.

Multi-drug-resistant TB in war and complex emergencies: Consequences, gaps and potential ways forward

I Monedero-Recuero,[1] [1]The Union / Action Damien, Vilanova i la Geltrú, Spain.
e-mail: monederoi@hotmail.com

This introductory session explores the modern war and shifting dynamics of TB in these complex scenarios, including their impact on multidrug-resistant tuberculosis (MDR-TB) due to disrupted TB services. It reviews available evidence and insights from regional Green Light Committee missions on MDR-TB management in crisis-affected countries. Key discussions include priority populations, research gaps, funding strategies, and policy development to enhance MDR-TB care in humanitarian settings.
The session also examines targeted interventions to improve patient outcomes, emphasizing the need for innovative, sustainable approaches to ensure treatment continuity amid instability.

Overcoming challenges of Multi-drug-resstant TB care in the Democratic Republic of Congo: The case of North Kivu

P Luliba Mwelwa,[1] [1]MSF, Goma, Congo (Democratic Republic).
e-mail: petersluliba@gmail.com

Médecins Sans Frontières (MSF) intervient dans des contextes parmi les plus complexes et instables au monde, tout en contribuant significativement à l'avancement du traitement de la tuberculose pharmacorésistante (TB-MR) par la recherche clinique et le soutien aux programmes nationaux de lutte contre la tuberculose. Cette présentation met en lumière l'expérience de MSF au Nord-Kivu, en République démocratique du Congo, une région marquée par une insécurité chronique, un système de santé affaibli et un accès limité aux soins. Nous explorons les principaux défis de la prise en charge de la TB-MR, notamment les déplacements de population, les lacunes en matière de soutien psychosocial et le manque d'engagement communautaire. L'accent est mis sur le renforcement des capacités locales, la garantie d'un approvisionnement fiable en médicaments et la promotion d'approches intégrées pour améliorer les résultats des patients.

Maintaining multi-drug-resistant TB services for refugees of the Ukraine war: The experience of Poland

J Ladomirska,[1] [1]Medecins Sans Frontieres, Den Haag, Netherlands.
e-mail: msfocb-poland-medco@brussels.msf.org

The war in Ukraine caused mass population movements, within and outside of the country as well as disrupting the TB program activities. To maintain continuity of treatment for TB patients forced to flee the country, adapted models of care in neighboring countries were necessary. This was achieved through political will and collaboration between host countries, WHO and supporting agencies. We describe the actions taken that have succeeded in ensuring quality of care of those affected.

Against all odds: Reduction of drug-resistant TB incidence in Niger, a public health success story

M Souleymane,[1] [1]Damien Foundation Niger, Niamey, Niger.
e-mail: bachirsoul@gmail.com

In a context of persistent insecurity and systemic challenges, Niger achieved a marked reduction in drug-resistant tuberculosis (DR-TB) from 2015 to 2024. Despite limited resources, the National Tuberculosis Program and partners like Damien Foundation implemented targeted interventions: continuous training for healthcare workers, private-sector-supported sample transport, expansion of rapid diagnostics and treatment centres, and quarterly supervision.
A strong focus on patient-centred, ambulatory care included transport and nutritional support, peer-led home visits, contact screening, shorter regimens, and robust pharmacovigilance. Strengthening the DR-TB drug supply chain was also prioritised. This multifaceted approach proved effective even in a fragile, insecure setting

Progress and lessons learnt in management of multi-drug-resistant TB in complex emergencies in the Eastern Mediterranean Region: 2018-2024

K Bennani,[1] [1]WHO, Kathmandu, Nepal.
e-mail: bennanik@who.int

In 2022, Global Fund-supported countries in the Eastern Mediterranean Region faced complex emergencies, accounting for 32% of estimated MDR/RR-TB cases. Progress and challenges in managing drug-resistant TB were assessed, reviewing rGLC mission reports and analyzing data. Testing for TB and RR increased significantly from 2018 to 2022, leading to a 24% rise in MDR/RR-TB patients treated.
All six countries implemented oral treatment regimens, with two adopting the 6-month BPaL(M) regimen. Treatment success varied, highlighting the need for improved management strategies.
Recommendations include enhancing diagnostic capacity, optimizing specimen transport, decentralizing services, and prioritizing the BPaL(M) regimen for expansion.

SY15-250-15 The paediatric TB meningitis SURE trial: What have we learnt?

Chair: Varinder Singh, Lady Hardinge Medical College and Assoc Kalawati Saran Children's Hospital,, New Delhi, India
Chair: James Seddon, Stellenbosch University, Cape Town, South Africa

Tuberculous meningitis (TBM) is the most severe form of tuberculosis in children with high mortality and rates of neurological sequelae. Evaluation of better anti-tuberculosis treatment regimens and adjuvant therapies is urgently needed. The SURE trial (short intensified treatment for children with Tuberculous Meningitis) is a randomised, factorial designed, controlled trial conducted at nine sites in Vietnam, India, Zambia, Zimbabwe, Uganda and co-ordinated through the MRC Clinical Trials Unit at UCL, London. The trial compares head-to-head for the first time, the non-inferiority of a short intensive TBM treatment regimen of four drugs, at higher doses for six months (H20 R30 Z40 L20) against standard 12-month WHO regimen and, factorially, the effect of aspirin 20 mg/kg versus placebo as adjuvant therapy for 8 weeks, on mortality and neurosequelae.
We will present baseline/outcome data from the primary 48-week analysis of 369 children, and results of main substudies, and describe experiences/challenges of trial implementation.

Overview of the SURE trial design, conduct and results

S Anderson,[1] [1]MRC Clinical Trials Unit, University College London, London, United Kingdom.
e-mail: suzanne.anderson@ucl.ac.uk

We will describe the rationale for the SURE trial, trial design and challenges in conducting the trial and results from the primary 48 week analysis.

Low paediatric lumbar puncture rates highlight the need for sustained and effective interventions to improve diagnosis of paediatric TBM

C Zulu,[1] [1]University Teaching Hospitals, Lusaka, Zambia, Lusaka, Zambia.
e-mail: christina.zulu@yahoo.com

Globally over 1.2 million children suffer from CNS infections annually, mainly in Africa and Southeast Asia, yet LP rates remain low. Without a LP children may fail to receive the correct diagnosis or optimal treatment for CNS infections with high mortality/morbidity. Barriers include societal fears, cultural beliefs, consent delays, untrained staff and resource shortages. We found weekly numbers of paediatric CSF samples routinely sent to laboratories at African SURE tertiary hospitals was low.
We show how training improved LP rates in the short-term, but sustained impact requires ongoing education, community awareness and strengthened healthcare resources.

Pharmacokinetics (PK) and pharmacodynamics (PD) of TB drugs in the SURE trial

R Aarnoutse,[1] [1]Radboudumc, Nijmegen, Netherlands.
e-mail: rob.aarnoutse@radboudumc.nl

We will describe the design of the SURE PK and PD substudy and the achieved exposure to TB drugs in plasma and CSF. Possible predictors of exposure (eg age, weight, gender, acetylator status) will be presented.
To facilitate the implementation of the intensified regimen we will assess if combination of dosing weight bands still results in attainment of adequate exposure to TB drugs. The relationship between drug exposure and efficacy and safety/tolerability will contribute to explaining findings of the SURE trial and provide possible leads for further treatment optimisation.

Neuro-imaging in the SURE trial

N Sankhyan,[1] [1]Advanced Paediatrics Centre, Postgraduate Institute of Medical Education & Research in Chandigarh, India, Chandigarh, India.
e-mail: drnsankhyan@yahoo.co.in

The MRI substudy evaluates the impact of aspirin on ischaemic brain changes in children with TBM across India and Vietnam. MRI scans at baseline and six months were centrally reviewed by neuroradiologists, blind to randomised arm, using standardised protocols.
This substudy aims to generate robust imaging-based evidence to guide TBM management and, additionally, it enables us to present detailed imaging findings of childhood TBM in high-prevalence regions. Results should inform future clinical and research practice.

Post-TBM neurological sequelae: outcomes and challenges

J Huynh,[1] [1]Oxford University Clinical Research Unit, Ho Chi Minh City, Vietnam.
e-mail: jhuynh@oucru.org

TB meningitis causes long-term neurological disability in over 50% of children who survive. However, functional impairments are poorly characterised especially in LMICs. All children had functional assessments performed at baseline, 24, 48 and 72 weeks by trained staff using the paediatric modified Rankin Scale (mRS) and Liverpool Outcome Score (LOS).
We will report mRS and LOS outcomes at 24 and 48 weeks post-diagnosis, including differences between antituberculous treatment groups, anti-inflammatory (aspirin vs placebo) arms, as well as relationship to baseline factors. These results will provide a better understanding of disease burden in this vulnerable population across different geographical regions globally.

SY16-260-16 CAD-supported chest radiography for TB screening and diagnosis in children as well as young adolescents: Key advances and remaining gaps

Chair: Martina Casenghi, Independent Consultant, Geneva, Switzerland
Chair: Cecily Miller, World Health Organization , Geneva, Switzerland

Children and young adolescents with TB are disproportionally under-diagnosed and remain amongst the most vulnerable groups affected by this disease. Although the role of chest X-Ray (CXR) in supporting diagnosis of intrathoracic TB and in assessing disease severity in children is increasingly recognized, access to quality CXR reading and interpretation remains a significant barrier in TB endemic settings. In older adolescents and adults, CXR interpretation has recently been facilitated using software for computer-aided detection (CAD) of TB, recommended by WHO for TB screening in these populations. However, its applicability to children and young adolescents remains to be determined.
This session will discuss ongoing efforts on the optimization of CAD software for applicability to people below 15 years of age and review most recent evidence on performance of CAD-supported CXR for screening and diagnosing TB in this population. We will also discuss remaining knowledge gaps and strategies to address them.

Performance of available CAD algorithms for identifying TB in children and adolescents: Results from the CAPTURE Consortium multi-country CXR dataset

M Palmer,[1] [1]Stellenbosch University, Cape Town, South Africa.
e-mail: meganpalmer@sun.ac.za

Through the CAPTURE consortium initiative, we established a large (>8000 images), well-characterized, multi-country archive of CXR images from children and young adolescents (0-14 years) with presumptive TB.
We used this repository to conduct an independent evaluation of the accuracy of 7 currently available CAD algorithms to identify childhood TB against several reference standards including composite clinical (standard NIH clinical case definitions), microbiological (confirmed TB) and radiological (expert human classification).
We present the results of this evaluation.

Start4All: The evaluation of CAD for childhood TB in Cameroon and Viet Nam

R Byrne,[1] [1]Liverpool School of Tropical Medicine, Liverpool, United Kingdom.
e-mail: Rachel.byrne@lstmed.ac.uk

Start4All is a global tuberculosis research consortium working across seven high burden countries funded by Unitaid and hosted by the Liverpool School of Tropical Medicine in collaboration with Stop TB Partnership.
Start4All has prospectively recruited children with TB symptoms aged 14 years and below from healthcare facilities in Cameroon (n=518) and Viet Nam (n=291) to develop a paediatric CXR library with microbiological, clinical and human interpreted radiological reference standards.
Start4All invited CAD manufacturers to share their paediatric software to perform an independent evaluation. Here we present the results.

Evaluation of CAD performance for diagnosis of TB in children: Evidence from the multi-country TACTiC study

J Min,[1] [1]Médecins Sans Frontières (MSF), Amsterdam, Netherlands.
e-mail: juno.min@amsterdam.msf.org

TACTiC is a multi-country initiative led by MSF to support the implementation of the 2022 WHO guidelines for TB management in children and adolescents. As part of TACTiC, approximately 750 chest X-rays (CXR) have been collected with corresponding clinical information, laboratory results and expert radiologists' interpretations. These CXR images were retrospectively analyzed using the latest CAD version of qXR (Qure.ai), trained specifically to identify TB in children. The performance of qXR was evaluated against different reference standards, including bacteriologic confirmation, expert CXR interpretation and a composite standard, to assess the potential of CAD in supporting TB diagnosis in children

Evaluating CAD performance in combination with minimally invasive tools for young children with presumed TB: First findings from the NOD-pedFEND study

F Basile,[1] [1]University of Oxford, Oxford, United Kingdom.
e-mail: francesca.basile@paediatrics.ox.ac.uk

NOD-pedFEND is a multi-country diagnostic accuracy study focusing on children under five with signs and symptoms suggestive of tuberculosis (TB)– a distinct, challenging, and often overlooked cohort.

This presentation will discuss preliminary findings on the performance of selected CAD products compared to expert readers and clinical/microbiological reference standards, as well as their use in combination with other diagnostic tools in the NOD-pedFEND cohort.
The talk will provide insights into the role that CAD can have in pediatric TB diagnosis today, while prompting considerations on future avenues for CAD integration into diagnostic pathways and optimized testing modalities for young children.

Development of a paediatric TB-CAD evaluation framework: Key updates from a consensus building process

I Aulianisa,[1] [1]Seoul National University College of Medicine, Seoul, Korea, Republic of.
e-mail: irinaaulia@snu.ac.kr

To support generation of the evidence needed to inform WHO recommendations on the use of computer-aided detection (CAD) for TB in children, a scoping review and a Delphi survey were conducted.
The review found promising diagnostic accuracy but limited pediatric-specific data and high variability in reference standards used. The Delphi process refined criteria for study design, training needs, and ethics. Experts emphasized the critical importance of prospective data collection, inclusion of high-risk subgroups, and equity assessment.
Insights from both exercises informed the development of a pediatric TB-CAD evaluation framework, which will be presented and discussed

SY17-270-17 Tomorrow is here: Innovative financing for the future of TB funding

Chair: Wim Vandevelde, Global TB CAB & Unitaid Communities Delegation, South Africa
Chair: Lindsay Palazuelos, Partners In Health, Boston, United States

The collapse of USAID funding and cuts to aid budgets across Europe have completely transformed the global health landscape. The need for innovative approaches to funding TB programs and research has never been more evident and pressing.
This session will open by outlining major changes to the TB funding landscape since Union 2024 and the impact funding cuts and instability have on TB programs and communities most affected by TB. The second half of the symposium will introduce innovative approaches to creating fiscal space for domestic investments in TB and health programs in low- and middle-income countries: 1) new multilateral and domestic financing frameworks to bolster investments in TB and health; 2) sovereign debt relief and reform; and 3) special drawing rights for sustainable investment in TB programs. Paired together, these solutions can overcome the inherent instability of foreign assistance-led investments in health and meet the end TB goals.

Where are we now: A landscape of TB funding changes and challenges in 2025

J Hauser,[1] [1]Global TB Caucus Secretariat, London, United Kingdom.
e-mail: janika@cghproject.org

Funding for TB has long been inadequate, falling far short UN High Level Meetings on TB commitments. With some exceptions, the trend in domestic TB funding has been downwards since Covid-19 put unprecedented pressure on public finances. The termination of USAID grants and cuts to development aid across Europe created further funding shortfalls at all levels.
This presentation will analyze the transformation of the TB funding landscape in 2025, how the field adapted, who filled gaps, the role of parliamentarians in shaping domestic and foreign funding, and make the case for innovative approaches to funding critical TB services and research.

When aid fails: The impact of USAID terminations on TB affected communities

S Anguva,[1] [1]Pamoja TB Group, Nairobi, Kenya.
e-mail: steveanguva@gmail.com

The withdrawal of USAID funding left countless individuals across high-TB burden countries facing shuttered TB clinics, terminated clinical trials, looming drug shortages, and no clear options to receive TB care.
This presentation will share perspectives on the crisis from TB affected communities across Kenya. By demonstrating the impacts of funding withdrawals on communities most affected, this session will underscore the urgency of innovative, locally-led approaches to sustainable funding for TB programs and care.

Building a new funding order: Reforming TB finance towards domestic driven agendas

L Vo,[1] [1]Friends for International TB Relief (FIT), Ha Noi, Vietnam.
e-mail: luan.vo@tbhelp.org

The recent changes to the funding landscape has underscored the need for innovation in TB financing for service delivery and R&D in order to meet the 2023 UN High Level Meeting commitments and ambition to end TB. This session focuses on novel financing solutions to unlock fresh sources and mechanisms of investment for TB.
The session will provide an overview on innovative multilateral and domestic funding models (e.g., health levies, social health insurance schemes, blended finance, etc.) and approaches to North-South lending that can be deployed towards investments in TB and health programs.

Sovereign debt relief and reform as pathway to domestic resource mobilisation for investments in TB

E McConnell,[1] [1]TAG, New York, United States.
e-mail: erin.mcconnell@treatmentactiongroup.org

Since 2010, global public debt has grown from $51 trillion to over $97 trillion, continuing to rise across the Global South – with payments to interest outpacing investment in health programs. Per IMF and WHO designations, 43% of high TB burden countries are in or approaching debt distress, unable to fulfill financial obligations. As debt burdens grow, countries turn to austerity measures to remain solvent and avoid default – at the expense of investing in TB programs, R&D, and other public services.
This session proposes debt relief and legislative reform as foundational tools toward robust, sustainable, and country-led TB financing.

The untapped potential of Special Drawing Rights (SDRs) in the fight against TB

I Vasic-Lalovic,[1] [1]Center for Economic and Policy Research, Serbia.
e-mail: vasiclalovic@cepr.net

Special drawing rights (SDRs) are a reserve asset allocated to IMF member countries to support global economic stability during crises. A recent distribution allocated $650 billion worth of SDRs to countries to fund COVID-19 response. SDR allocations can be leveraged by LMICs to create fiscal liquidity for domestic investments in health programs or by wealthier nations to fund trusts to invest in health and SDG goals in LIMCs, outside traditional development budgets.
This presentation lays out the pathway for the use of SDRs to fill immediate gaps in TB funding and to develop sustainable multilateral funding mechanisms beyond traditional ODA.

SY18-280-18 Optimising TB screening as a critical gateway to TB care: Recent advances in available and emerging tools and technologies

Chair: Cecily Miller, World Health Organization , Geneva, Switzerland
Chair: Martina Casenghi, Independent Consultant, Geneva, Switzerland

Screening for tuberculosis (TB) represents a critical tool in addressing the TB detection gap and for reducing TB prevalence and transmission in TB-endemic settings. Accurate, affordable and practical tools for TB screening are essential to enable its implementation. Recent advancements, including AI-driven computer-aided detection (CAD) for chest X-rays (CXR), rapid molecular diagnostics, and blood-based biomarkers, have enhanced the accuracy and coverage of TB screening in many high-burden settings.
However, key challenges persist in optimizing technology selection, accessibility, and large-scale deployment needed to bridge the detection gap and reduce TB burden globally. Development and evaluation of novel screening tools and approaches is urgently needed to identify solutions for rapid deployment at scale.
This session will present recent updates to the WHO target product profiles for TB screening tests, the latest evidence on WHO-recommended TB screening technologies, and early data on the most promising emerging innovations in the field.

Updated WHO Target Product Profiles for novel TB screening tools and technologies

C Miller,[1] [1]World Health Organization , Geneva, Switzerland.
e-mail: cmiller@who.int

This year, WHO released updated target product profiles (TPPs) for TB screening tools. Since the first TPPs for screening were released in 2014, there have been significant advancements in screening technology.
However, given the persistent global case detection gap and growing recognition of the burden of asymptomatic TB, underscoring the necessity of scaling up symptom-agnostic screening, there is an urgent need for screening tools with the accuracy, feasibility and cost profile required to implement effective screening at scale.
This talk will present WHO's updated TPPs for novel screening tools and highlight what is needed to spur future innovations.

Head-to-Head comparison of CAD-CXR, LF-LAM and CRP for TB screening: Results from the Start4All study

S Banu,[1] [1]Program on Emerging Infections, Infectious Diseases Division, International Centre for Diarrhoeal Diseases Research, Dhaka, Bangladesh.
e-mail: sbanu@icddrb.org

Start4All is a Unitaid-funded project, led by the Liverpool School of Tropical Medicine, focused on global improvement of TB screening, diagnosis, and linkage to care. During phase one, approximately 15,000 participants were recruited at facilities and communities across seven countries. Screening and diagnostic tests evaluated include the C-reactive protein assay, chest X-ray with computer aided detection (CAD), lateral flow urine lipoarabinomannan (LF-LAM), and rapid molecular testing on pooled sputum.
This presentation will share results from a head-to-head evaluation of diagnostic accuracy of screening tests, and modelled performance of the most promising algorithms, offering critical insights into optimized TB screening approaches.

CAD-supported CXR for TB screening: Review of latest evidence and WHO policy update

M Kohli,[1] [1]FIND, Geneva, Switzerland.
e-mail: mikashmi.kohli@finddx.org

In 20201, WHO issued a recommendation for use of computer aided detection (CAD) for CXR interpretation for TB screening, to enable implementation and scaleup of TB screening beyond what is possible with radiologists alone. Since then, there has been a proliferation of new CAD products and versions. In January 2025 WHO held a technical advisory group meeting to evaluate the current class of CAD products.
To enable this, FIND conducted an independent evaluation of diagnostic accuracy using two large, globally representative CXR libraries. Here we present the results of this evaluation and its implications for global policy for CAD.

Advances and challenges in AI-based cough analysis for TB screening

A Zimmer,[1] [1]Heidelberg University, Heidelberg, Germany.
e-mail: alexandra.zimmer@uni-heidelberg.de

Cough is a common symptom of pulmonary tuberculosis (TB), sparking interest in its potential as a biomarker for novel screening approaches. Recent advances in artificial intelligence and digital health have enabled researchers to explore the potential of algorithms capable of analyzing cough acoustics for TB detection. This non-invasive methodology has garnered attention due to its accessibility and ease of data collection across diverse settings. However, critical challenges regarding algorithm performance, validation, and real-world implementation remain underexplored.
This presentation examines developments in digital cough sound analysis for TB screening, evaluating technical capabilities, preliminary clinical findings, and implementation feasibility.

Leveraging oral swab-based molecular diagnostics for scalable TB detection

S Yerlikaya,[1] [1]Heidelberg University, Heidelberg, Germany.
e-mail: seda.yerlikaya@uni-heidelberg.de

Timely TB detection is critical to reducing transmission and mortality, yet nearly one-third of global TB cases remain undiagnosed annually. The World Health Organization advocates systematic screening in high-risk populations, but current tests face limitations in reach, accuracy, and cost, hindering scalable community-based active case finding (ACF). The expansion of molecular diagnostics during COVID-19 presents an opportunity to enhance TB screening using oral swabs as a non-invasive, accessible and accurate sampling method.
This presentation explores the potential of oral swabs for TB screening, their role in improving diagnostic efficiency, and their integration into ACF strategies in high-burden settings.

SY19-290-19 Emerging data in maternal and infant TB

Chair: Nicole Salazar-Austin, Johns Hopkins University School of Medicine, Department of Paediatrics, Baltimore, United States
Chair: Emma Kalk, University of Cape Town, Cape Town, South Africa

Owing to increased advocacy around the inclusion of pregnant women in research (and experiences around SARS-Co-V2 infection and vaccination) there has been increased prominence given to clinical and pharmaceutical studies during pregnancy, both in terms of the impact of disease and therapeutics on pregnant women and fetuses; and the longer term impact of antenatal exposures on infants and children. The increased risk of TB diagnosis during pregnancy and the postpartum period and the poor outcomes associated with untreated maternal disease have led to increased interest in antenatal screening and diagnosis of TB.
This Symposium will showcase recent TB research outputs across the maternal and neonatal care continuum and beyond. We have included both basic and applied, qualitative and quantitative studies from global sites engaged in maternal TB research.

Emerging data on TB prevention in pregnancy: Where do we go from here?

J Mathad,[1] [1]Weill Cornell Medicine, New York, United States.
e-mail: jsm9009@med.cornell.edu

For women, the risk of TB is highest during and immediately after pregnancy. Maternal TB results in adverse maternal, pregnancy and infant outcomes. Yet, there is no global consensus on how best to prevent TB during pregnancy.
In this talk, we will review existing data on TB prevention regimens in pregnancy and while breastfeeding. This will include a detailed review of new short-course rifapentine-containing regimens, including 1HP and 3HP, from clinical trials including DOLPHIN Moms and IMPAACT 2001.

Population pharmacokinetic modelling of second-line TB drugs in pregnancy and lactation: Insights from levofloxacin and delamanid

S Sawe,[1] [1]University of Cape Town, Cape Town, South Africa.
e-mail: swxsha001@myuct.ac.za

Pregnant and breastfeeding women have historically been excluded from tuberculosis drug trials, resulting in limited pharmacokinetic data to guide dosing of tuberculosis drugs in these populations. Using mathematical modelling, we aim to bridge this gap by characterizing the pharmacokinetics of key second-line drugs during pregnancy and lactation. We apply nonlinear mixed-effects modelling to evaluate the impact of physiological changes in pregnancy and postpartum on drug disposition, using limited but rich datasets from South African trials of rifampicin-resistant tuberculosis.
We will share findings on levofloxacin and emerging data on delamanid, including penetration into breastmilk and infant exposure.

Impact of pregnancy on TB treatment outcomes: An analysis of national surveillance data

S Chiang,[1] [1]Brown University - Warren Alpert School of Medicine, Providence, United States.
e-mail: silvia_chiang@brown.edu

In most settings, pregnancy is not routinely captured in TB reporting and little is known about its impact on TB treatment outcomes. This presentation will describe surveillance data from Brazil's Ministry of Health including 96,868 women 11-49 years old, newly diagnosed with drug-susceptible TB disease between 2016-2022 who had a known treatment outcome. Among 1870 pregnancies, pregnancy was associated with unfavorable TB outcomes differentially by age with adolescents having a higher odds of loss to follow-up and death, women aged 20-39 years having a higher loss to follow-up, and women aged 40-49 years having a higher risk of death.

Radiant-Moms: Generating evidence to support the evaluation, adoption, and safe practical implementation of novel TB treatment regimens for pregnant and lactating women

M Castro,[1] [1]The Nutrition Center of the Philippines, Muntinlupa City, Philippines.
e-mail: mccastro@ncp.org.ph

The Radiant-Moms study aims to examine preferences among pregnant and breastfeeding women and their healthcare providers regarding novel shorter TB treatment regimens during the pregnancy and postpartum periods.
In phase one, we qualitatively explore these preferences through in-depth interviews with key stakeholders, including community influencers, pregnant and breastfeeding women, and South African and Filipino providers.
This novel group of participants reported that pregnant and breastfeeding women would largely be interested in participating in TB clinical trials and highlighted the importance of a family-centered approach to TB treatment so that all household members have access to the same treatment regimen.

Integrating TB care with maternal and child health: Lessons learned in Papua New Guinea

P Masta,[1] [1]University of Papua New Guinea, Port Moresby, Papua New Guinea.
e-mail: lyn.masta@gmail.com

Port Moresby General Hospital maternal and newborn division cares for >15,000 deliveries annually. TB is the leading infectious cause of maternal mortality at PMGH. Historical data shows approximately 50 pregnant women and 30 infants <6 months old diagnosed with TB annually. Pregnant and postpartum women are a priority group for TB screening by PNG NTP and WHO. Our TB Free PNG program supported by TB Reach, supports TB screening, the use of chest radiography with AI reading, TB treatment and linkage to care for women and TB case finding and preventive treatment in their newborns and families.

SY20-300-20 Impact of recent and expected reductions in international donor funding for TB prevention and care

Chair: Jeremiah Chakaya, Respiratory Society of Kenya and Kenya Medical Research Institute, Nairobi, Kenya
Chair: Katherine C. Horton, London School of Hygiene and Tropical Medicine, London, United Kingdom

Contributions from the United States typically account for half of all donor funding to tuberculosis prevention, diagnostic, and treatment services. Earlier this year, the US dismantled USAID, abruptly ending much of this support, and a number of other donor countries have announced reductions in contributions to bilateral aid programmes and multinational organisations. These funding cuts threaten to reverse decades of progress to reduce tuberculosis morbidity and mortality.
This session offers community and policy perspectives on the impact of funding cuts; presents the projected epidemiological impact of cuts in TB and HIV funding; and discusses mitigation strategies and ways forward.

Impact of US government funding halt on TB responses in high-burden TB countries

S Sahu,[1] [1]Stop TB Partnership, Switzerland.
e-mail: sahus@stoptb.org

The US Government funding halt, particularly through USAID, has significantly disrupted tuberculosis (TB) response efforts in several high TB burden countries. This presentation presents results from the Stop TB Partnership's work outlining the key areas of disruption, the specific impacts on TB programmes, and the mitigation measures being implemented or planned to address these challenges.
The presentation is structured around the broad areas of work affected, including TB screening, diagnosis, treatment, prevention, community-led activities, private sector engagement, monitoring and evaluation, supply chain management, operational research, technical assistance, capacity building, and other critical activities.

Community perspectives on the impact of funding cuts in South Africa

P Tisile,[1] [1]TB Proof, Cape Town, South Africa.
e-mail: phumeza@tbproof.org

Funding cuts are hitting communities hard, especially in healthcare and TB services. In this session, I will talk about how these cuts affect access to treatment, patient support, and advocacy in South Africa. I will share real experiences, highlight key challenges, and show why sustainable funding is essential. We need to listen to those most affected and push for change to protect vital services.

Predicting the epidemiological impact of TB funding cuts in low- and middle-income countries

R Clark,[1] [1]London School of Hygiene and Tropical Medicine, London, United Kingdom.
e-mail: rebecca.clark@lshtm.ac.uk

Tuberculosis prevention, diagnostic, and treatment services in many settings rely heavily on international donor funding. In this presentation, I will discuss results from our work modelling the impact of reductions in international donor funding on the tuberculosis burden in 79 low- and middle-income countries. We estimated substantial direct impacts of funding cuts on tuberculosis morbidity and mortality, particularly in the WHO African Region and low-income countries.

Predicting the epidemiological impact of HIV and TB funding cuts on TB in South Africa

M Kubjane,[1] [1]Health Economics and Epidemiology Research Office, Johannesburg, South Africa.
e-mail: mkubjane@heroza.org

This presentation describes a South African-led modelling exercise to predict the potential impact of recent USAID/PEPFAR funding cuts on HIV and TB in South Africa. This is based on analyses of past US spending on different components of the HIV and TB programmes. We assess the impact of proportionally reducing the coverage of different HIV and TB services using the Thembisa model, which fully integrates HIV and TB.
In South Africa, where most incident TB is due to HIV, we predict much of the impact of the funding cuts on TB will be exacerbated by disruptions to HIV services.

Reckoning with the roots of TB's funding crisis

U Khan,[1] [1]McGill University / Independent Consultant, Montreal, Canada.
e-mail: uzma.khan@ird.global

This presentation investigates how systemic failures—far predating recent funding cuts—created today's crisis. Through Pakistan's experience, we examine how chronic underinvestment, donor-centric models, and fragmented governance institutionalized dependency while eroding resilience. True accountability requires confronting these structural roots to break the cycle—and to forge a new one. We explore pathways forward: domestic resource mobilization, equitable global partnerships with meaningful local leadership, and community-led governance mechanisms.
This session challenges participants to transform understanding into action—because diagnosing why systems fail is only the first step toward building lasting solutions.

SY21-310-21 Investment case: Why community engagement is critical to ending TB

Chair: Tauhid Islam, Global Tuberculosis Programme – WHO, Geneva, Switzerland
Chair: Nimalan Arinaminpathy, World Health Organization TB Monitoring, Evaluation & Strategic Information, Geneva, Switzerland

This symposium will present the emerging investment case for community engagement (CE) in national TB responses. While CE is widely acknowledged as essential to people-centered TB care, its full potential remains underfunded and underleveraged. Drawing on new evidence from a global scoping review, financial modeling, and expert consultations, the session will explore how different types of community participation contribute to improved TB outcomes, and how these efforts can be costed and sustained.
The symposium aims to deepen understanding of CE's impact on resilient health systems, and to provide actionable recommendations for integrating CE into national strategic plans and TB financing frameworks. Participants will leave with evidence-informed arguments to support greater investment in CE, tailored to diverse policy and programmatic contexts.

Community engagement for ending TB: Why it matters and what it takes

T Islam,[1] [1]Global Tuberculosis Programme – WHO, Geneva, Switzerland.
e-mail: islamt@who.int

This presentation will introduce the WHO Guidance on the engagement of communities and civil society to end TB as the normative backbone of the investment case. It will outline the strategic roles of communities across the TB response and emphasize how the guidance articulates the why, what, and how of meaningful engagement.
By linking principles such as co-creation, accountability, and sustainability to financing and implementation, this talk will establish the case for moving from political commitment to concrete investment in community-led action.

Making it count: Evidence of impact from community engagement in national responses

K Kielmann,[1] [1]Queen Margaret University, United Kingdom.
e-mail: KKielmann@qmu.ac.uk

Community engagement (CE) is widely endorsed in TB programming, yet evidence of its impact remains uneven and under-theorised. CE encompasses a wide range of practices—from consultation and co-production to instrumentalised support—raising questions what type of engagement serves programmes best.
Finally, pathways linking CE to improved TB outcomes remain unclear. A realist review can uncover these complexities by asking: what works, for whom, in what contexts, and how—yielding insights to inform more equitable and effective TB responses.

Insights from a scoping review: Understanding how community engagement drives TB outcomes

S Atkins,[1] [1]Tampere University, Tampere, Finland.
e-mail: salla.atkins@tuni.fi

Based on a realist-informed scoping review of over 180 studies, this presentation will explore how and why community engagement contributes to improved TB outcomes across diverse contexts. It will examine the mechanisms—such as trust-building, peer-led support, and community-led monitoring—that enable interventions to succeed.
The presentation will also highlight how factors like local ownership, stigma reduction, and responsiveness to community needs influence effectiveness. These insights help clarify not just whether, but how and under what conditions community engagement improves access, quality, and equity in TB services.

Modeling the health and economic impact of community engagement in TB

B Pal,[1] [1]Visva-Bharati, India, Berhampore, India.
e-mail: bikrampal993@gmail.com

This presentation will share results from epidemiological modeling that estimates the potential impact of CE on incidence and mortality, and its return on investment. It will highlight illustrative scenarios showing how CE can enhance treatment completion and case detection, and reduce mortality.
The session will also explore future modeling directions, including assessing catastrophic cost reduction, stigma mitigation, and improved equity. These data aim to inform policymakers and funders seeking to make smart, evidence-based investments in community-driven TB strategies?

SY22-320-22 Charting the course of post-TB lung health and well-being: Advances and opportunities in the field

Chair: Marieke van der Zalm, Stellenbosch University, Cape Town, South Africa
Chair: Stellah Mpagama, Kibong'oto Infectious Diseases Hospital, Siha, Tanzania

This symposium explores emerging evidence and priorities in post-tuberculosis lung health and well-being, spanning children, adolescents, and adults. It highlights progress in characterising the early natural history of post-TB lung disease (PTLD), refining research definitions, and integrating survivor voices through community engagement and advocacy. Advances in paediatric PTLD research will be shared, alongside adolescent and adult perspectives, emphasising the need for age-appropriate approaches and data.
By bringing together research, clinical, and community viewpoints, the session aims to inform ongoing discussions on clinical management, policy development, and equitable care for TB survivors across the life course.

Advocacy priorities for post-TB care

P Tisile,[1] [1]TB Proof, Cape Town, South Africa.
e-mail: phumeza@tbproof.org

This session will highlight advocacy priorities for post-TB care, with a focus on community engagement and survivor-led action. Drawing on key conclusions from the advocacy working group at the 3rd International Post-TB Symposium, the session will expand on strategies to elevate the voices of TB survivors, promote equitable access to post-TB care, and integrate long-term health and well-being into TB programmes. Phumeza will reflect on experiences from diverse settings and discuss how advocacy can drive research, policy, and service delivery.
The session aims to build momentum for a global, inclusive approach to addressing the lasting impact of TB.

Global consensus on PTLD: A research-focused definition for children, adolescents, and adults

G Bisson,[1] [1]University of Pennsylvania, Philadelphia, United States.
e-mail: bisson@pennmedicine.upenn.edu

A globally representative group of post-TB lung disease (PTLD) experts has collaboratively developed a research-focused definition of PTLD to support standardised data collection across PTLD studies involving children, adolescents, and adults.
This initiative was first presented during at the 2nd International Post-TB Symposium in Stellenbosch, and has since evolved into a manuscript, targeted for submission in April 2025. Contributors include experts from diverse regions and disciplines, reflecting broad clinical and research expertise across the life-course.
The proposed definition and reporting framework aim to harmonise PTLD research efforts globally and improve the synthesis of evidence in this complex and growing field.

Adolescent post-TB lung disease: Emerging evidence

S Chiang,[1] [1]Brown University - Warren Alpert School of Medicine, Providence, United States.
e-mail: silvia_chiang@brown.edu

This presentation will review data on adolescent post-TB lung disease (PTLD), focusing on a new study conducted in Lima, Peru. While PTLD is increasingly recognised in adults, data specific to adolescents remain limited, despite their distinct developmental and healthcare needs.
This presentation will highlight research strategies and priorities to better understand PTLD in this critical age group.

Advancing post-TB care through individual participant data meta-analysis

J Campbell,[1] [1]McGill University, Montreal, Canada.
e-mail: jonathon.campbell@mcgill.ca

Epidemiology provides essential tools to understand the long-term consequences of tuberculosis, yet critical gaps remain in our knowledge of post-TB health.
This presentation will highlight how individual participant data meta-analysis (IPD-MA), grounded in rigorous epidemiologic methods and thoughtful study design, can help advance our understanding of post-TB respiratory sequalae. We will demonstrate how global data can be used to estimate prevalence in key subgroups, identify

epidemiological determinants of post-TB outcomes, and develop risk prediction models to guide clinical decision-making.
This work aims to generate actionable evidence to support more targeted, equitable care for people affected by TB.

Understanding the early natural history of post-TB lung disease: Insights from the TB aftermath study

A Gupte,[1] [1]Boston University, Boston, United States.
e-mail: agupte1@bu.edu

This presentation will summarize key lung health findings from the TB Aftermath study including:
1. Burden, clinical presentation and severity of post-tuberculosis lung disease (PTLD) among successfully treated individuals with pulmonary and extra-pulmonary tuberculosis;
2. Phenotypes of PTLD and their evolution during post-treatment follow-up;
3. Feasibility of performing de-centralized point-of-care spirometry at outpatient respiratory clinics in a programmatic setting, and in the TB affected communities;
4. Performance of a simple point-of-care case finding tool for PTLD screening/triage.
Taken together, the presentation aims to characterize the early natural history of PTLD and meaningfully contribute to ongoing clinical and policy discussions.

SY23-330-23 Beyond explanatory phase III adult trials: Innovative TB treatment trials for effectiveness in programmatic settings and inclusion of priority populations

Chair: Geraint (Gerry) Davies, University of Liverpool, Liverpool, United Kingdom
Chair: Tiziana Masini, World Health Organization, Geneva, Switzerland

Challenges such as treatment complexity, adherence difficulties, and poor tolerability, highlight the need for high-quality, pragmatic evidence to new international recommendations and optimize uptake in programmatic settings. Moreover, exclusion of specific populations from adult trials (pregnant and lactating women, adolescents) and delay in paediatric development result in lack of or late access to latest available innovations for many of the most vulnerable people affected by TB.
The symposium will provide insights on how to optimize the TB clinical trial landscape, to reflect on how to fill the gap between evidence generated in explanatory efficacy studies in adults, and its integration into global and national policies and implementation across all relevant populations.

Country-led, collaborative platform for clinical trials of TB: A paradigm shift in TB research

S Schumacher,[1] [1]World Health Organization, Geneva, Switzerland.
e-mail: schumachers@who.int

Pragmatic, streamlined clinical trials have proven effective in generating large-scale, high-quality evidence quickly and cost-efficiently—most notably for COVID-19 and other diseases. Applying these methods to tuberculosis (TB) presents a major opportunity to improve the evidence base for global treatment guidelines.
In this session, Dr. Schumacher will present the rationale for rethinking late-stage trials of licensed TB medicines, discuss key methodological shifts needed, and introduce plans for a WHO-facilitated trial platform designed to support direct collaboration among high-TB burden countries.

A platform approach for phase I/II trials of new TB drugs in children

S Nambiar,[1] [1]Johnson and Johnson / Child Health Innovation and Leadership Department, Raritan, United States.
e-mail: SNambia4@ITS.JNJ.com

Platform trials are innovative approaches to reduce the significant lag between adult and pediatric approvals by providing clarity regarding trial design and necessary investment in trial sites and ideally be embedded in the public health systems.
As efficacy can generally be extrapolated from adults to children, platform trials would include a master protocol and compound-specific protocols for single-arm trials to assess pharmacokinetics, safety, and tolerability of the individual compounds of a novel regimen; in some cases, this will obviate the need to study different regimens in children. Quality systems, data standardization and governance will also need to be addressed.

Strategy trials in children: Reflecting on the need for randomised, controlled efficacy trials in children

A Hesseling,[1] [1]Desmond Tutu TB Centre, Stellenbosch University, Cape Town, South Africa.
e-mail: annekeh@sun.ac.za

As children with most forms of TB respond as well or better to TB treatment compared to adults, it is reasonable to extrapolate efficacy of TB drugs and regimens from adult trials to children. Therefore, the priorities for many paediatric trials are pharmacokinetics, dose, safety and acceptability. However, there remains an important place for efficacy trials in children to establish when they may be effectively treated with shorter treatment durations or fewer drugs, as in the SHINE trial. This presentation will outline the rationale for strategy trials in children, describe approaches to design, and share examples of planned trials.

Inclusion of pregnant women in clinical trials

J Mathad,[1] [1]Weill Cornell Medicine, New York, United States.
e-mail: jsm9009@med.cornell.edu

For women, the highest risk time to develop active TB is during and immediately after pregnancy. Maternal TB leads to adverse pregnancy and infant outcomes. Despite these epidemiologic facts, pregnant and lactating women continue to be excluded from the majority of TB treatment and prevention trials.
In this talk, Dr. Mathad will discuss new approaches to early and optimal inclusion of pregnant and lactating women in TB drug and vaccine research, based on the recent WHO-convened TB pregnancy consensus project.

Beyond efficacy and safety: The importance of person-centred outcomes

O Rucsineanu,[1] [1]Society of Moldova against Tuberculosis, Moldova.
e-mail: oxana_rucs@yahoo.com

This presentation will discuss recent work to develop outcomes which can be routinely used in TB treatment and prevention studies to measure experiences that are important to people facing TB. Examples include quality of life, treatment tolerability, ease of administration, fewer low grade AEs, acceptability, that might not reach thresholds to be considered important events from clinical view but critically important from a TB person' s affected perspective.

SY24-340-24 Unveiling TB narratives: The power of storytelling

Chair: Petra Heitkamp, McGill University Health Center, Research Institute, Ottawa, Canada
Chair: Lindsay Palazuelos, Partners In Health, Boston, United States

Four dynamic women authors converge to unveil the untold stories of tuberculosis. This symposium provides practical guidance on the intersection of science communication and storytelling. Through provocative discussions and brief exercises the audience will learn how to amplify the voices of those affected by TB, and master techniques in writing that provoke thought and rouse one to action. If location allows, break-out groups will be organized.
This session focuses on key aspects of storytelling–science communications, narrative arc, and structure to elevate the voice of people affected by TB and reach the widest possible audience. Sharp and incisive writing has the power to create much-needed conversation around important events and public health issues. Participants will leave the session equipped with insights into the importance of storytelling in TB advocacy, practical techniques for crafting impactful narratives, and the tools to sharpen their voices in addressing this global health challenge.

Techniques in writing and storytelling for targeted impact

V Krishnan,[1] [1]Independent, Goa, India.
e-mail: vidyakrishnan@protonmail.com

Effective Techniques in Writing and Storytelling for Reaching Relevant Audiences and Strategies for Provoking Thought and Spurring Action through Sharp and Incisive Writing. The presentation will be followed by an interactive exercise for all participants.

Beyond the data: The Art of storytelling in science communication

M Smilios,[1] [1]Independent, Human Centered Storytelling in Public Health, Asheville, United States.
e-mail: maria.smilios2@gmail.com

In this interactive workshop, we will explore the intersection of storytelling and science communication. While data and facts are essential, the most impactful science stories are those that resonate on a human level.
Through a blend of practical exercises and thought-provoking discussions, participants will learn how to transform complex scientific concepts into compelling narratives that engage, educate, and inspire diverse audiences. From crafting relatable stories to enhancing clarity and emotional connection, this workshop will introduce you to the tools for communicating science in a way that goes beyond numbers and data points and speaks to the heart of your listeners.

Framing narratives to empower those affected by TB and directing voices to build empathy and influence decisions

H Enkh-Amgalan,[1] [1]International Rescue Committee, Berlin, Germany.
e-mail: handaa.rea@gmail.com

Building on the previous speaker, Handaa outlines how we can frame narratives to empower those affected by TB. Her presentation outlines various aspects on directing voices to build empathy and compassion while aiming to influence decisions of policymakers.

SY25-350-25 Implementation research to prepare for the introduction of new TB vaccines for adults and adolescents

Chair: Saskia Den Boon, World Health Organization, Geneva, Switzerland
Chair: Vanessa Veronese, Special Programme for Research and Training in Tropical Diseases, Switzerland

This symposium will explore the critical role of implementation research in the successful introduction of new TB vaccines for adults and adolescents. Presentations will cover key outstanding evidence needs, willingness to receive new TB vaccines in Mozambique, an exploration of strategies to integrate novel TB vaccines with other existing health services in South Africa, and health economic modelling in India. We will also learn about the role of civil society and affected communities in translating political commitments into action to deliver new TB vaccines.
Attendees will gain valuable insights into the practical challenges and solutions for vaccine introduction, addressing evidence gaps through targeted implementation research, learn about the research methodologies to address these evidence gaps and challenges, and understand the importance of early preparation.
This session is essential for those dedicated to the effective and equitable rollout of new TB vaccines for adults and adolescents.

Gavi's Investment Case and Learning Agenda for new TB Vaccines

M Tufet Bayona,[1] [1]Gavi, the Vaccine Alliance, Switzerland.
e-mail: mtufet@gavi.org

Gavi will present its investment case which signalled in-principle support for future new TB vaccines for adults and adolescents. The presentation will outline priority areas for a learning agenda addressing key evidence gaps, including delivery strategies for the new adolescent immunisation touchpoint, integration with existing immunisation and TB intervention pathways, and understanding acceptability.

Evaluation of the acceptability of new and repurposed tuberculosis vaccines in southern Mozambique

A Lima,[1] [1]Manhiça Health Research Center, Maputo, Mozambique.
e-mail: agostinho.lima@manhica.net

New TB vaccines for adolescents and adults offer a vital opportunity to reduce TB burden in high-incidence settings like Mozambique, where most vaccines target only young children. Barriers such as long distances to health facilities, vaccine shortages, and limited vaccine availability hinder coverage. Additionally, local beliefs about TB influence risk perception. Understanding community attitudes toward new vaccines is essential for effective introduction and equitable access.
In this presentation, we will share data on the willingness of adolescents, adults, and their caregivers to receive a new TB vaccine or BCG booster, providing insights to inform future vaccine introduction efforts.

Integrated model of delivery for novel TB vaccines in South Africa

L Lebina,[1] [1]Africa Health Research Institute, Durban, South Africa.
e-mail: Limakatso.lebina@ahri.org

Adolescents and adults should be targets of novel TB vaccination for the greatest impact. Globally, experience in delivering vaccines to these populations is limited. Novel TB vaccines delivery through campaigns without integration to other health services will increase costs for the program and might not be sustainable or reach the heterogeneous populations that may benefit from the TB vaccines.
In this talk we will present data from literature review and participatory workshops with key stakeholders on strategies to integrate novel TB vaccines with other existing health services, including but not limited to primary healthcare clinics, schools and occupational health services

Optimizing TB Vaccine Strategies: Harnessing Local Evidence and Modeling Insights in the Indian context

J Joseph,[1] [1]IAVI (India), Delhi, India.
e-mail: jjoseph@iavi.org

In resource limited settings like India, vaccine deployment strategies enabling maximal impact and cost-effectiveness are critical for timely policy decisions. Early understanding of priorities - who, what, why, how, when – can help optimize national efforts.
We present an integrated and responsive in-country model from India which is leveraging country-specific insights – target population, priority delivery scenarios, programmatic feasibility and integration, and end-user acceptability - to predict most impactful strategies. Aligning local evidence such as national level data, stakeholder insights, and programmatic lessons including from BCG revaccination would be key for shaping policy pathways and ensuring country preparedness.

Advocacy for policy impact: translating political commitments to action to deliver new TB vaccines

S Palmer,[1] [1]IAVI, Amsterdam, Netherlands.
e-mail: spalmer@iavi.org

Civil society and affected communities play essential roles in translating political commitments to develop and deliver new TB vaccines into reality. This includes calls for context-specific approaches and multilateral collaboration to maximize impact. This speaker will present on the work of the TB Vaccine Advocacy Roadmap in advocating for novel financing and access models for TB vaccine development and delivery.
Reflections will also be shared on global campaigns in support of this effort and community-led demands for inclusive and equitable research and implementation outlined in the Community Declaration of the 7th Global Forum on TB Vaccines in October 2024.

SY26-360-26 A world without TB must not be a world without ethics: The AI dilemma

Chair: Razia Kaniz Fatima, UNOPS Consultant TB technical assistance TB strategic planning and Global Fund Grants, Islamabad, Pakistan
Chair: Nesri Padayatchi, CAPRISA, University of Kwa ulu Natal, Durban, South Africa

As the TB community works towards a 'World without TB', by pioneering new technology, finding new drugs and fostering partnerships, let us uphold the most critical partner in this fight, the person with TB! Health disparities over access to new drugs and technologies require a review, revival, and a reminder of ethics. As we innovate, we need to continue looking forward. Artificial intelligence (AI) could be the key to creating first-of-a-kind solutions, OR NOT. The usefulness of AI in TB diagnostics has generated enthusiasm to accelerate this technology into other areas of TB care and prevention.
This session will provide a forum for discussions around AI and ethics in health, specifically populations affected by TB. Given the climate-related consequences and monetary costs of using AI, we must resist being seduced by new tools just because they're new or just because they're being used elsewhere in medicine.

Ethical considerations in ultrashort TPT trials

J Denholm,[1] [1]Victorian Tuberculosis Program, Melbourne, Australia.
e-mail: justin.denholm@mh.org.au

Tuberculosis preventive treatment (TPT) is one tool in the TB elimination toolbox, and is offered to those with presumptive TB infection to prevent disease. While though the duration of TPT has been shortened, uptake remains low.
This presentation will highlight ethical considerations around the investigation of ultra-short course TB preventive therapy with the aim of identifying the optimal trade-off between efficacy and acceptability.

The ethics of artificial intelligence in health

K Moodley,[1] [1]Stellenbosch University, South Africa, South Africa.
e-mail: km@sun.ac.za

The doctor-patient relationship is steeped in tradition, all of which are poised for disruption by digitization, emerging technologies and AI. The transition to electronic health records (EHRs), wearables, etc. has created new possibilities to scale up data collection to unprecedented

levels. While innovation will improve TB care and prevention, we ought to be mindful of the ethical, legal and social challenges. Global guidelines are emerging to ensure governance in AI but many low-and middle-income countries are yet to adapt and contextualise these frameworks. This talk will focus on the ethical principles of relevance of AI as outlined in WHO guidelines.

AI in TB care: Just because the cool kids are doing it doesn't mean you have to do it too

D Silva,[1] [1]University of Sydney, Sydney, Australia.
e-mail: diego.silva@sydney.edu.au

In order to be of use, we should be clear what question we're trying to answer using AI and whether AI is better or more efficient at answering that question than the current standard. Even if there is a question for which AI is useful (e.g. diagnostics) we should ask whether it will lead to better outcomes (e.g. is diagnosis the main barrier within the cascade of TB care?).
I will outline some ethical challenges related to adopting AI in a historical and present-day context that has failed to address the socioeconomic and political determinants of TB infection and disease.

Perceptions of TB-affected communities about AI in TB care

K Sagili,[1] [1]Health Research and Advocacy Consultancy, Amsterdam, Netherlands.
e-mail: drkarunas@gmail.com

AI is being widely launched in healthcare, including TB. Traditionally, persons with TB (PwTB) prefer the human element in their TB care. For example, digital adherence tools were promoted widely, but evidence suggests PwTB still prefer healthcare workers to guide them through their treatment. In light of accelerating AI use in TB care, this session will focus on how beneficiaries perceive AI.
We will discuss questions like - Are PwTB aware of AI or understand how it works in TB care? Any concerns regarding quality of care they receive? Do PWTB have any right to say no to AI-enabled care?

SY27-370-27 Bridging the gap: Accelerating development and approval of priority formulations for children with TB

Chair: Anneke C. Hesseling, Desmond Tutu TB Centre, Stellenbosch University, Cape Town, SY27-370-27
Chair: Catherine Hewison, Médecins Sans Frontières, Paris, France

Paediatric tuberculosis formulation development and investigation should begin while phase II/III trials are underway in adults. However, the development of tuberculosis medicines for children still dramatically lags behind that for adults mainly due to limited investments and market incentives. With novel compounds in the tuberculosis drug pipeline moving into late-phase clinical evaluation in adults, there is now momentum to accelerate paediatric trials and approvals of priority tuberculosis medicines to ensure that children can benefit more rapidly from latest therapeutic innovations.
This symposium will share emerging innovative approaches to streamline paediatric studies, from designing and implementing more efficient trials through a paediatric research platform, and state-of-the-art pharmacometrics approaches, to accelerating their approval, building capacity for clinical trials, with specific needs of children and adolescents.
We will present ganfeborole as a case study demonstrating how global cross-cutting collaboration in the paediatric research community can help accelerate tuberculosis drug development in children.

CHasing Expedited and Equitable Treatment Access (CHEETA) for children

A Garcia-Prats,[1] [1]University of Wisconsin-Madison, Madison, United States.
e-mail: garciaprats@wisc.edu

There have been 8–13-year delays between when new TB drugs have been approved for use in adults and when pediatric trials of those drugs have been completed across the age spectrum. This results in preventable morbidity and mortality in children. As a growing pipeline of exciting new TB compounds moves through adult studies, these delays are expected to continue without innovative new approaches.
This presentation will describe critical sources of delays in pediatric trials of new TB drugs and crosscutting solutions of the CHEETA Consortium and other key stakeholders to speed pediatric evaluations of new TB drugs.

State-of-the-art pharmacometric approaches to paediatric trials

E Svensson,[1] [1]Uppsala University - Department of Pharmacy, Uppsala, Sweden.
e-mail: elin.svensson@farmaci.uu.se

Pharmacometric modeling is a powerful tool to accelerate pediatric anti-TB drug development. The presentation will showcase how pharmacometrics can be used to select minimal sampling schedules and number of participants, and to inform trial formulation and dosing. The use of modeling for interim and final analysis, as well as for the generation for practically implementable dosing schedules will also be discussed.
Lastly the impact on global dosing guidance will be demonstrated by the example of how bedaquiline dosing for children <6years made it into WHO Operational handbook.

Child-friendly formulations and acceptability: Not an afterthought

T Masini,[1] [1]World Health Organization, Geneva, Switzerland.
e-mail: tmasini@who.int

Historically, the lack of child-friendly formulations of TB medicines has limited access to treatment for children. Manipulation of adult formulations may result in inaccurate dosing, and they may be unpalatable and unacceptable to children and caregivers. While currently used TB medicines are available in child-friendly formulations, we have a unique opportunity to ensure prompt availability of paediatric formulations for medicines that are still being investigated.
This presentation will reflect on strategies to ensure prompt availability of suitable formulations for children, and will provide insights on bridging strategies that can be implemented not to delay access to new therapeutics for children.

Towards regulatory approval: Paediatric investigation plans

L Fregonese,[1] [1]European Medicines Agency - Department of Public Health, A, Netherlands.
e-mail: laura.fregonese@ema.europa.eu

The presentation will address the current requirements for the approval of TB medicines for children in the EU, including the need and scientific contents of paediatric investigation plans (e.g. population, type of study designs, context of use of extrapolation) and the opportunities for developers to interact with regulatory authorities across the whole lifecycle of development of paediatric TB medicines.
The talk will also touch upon international regulatory initiatives and collaborations supporting the availability of paediatric TB medicines in other geographic areas of the world.

SY28-380-28 Global political and financial shifts: Impact on TB communities and a collective action response

Chair: Petra Heitkamp, McGill University Health Center, Research Institute, Ottawa, Canada

Abrupt U.S. funding cuts have put the health infrastructure in many countries with a high burden of TB at risk. Health systems and lives are impacted, with frontline organizations and staff stopping their life saving work and millions more people being projected to fall ill from and die of TB. To document the impacts of the stop-work order and funding freezes on TB programs and partners, and to mobilize action and resources, the TB Community Coordination Hub - a volunteer initiative launched in response to the crisis - ran a TB-specific impact survey from February 11 - 24, 2025.
This session will share findings from the survey, in-depth case examples of impacts of US funding withdrawals from three countries, and overarching experiences and lessons learned from this community effort to mobilize and coordinate an organized community response during this time of crisis.

Assessing the USAID fallout: Comprehensive survey insights on TB programme impacts

K Ul Eman,[1] [1]Dopasi Foundation, Islamabad, Pakistan.
e-mail: kinza_kz@yahoo.com

This presentation will explore the impacts of USAID's abrupt stop work orders and funding terminations on global TB response efforts. It will provide an overview of the challenges and setbacks faced by TB programs worldwide, documented through a TB-specific impact survey conducted by the TB Community Coordination Hub. The presentation will highlight key findings, showcasing the severe disruptions in TB services across various countries.
Through data-driven insights the presentation aims to share findings from the survey and underscore the urgent need for robust and sustainable TB financing solutions, and to foster a collaborative dialogue on how to mitigate disruptions.

TB lives disrupted: The human cost of interrupted support in Ukraine

O Klymenko,[1] [1]CO TBPeople, Kyiv, Ukraine.
e-mail: olyaklymenko2910@gmail.com

In this presentation, Olya draws on the experience from Ukraine and other countries to explain how the consequences of funding cuts are real and deeply personal. Individuals face treatment interruptions due to medicine shortages, the absence of psychosocial support, and reduced availability of community-based services. Stigma compounds the problem — people are avoiding TB centers for fear of being seen, while others are forced into impossible choices. Olya explains how when people are left behind, TB doesn't just affect them — it threatens the broader community. The long-term impact of disruptions will cause rising transmission and worsening health outcomes for people.

TB Healthcare workers furloughed: The impact and experience in Cambodia

S Choub,[1] [1]KHANA, Phnom Penh, Cambodia.
e-mail: csokchamreun@khana.org.kh

The community health workers who have ensured the delivery of TB services until now have been sent home, either furloughed or fired. In this presentation, Chamreun shares the experience from Cambodia and his organization, where hundreds of front line healthcare workers have lost their jobs. In just two months, this resulted in a 66% decrease in TB case notifications. Hundreds of people sick with TB are now going undiagnosed and not able to start treatment and the dedicated staff, often choosing the work for the purpose first, are now seeking to find employment to make a living.

TB Programmes in distress: Experiences from Kenya

E Kibuchi,[1] [1]Stop TB Partnership-Kenya, Nairobi, Kenya.
e-mail: ekibuchi@gmail.com

National programs are hard pressed to replace the funding cuts. Choices are being made in what services get priority and what gets cut. In this presentation, Evaline shares experiences from Kenya, revealing how services are being prioritized and what the impact on the overall TB response in the country is. All essential services, including identifying persons at risk of TB (screening, transport and testing sputum specimens), enrolling people affected by TB on the correct treatment regimen (including preventive treatment), supporting people to adhere to and complete their treatment (including mental health and nutrition), and more have been impacted.

TB Community Coordination Hub: The TB community takes collective action to lead a response in crisis

R Waite,[1] [1]Independent Consultant, Ottawa, Canada.
e-mail: robynchristinewaite@gmail.com

In response to the crisis of U.S. stop work orders, the TB Community Coordination Hub was resurrected to support the development of an informed and organized community response.
In this session you learn more about how and why the Hub was mobilized, and Robyn will explore key lessons learned, challenges, and the value-add of an independent community led coordination platform. Should the work of the Hub be sustained or replicated in the future, this presentation will set the community up for success. The presentation and session will close with calls to action from the community still in need of attention.

SY29-390-29 Addressing TB in migrant populations: Challenges, evidence, and strategies for action

Chair: Delia Goletti, National Institute for Infectious Diseases-IRCCS L. Spallanzani, Italy
Chair: Daria Podlekareva, International Reference Laboratory of mycobacteriology (IRLM), Statens Serum Institut, Department of Respiratory- and Infectious Diseases, Copenhagen University Hospital - Bispebjerg, Centre of Excellence for Health, Immunity and Infections (CHIP) Copenhagen University Hospital – Rigshospitalet, Copenhagen, Denmark

Background and Rationale: Migrant populations, including labor migrants, asylum seekers, and refugees, face a disproportionate burden of tuberculosis (TB). Social determinants such as poor living conditions, barriers to healthcare access, and legal constraints contribute to increased vulnerability. Despite global commitments to TB elimination, gaps remain in screening, prevention, and treatment tailored to these populations.
This symposium will provide a comprehensive overview of the latest evidence, best practices, and policy considerations in addressing TB among migrants.
Objectives:
* Discuss the epidemiology and burden of TB among migrants, including subpopulations with increased risk.
* Discuss TB screening, prevention, and care models tailored to migrant communities.
* Explore the challenges of ensuring equitable TB services for refugees and asylum seekers, drawing on international experiences.
* Identify policy and programmatic solutions to improve TB outcomes in migrant populations.
* Present findings from the consensus on TB management in migrant populations.

Overview of TB in migrant populations: Epidemiology and barriers to care

L Guglielmetti,[1] [1]IRCCS Sacro Cuore Don Calabria Hospital; Department of Infectious, Tropical Diseases and Microbiology, Verona, Italy.
e-mail: lorenzo.guglielmetti@paris.msf.org

An overview of the global burden of tuberculosis among migrant populations, often facing higher risks due to socioeconomic vulnerability and limited access to healthcare.
We will examine **structural and systemic barriers** (restrictive policies, stigma, language/cultural challenges), **that hinder timely TB diagnosis and treatment.**
Emphasis will be placed on **strategies to improve access to TB services** (inclusive health policies, culturally appropriate services, cross-sector collaboration).

Addressing TB in migrant populations is essential for both equity and effective TB control, requiring coordinated efforts across public health, policy, and community engagement.

Re-emergence of drug-resistant TB because of instable geopolitics

I Monedero-Recuero,[1] [1]The Union / Action Damien, Vilanova i la Geltrú, Spain.
e-mail: monederoi@hotmail.com

Internally displaced populations (IDPs) are the most vulnerable and neglected. We explore the re-emergence of DR-TB in the context of unstable geopolitics and population displacement. Armed conflict, political crises, and natural disasters disrupt health systems, leading to interrupted TB-treatment and rising antimicrobial resistance. Migrants, refugees, and IDPs face immense barriers to care across borders—from loss of medical records to lack of legal status.
We discuss key challenges in maintaining treatment continuity and present strategies such as cross-border referral systems, mobile health interventions, and policy frameworks that prioritize TB-care in emergencies, with a focus on reaching the most vulnerable populations.

TB and refugees: Challenges and solutions from a global perspective

C Wejse,[1] [1]Aarhus University Hospital, Aarhus N, Denmark.
e-mail: wejse@clin.au.dk

Talk addresses the complex interplay between tuberculosis and refugee health. It identifies unique challenges faced by refugee populations, such as limited access to healthcare, overcrowded living conditions, and disrupted treatment regimens. We explore effective screening strategies tailored to refugee camps and host countries, emphasizing early detection and prevention as well as addressing cross-cultural and language barriers.
Additionally, it will discuss innovative treatment solutions that consider the mobility and resource constraints of refugee settings. By sharing global perspectives and best practices, the talk enhances collaboration among healthcare providers, policymakers, and humanitarian organizations to improve TB control and care for refugees worldwide.

Consensus-based recommendations for TB prevention and care in migrants

R Duarte,[1] [1]Director, Centro de Saúde Pública Gonçalves Ferreira (CSPGF) Porto, Portugal, Porto, Portugal.
e-mail: raquelafduarte@gmail.com

This talk presents key findings from the recently submitted consensus-based recommendations for tuberculosis control in migrant populations. Developed through expert collaboration, the consensus outlines critical gaps and priorities in addressing TB among migrants, emphasizing equity, continuity of care, and culturally competent services. We will review key policy and clinical practice recommendations, including access to screening, diagnosis, and uninterrupted treatment regardless of legal status.
Finally, we'll explore strategies for implementation at both regional and global levels—such as harmonized protocols, cross-border coordination, and stakeholder engagement—to ensure these recommendations translate into impactful, sustainable action across diverse healthcare settings.

SY30-400-30 Accelerating the introduction of new sample types and near point of care platforms to close gaps in TB diagnosis

Chair: Nazir Ismail, Wits University, Johannesburg, South Africa
Chair: Tejaswini Dharmapuri Vachaspathi, Treatment Action Group, New York, United States

The limits of existing low complexity rapid molecular tests and continued reliance on sputum directly contribute to the TB testing gap, estimated to be 2.7 million people in 2023. The TB diagnostic product pipeline contains promising tools with the potential to improve TB case detection using new sampling techniques, such as oral swabs, and near point-of-care (POC) tests, which are expected to undergo WHO review in the latter-half of 2025.
Early planning for introduction of new sample types and platforms, including discussions on how they can be introduced into current national diagnostic networks and complement existing infrastructure and fill gaps, is essential.
This session will give an overview of emerging technologies to detect TB using oral swabs at the near point-of-care. Speakers will highlight results from studies evaluating these tools, considerations on preferences and acceptability, and trade-offs and opportunities that may inform uptake and implementation.

Performance of tools in the pipeline using oral swabs for TB detection

A Andama,[1] [1]Makerere University, KAMPALA, Uganda.
e-mail: andama.alf@gmail.com

Tools in the TB diagnostics pipeline that use oral swabs and can be placed near the point of care have the potential to transform TB detection.
This presentation will provide an overview of these tools, how they perform compared to traditional sputum-based methods in terms of diagnostic accuracy and yield, and what further research is needed to inform introduction and uptake.

Trade-offs and considerations: Sample types and placement

A Kerkhoff,[1] [1]University of California, San Francisco, San Francisco, United States.
e-mail: Andrew.Kerkhoff@ucsf.edu

Trade-offs between accuracy, accessibility, and placement need to be carefully considered before integrating oral swab-based diagnostic tools into existing TB diagnostics networks and algorithms. Some of the trade-offs and other considerations that will be explored in this presentation include: diagnostic accuracy vs. yield; technical limitations of tools designed for decentralized settings, including integration of drug-sensitivity testing; and the preferences of end-users and how their views on trade-offs can be better captured in preference surveys and discrete choice experiments designed to inform product development and introduction.

The Global Fund next-generation market shaping strategic initiative: Early demand estimations for near-point of care tests to support affordable access to new TB diagnostics

G Brigden,[1] [1]The Global Fund, Switzerland.
e-mail: Grania.Brigden@theglobalfund.org

With several diagnostic products in the late-stages of development, the Global Fund is working with country programs and other global health actors to plan for their market introduction. Part of this work is estimating the market for new Near Point of Care tests. Global Fund will present their approach and early data on potential demand forecasts for various use cases, based on regional dialogues with national programs, lab directors, and civil society for the Global Fund 25 priority countries.

The Diagnostics Equity Consortium: A civil society-led mechanism for ambition and accountability for closing diagnostic gaps

T Kujinga,[1] [1]Pan-African Treatment Access Movement, Harare, Zimbabwe.
e-mail: director@patam.org

The Diagnostics Equity Consortium is a civil society-led movement focused on advocacy to scale up access to essential diagnostics.This session will describe DEC and the role of civil society to improve ambition and accountability for the introduction and scale up of new TB diagnostics at the national level.

SY31-410-31 It takes a village: Advancing late-stage TB vaccine trials in adults and adolescents through global collaboration

Chair: Elana Van Brakel, IAVI, Stellenbosch, South Africa
Chair: Alexander Schmidt, Gates Medical Research Institute, Germany

New TB vaccines are on the horizon with multiple candidates now in late-stage development. Bringing a vaccine candidate across the finish line requires close collaboration with multidisciplinary partners around the world, leveraging expertise in clinical trial design, epidemiology, and immunology, among others. In this timely session, speakers will explore the breadth of work necessary to successfully run a late-stage clinical trial.
The session will open with status updates from the moderators on two promising late-stage candidates, M72/AS01E and MTBVAC, followed by a series of presentations on key design considerations for late-stage trials, including asymptomatic TB, the role of epidemiology, participant recruitment and community engagement.
Speakers will further reflect on important challenges, opportunities, and lessons learned to launch and run a late-stage trial, including insights on vaccine hesitancy.

Epidemiology in support of late-stage TB vaccine trials

P Pelzer,[1] [1]IAVI, Amsterdam, Netherlands.
e-mail: ppelzer@iavi.org

Epidemiological research is critical in guiding strategies to accelerate TB vaccine development. Epidemiological models provide insights into disease transmission dynamics, optimal age groups for vaccination, and the impact of local healthcare infrastructure on implementation strategies.
The X103 HOPE Study, an epidemiological support initiative, will generate robust data to address regional variations in TB prevalence and resource availability, particularly in high-burden regions like sub-Saharan Africa. Collaborative efforts to integrate epidemiological insights into vaccine development pipelines are necessary to deliver new vaccines that are both effective and adaptable to diverse populations, paving the way for transformative solutions in combating TB.

Asymptomatic TB: Unique opportunities in tuberculosis vaccine trials

K Dheda,[1] [1]University of Cape Town Lung Institute, Cape Town, South Africa.
e-mail: keertan.dheda@uct.ac.za

Active tuberculosis disease can be asymptomatic (subclinical tuberculosis) or symptomatic with the former comprising approximately 50–60% of prevalent tuberculosis in endemic countries and largely remaining undetected and globally underestimated. TB vaccine development targets prevention of active pulmonary TB disease but may need to be broadened to address the challenging dimension of asymptomatic TB. No TB vaccine has been assessed for its ability to prevent asymptomatic TB and there is limited evidence about the natural history of asymptomatic TB progression. Preventing asymptomatic tuberculosis is likely to save lives, reduce the amplification of the epidemic, and reduce long-term pulmonary disability.

Recruitment of adolescents for late-stage TB vaccine trials

E Hellström,[1] [1]Be Part Yoluntu NPC/ Research Centre, Paarl, South Africa.
e-mail: pi@bepart.co.za

Enrolling adolescents for late-stage vaccine trials presents several challenges. Complex informed consent processes, ethical concerns, especially in low resource settings, and cultural norms around enrolling minors, concerns about vaccine safety and potential side effects as well as contraception requirements for adolescent girls with first debut sexual activity affect recruitment. Adolescents' school commitments and parents' work schedules can limit availability for trial visits. Being a highly mobile population makes it difficult to ensure long-term follow-up.
Various strategies such as community engagement, clear communication about trial benefits and risks, and flexible scheduling can be implemented to overcome these challenges.

Vaccine hesitancy and TB vaccine development

A Koch,[1] [1]Eh!woza, Cape Town, South Africa.
e-mail: tash@ehwoza.com

Vaccine hesitancy poses a significant challenge to trial participation, impacting the success of vaccine trials across various diseases, including tuberculosis (TB). Lessons from the Covid-19 vaccine roll-out as well as from HIV interventions can be used to mitigate vaccine hesi-

tancy for new TB vaccines, while remaining cognizant that there are likely key differences. Community engagement, transparent communication, and partnership development are vital to build trust in new TB vaccines. Understanding local cultural beliefs and socio-political contexts is crucial. Effective implementation and equitable access are key, with civil society-private sector partnerships offering potential for trust-building.

SY32-420-32 Ensuring global access to shorter, better regimens for multi-drug-resistant/rifampicin-resistant TB for children, adolescents and pregnant women

Chair: Martina Casenghi, Independent Consultant, Geneva, Switzerland
Chair: Jennifer Furin, Harvard Medical School, Department of Global Health and Social Medicine, boston, United States

Significant progress has been made in recent years in identifying shorter, all-oral treatment regimens for managing multidrug/rifampicin-resistant TB (MDR/RR-TB). These regimens should be prioritized for children, adolescents, and pregnant/lactating women to improve tolerability and ensure favorable outcomes in these vulnerable populations. However, these groups risk being left behind, as the 6-month BPaLM regimen (bedaquiline, pretomanid, linezolid, moxifloxacin) is not currently recommended for use in these populations.
Recently, WHO has endorsed several alternative shorter, all-oral regimens based on emerging evidence. These include a 6-month regimen of bedaquiline, linezolid, levofloxacin, delamanid, and clofazimine, as well as various 9-month regimens centered around bedaquiline, linezolid, and pyrazinamide, combined with third-generation fluoroquinolones and/or delamanid, for use in children and adolescents and during pregnancy/lactation.
This session will present early experiences from national programs and implementing partners in rolling out the alternative shorter regimens for these vulnerable populations, highlighting key lessons learned, implementation challenges, and practical solutions.

Treatment as short as six months for drug-resistant TB in children, adolescents and pregnant/lactating women: An update on global guidance

S Verkuijl,[1] [1]World Health Organization, Geneva, Switzerland.
e-mail: verkuijls@who.int

Based on evidence from the BEAT tuberculosis and End TB trials, WHO recently recommended a regimen composed of 6 months of bedaquiline, delamanid, linezolid, levofloxacin or clofazimine as well as three additional 9-month regimens for the treatment of MDR/RR-TB. Through extrapolation of efficacy in adults, these regimens can be used in children and adolescents and during pregnancy/lactation as well.
This presentation will cover the evidence as well as implementation considerations for the use of these regimens, including drug susceptibility results (of the child or the source of infection), availability of paediatric formulations, severity of disease and monitoring ability, among others.

Early experiences with shorter, all-oral multi-drug-resistant TB regimens in children and adolescents in Papua New Guinea

G Pukai,[1] [1]The University of Papua New Guinea School of Medicine and Health Sciences, Port Moresby, Papua New Guinea.
e-mail: gordonpukai45@gmail.com

This presentation describes Papua New Guinea's transition to shorter, all-oral MDR-TB regimens for children. After phasing out injectable drugs in 2019, PNG adopted an individualized 18-month all-oral regimen. In January 2024, a 9–12 month individualized regimen was introduced, followed by official adoption of the WHO-recommended 6-month regimen (based on the BEAT-Tuberculosis trial) in December 2024. The first children were enrolled in early 2025. This transition was guided by consultation with the paediatric community, National TB Program, partners, and global experts, accounting for challenges such us workforce limitations, drug supply logistics, and high rates of malnutrition and severe TB.

Introducing shorter drug-resistant TB treatment regimens for children and pregnant/lactating women in South Africa: Key lessons learned

J Hughes,[1] [1]Stellenbosch University, Cape Town, South Africa.
e-mail: jhughes@sun.ac.za

Pregnant women and children are usually excluded from clinical trials investigating new therapeutic agents. Historically, this has severely restricted access to novel antituberculosis drugs and treatment regimens for children and pregnant women with MDR/RR-TB. Based on the results of progressive clinical research studies such as endTB and BEAT-Tuberculosis, the WHO now recommends shorter MDR/RR-TB treatment regimen alternatives for pregnant and lactating women as well as children.
Here we present the successes and challenges of implementing shorter regimens for routine treatment of MDR/RR-TB in children and pregnant and lactating women in the South African National Treatment Programme

Using shorter all-oral regimens for children and adolescent with multi-drug-resistant/rifampicin-resistant TB: Experience from Peru

A Alarcon,[1] [1]Peru National TB Program, Lima, Peru.
e-mail: valarcon@minsa.gob.pe

Since October 2023, Peru has been implementing shorter, all-oral regimens for patients with MDR/RR-TB, including children and adolescents, under programmatic conditions.
In this presentation, we will share the experience of introducing and scaling up these regimens and present treatment outcomes for children and adolescents with MDR/RR-TB who received either a 9-month regimen (e.g., Bdq, Lzd, Lfx, Cfz, Z/Cs; Bdq, Lzd, Mfx, Z; or Bdq, Lzd, Cfz, Lfx, Dlm) or a 6-month regimen (Bdq, Pa, Lzd, Mfx) at Ministry of Health facilities across Peru

Ensuring access to shorter multi-drug-resistant/rifampicin-resistant TB regimens for children using a novel web-based costing tool

A Garcia-Prats,[1] [1]University of Wisconsin-Madison, Madison, United States.
e-mail: garciaprats@wisc.edu

Child-friendly dispersible tablet formulations are now available for all second-line TB drugs. These formulations improve the accuracy of dosing, are more palatable and easier to administer, and are strongly preferred by children and their caregivers. Uncertainty around costs of drugs and formulations for children introduces challenges for planning and can be a barrier to procurement of these preferred formulations.
This presentation will discuss a newly developed freely accessible web-based tool that incorporates weight-banded dosing and available child-friendly formulations, in which costs and regimens can be adapted to local contexts to facilitate setting-specific planning and procurement.

SY33-430-33 Lymph node TB: Identifying priorities, challenges, and finding better treatments faster

Chair: Graeme Meintjes, Queen Mary University of London; University of Cape Town, United Kingdom
Chair: Conor Tweed, University College London, London, United Kingdom

Lymph node tuberculosis (LNTB) is the most common presentation of extra-pulmonary TB globally, accounting for an estimated 15 – 20% of cases globally. However, our understanding of the diagnosis, disease course and management of this disease is poor compared to pulmonary TB.
This symposium will begin with addressing the priorities relating to diagnosis, management, and novel treatments of people affected by LNTB. LNTB in clinical trials since 1993 will be presented to demonstrate how this common presentation has been represented when generating evidence for treatment.
Our current understanding of the immunology of LNTB and paradoxical reactions will be discussed, including what we know about the host-pathogen interaction and post-treatment paradoxical reactions.
These areas both have implications for developing novel treatments, in particular host-directed therapies, and the session will conclude with a consideration of the questions we need to answer in clinical trials to get to better treatments faster.

The perspective of persons affected by lymph node TB

B Kumar,[1] [1]Global Coalition of TB Advocates, New Delhi, India.
e-mail: blessi.k@gmail.com

The perspectives of the people who will be investigated and treated for LNTB must be central when evaluating the current situation and discussing future directions for research.
Blessi Kumar will speak about her personal experience with LNTB and to the challenges of diagnosis, how people being treated view paradoxical reactions, and treating a condition with no clear definition of cure. The implications for researchers developing novel regimens will also be discussed when the aim is to cure a disease more commonly causing morbidity rather than mortality.

Missing nodes: A systematic review of representativeness of lymph node TB in randomised treatment trials

I Motta,[1] [1]University College London (UCL), Medecines Sans Frontieres (MSF), London, United Kingdom.
e-mail: i.motta@ucl.ac.uk

Randomized clinical trials are considered the gold standard for evidence on treatment effect, and underrepresentation of different populations or disease presentations means these groups will be treated based on poorer quality of evidence.
This talk presents results from a systematic review assessing the representation of lymph node tuberculosis (TB) in randomized treatment trials from 1993. The aim is to compare the inclusion and reporting of lymph node TB trials with the global epidemiological data to highlight gaps and implications for the generalizability of current evidence.

The immunology of lymph node TB and the host-pathogen interaction

V Rozot,[1] [1]South African Tuberculosis Vaccine Initiative, Cape Town, South Africa.
e-mail: virginie.rozot@uct.ac.za

Our understanding of the host-pathogen interaction in LNTB without overt TB disease is limited, but is an essential component in the development of new treatments. After entering the body by aerosol inhalation, mycobacteria will migrate to the lymph nodes, and some will develop isolated LNTB disease.
This talk will use data obtained from a cohort of postmortem cases from South Africa to present findings on the relationship between mycobacterial synthetic activity and the host immune system in people who had clinically active disease, and those with no clinical signs but mycobacteria detected in lymph node samples.

Untangling paradoxical reactions: What, when, who and where?

S Hermans,[1] [1]Amsterdam University Medical Centre, Amsterdam, Netherlands.
e-mail: s.m.hermans@amsterdamumc.nl

Paradoxical reactions represent one of the greatest dilemmas for the clinician managing TB and the response will vary widely between healthcare practitioners. In this session, the results from a recent systematic review will be used to present the latest evidence on what paradoxical reactions look like in LNTB and what is known about the drivers.

How this compares to disease affecting other body systems, and the impact on treatment and assessment of cure will be addressed. The talk will close with a review of post-treatment paradoxical reactions and the complexity they generate.

Lymph node TB clinical trials: How do we pick the low-hanging fruit?

F Conradie,[1] [1]University of the witwatersrand, Johannesburg, South Africa.
e-mail: fconradie@witshealth.co.za

LNTB presents many challenges for the clinical trialist seeking to identify new, efficacious treatment regimens, and the final talk of the symposium will address questions relating to trial design and conduct, such as how to approach the issue of diagnosis and inclusion criteria for a LNTB treatment trial.
For example, what are the implications for including only microbiologically-confirmed disease?
What is the most appropriate design to account for paradoxical reactions, and what are the implications for each approach?
How could immunomodulating therapy be incorporated into a trial?
The talk will conclude with an overview of a suggested LNTB trial.

SY34-440-34 Generating social science evidence alongside TB trials: Opportunities and impacts

Chair: Rovina Ruslami, Universitas Padjadjaran, Bandung, Indonesia
Chair: Samuel Schumacher, World Health Organization, Geneva, Switzerland

Social science evidence on equity, cost, feasibility, acceptability and user values are increasingly valued in policy recommendations regarding new tools and technologies, and now called for within WHO guidance on evidence generation in TB. Social science can be particularly relevant when clinical data show equivalent outcomes between a novel intervention and comparator arm, or when trialed interventions have failed to show impact in programmatic settings.
This SSHIFTB session showcases various approaches and experiences of integrating social science research alongside clinical trials on diagnostic accuracy, whole genome sequencing, novel regimens, and other treatment interventions, from researchers and community actors working through multiple disciplines in diverse global regions.
Taken together these talks will provide recommendations for how to build a broader and stronger knowledge base for policy development, which can ultimately lead to stronger recommendations for novel TB interventions.

Community engagement in TB trials: How to optimise impact and overcome challenges

I Schoeman,[1] [1]TB Proof, Pretoria, South Africa.
e-mail: ingrid.tbproof@gmail.com

Effective community engagement can improve the quality of evidence generated from clinic trials and research studies, as well as dissemination of results and uptake of recommendations. Context-appropriate mechanisms to engage communities in research need to be prioritised as to enable community voices to shape research priorities. Ingrid will highlight key opportunities for community contributions to optimise planning and implementation of research using examples from South African research studies. She will share lessons learned to overcome challenges such as insufficient resources, language barriers, cultural differences and power dynamics.

Integrating mixed-methods research in a paediatric TB diagnostic accuracy trial in Uganda and Peru

F Basile,[1] [1]University of Oxford, Oxford, United Kingdom.
e-mail: francesca.basile@paediatrics.ox.ac.uk

In this presentation, we highlight practical insights gained from adopting a mixed-methods approach in the NOD-pedFEND study, a paediatric TB diagnostic accuracy trial involving intensive sample collection. We explored the lived experiences, preferences, and trade-offs faced by caregivers, clinicians and National TB Program stakeholders in their paediatric TB diagnostic journey in Uganda and Peru.
Findings from interviews, focus group discussions and a discrete choice experiment not only offered insight on diagnostics acceptability and the implementability of person-centred diagnostic pathways, but also shaped our understanding of trial acceptability. We present key findings while reflecting on operational challenges and lessons learned.

Laying the groundwork for the ethical implementation of genomic sequencing for TB in Botswana

S Molldrem,[1] [1]University of Texas Medical Branch, Galveston, United States.
e-mail: stmolldr@UTMB.EDU

This talk highlights how social science evidence and approaches can shape the uptake of TB innovations pre-trial. In two qualitative studies with TB stakeholders in Botswana aimed at assessing the ethics and feasibility of implementing genomic sequencing for TB, we engaged healthcare workers, policymakers, people with and affected by TB, advocates, and others.
In interviews and deliberative dialogues for the first study, participants supported sequencing and provided recommendations for ethical implementation.
The second study uses interviews and focus groups to develop generalizable implementation strategies for targeted next-generation sequencing, following WHO recommendations. These strategies can later be trialed to assess effectiveness.

Methodological and resource considerations for the successful execution of social science studies alongside TB treatment trials

A Daftary,[1] [1]York University, Toronto, Canada.
e-mail: adaftary@yorku.ca

This presentation conveys the relevance and added-value of running social science studies to support the design, implementation, interpretation of outcomes, and 'real-world' effectiveness of TB treatment trials and interventions.
Borrowing on examples of studies undertaken pre-, during and post-trial, the talk will explicate:
1. Methodological considerations, relevant frameworks, and resource needs for planning social science oriented aims alongside trials, and;
2. Exemplify the diversity of evidences that may be consequently gained, such as data on patient values and preferences, acceptability, equity and feasibility considerations, pathways of intervention effect, intervention fidelity, differential outcomes in subpopulations, and unintended harms and benefits.

Bringing social science evidence on novel TB interventions to global guideline development

N Engel,[1] [1]Vrije Universiteit Amsterdam, Amsterdam, Netherlands.
e-mail: n.c.engel@vu.nl

This talk details how social sciences evidence on the added value, feasibility, usability, acceptability, equity and implementation considerations of new TB interventions can be brought to bear on decision-making tables at WHO.
We will draw on five qualitative studies and a systematic review on user perspectives about different diagnostics with clinicians, laboratory staff, programme officers, TB survivors, and community representatives across multiple countries in Africa, Eastern Europe, Central and South Asia.
We will discuss key insights on new interventions that these studies enabled and how they act as a tool of engagement in the development of global guidance.

SY35-450-35 TB in an era of arctic self-determination

Chair: Jennifer Munick-Watkins, Nunavik Regional Board of Health & Social Services, Canada
Chair: Faiz Ahmad Khan, McGill University & the Research Institute of the McGill University Health Centre, Montreal, Canada

Inuit are Indigenous peoples of the Arctic. Inuit in Canada, Greenland, and Denmark —the majority of the world's Inuit population—experience high rates of tuberculosis, albeit with differing trends.
In Canada, tuberculosis incidence amongst Inuit is over 300-times the incidence amongst Canadian-born non-Indigenous people and has been rising in some jurisdictions.
In Greenland, in the past decades incidence has fallen since peaking in 2010. **In Denmark**, incidence is highest amongst the Greenlandic origin population. Inuit, as other Indigenous peoples around the world whose lands were colonized, are increasingly regaining self-determination over their land and health services.
Our objective is to compare tuberculosis history, epidemiology, and elimination strategies in Canada, Greenland, and Denmark, with a specific focus on alignment with Inuit self-determination. Participants will hear from **a diverse panel representing 3 nations & including four Inuit speakers** sharing policy & research experiences addressing tuberculosis at local, regional and national levels.

Inuit Tuberculosis Elimination Working Group: A space for Canadian Inuit self-determination and learning

R Obed,[1] [1]Inuit Tapiriit Kanatami, Ottawa, Canada.
e-mail: robed@itk.ca

With the development and implementation of the Inuit Tuberculosis (TB) Elimination Framework in 2018, Inuit Treaty Organizations (ITOs) have been leading TB elimination activities in Inuit Nunangat. Through the Inuit Tuberculosis Elimination Working Group, ITOs have a convening space to share and learn from each other and advance TB elimination together across Inuit Nunangat.
ITOs discuss successes, challenges and processes of TB programming, which include implementing interferon gamma release assay (IGRA) in remote settings, different education and engagement strategies, and healthcare provider training and education.

Parnasimautik: A Nunavik Inuit story of reclaiming self-governance applied to TB

M Emudluk Sr.,[1] [1]Puvaqatsianirmut (Nunavik Lung Health Steering Committee), Kangiqsualujjuaq, Canada.
e-mail: maggieemudluksr@gmail.com

Nunavik is the colonized Inuit homeland within the province of Quebec, Canada. Since the 1970s, Nunavimmiut (Nunavik Inuit) have been reclaiming increasing authority over their land, resources, and lives. In this riveting talk, the audience will hear from someone who has spent much of their life in public service in Nunavik, both in her home community and across the region.
The talk will provide an overview of historical and present-day actions through which Nunavimmiut reclaim sovereignty, and how these have led to the launching of a recent regional initiative to create the first ever Nunavimmiut Declaration on TB in Nunavik.

Community-based research to action: Inuit experiences with TB in Nunavik shaping a community public health worker programme

G Sandy,[1] [1]Nunavik Regional Board of Health & Social Services, Kuujjuaq, Nunavik, Canada.
e-mail: glenda.sandy.ciussscn@ssss.gouv.qc.ca

Nunavimmiut—Inuit indigenous to Nunavik (in Quebec, Canada)—face tuberculosis rates over 150-times the provincial average of Quebec.
This presentation will describe how a community-based participatory research project involving Nunavik's health authorities, leaders, and an Inuit steering committee, was developped and executed. The audience will learn how research results are shaping tuberculosis policies alongside informing roles and training for ?Inuit lay public health workers.

Kalaallit (Inuit) on the frontline of TB care in Kalaallit Nunaat (Greenland)

M Olsen-Morch,[1] [1]Denmark.
e-mail: miom@peqqik.gl

Greenland has self-governance of the Health System since 1992. The majority of Greenland's population is Kalaallit. University of Greenland, Ilisimatusarfik, has capacity for 15 new nursing students per year. Kalaallit can be assigned as medical students in a Danish University.
Today, there are about 15 Greenlandic medical students in Denmark. By contrast, the Faroe Islands, with the same population size as Greenland, has 120 medical students in Denmark. The fight against tuberculosis in Greenland necessitates nurses and doctors speaking Greenlandic for

better compliance and patient empowerment. In general, Greenland needs empowerment through more Kalallit doctors and nurses for more sustainability.

A historical and epidemiological overview of TB and its elimination strategies in Greenland and in Inuit in Denmark

A Koch,[1] [1]Statens Serum Institut, Copenhagen, Denmark.
e-mail: ako@ssi.dk

Like in Arctic Canada and Alaska, tuberculosis (TB) incidence in Greenland in the 1950s was alarmingly high, leading to a range of efforts against TB. TB incidence in the country reached low levels in the 1980s, but increased since then, leading to new national TB reduction strategies. About 17,000 Greenlanders live in Denmark, corresponding to 30% of the population of Greenland. Of all ethnic groups in Denmark, this group has the highest TB incidence in the country.
This presentation will give an overview of the epidemiology and elimination strategies for TB in Greenland and Greenlanders in Denmark.

SY36-460-36 Scaling-up community-wide TB screening irrespective of symptoms: Recognising and overcoming the barriers

Chair: Hanif Esmail, University College London, London, United Kingdom
Chair: Anna Coussens, Walter and Eliza Hall Institute of Medical Research (WEHI), Melbourne, Australia

There has been little change in global TB incidence in the 21st century with progress towards the End TB targets off track. Recently there has been increased recognition that many people with undiagnosed, potentially infectious TB are asymptomatic and that they can be identified by symptom-agnostic screening (e.g. with chest X-Ray).
While this screening activity is increasing globally, current levels fall far short of what is needed to impact transmission and significant scale-up within communities is required. There are major challenges to undertaking such scale-up but this is not without precedent and is needed if we are serious about ending TB by 2050.
In this symposium we will explore the political, financial and health system barriers and solutions to scaling up community wide screening, discuss the opportunities and challenges of different screening strategies and treatment approach and reflect on how communities can best be engaged to participate in screening activities

Show me the money: Making the investment case for community-wide screening

L Vo,[1] [1]Friends for International TB Relief (FIT), Ha Noi, Vietnam.
e-mail: luan.vo@tbhelp.org

While community screening is the only intervention proven to have population wide and persistent epidemiological impact, the required resources are beyond existing TB budgets. To mobilise funds, it is important to identify novel financing sources and make a clear investment case with tailored messaging to the range of audiences that meet their demand.
This presentation will describe the need for a community screening investment case, available and innovative financing sources, as well as prominent examples of innovative financing towards ending TB.

Participation is key: Community sensitisation

T Dharmapuri Vachaspathi,[1] [1]Treatment Action Group, New York, United States.
e-mail: teju.dv@treatmentactiongroup.org

In order to have sufficient population coverage to have impact, screening requires the acceptance and participation from the community. Achieving this needs a co-ordinated approach involving meaningful community engagement and participation, effective and sustained sensitization through a variety of traditional and social media campaigns, broader education initiatives and incentivization for majority participation.
This talk will reflect on some of the successful approaches used both historically and more recently.

To X-Ray or not to X-Ray: That is the question

T Nguyen,[1] [1]University of Sydney Vietnam Institute, Ho Chi Minh city, Vietnam.
e-mail: thuanh.nguyen@sydneyvietnaminstitute.org

Historic data demonstrate that recurrent rounds of symptom-agnostic community wide CXR screening had the greatest reduction in TB incidence over 20 years when population coverage was highest. Despite technological advances in CXR portability and AI-CAD reading, logistical and human resource requirements remain the greatest challenges to achieving testing access for all communities.
This talk will discuss the operational considerations, community engagement experience and diagnostic implications of using either a 2-step CXR for all + Xpert confirmation, or 1-step Xpert for all screening strategies.

The health system: Challenges in scaling up and scaling down

O Chijioke-Akaniro,[1] [1]National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Nigeria, Abuja, Nigeria.
e-mail: ocakaniro@gmail.com

Population-wide, symptom-agnostic TB screening represents a paradigm shift in case detection for most countries. While technological advancements have improved screening capabilities, successful implementation demands strategic planning and coordination across all WHO building blocks.
This talk will focus on the operational considerations for scaling up, and ultimately scaling-down, screening, including governance mechanisms, strategies for maintaining and expanding screening capabilities beyond chest imaging, coordinating management of non-TB abnormalities, addressing human resource needs, and exploring innovative financing models for cost-effective participation and support in TB screening efforts. Engaging both public and private healthcare providers will be crucial for comprehensive coverage.

Do no harm: Evaluating the risk of over-treatment in community screening

R Houben,[1] [1]London School of Hygiene and Tropical Medicine, London, United Kingdom.
e-mail: rein.houben@lshtm.ac.uk

A key risk of community screening is over-treatment; initiating asymptomatic individuals on TB treatment after a false positive CXR or Xpert diagnosis. Standard calculations suggest that even at the current threshold of 500/100k prevalence, most screening tools would lead to unacceptably high rates of over-treatment. However, these calculations have many flaws, some of which can be quantified.
This presentation will explore how our estimates of over-treatment change when considering test performance in the community rather than clinic, and critically evaluate the validity of the reference standard of sputum culture. Together, they may support a much lower threshold for screening.

SY37-470-37 A forgotten population: Finding TB and disparities within prisons

Chair: Jason Andrews, Stanford University School of Medicine, Stanford, United States
Chair: Salome Charalambous, The Aurum Institute, Johannesburg, South Africa

Tuberculosis rates in prisons are extremely high globally, with incidence greater than 10 times those of surrounding communities on average and major gaps in case detection and care. There remain critical questions about how to implement effective strategies to reduce this burden and address disparities affecting persons deprived of liberty. This symposium will share the latest evidence and experience from a diverse group of researchers and implementers representing five continents and varying epidemiologic contexts.
Presentations will cover lessons learnt in various settings, including Malawi, Kazakhstan, Ukraine, Paraguay and Cameroon. We have also included some talks that raise policy questions and evaluate the cost-effectiveness of possible TPT interventions.

Modelling TB preventive Therapy in Brazil's prisons

L Goscé,[1] [1]London School of Hygiene and Tropical Medicine, London, United Kingdom.
e-mail: Lara.Gosce@lshtm.ac.uk

Tuberculosis incidence has been increasing in Brazil in the past ten years, and the rise in incarceration has proved to be one of the leading causes.
We performed modelling and health economic analysis to investigate the impact of Tuberculosis Preventive Treatment (TPT) for Brazilian inmates on the TB epidemic in the country. Through scenario analysis we varied future rates of recidivism in the prison population and estimated the cost-effectiveness of possible TPT interventions.

Experience of use of Chest X-ray and CAD4TB for TB screening in Paraguay

C Magis-Escurra,[1] [1]Radboud University, Nijmegen, Netherlands.
e-mail: Cecile.Magis-Escurra@radboudumc.nl

Digital Chest X-ray with CAD4TB software for automated readings in 5 different prisons in Paraguay reached a high specificity (>90%) but the sensitivity did not reach the WHO Target Product Profiles for a screening test. With the help of machine learning studying our database of almost 4000 participants we identified a potential method to improve the sensitivity of this screening tool without affecting its specificity. The costs involved with mass screening projects may be reduced significantly applying this method.

Experience of policy change to integrate prison infirmaries in the district health system in Cameroon

S Mounde Ndam,[1] [1]Join Acting Process For The Success Of Sustainable Objectives (JAPSSO), Yaoundé, Cameroon.
e-mail: soulemanmounde@ong-japsso.org

We will describe the experience and outcomes of a policy change to integrate prison infirmaries to render quality care of TB, HIV, and of general health services in prisons in Cameroon. In practice, the integration with the National District Health Information System (DHIS2) where all health indicators including notification and care of TB cases.
Challenges identified during implementation include: overcrowding and undernutrition (structural); lack of performance of NTP with regards to drug shortages/ laboratory delays; lack of motivation of health staff and incentives for peer educators; lack of continuity of care; poor acceptance of prisons as health district entities.

ABSTRACT PRESENTATIONS TUESDAY 18 NOVEMBER 2025

ORAL ABSTRACT SESSION (OA)

OA01 Forgotten lungs: Emerging from the shadow of TB, silicosis, and NTM

OA01-100-18 Comprehensive epidemiological analysis of silicosis (J62) and concurrent tuberculosis (J65) in Brazil, 2006-2024

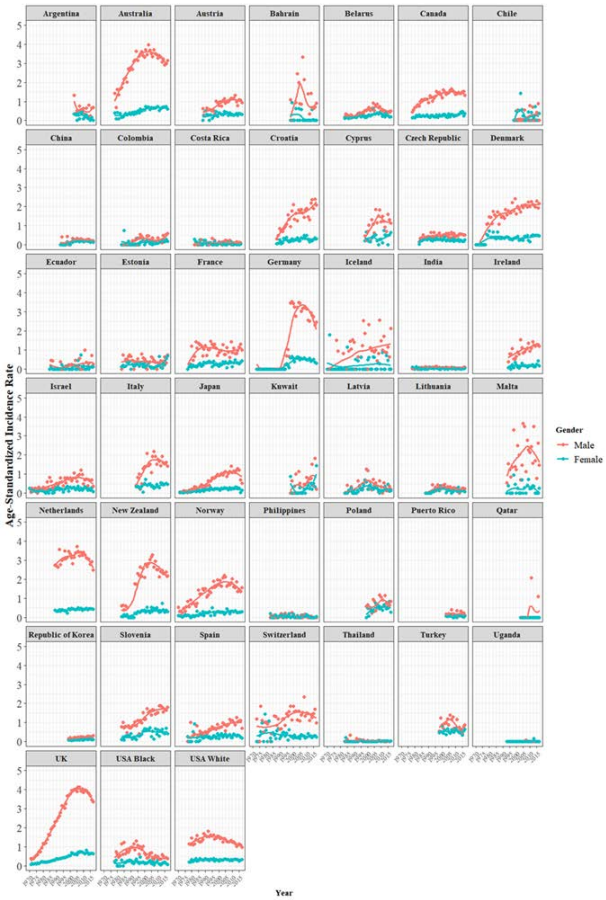
F.A. Dias e Sanches,[1,2] F.L. Romero Vega,[3] J.N.d. Barros Silva,[3] F. Dockhorn,[3] [1]Federal University of Rio de Janeiro, Tuberculosis Research Center, Rio de Janeiro, Brazil, [2]Piquet Carneiro University Policlinic, Governance and Compliace and Infection Prevention and Control comission, Rio de Janeiro, Brazil, [3]Ministry of Health, Brazil, National Tuberculosis Program, Brasília, Brazil
e-mail: sanches@hucff.ufrj.br

Background: Silicosis is a progressive fibrotic pneumoconiosis caused by crystalline silica inhalation. It represents a significant comorbidity as individuals with silicosis have increased susceptibility to Mycobacterium tuberculosis infection, making it a serious public health concern.
This study investigates the epidemiological profile of silicosis and its association with concurrent silicosis and TB in Brazil over nearly two decades.
Design/Methods: This descriptive and analytical epidemiological study utilized secondary data from Brazil's National Disease Notification Information System (SINAN) for the period 2006-2024. We calculated proportion indicators, relative risk, and temporal trends, and conducted multivariable analyses comparing isolated silicosis and concurrent silicosis and TB. Advanced statistical methods included chi-squared tests, risk ratio calculations, time series analysis with moving averages, linear regression for trend detection, and population attributable risk calculations.
Results: Among 2,784 reported individuals with silicosis, 39 people with concurrent silicosis and TB were identified (1.40%). Temporal trend analysis revealed increasing numbers of people with silicosis (coefficient +7.65/year, $R^2 = 0.17$) and slightly decreasing concurrent TB (-0.14/year, $R^2 = 0.13$).
The proportion of TB among people with silicosis showed significant reduction over time, from 3.15% in 2006-2011 to 0.31% in 2018-2024 ($\chi^2 = 403.81$, $p<0.001$). Risk ratio analysis revealed a 10.12-fold higher risk in the earliest period compared to the latest period. Significant demographic disparities were observed, with indigenous populations showing a 76.86-fold higher relative risk compared to white populations.
Based on international literature, we estimated 90.66% underreporting of concurrent silicosis and TB, with significant economic and health impacts.
Conclusions: Our findings demonstrate a decreasing proportion of tuberculosis among people with silicosis over time, despite an increasing trend in isolated silicosis. Substantial underreporting and heterogeneity in diagnostic methods suggest the need for strengthening occupational epidemiological surveillance.
Additionally, people-centered interventions addressing demographic disparities and high-risk occupational sectors, particularly mining, are urgently needed.

OA01-101-18 Global patterns and trends in mesothelioma incidence in 185 countries: A population-based study

L. Fu,[1] K. Liu,[1] Y. Sun,[1] W. Shu,[1] Y. Ning,[1] J. Du,[1] L. Li,[1] [1]Beijing Chest Hospital, Office of the National TB Clinical Center, Beijing, China
e-mail: fuleiwen777@qq.com

Background: Mesothelioma is a rare and aggressive cancer primarily caused by asbestos exposure, predominantly affects older adults with occupational asbestos exposure.
Design/Methods: This population-based study utilized the GLOBOCAN 2022 database to estimate mesothelioma incidence and mortality across 185 countries in 2022.
Long-term trends were assessed using the Cancer Incidence in Five Continents (CI5) Volume XII and CI5 *plus* databases. Age-standardized incidence rates (ASIRs) were calculated, and Joinpoint regression analysis was employed to assess trends in mesothelioma ASIRs by estimating the average annual percentage change (AAPC).
Results: In 2022, there were an estimated 30,633 new mesothelioma cases globally, with an ASIR of 0.28 per 100,000. Europe had the highest burden, accounting for 48.1% of global cases and 48.4% of deaths. There was a significant positive correlation between the ASIR or ASMR and Human Development Index.
From 2003 to 2017, while mesothelioma incidence decreased in many regions, significant increases were observed among male in Croatia (AAPC: 2.5, 95% CI: 0.3 to 4.8), the Republic of Korea (2.5, 1.2 to 3.7), and Slovenia (1.2, 0.1 to 2.2), as well as in female in Canada (4.5, 1.3 to 7.9).
Mesothelioma incidence declined significantly in males in Australia, Belarus, Germany, Israel, the Netherlands, New Zealand, Norway, Turkey, the UK, and White Americans, and in females in Belarus, Germany, and Turkey.



Conclusions: Mesothelioma remains a significant global health challenge, with notable geographic and socioeconomic disparities. Sustained public health efforts are needed to eliminate asbestos exposure and reduce disease burden, particularly in regions with rising incidence and underdiagnosis.

OA01-102-18 Respiratory symptoms in Rwandan mineworkers with silicosis

H. Pacifique,[1] [1]Partners In Health, Clinics, Kigali, Rwanda
e-mail: phagenimana@pih.org

Background: Little is known about the burden of respiratory symptoms amongst mineworkers with silicosis and how they are impacted by the presence of fibrosis. In 2022, Partners In Health conducted the first silicosis case-finding program in Rwanda, identifying a 9.2% prevalence amongst active Cassiterite mineworkers in Kayonza District.

Design/Methods: We conducted an observational cross-sectional study of mineworkers with confirmed radiographic silicosis during their initial visit to a dedicated silicosis clinic at Rwinkwavu District Hospital, Rwanda. During visits, clinic staff measured pulse oximetry and administered the four item Respiratory Symptom Questionnaire (RSQ). We also collected baseline clinical and demographic characteristics. We compared outcomes based on the presence of fibrosis on screening chest radiography.

Results: Pulse oximetry and RSQ data were recorded for 83 patients with confirmed radiographic silicosis during their initial follow-up clinic visit. The median age was 42 (IQR 37-47) and mineworkers had spent a median of 15 years mining (IQR 12-20). 14 (16.9%) mineworkers had accelerated silicosis (i.e. silicosis that developed with less than 10 years of exposure) and 18 (21.7%) had evidence of fibrosis on chest x-ray. 6 (7.2%) patients were hypoxemic on room air at their follow-up visit, including 3 (16.7%) patients with fibrosis and 3 (4.6%) without fibrosis (p-value 0.08). 60 (72.3%) reported respiratory symptoms.

The median RSQ score for all mineworkers with silicosis was 2 (IQR 0-2) out of a possible 16. Mineworkers with fibrosis had significantly higher median RSQ scores (6 [IQR 1-9]) compared to those without fibrosis (2 [IQR 0-3], p-value 0.003).

Among mineworkers with fibrosis, 13 (72.2%) reported activity limitation due to respiratory symptoms, compared to 27 (41.5%) without fibrosis (p-value 0.021).

Conclusions: Respiratory symptoms are common amongst mineworkers with silicosis. The presence of fibrosis is associated with an increased burden of symptoms. Despite the burden of symptoms, few patients reported using inhaled medications.

OA01-103-18 Detecting radiological signs suggestive of silicosis in chest radiographs using artificial intelligence: A pilot retrospective cross-sectional study

A. Kumar Singh,[1] H. Varatharajan,[2] J.A. Chiramal,[3] S. Sridhar,[4] M. Tadepalli,[1] D. Robert,[5] [1]Qure.ai Technologies Private Limited, R&D, Bengaluru, India, [2]Qure.ai Technologies Private Limited, Product, Bengaluru, India, [3]Qure.ai Technologies Inc., Product, Atlanta, United States of America, [4]Qure.ai Technologies Private Limited, Product, Bangalore, India, [5]Qure.ai Technologies Private Limited, Clinical Research, Bengaluru, India
e-mail: justy.antony@qure.ai

Background: Silicosis is a growing occupational health concern, especially in mining and construction. It increases the risk of tuberculosis (TB), creating a dual burden in high-risk populations. Chest X-rays (CXR) are commonly used for diagnosis, but limited radiology expertise leads to underdiagnosis. High-resolution CT offers better accuracy but is costly and less accessible. Delayed diagnosis postpones compensation and prolongs exposure. AI-based computer-aided detection (CAD) tools like qXR, already used for TB screening, offer scalable solutions to improve silicosis detection. We evaluated qXR's performance in identifying silicosis on CXR for integrated lung health screening.

Design/Methods: The qXR silicosis model, based on a Swin Transformer architecture, was trained on CXRs labelled by radiologists or occupational health specialists from multiple regions. We retrospectively evaluated its performance on 633 CXRs using radiologist reports as reference. Diagnostic metrics—sensitivity, specificity, precision, F1 score, and area-under-the-receiver-operating-characteristic-curve (AUROC) - were calculated. Gwet's AC1 was used to assess model–radiologist agreement, and TB overlap was evaluated using a confirmed TB dataset.

Results: Among 633 CXRs, 183 (28.9%) were labeled as silicosis by radiologists, supported by a history of RCS exposure and CT confirmation. At a threshold of 0.29, the Swin-based qXR silicosis model achieved: **sensitivity 98.36%, specificity 98.67%, AUROC 0.9994, precision 96.77%, F1 score 0.9756, and Gwet's AC1 0.9656**. The confusion matrix showed 180 true positives, 444 true negatives, 6 false positives, and 3 false negatives. In 110 TB-only cases, the model produced just 5 false positives, highlighting its ability to differentiate silicosis from TB despite overlapping radiographic features.

	Radiologist positive	Radiologist negative
AI positive	180	6
AI negative	3	444

Table 1: Confusion Matrix (AI vs Radiologist Ground Truth at Threshold = 0.29).

Conclusions: The qXR silicosis model demonstrated excellent diagnostic accuracy, with near-perfect sensitivity and specificity against radiologist reports, and minimal overlap with radiological signs of TB. Integrating such tools into occupational health programs could enable timely diagnosis, support worker compensation processes, and advance combined silicosis-TB screening strategies in high-risk populations.

OA01-104-18 Epithelial-macrophage interactions in cystic fibrosis are responsible for accelerated *Mycobacterium abscessus* growth

A.T. Lorenz,[1,2] B.M. Saunders,[3] W.J. Britton,[2,4] M.D. Johansen,[1] [1]Centre for Inflammation, University of Technology Sydney and Centenary Institute, Sydney, Australia, [2]Tuberculosis Research Program, Centenary Institute, Sydney, Australia, [3]School of Life Sciences, University of Technology Sydney, Sydney, Australia, [4]Department of Clinical Immunology, Royal Prince Alfred Hospital, Sydney, Australia

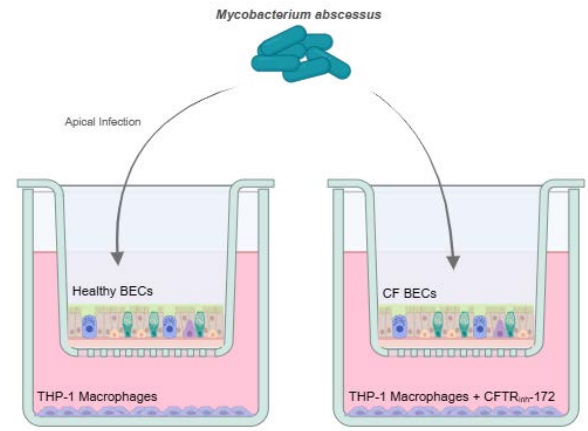
Background: *Mycobacterium abscessus* (MABS) is of global concern due to high antimicrobial resistance and poor treatment prognosis. It is of particular concern in Cystic Fibrosis (CF), a disease caused by mutations in the *CFTR* gene. Whilst macrophages are the preferred mycobacterial niche, the role of the respiratory epithelium in MABS infection is largely uncharacterised.

Furthermore, the complex epithelial-immune interactions underpinning MABS infection in CF airways are unknown.

Design/Methods: To examine epithelial-macrophage interactions during MABS infection we established a novel co-culture system of bronchial epithelial cell lines (BECs) at the air-liquid interface, and THP-1 macrophages in the basolateral compartment of a transwell. Co-cultures consisted of healthy BECs and THP-1 macrophages or CF BECs with THP-1 macrophages treated with the CFTR inhibitor- $CFTR_{inh}$-172.

Co-cultures were infected apically with MABS, then bacterial growth and cytokine secretion were compared between healthy and CF conditions.

In additional experiments, compounds modulating CFTR or TNF were added to the basolateral compartment.



Results: CF BECs cultured with $CFTR_{inh}$-172 treated macrophages, displayed significantly higher MABS growth compared to healthy BECs. $CFTR_{inh}$-172 treated macrophages alone showed no increase in MABS uptake or growth, suggesting CF susceptibility to MABS requires

defective CFTR function in both BECs and macrophages. TNF, IL-8 and IL-10 secretion was markedly reduced in CF conditioned cells, indicating dysregulated epithelial-immune cross-talk.
The addition of Etanercept (TNF-receptor antagonist) did not impact bacterial burden in the co-culture system, illustrating accelerated MABS growth in CF conditions is due to TNF-independent mechanisms. Restoring CFTR function in CF co-cultures, using Trikafta, a CFTR modulator therapy (Elexacaftor/Tezacaftor/Ivacaftor), reduced MABS growth to levels observed in healthy co-cultures, demonstrating that deficient CFTR function drives increased MABS burden.
Conclusions: This study demonstrates the importance of epithelial-macrophage interactions in the host response to MABS infection and fundamentally implicates CFTR as a driver of MABS susceptibility.

OA01-105-18 Antibiotic prescriptions - A risk factor for nontuberculous mycobacterial disease?

A.A. Pedersen,[1,2,3] A. Løkke,[4,5] A. Fløe,[6] O. Hilberg,[4,5,3] I.S. Johansen,[1,2,3] [1]Odense University Hospital, Department of Infectious Diseases, Odense, Denmark, [2]University of Southern Denmark, Department of Clinical Research / Research Unit of Infectious Diseases, Odense, Denmark, [3]Odense University Hospital, Mycobacterial Centre for Research Southern Denmark (MyCRESD), Odense, Denmark, [4]University Hospital of Southern Denmark, Department of Medicine, Vejle, Denmark, [5]University of Southern Denmark, Department of Regional Health Research, Odense, Denmark, [6]Aarhus University Hospital, Department of Respiratory Diseases and Allergy, Aarhus, Denmark
e-mail: andreas.arnholdt.pedersen@rsyd.dk

Background: Nontuberculous mycobacterial (NTM) infections are difficult to diagnose, often resulting in diagnostic delays. Studies have identified advanced age, prior tuberculosis, underlying pulmonary diseases, and immunosuppression as risk factors for NTM disease. We aimed to investigate whether antibiotic use prior to diagnosis was more prevalent in patients with NTM disease compared to matched comparators.
Design/Methods: We conducted a nationwide register-based cohort study, including all adult patients diagnosed with NTM disease (based on ICD-code) in Denmark from 2000-2017. Denmark is a high-income country with free, uniform and tax-funded healthcare. Patients were categorised as either pulmonary NTM (P-NTM) or extra-pulmonary NTM (E-NTM) based on diagnostic and procedural codes. Patients were matched 1:4 to comparators by age, sex, cohabitation, and municipality. Differences between groups were assessed using the χ^2 test. Antibiotic use prior to diagnosis was evaluated using a negative binomial regression model.

Results: Patients with either P-NTM (n=661, 49.6% female) or E-NTM (n=485, 40.4% female) were prescribed significantly more antibiotic treatments in the three years preceding NTM diagnosis compared to comparators, both in overall antibiotic prescriptions and specifically for beta-lactams, macrolides, and quinolones (Table 1).

	P-NTM			E-NTM

Any type antibiotics	3.41 *** (2.94-3.95)	3.31*** (2.86-3.84)	4.89*** (4.27-5.59)	1.89*** (1.55-2.30)	2.35*** (1.95-2.82)	4.04*** (3.46-4.71)

Table 1: Table of antibiotic use (incidence of prescriptions) for patients with P-NTM and E-NTM compared to matched controls.

*#Other antibacterials include all classes not otherwise mentioned. IRR: Incidence rate ratio, P-NTM: Pulmonary nontuberculous mycobacterial disease, E-NTM: Extrapulmonary nontuberculous mycobacterial disease. 95% CI: 95% Confidence Interval. * p<0.05, **: p<0.01***: p<0.001*

Conclusions: Patients diagnosed with NTM disease were prescribed significantly more antibiotics across most classes compared to matched comparators up to three years prior to diagnosis. Increased antibiotic use could be a risk factor for NTM disease, by disturbing the normal microbiome. However, increased antibiotic exposure likely also reflects diagnostic difficulties or higher comorbidity burden necessitating antibiotic treatment.
Clinicians should consider NTM disease when experiencing frequent antibiotic use, especially in patients with additional risk factors. Further studies are needed to elucidate if pre-diagnosis exposure to specific antibiotics is associated with antibiotic resistance, or outcomes, of NTM disease.

OA01-106-18 GeneXpert-negative samples with *rpoB* amplicons reveal High NTM prevalence: A diagnostic opportunity

M.K.M. Uddin,[1] A.A. Rupa,[1] S.N. Kabir,[1] A. Islam,[1] R. Nasrin,[1] S.M.M. Rahman,[1] A.S.S. Adel,[1] S. Banu,[1]
[1]icddr,b, Infectious Diseases Division, Dhaka, Bangladesh
e-mail: kmuddin@icddrb.org

Background: Non-tuberculous mycobacteria (NTM) pose a diagnostic challenge due to their symptom overlap with tuberculosis (TB). The GeneXpert Ultra assay, a widely used diagnostic tool for TB, could show *rpoB* probe amplification for samples negative for *Mycobacterium tuberculosis* complex (MTBC).
We hypothesized these samples could be NTM, and thus investigated the utility of the *rpoB* probes in identifying samples requiring NTM confirmation.
Design/Methods: Samples that were GeneXpert-negative for MTBC but showed *rpoB* amplification were subjected to confirmatory testing. Conventional PCR for *rpoB* and IS*6110*, culture on Lowenstein-Jensen (L-J) media, and targeted next-generation sequencing were performed to confirm the presence of NTMs and to identify species. Diagnostic performance of *rpoB* Ct values was evaluated to differentiate NTMs from other outcomes.
Results: Among 50 GeneXpert-Negative samples showing *rpoB* amplification, conventional PCR confirmed *rpoB* positivity in all cases. Culture on L-J slants revealed atypical mycobacterial growth in 86% (43/50) of samples, which was further confirmed by tNGS. tNGS identified 34 NTM isolates, with *M. gordonae* (20.5%) and *M. abscessus* (17.6%) being the most common (Figure 1).
Three Samples were found to be MTBC, and six were not detected in tNGS. Analyzing the Ct values of the *rpoB*2 probe showed significant differences between NTM, MTBC, and not-detected groups. An optimal Ct cutoff of 32.7 to detect NTM achieved a sensitivity of 82.4%, specificity of 77.8%, and a strong positive predictive value of 93.3%, though the negative predictive value was lower at 53.85%.

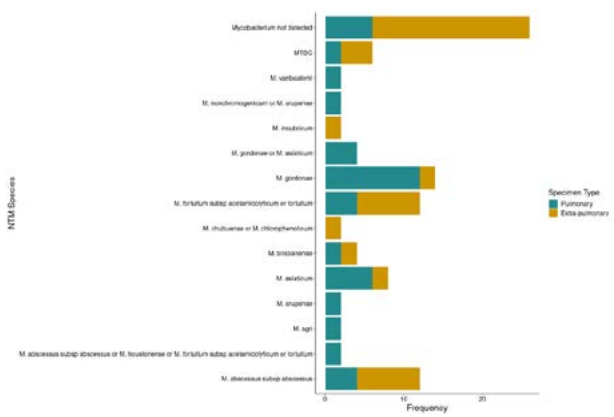

Figure 1.

Conclusions: This study highlights the added utility of *rpoB*2 Ct values from the GeneXpert Ultra assay for screening NTMs in GeneXpert-negative cases, enhancing diagnostic efficiency without additional cost.
The findings emphasize the need for confirmatory molecular and culture-based testing to accurately identify NTMs and guide appropriate treatment. Incorporating *rpoB* screening into routine GeneXpert workflows offers an improvement for NTM identification.

OA01-107-18 Speciation, antimicrobial resistance and virulence factors of clinical isolates of non-tuberculous mycobacteria from a tertiary care hospital in South India

N.M. Joseph,[1] K. Oudhaya,[1] K. Ellappan,[1] K.P.V. Hyma,[1] J. Sangitha,[1] [1]Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Microbiology, Puducherry, India
e-mail: noyal.c@gmail.com

Background: Accurate and rapid identification of non-tuberculous mycobacteria (NTM), along with drug resistance and virulence factors, is crucial for effective NTM patient management and control, especially in TB-endemic regions.
The aim of our study was to speciate and identify the mechanism(s) of drug resistance and virulence factors in clinical isolates of NTM.
Design/Methods: A total of 840 NTM suspected clinical samples were included in this study. All samples that were found to be GeneXpert negative and NTM-RT PCR positive were cultured in MGIT 960 system. The MGIT cultures that were positive for acid-fast bacilli and MPT64 antigen negative were speciated using line probe assay and MALDI-TOF. After speciation, GenoType NTM-DR and phenotypic drug susceptibility testing (DST) by micro broth dilution were performed to detect drug resistance. We assessed colony morphology and biofilm-forming ability of NTM species using Trypticase-soy agar and 96-well microplates, respectively.
Results: Of the total 840 samples, 56 (6.67%) were found to be positive for NTM species. *M. abscessus* (42.8%) was the most common NTM species followed by *M. fortuitum* (26.7%), *M. intracellulare* (23.2%), *M. chelonae* (3.57%) and *M. mageritense* (3.57%). Based on GenoType NTM-DR assay, 10.71% of *M. abscessus* strains were found to be resistant to clarithromycin, while *M. intracellulare* and *M. chelonae* were sensitive to both amikacin and clarithromycin.
All the NTM strains were sensitive to amikacin by DST. Biofilm formation was predominantly observed in *M. abscessus* (28.5%), followed by *M. fortuitum* (19.6%) and *M. intracellulare* (5.3%). Smooth and rough morphotypes were observed among 26.7% and 16.07% of *M. abscessus* strains, respectively.

Conclusions: The common NTM species isolated from our hospital were *M. abscessus*, *M. fortuitum* and *M. intracellulare*. We observed clarithromycin resistance only in *M. abscessus*. Rapid and accurate detection of drug resistance in NTM species would help clinicians initiate appropriate treatment, increasing the chance of a successful outcome.

OA01-108-18 Baseline EQ-5D-5L improves prediction of treatment discontinuation in non-tuberculous mycobacterial pulmonary disease: Analysis from a nationwide cohort study

Y. Shim,[1] D. Koo,[2] N. Kwak,[2] J.-Y. Kim,[3] D.K. Kim,[4] J.-J. Yim,[2] H. Sohn,[1] [1]Seoul National University, College of Medicine, Seoul, Republic of Korea, [2]Seoul National University Hospital, Department of Internal Medicine, Division of Pulmonary and Critical Care Medicine, Seoul, Republic of Korea, [3]Harvard Medical School, Department of Microbiology, Boston, United States of America, [4]Seoul Metropolitan Government-Seoul National University Boramae Medical Center, Department of Internal Medicine, Division of Pulmonary and Critical Care Medicine, Seoul, Republic of Korea
e-mail: youbeenshim@snu.ac.kr

Background: Premature treatment discontinuation of non-tuberculosis mycobacterial pulmonary disease(NTM-PD) treatment is a critical problem that can impact long-term health outcomes. Health-related quality of life(HRQOL) is often impaired in NTM-PD patients, but the relationship between HRQOL metrics and treatment outcomes remains poorly understood.
Design/Methods: 180 patient data from the NTM-KOREA prospective cohort study with follow-up visits at approximately 6-month intervals since treatment initiation were included in our analysis.
Participants completed EQ-5D-5L questionnaires at each visit and quality-adjusted life years(QALYs) were estimated using the Korean value set. After the third follow-up, the patients were categorized into three groups: "culture-conversion achieved", "culture-conversion failed w/maintained treatment", and "treatment halted" groups.
Kruskal-Wallis tests and ANCOVA were used to assess the differences in outcomes between the groups. We developed two binary logistic regression models to predict treatment discontinuation at 18 months:
1. Baseline model including age, sex, smoking history, cavity presence, BMI, and ESR levels, and;
2. QALY-added model. Models underwent 5-fold cross-validation to assess performance.
Results: Among enrolled participants, those who prematurely discontinued treatment demonstrated lower baseline EQ-5D-5L utility scores compared to patients who completed treatment. Adding baseline EQ-5D-5L improved the model's ROC-AUC from 0.628 to 0.697(cross-validated AUC:0.483±0.113 vs. 0.595±0.149), while further adding 6-month QALY updates provided no additional advantage (AUC:0.694). The QALY-added model maintained high sensitivity (0.870±0.083) but with limited specificity (0.323±0.099) in predicting treatment discontinuation at the 0.2 threshold level.

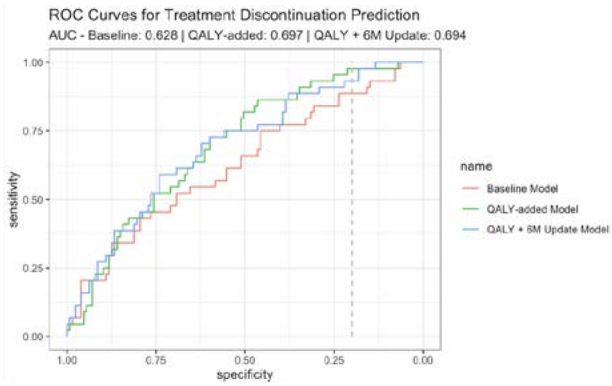

Figure.

Conclusions: Despite modest overall predictive power, EQ-5D-5L scores improve the identification of NTM-PD patients at-risk for treatment discontinuation. This brief patient-reported measure requires no follow-up assessments and is less burdensome than disease-specific instruments like QOL-B. Patients identified to be at-risk for premature treatment discontinuation may require enhanced side-effect monitoring, more frequent follow-up, or adjusted treatment regimens.
Future research should focus on determining clinically meaningful EQ-5D-5L thresholds and validating these findings in external cohorts to facilitate routine clinical implementation.

OA01-109-18 Phage-derived endolysins as anti-microbial agents against multidrug-resistant *Mycobacterium abscessus* clinical isolates

H. Kim,[1] H. Kwon,[1] G. Kang,[1] S.H. Lee,[1] Y. Park,[1] J. Ko,[1] G.I. Lee,[2] [1]The Korean Institute of Tuberculosis, Korean National Tuberculosis Association, Research and Development Center, Cheongju, Republic of Korea, [2]The Korean Institute of Tuberculosis, Korean National Tuberculosis Association, Cheongju, Republic of Korea

Background: *Mycobacterium abscessus* (*M. abscessus*), a drug-resistant nontuberculous mycobacteria, poses significant treatment challenges. Phage-derived endolysins are emerging as potential alternatives due to their rapid lytic activity and bacterial specificity.
Mycobacteriophages typically encode multiple endolysins to degrade the structurally complex and hydrophobic mycobacterial cell envelope: Lysin A hydrolyzes peptidoglycan, while Lysin B functions as a lipase or esterase,

cleaving the linkage between the mycolic acid-rich outer membrane and arabinogalactan, thereby releasing free mycolic acids.
Design/Methods: To explore the therapeutic potential of phage-derived endolysins, a lytic mycobacteriophage targeting *M. abscessus* clinical isolate was isolated and whole genome-sequenced. Based on functional annotation, *lysA* and *lysB* genes were identified, cloned, and expressed in *Escherichia coli*. The purified proteins' enzymatic activities were assessed. To evaluate their lytic activity against *M. abscessus* clinical isolates, minimum inhibitory concentration (MIC) and growth inhibition assay were performed.
Results: Lysin A exhibited dose-dependent lysozyme activity when tested using *Micrococcus lysodeikticus* as a substrate, supporting its peptidoglycan-degrading function. Lysin B showed dose-dependent lipolytic activity, as evidenced by the release of p-nitrophenol from p-nitrophenyl butyrate. Growth inhibition assay revealed that both endolysins exhibited bacteriolytic activity against multidrug-resistant *M. abscessus* clinical isolates, with significantly increased activity observed against rough morphotypes compared to smooth colony types. Lysin A inhibited bacterial growth at concentrations up to 7.0 μM, while Lysin B exhibited superior effectiveness, achieving inhibition at a MIC of 0.125 μM.
Conclusions: Our findings demonstrate the potential of phage-derived endolysins as alternative antimicrobial agents against multidrug-resistant *M. abscessus* clinical isolates. Both endolysins showed in vitro bacteriolytic activity, and further research is needed to evaluate their therapeutic applicability.

OA02 Life after TB

OA02-110-18 Quantifying lifetime mortality burden following active tuberculosis: A matched cohort study in Taiwan

B.-S. Zeng,[1] J. Lin,[1] Y. Hsieh,[2] J.-S. Hwang,[3] H.-H. Lin,[1]
[1]National Taiwan University, Institute of Epidemiology and Preventive Medicine, Taipei, Taiwan, [2]Harvard TH Chan School of Public Health, Center for Health Decision Science, Boston, United States of America, [3]Academia Sinica, Institute of Statistical Science, Taipei, Taiwan

Background: Survivors of active tuberculosis faced increased long-term mortality risk compared to individuals without tuberculosis. There was limited evidence on the excess lifetime mortality burden among individuals with tuberculosis, using a large cohort with long term follow up.
Design/Methods: We used a matched cohort design with survival extrapolation to estimate lifetime years of life lost due to active tuberculosis. The study was nested within a large private health screening program involving over 0.6 million individuals in Taiwan. Individuals with newly diagnosed active tuberculosis between January 1, 2006 and December 31, 2020 were identified through linking the data with National Tuberculosis Registry. Using a risk set matching approach, tuberculosis cases were matched to controls (1:3 case-to-control ratio) from the same screening program.
Coarsened exact matching was performed, matching on age, sex, body mass index, education level, smoking, alcohol, and comorbidities. Survival extrapolation methods were then applied to estimate survival curves and lifetime years of life lost (YLL) due to active tuberculosis.
Results: The matched cohort included 1,874 individuals with active tuberculosis and 5,262 matched controls. Among the TB cases, the mean baseline age was 63.5 years, with a median follow-up time of 7.0 years (Q1: 3.1, Q3: 11.5). Among the matched controls, the mean baseline age was 62.2 years, with a median follow-up time of 9.2 years (Q1: 4.8, Q3: 12.7).
The estimated remaining life expectancy from the time of active TB diagnosis was 20.2 years (95% confidence interval: 15.1-21.5) for TB cases and 27.5 years (95% confidence interval: 22.5-31.0) for matched controls, corresponding to a lifetime YLL of 7.3 years due to active tuberculosis.
Conclusions: We estimated the lifetime YLL associated with active tuberculosis in the intermediate burden setting of Taiwan. Future work incorporating nonfatal health loss will enable a more comprehensive assessment of the lifetime burden of active tuberculosis.

OA02-111-18 Tuberculosis recurrence and associated factors: A 12-year retrospective cohort study in Brazil

E. Lepka de Lima,[1] I. Salles,[2] S. Cohn,[2] A.A. Lindoso,[3,4] S. Fukasava,[4] S. Cox,[5,1] J. Golub,[1,2] [1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States of America, [2]Johns Hopkins School of Medicine, Center for Tuberculosis Research, Baltimore, United States of America, [3]Emilio Ribas Institute of Infectious Diseases, Epidemiology Surveillance, Sao Paulo, Brazil, [4]São Paulo State Department of Health, Epidemiologic Surveillance Center, São Paulo, Brazil, [5]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States of America
e-mail: edelima1@jh.edu

Background: Recurrences comprise a substantial proportion of the global TB burden, particularly in high-prevalence settings and among people living with HIV (PLHIV). In Brazil, a high TB-burden country, recurrence remains challenging and is associated with poor outcomes. São Paulo accounts for ~25% of TB cases nationally. Better recurrence estimates are essential to guide control strategies.
Design/Methods: We conducted a retrospective cohort study using TBweb, São Paulo's TB surveillance system, including individuals with a first TB episode and treatment success between 2013 and 2024. Participants were followed from treatment completion until the first recurrence, death, or administrative censoring. The primary outcome was primary recurrent episode. Date of death was ascertained via linkage with the National Mortality Database (SIM) and treated as a competing event. We applied a Fine and Gray competing risks model to estimate the cumulative incidence of recurrence and identify risk factors, expressed as subdistribution hazard ratios (SHRs) with 95% confidence intervals.
Results: Of 154,579 individuals, 107,646 (69%) were male, 149,356 (97%) aged ≥15 years, and 9,493 (7%) were HIV-positive. Over 12 years, 9,464 (6%) experienced TB recurrence. Median time to recurrence was 27.7 months (IQR:10.8-53.9), and longer in those <15 years (36.1; IQR:15.1-64.7) than in adults (28.1; IQR:10.8-53.9). Females had shorter time to recurrence (22.2; IQR: 8.8-46.4) than males (29.6; IQR:11.7-55.7).
Among PLHIV, median time was 23.6 months (IQR:9.8-49.4) vs. 28.8 (IQR=11.2-54.6) in HIV-negative. All comparisons p<0.001.
In our multivariable analyses, TB recurrence was associated with male sex (SHR:1.23; 95%CI:1.16-1.30), HIV (SHR:2.10; 95%CI=1.97-2.26), incarceration (SHR:2.02; 95%CI:1.91-2.13), homelessness (SHR=2.06; 95%CI=1.85-2.29), alcohol use (SHR:1.25; 95%CI:1.17-1.33), drug use (SHR:1.23; 95%CI=1.08-1.37), tobacco use (SHR:1.14; 95%CI:1.0-1.20), treatment interruption (SHR=1.91; 95%CI:1.74-2.10). Extrapulmonary TB was associated with lower risk (SHR:0.53; 95%CI=0.53-0.57).

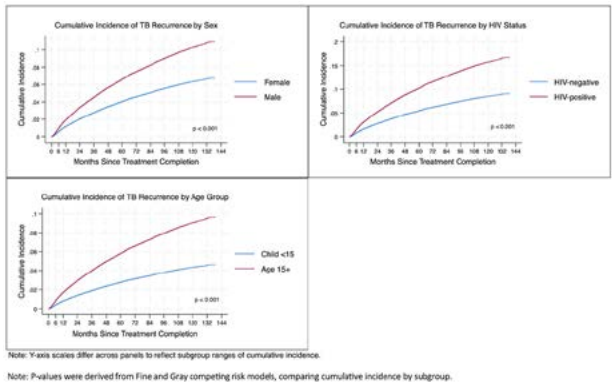

Figure 1. Cumulative incidence function of tuberculosis recurrence, accounting for competing risk of death.

Conclusions: Long-term risk of recurrence highlights the importance of risk-tailored post-treatment follow-up strategies to reduce long-term TB burden, particularly among individuals with persistent biological and social vulnerabilities.

OA02-112-18 Long-term mortality causes of tuberculosis in Korea: A population-based matched cohort study

D. Jeong,[1] H. Sohn,[1,2,3] H. Choi,[4] Y.A. Kang,[5,6]
[1]Seoul National University College of Medicine, Department of Preventive Medicine, Seoul, Republic of Korea, [2]Seoul National University College of Medicine, Department of Human Systems Medicine, Seoul, Republic of Korea, [3]Seoul National University, Institute of Health Policy and Management, Seoul, Republic of Korea, [4]Korea University, Division of Health Policy and Management, Seoul, Republic of Korea, [5]Yonsei University College of Medicine, Institute for Immunology and Immunological Disease, Seoul, Republic of Korea, [6]Severance Hospital, Yonsei University College of Medicine, Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, SeoulRepublic of, Republic of Korea
e-mail: jddwn6489@gmail.com

Background: Individuals surviving from tuberculosis (TB) exhibit significantly higher mortality rates following treatment relative to those without TB. However, there lacks clear understanding on specific causes and relative risks associated with post-TB mortality. Using the K-TB-N cohort data, our study examined the factors associated with long-term mortality and provide insights on specific causes of death among TB survivors.
Design/Methods: We conducted a retrospective case-control study using the K-TB-N cohort, a linked South Korean national database of TB notification (N=441,989), health insurance claims, and cause of death statistics with 4% random sample of the general population. We constructed our study cohort of 129,785 drug-susceptible TB patients aged ≥20 years from 2012 to 2021, and 1:5

age- and sex propensity score matching matched controls (N=648,332). Cox regression analysis was performed to identify mortality risks. The ranking of mortality rates by cause of death was calculated among the 60 causes of death listed in the general classification table provided by the Cause-of-Death Statistics.

Results: The overall mortality rate was 39.0 in TB versus 16.1 in the age- and sex-matched control cohort per 1,000 person-years ($p < .001$) after a median follow-up period of 72 months from the TB treatment start date. After adjusting for mortality-associated confounders, TB patients had a 2.7-fold higher risk of all-cause mortality (adjusted hazard ratio [HR], 2.7; 95% confidence interval [CI], 2.7–2.8). Within the first twelve-months following diagnosis, TB itself was the leading cause of death among TB patients. In the subsequent years, cancer (lung and bronchus), pneumonia, and cerebrovascular disease were dominant causes of death in the TB population.

Figure 1. Top 10 Causes of Death by Follow-up Period Based on Cause-of-Death Statistics from Statistics Korea

Conclusions: TB survivors face considerably higher mortality risks relative to the general population. Our study provides insights onto key contributing causes of long-term mortality associated with TB and emphasizes the need for integrated management comorbidities of during and post-TB treatment.

OA02-113-18 Restrictive lung disease and abnormal diffusing capacity are more frequent than airflow obstruction in Ugandans post-TB

L. Huang,[1] K. Byanova,[1] J. Zawedde,[2] I. Sanyu,[2] J. Hsieh,[3] P. Byanyima,[2] S. Kaswabuli,[2] N. Chung,[1] A. Sessolo,[2] R. Abelman,[1] C. North,[4] W. Worodria,[5] I AM OLD-DA Study
[1]University of California San Francisco, Medicine, San Francisco, United States of America, [2]Infectious Diseases Research Collaboration, None, Kampala, Uganda, [3]San Francisco General Hospital, Anesthesia and Respiratory Therapy, San Francisco, United States of America, [4]Harvard University, Medicine, Boston, United States of America, [5]Makerere University College of Health Sciences, Medicine, Kampala, Uganda
e-mail: Katerina.Byanova@ucsf.edu

Background: A meta-analysis among TB survivors found that 47% have abnormal spirometry and that people with HIV (PWH) have a lower prevalence of post-TB lung disease (PTLD) than people without HIV. Currently, data on the prevalence of abnormal total lung capacity (TLC) and diffusing capacity for carbon monoxide (DLco) after TB is sparse.

Our objective was to perform full pulmonary function testing (PFTs) after TB to determine the prevalence of abnormal lung function and whether this is modified by HIV status.

Design/Methods: This was a prospective study of adults (>18 years) with and without HIV in Kampala, Uganda who had PFTs within 3 months of TB treatment completion. Tests meeting American Thoracic Society/European Respiratory Society criteria for acceptability and reproducibility were included.

The Global Lung Initiative (GLI) reference equations for spirometry (GLI-Global), TLC, and DLco were used, and abnormal tests were defined using the lower limit of normal (LLN). The impact of HIV was analyzed using logistic regression adjusted for smoking and biomass fuel exposure.

Results: 381 participants (32.3% PWH) underwent spirometry (Jan 2016-present). Among those, 120 (40.0% PWH) had lung volumes and DLco in addition to spirometry (October 2021-present).

Spirometry only: Using only spirometry, 200 (52.5%) had normal spirometry, 51 (13.4%) had obstruction, and 129 (34.0%) had a restrictive spirometry pattern (RSP), preserved ratio impaired spirometry (PRISm), or both.

Full PFTs: Among patients who underwent full PFTs, both abnormal TLC (30.0%) and abnormal DLco (29.2%) were more prevalent than obstruction (14.2%), and the patterns of lung function abnormalities were more complex. HIV was associated with significantly lower adjusted odds of airflow obstruction, RSP, and PRISm.

Conclusions: Using full PFTs, the abnormal lung function patterns observed after TB are complex, and both restrictive lung disease and abnormal DLco are more frequent than airflow obstruction.

OA02-114-18 Looking beyond active disease: Burden and characteristics of post-TB lung disease among TB household contacts in Southern Africa

A.M. Malhotra,[1,2] C. Calderwood,[3,2] E. Marambire,[4,2] L. Larsson,[4] D. Banze,[4,5] A. Mfinanga,[4,6] K. Held,[4] A. Rachow,[4] N. Heinrich,[4] C. Khosa,[5] K. Kranzer,[7,8,4] [1]Liverpool School of Tropical Medicine, Clinical Sciences, Liverpool, Zimbabwe, [2]Biomedical Research and Training Institute, Harare, Zimbabwe, The Health Research Unit Zimbabwe, Harare, Zimbabwe, [3]London School od Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, Zimbabwe, [4]LMU University, Institute of Infectious Diseases and Tropical Medicine, Munich, Zimbabwe, [5]Instituto Nacional de Saúde, Marracuene, Instituto Nacional de Saúde, Marracuene, Maputo, Mozambique, [6]Mbeya Medical Research Centre, National Institute for Medical Research, Mbeya, United Republic of Tanzania, [7]Biomedical Research and Training Institute, The Health Research Unit Zimbabwe, Harare, Austria, [8]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, Zimbabwe
e-mail: akanksha.mimi@gmail.com

Background: Post-TB lung disease (PTLD) affects 50% of pulmonary TB survivors post treatment completion. The greatest burden is experienced in high-incidence, low-income settings. Sequalae include respiratory symptoms, functional impairment and structural lung damage. Evidence describing who is most likely to develop PTLD and duration of impairment is limited.
Design/Methods: Secondary data analysis was conducted from a longitudinal cohort study of TB household contacts (HHC) in Zimbabwe, Mozambique and Tanzania. 1488 HHCs (≥18 years) of confirmed (medium/high Xpert MTB/RIF) people with TB were enrolled (2021–2024). Procedures included questionnaires, symptom screen, spirometry, HIV testing and CXR.
Descriptive statistics and chi-squared testing were utilised to compare characteristics of HHC with and without previous TB. Logistic regression adjusting for confounders was used investigate the association of previous TB with impaired post-bronchodilator spirometry utilising GLI-other. Poverty was defined as <USD$1.9 household income per day.
Results: High-quality spirometry data was available for 68.7% of HHC (n=1022). The majority (65.6%) were female, median age was 33.4 years (IQR 24.1–44.4), 12.7% (n=130) had evidence of previous TB (median 9 years (IQR 3-15.5) before enrolment). HHC with previous TB had a higher prevalence of impaired spirometry compared to those without (50.6% versus 30.6%, aOR 2.51, 95% CI1.6-4.0, P<0.001). Despite this, only 8.5% stated a history of lung disease.
After adjustment for age, sex, BMI, and HIV status, HHC with previous TB had 2.9 times higher odds of impaired spirometry (95%CI 1.7–4.7, P<0.001) compared to those without previous TB. The effect size was larger (aOR 3.7 ; 95%CI 2.1–6.4, P<0.001) when additionally adjusting for poverty, as a potential effect modifier.
Conclusions: Previous TB is a major risk factor for persistent pulmonary impairment. PTLD remains under-diagnosed and under-treated with consequences of ongoing health-seeking and income loss. Our data emphasises the need for preventive strategies and tailored interventions.

OA02-115-18 Cured yet struggling: The lingering impact of tuberculosis on mind and life

D. Walia,[1] S. Goel,[1] M. Chopra,[1] A. Singh,[1] M.S. Sivapuram,[2] [1]Post Graduate Institute of Medical Education and Research, Chandigarh, Department of Community Medicine and School for Public Health, Chandigarh, India, [2]The Union, Conference Department, Vijayawada, India
e-mail: dikshawalia05@gmail.com

Background: Tuberculosis (TB) remains a major global health burden, with 10.6 million cases and 1.3 million deaths reported in 2022. The rise of multidrug-resistant TB (MDR-TB) complicates treatment and control efforts. Tuberculosis (TB) survivors often suffer from long-term mental health issues and reduced quality of life (QoL), yet these outcomes remain insufficiently addressed in post-treatment care.
This systematic review aims to assess the burden of depression and QoL impairments among adults who have completed TB treatment using a structured PICO framework.
Design/Methods: A systematic review was conducted following PRISMA guidelines. Literature was identified through comprehensive searches in PubMed (n=13), Scopus (n=31), and Web of Science (n=18), yielding a total of 62 studies. After screening and applying inclusion criteria, six studies were included in this synthesis. The review focused on adults (≥18 years) with a history of completed TB treatment (P), assessing exposure to TB disease (I), with or without comparator groups (C), and outcomes including prevalence/severity of depression, risk factors, and QoL impacts (O). Only peer-reviewed studies using validated tools were included.
Results: Across 06 Studies, depression prevalence ranged from 13% to 65%; anxiety was reported in 54%, and 9% experienced suicidal ideation. Tools used included CES-D and EQ-5D-3L. Despite 98% reporting some improvement in QoL post-treatment, residual impairments were common: 33% reported persistent dyspnoea, and 26% had reduced exercise capacity. Psychosocial factors such as stigma, isolation, and economic burden contributed to poor mental health, yet structured psychological care was notably absent.

Conclusions: Depression and diminished QoL are highly prevalent among TB survivors. Mental health screening and psychosocial support should be integrated into post-TB care, particularly in resource-limited settings.
Recognition of these long-term consequences is essential for effective TB control and survivor rehabilitation strategies.

OA02-116-18 Beyond the cure: The link between food insecurity and disability in recent tuberculosis survivors in Uganda

J. Sekandi,[1] T. Quach,[2] D. Nakkonde,[3] A. McDonald,[1] G. Nassanga,[3] P. Kaggwa,[1] A. Joseph,[1] R. Kakaire,[2] S. Zalwango,[4] [1]University of Georgia, Epidemiology and Biostatistics/ Global Health, Athens, United States of America, [2]University of Georgia, Global Health Institute, Athens, United States of America, [3]Makerere University, School of Public Health, Department of Epidemiology and Biostatistics, Kampala, Uganda, [4]Kampala Capital City Authority, Directorate of Public Health Services and Environment, Kampala, Uganda
e-mail: jsekandi@uga.edu

Background: Food insecurity is linked to tuberculosis (TB) through a malnutrition pathway leading to progression to active TB disease and poor treatment outcomes. The effect of food insecurity on overall health and well-being post-TB treatment is understudied.
We examined the relationship between food insecurity and self-reported disability among TB survivors.
Design/Methods: In a cohort study, we enrolled adults ≥18 years who completed TB treatment within 4 weeks in Kampala, Uganda. Questionnaires were administered at baseline, 4, and 8 weeks. We used three questions from the Food Insecurity Experience Scale.
Food insecurity was present if "Yes" to ≥1 question during any visit. Severe insecurity was defined as "Yes" to all three questions; persistent insecurity was "Yes" to ≥1 question in ≥2 visits.
Disability was measured using 12 items from the WHO Disability Assessment Schedule across six domains: cognition, mobility, self-care, getting along, life activities, and social participation (1 = none to 5 = extremely/cannot do).
Disability was categorized as "No" if the score was one and "Yes" if greater than one on any item at any visit. Severe disability was defined as reporting 'Extreme or cannot do' on at least one item at any visit. Univariate and multivariable analyses were conducted.
Results: We analyzed 150 participants who had completed all three visits. The median age (IQR) was 37 (28 - 46) and 53% were female. The prevalence of overall food insecurity, persistent food insecurity and severe food insecurity 71%, 50% and 29% respectively. The prevalence of any self-reported disability in was 90% while severe disability was 29%.
Persistent and severe food insecurity were significantly associated with severe disability (**AOR 2.53**, 95% CI 1.37-4.69 & **1.88**, 95% CI 1.13, 3.14) after adjusting for age, sex and income.
Conclusions: The findings highlight the need for nutritional support as part of the post-TB care continuum.

OA02-117-18 Multimorbidity and the risk of post-tuberculosis lung functional impairment: A systematic review and meta-analysis

K. Hill,[1] M. Scopazzini,[2] I. Mbabazi,[3] B. Warner,[4] S. Mills,[1] C. Sekaggya-Wiltshire,[5] S. Mpagama,[6] H. Stagg,[2] D. Sloan,[1] [1]University of St Andrews, School of Medicine, St Andrews, United Kingdom of Great Britain and Northern Ireland, [2]London School of Hygiene & Tropical Medicine, Faculty of Epidemiology & Population Health, London, United Kingdom of Great Britain and Northern Ireland, [3]Infectious Diseases Institute, Research deparment, Kampala, Uganda, [4]University of Glasgow, School of Health and Wellbeing, Glasgow, United Kingdom of Great Britain and Northern Ireland, [5]Infectious Diseases Institute, Research department, Kampala, Uganda, [6]Kibong'oto Infectious Diseases Hospital, Research deparment, Kilimanjaro, United Republic of Tanzania
e-mail: kh280@st-andrews.ac.uk

Background: Post-tuberculosis lung disease (PTLD), a chronic respiratory syndrome affecting up to 87% of tuberculosis (TB) survivors, is an emerging public health threat in high TB-burden, low- and middle-income countries (LMICs). The prevalence of multimorbidity, defined as two or more co-existing chronic health conditions, is increasing in LMICs but it is unclear how this affects the risk of PTLD. This systematic review aimed to explore if multimorbidity affects the risk of PTLD.
Design/Methods: We systematically searched Medline, EMBASE, Web of Science, Global Health, and Scopus databases up to 7th March 2024. Studies in LMICs assessing PTLD using spirometry (the most used tool for diagnosing PTLD) and either a single co-morbidity or multimorbidity present together with TB were included. Random effects meta-analyses were performed where data were sufficient.
Results: 10,321 papers were screened and 20 met the inclusion criteria. PTLD prevalence was 14-91%. No studies specifically analysed multimorbidity. The odds of PTLD were reduced in adults living with HIV (odds ratio (OR) 0.68 (95% confidence interval (CI) 0.52-0.88); 10 papers) (figure 1). There was no evidence for an association between PTLD and the presence of diabetes (1.29 (0.94–1.78); 3 papers), but its effect may vary by spirometry pattern. Undernutrition (BMI <18.5) increased the odds of PTLD in adults (1.99 (1.02-3.87); 3 papers) and in children (8.30 (2.0-35.2); 1 paper). Lack of studies or variability in co-morbidity definition prevented evidence synthesis for other co-morbidities.

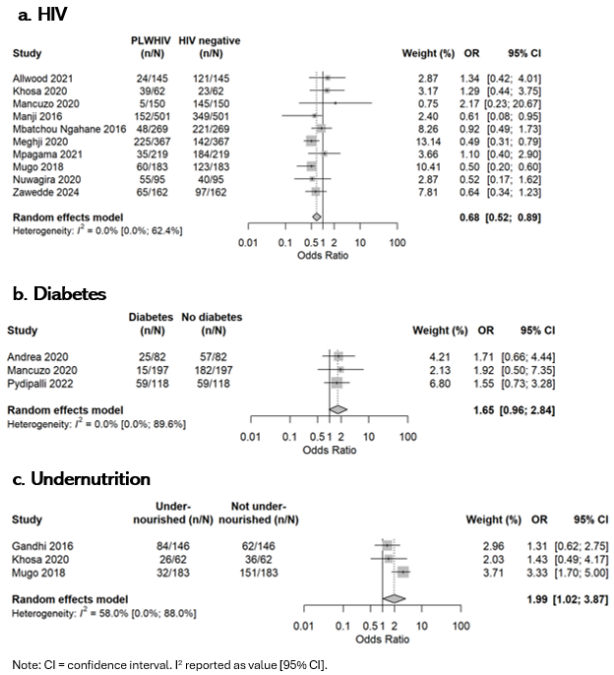

Figure 1: Forrest plots of association of abnormal spirometry in adults according to. HIV status, b. diabetes mellitus, and c. undernutrition.

Conclusions: We found an association with increased odds of PTLD in adults who are HIV-negative or undernourished. Research into the effect of other co-morbidities is critically needed.

OA02-118-18 Prevalence and predictors of post-tuberculosis lung disease among people living with HIV in Pune, India

I. Marbaniang,[1,2] R. Borse,[3] I. Ansari,[4] S. Nimkar,[1] A. Gupte,[5] S. Londhe,[1] P. Padriwad,[1] S. Surwase,[1] K. Zarekar,[1] G. Lele,[1] V. Potphode,[1] V. Mave,[1,6] [1]BJGMC - JHU, CRS, Pune, India, [2]McGill University, Epidemiology, Montreal, Canada, [3]Byramjee Jeejeebhoy Government Medical College, General Medicine, Pune, India, [4]Byramjee Jeejeebhoy Government Medical College, Radiology, Pune, India, [5]Boston University, Global Health, Boston, United States of America, [6]Johns Hopkins University, Internal Medicine, Baltimore, United States of America
e-mail: vidyamave@gmail.com

Background: Post-tuberculosis lung disease (PTLD) is not well characterized in people living with HIV (PLHIV), particularly in high TB burden settings. We evaluate the prevalence and predictors of PTLD in Indian PLHIV.
Design/Methods: We analyzed baseline data (January 2023–October 2024) from an ongoing lung health cohort at BJ Government Medical College, Pune, India.
Participants were categorized into four mutually exclusive outcome groups based on spirometry and TB history:
Group1: normal spirometry, no TB;
Group2: normal spirometry, post-TB;
Group3: abnormal spirometry, no TB, and;
Group4 (PTLD): abnormal spirometry, post-TB.
Abnormal spirometry included obstructive (FEV1/FVC <5th percentile) **or** restrictive (FVC <5th percentile with normal FEV1/FVC) patterns on pre-bronchodilator testing, using race-neutral 2012 Global Lung Initiative equations. Sociodemographic, HIV-related, smoking-related, and air pollution-related factors were assessed as predictors. Multinomial logistic regression was used to estimate associations between predictors and outcome groups, with odds ratios converted to prevalence ratios (PRs).
Results: Among 456 participants, 26% (n=121) had normal spirometry without prior TB (**Group1**), 10% (n=47) had normal spirometry post-TB (**Group2**), 44% (n=200) had abnormal spirometry without prior TB (**Group3**), and 19% (n=88) met criteria for PTLD (**Group4**).
Among those with PTLD, 81% had restrictive spirometry patterns. Relative to Group1, Group3 was associated with higher viral load, being underweight, and employment, while Group4 was associated with longer antiretroviral therapy duration, being overweight/obese, and employment (Table 1).

	Reference outcome: Group1[1] Comparator outcome: Group2 Adjusted[2] PR (95% CI)	Reference outcome: Group1[1] Comparator outcome: Group3 Adjusted[2] PR (95% CI)	Reference outcome: Group1[1] Comparator outcome: Group4 (PTLD) Adjusted[2] PR (95% CI)
Age (years)	1.05 (1.01, 1.08)	1.01 (0.98, 1.03)	1.01 (0.98, 1.04)
CD4 count/100 (cells/mm^3)	0.81 (0.69, 0.95)	1.00 (0.91, 1.10)	0.98 (0.87, 1.10)
Antiretroviral therapy (ART) duration (years)	1.11 (1.02, 1.20)	0.97 (0.92, 1.02)	1.11 (1.04, 1.19)
Viral load			
<=200 copies/mL	Ref	Ref	Ref
>200 copies/mL	1.02 (0.09, 12.13)	6.17 (1.35, 28.28)	3.80 (0.67, 21.34)
BMI categories (Asian Indians)			
Normal (≥18.5 & <23.0)	Ref	Ref	Ref
Underweight (<18.5)	2.21 (0.70, 7.00)	3.18 (1.37, 7.38)	1.72 (0.64, 4.58)
Overweight & obese (≥23.0)	0.71 (0.31, 1.60)	0.76 (0.44, 1.34)	0.50 (0.26, 0.97)
Employed			
No	Ref	Ref	Ref
Yes	1.54 (0.60, 3.96)	2.22 (1.19, 4.12)	3.44 (1.52, 7.78)

Only significant covariates in the adjusted model are shown.
[1]Group1: Normal spirometry, no TB; Group2: Normal spirometry, post-TB; Group3: Abnormal spirometry, no TB; Group4 (PTLD): Abnormal spirometry, post-TB
[2] Adjusted for age, sex, BMI, CD4 counts, viral load, employment, smoking status and duration on ART.

Table 1: Prevalence ratios (PR) and 95% confidence intervals (CI).

Conclusions: Approximately one-fifth of PLHIV had PTLD. Longer ART duration and employment were positively associated with PTLD, whereas higher BMI was negatively associated with PTLD.
In contrast, abnormal spirometry without prior TB was associated with higher viral load, underweight status, and employment. These findings suggest that correlates of post-TB and non-TB-related lung abnormalities may differ in PLHIV, indicating the value of larger longitudinal studies to better clarify underlying mechanisms for each.

OA02-119-18 Interplay between biological & social vulnerability and poor TB treatment outcome in Brazil: A nationwide study of disease registry data

B. Barreto-Duarte,[1] K. Villalva-Serra,[1] V. M. S. Campos,[1] M. Cordeiro - Santos,[2] V. C. Rolla,[3] A. L. Kritski,[4] L. Martinez,[5] P. F. Rebeiro,[6] T. R. Sterling,[6] M. M. Rodrigues,[7] B. B. Andrade,[8] [1]Institute of Research in Priority Populations, Epidemiology, Salvador, Brazil, [2]Dr. Heitor Vieira Dourado Tropical Medicine Foundation, Infectious diseases, Manaus, Brazil, [3]Fundação Oswaldo Cruz, Instituto Nacional de Infectologia Eva ndro Chagas, Rio de Janeiro, Brazil, [4]Universidade Federal do Rio de Janeiro, Programa Acadêmico de Tuberculose da Faculdade de Medicina, Salvador, Brazil, [5]Boston University, Epidemiology, Boston, United States of America, [6]Vanderbilt University School of Medicine, Division of Infectious Diseases, Nashville, United States of America, [7]Fundação Oswaldo Cruz, Laboratório de Análise e Visualização de Dados, Porto Velho, Brazil, [8]Institute of Research in Priority Populations, Clinical Research, Salvador, Brazil
e-mail: beatrizbbd@hotmail.com

Background: A focus on socially vulnerable sub-populations at increased risk oftuberculosis is warranted to decrease the disease burden. In this study, we evaluatedwhether homelessness, living withHIV, incarceration, pregnancy, immigration, drug use, and healthcare work are risk factors for unfavorable anti-tuberculosis treatment (ATT) outcomes in Brazil through analysis of national disease registry data (SINAN).

Design/Methods: We conducted an observational study of tuberculosis cases >18 years-old reported to the SINAN between 2015 and 2023. Clinical and epidemiologic variables were compared between groups (non-vulnerability, homeless, people deprived of their liberty, pregnant women, people with HIV, people who use drugs, immigrants and healthcare worker).

Additionally univariate comparisonswere employed to identify characteristics most common in those with a composite unfavorable ATT outcome, or specifically deathor LTFU. Multivariate modelling with Excess risk due to interactions (RERI) were calculated to estimate how the co-occurrence of vulnerabilities further increasesthe riskof unfavorable outcomes.

Results: Homelessness had the highest frequency of unfavorable ATT outcomes in theoverall population, followed by living with HIV and drug use. Unfavorable outcomes were also common among pregnant and immigrant populations. Living with HIV was the main risk for death, whereas homelessness was the major risk factor for LTFU. Furthermore,drug abuse further increased the risk of unfavorable outcomes among those living with HIV, with a RERI of 225% [174–304%]. Directly observed treatment (DOT), incarceration,and healthcare work were associated with favorable outcomes.

Interactions	Odds Ratio [95% CI]	RERI
	Social Vulnerabilities	
Tobacco Use & Alcohol Use		**0.1 [0.04 - 0.17]**
Effect of Tobacco Use Among Non-Alcohol Users (A+ | B−)	1.35 [1.28 - 1.43]	
Effect of Alcohol Use Among Non-Tobacco Users (B+ | A−)	1.5 [1.41 - 1.59]	
Effect of Tobacco Use Among Alcohol Users (A+ | B+)	1.3 [1.23 - 1.38]	
Effect of Alcohol Use Among Tobacco Users (B+ | A+)	1.44 [1.36 - 1.53]	
Combination Tobacco Use & Alcohol Use	1.95 [1.82 - 2.09]	
Not PPL & Retreatment		**2.25 [1.74 - 3.04]**
Effect of Not PPL Among New Cases(A+ | B−)	1.78 [1.73 - 1.83]	
Effect of Retreatment Among PPL (B+ | A−)	1.59 [1.28 - 1.98]	
Effect of Not PPL Among Retreatment (A+ | B+)	2.9 [2.78 - 3.02]	
Effect of Retreatment Among Not PPL(B+ | A+)	2.6 [2.1 - 3.21]	
Combined Not PPL & Retreatment A+ & B+	4.62 [3.73 - 5.71]	
Not PPL & Immigrants		**0.61 [0.08 - 1.02]**
Effect of Not PPL Among Non-Immigrants(A+ | B−)	1.78 [1.73 - 1.83]	
Effect of Immigrants Among PPL (B+ | A−)	1.37 [1 - 1.89]	
Effect of Not PPL Among Immigrants (A+ | B+)	1.55 [1.43 - 1.69]	
Effect of Immigrants Among Not PPL(B+ | A+)	2.6 [2.1 - 3.21]	
Combined Not PPL & Immigrants A+ & B+	2.76 [2.53 - 3.02]	
	Biological Vulnerabilities	
HIV & Alcohol Use		**0.45 [0.23 - 0.73]**
Effect of HIV Among Non-Alcohol Users (A+ | B-)	2.99 [2.71 - 3.3]	
Effect of Alcohol Use Among Non-HIV (B+ | A-)	1.5 [1.41 - 1.59]	
Effect of HIV Among Alcohol Users (A+ | B+)	1.32 [1.22 - 1.42]	
Effect of Alcohol Use Among HIV (B+ | A+)	2.63 [2.37 - 2.93]	
Combined HIV & Alcohol Use (A+ & B+)	3.94 [3.49 - 4.45]	
HIV & Drug Use		**1.72 [1.28 - 2.28]**
Effect of HIV Among Non-Drug Users (A+ | B-)	2.99 [2.71 - 3.3]	
Effect of Drug Use Among Non-HIV (B+ | A-)	2.42 [2.22 - 2.63]	
Effect of HIV Among Drug Users (A+ | B+)	2.54 [2.27 - 2.83]	
Effect of Drug Use Among HIV (B+ | A+)	2.05 [1.86 - 2.25]	
Combined HIV & Drug Use (A+ & B+)	6.13 [5.38 - 6.98]	

Table Note: Interaction analysis of overlapping vulnerabilities on unfavourable TB outcomes; additive (RERI) and multiplicative effects reported.

Conclusions: Homelessness, living with HIV and drug use, were strongly associated with unfavorable ATT outcomes in the Brazilian population. The superposition ofinterlacing social and biological vulnerabilities significantly worsened the risk of both death and LTFU in our population.

This study highlights the importance of DOT and the need to provide social protection that could improve TB treatment outcomes among vulnerable populations.

OA03 Innovations in assessing TB transmission across different settings

OA03-120-18 Use of genomic and spatiotemporal correlation for enhanced tuberculosis control in New South Wales, Australia

X. Zhang,[1] C. Suster,[1] E. Sim,[1] C. Lam,[1] E. Martinez,[2] T. Crighton,[3] E. Donnan,[4] B. Marais,[1] V. Sintchenko,[1]
[1]The University of Sydney, Sydney Infectious Diseases Institute (Sydney ID), Sydney, Australia, [2]Institute of Clinical Pathology and Medical Research, NSW Health Pathology, Centre for Infectious Diseases and Microbiology-Public Health, Westmead, Australia, [3]Institute of Clinical Pathology and Medical Research, NSW Mycobacterium Reference Laboratory, Westmead, Australia, [4]Health Protection NSW, Sydney, New South Wales, Australia, New South Wales Tuberculosis Program, Westmead, Australia
e-mail: xiaomei.zhang@sydney.edu.au

Background: Tuberculosis (TB) remains a global public health challenge. Even low TB incidence countries, like Australia, are struggling to achieve ambitious targets to eliminate local TB transmission. Whole genome sequencing (WGS) of *Mycobacterium tuberculosis* facilitates accurate transmission tracking, but its integration into public health response remains limited.
This study conducted spatiotemporal analyses of routinely collected WGS data and assessed its potential value to guide programmatic TB control responses.
Design/Methods: WGS and geolocation data from 2,492 *M. tuberculosis* isolates were examined, representing 94.9% of culture-confirmed cases and 64.0% of all notified TB cases in NSW, Australia (2017–2023).
We performed detailed genomic clustering, assessed genetic and geographic distances between cases, and applied Bayesian dated phylogeny to estimate the likely time of strain introduction.
Results: Most (64.2%) notified TB cases were successfully sequenced and geolocated, with 88.3% of TB cases residing in metropolitan Sydney. The local health districts (LHDs) with the highest case counts were South Western (21.0%) and Western (19.1%) Sydney. WGS identified 106 putative transmission clusters, involving 288 cases (11.7%), with 50% spanning multiple LHDs. Eight large clusters (gre 5 members) were identified, containing 64 cases (2.6%).
The largest cluster (17 members) was caused by a Lineage 1 strain, although most large clusters were caused by Lineage 2 strains; two were isoniazid resistant. There was poor correlation between genetic and geographic distances, which showed some improvement with removal of outliers. Most recent common ancestor (MRCA) estimates suggested recent introduction of strains associated with local transmission. Strain clustering and lineage-through-time analyses revealed temporal patterns of cluster expansion and contraction, with accurate temporal monitoring of large clusters providing a valuable metric of epidemic control.
Conclusions: The findings demonstrate the added value of integrating genomic and spatiotemporal clustering data to inform better targeted interventions pursuing the aspirational goal of "zero local TB transmission".

OA03-121-18 Ungrouped whole genome sequencing isolates: What can it tell us?

D.H. Ng,[1] E.K. Mak,[1] L.K.-Y. Lim,[1] W.M. Kyaw,[1]
[1]Communicable Diseases Agency, National Tuberculosis Programme, Singapore, Singapore
e-mail: deborah_ng@cda.gov.sg

Background and challenges to implementation: Singapore has been conducting universal whole genome sequencing for all isolates of Mycobacterium tuberculosis since November 2020, to identify clusters of transmission that could guide public health actions. However, little is known about the characteristics of isolates that are ungrouped.
Intervention or response: A retrospective cohort study was done on all isolates sequenced from patients who were notified to the National TB Registry from 1 November 2020 to 31 December 2024. A single nucleotide polymorphism (SNP) cutoff of 7 was used to define clusters. Isolates more than 7 SNP apart were defined as ungrouped. The demographic, clinical and bacteriologic characteristics of the ungrouped isolates were reviewed.
Results/Impact: During the 50-month study period, isolates from 5378 unique patients were sequenced. Of these, 4184 (78%) were ungrouped. Of the 4184 cases, majority were male (2495, 60%) and the median age was 53 years (IQR, 35-71).
Majority of cases (4056, 97%) were new cases, with only 3% due to relapse. The proportion of ungrouped isolates was significantly higher among those aged 71 years and above (26%) compared to younger age groups (p<0.001) (Figure 1).

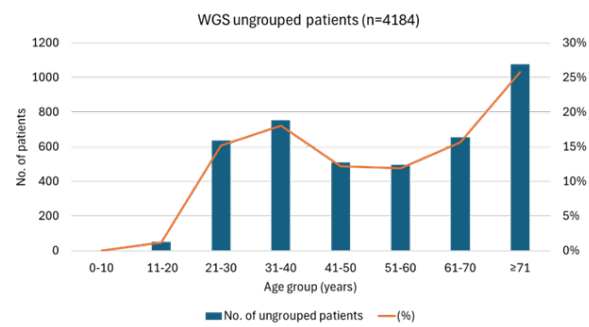

Figure 1.

The most common sites of disease were pulmonary (3515, 84%), followed by lymph node (358, 9%) and pleural (125, 3%). Only 44% (1860) had symptoms of cough, and 63% (2634) were smear-negative. About a quarter (968, 23%) of cases had been diagnosed with diabetes prior to TB diagnosis.

Conclusions: Our study demonstrates that majority of TB cases may be due to reactivation of latent infection, with only about 20% of sequenced cases due to transmission.

As a majority of cases also did not report symptoms of cough, strategies to detect and treat early or pre-disease states in high-risk groups such as diabetics or elderly should be evaluated further.

OA03-122-18 Tuberculosis transmission among older adults in Southern Taiwan

C.-Y. Wu,[1] P.-L. Lu,[2] H.-H. Lin,[1] [1]National Taiwan University, Institute of Epidemiology and Preventive Medicine, Taipei, Taiwan, [2]Kaohsiung Medical University, College of Medicine, Kaohsiung, Taiwan

Background: Tuberculosis (TB) in older adults represents a growing global concern, especially in settings with declining TB transmission and population ageing. TB in older adults is often attributed to reactivation from remote infection.

Few studies have systematically evaluated the role older adults in TB transmission.

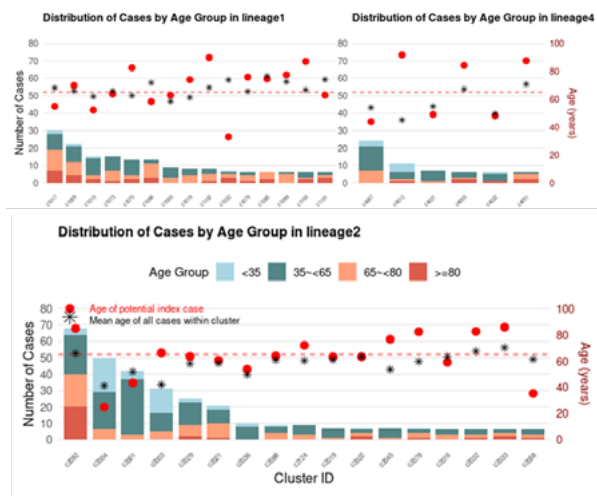
Design/Methods: We analyzed data from a population-based cohort in Kaohsiung, Taiwan, from 2019 to 2023. 4,836 culture-positive TB cases were identified, with 3,787 (82%) undergoing whole genome sequencing. Genomic clustering was defined as ≤20 single nucleotide polymorphisms between isolates. In median and larger clusters (≥6 cases), we used the TransPhylo package to infer transmission pairs and potential index cases.

In smaller clusters (≤5 cases) where the notification dates of cases were at least 3 months apart, we assumed the first notified case as the index case.

Results: Overall, 70.8% of cases were male, and 60.9% were older adults (≥65 years). Of all cases, 38.7% were genetically clustered, with older adults contributing to 49.2% of clustered cases despite having a lower clustering rate (31.3%) than the other age groups.

Notably, older adults were involved in 87.9% of the clusters (≥3 cases), and in 45.5% of the clusters older adults accounted for >50% of the cases. In median and larger clusters (≥6 cases), TransPhylo identified older adults as the index case in 47.4% (18/38).

Among the inferred transmission pairs, 31.1% (61/196) of infectors and 34.6% (73/211) of infectees were older adults. In smaller clusters (3<cases≤5), older adults were the first notified case in 29.9% (38/127).



Conclusions: Our findings suggest that older adults play a significant role in TB transmission not only as recipients but also as potential sources of transmission. Understanding transmission dynamics within this age group and across age groups, particularly in settings with aging populations, is crucial for designing effective, age-targeted control strategies.

OA03-123-18 CAD score of chest radiograph vs. cough as determinants of household *Mycobacterium tuberculosis* transmission risk among people with sputum-positive TB

P.Y. Khan,[1] N. McCreesh,[2] I. Govender,[1] S. Sweeney,[3] E. Mkwanazi,[4] G. Ording-Jespersen,[5] T. Smit,[5] M. Sithole,[4] R.G. White,[2] R. Houben,[2] K.L. Fielding,[6] A.D. Grant,[1] [1]London School of Hygiene & Tropical Medicine, Clinical Research Department, London, United Kingdom of Great Britain and Northern Ireland, [2]London School of Hygiene & Tropical Medicine, Department of Infectious Disease Epidemiology and Dynamics, London, United Kingdom of Great Britain and Northern Ireland, [3]London School of Hygiene & Tropical Medicine, Department of Global Health and Development, London, United Kingdom of Great Britain and Northern Ireland, [4]Africa Health Research Institute, Data Science Unit, Durban, South Africa, [5]Africa Health Research Institute, Diagnostic Research Division, Durban, South Africa, [6]London School of Hygiene & Tropical Medicine, Department of Infectious Disease Epidemiology and International Health, London, United Kingdom of Great Britain and Northern Ireland
e-mail: palwasha.khan@lshtm.ac.uk

Background: If digital chest radiography with computer-aided detection (CAD) software, increasingly used for TB screening, is a better indicator of infectiousness than cough, this would justify its wider use.

To evaluate this, we assessed the association of *Mycobacterium tuberculosis* (*Mtb)* transmission risk to household contacts with:

i. CAD4TB quantitative output and;
ii. Cough status at the start of treatment among index people with tuberculosis (PWTB).

Design/Methods: We recruited programmatic sputum-positive index PWTB starting treatment in uMkhanyakude, a rural/peri-urban district in KwaZulu-Natal, South Africa. Household *Mtb* transmission risk was assessed using QuantiFERON-TB Gold plus (QFT) positivity among household contacts (2-14 years). A Bayesian multilevel multivariable logistic regression model was used to assess the causal association of QFT-positivity with cough status (defined as presence of cough of any duration versus none [Model 1]); CAD4TB score in 10-unit strata (Model 2); and a final model including CAD4TB score and cough status (Model 3). The minimal adjustment set was informed by directed acyclic graphs. Adjusted population attributable fractions (PAF) were calculated.

Results: 603 child household contacts of 243 index PWTB were included in the analysis. After adjustment, there was weak evidence for an association of QFT positivity (OR 3.0: 95% CI1.0 – 10.7) with cough status (Model1, Table), whereas there remained strong evidence for a **40% increase in odds of QFT-positivity per 10-unit increase in CAD4TB score** (Model 2). PAFs were similar for CAD4TB score and cough. Including both cough status and CAD4TB score (Model 3), strong evidence for the association with CAD4TB remained whereas cough status was no longer associated with QFT-positivity.

		Unadjusted	Multivariable		
	Proportion of child contacts QFT+ (n/N)	OR (95% CI)	Model 1[$] OR (95% CI)	Model 2[$] OR (95% CI)	Model 3[$] OR (95% CI)
Cough status of index PWTB					
None	0.11 (19/177)	-	-	-	-
Present	0.19 (82/426)	3.0 (1.2 - 7.9)	3.0 (1.0 - 10.7)	-	1.5 (0.5 - 5.5)
CAD4TB score of index PWTB (per 10-unit increase)	-	1.3 (1.1 - 1.6)	-	1.4 (1.1 - 1.7)	1.3 (1.1 - 1.7)
PAF	-	-	54%	59%	-

OR = odds ratio; CI = credible interval; PAF = population attributable fraction
[$]Minimal adjustment set included index person with tuberculosis characteristics (age, sex, HIV status, history of previous TB), household socioeconomic status and residential area

Table.

Conclusions: CAD4TB score and cough are associated with household transmission risk. CAD scores may be more useful than cough to identify the most infectious PWTB in the community.

OA03-124-18 Household transmission of tuberculosis from smear-negative index patients

E. Shen,[1] C.-C. Huang,[2,3] C. Contreras,[4] J. Jimenez,[4] L. Lecca,[4,3] M. Becerra,[3] R. Yataco,[4] R. Calderon,[5] Z. Zhang,[2] M. Murray,[2,3,6] [1]Harvard Medical School, Department of Medicine, Boston, United States of America, [2]Brigham and Women's Hospital, Division of Global Health Equity, Boston, United States of America, [3]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States of America, [4]Socios En Salud, Socios En Salud, Lima, Peru, [5]Advanced Research and Health, Advanced Research and Health, Lima, Peru, Peru, [6]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States of America

Background: Although smear-negative pulmonary tuberculosis (TB) has traditionally been considered less infectious than smear-positive TB, growing evidence indicates that smear-negative index patients may still contribute substantially to overall disease burden. However, data on transmission from this population remains limited.

We used a household-based cohort in Lima, Peru, to evaluate the contribution of smear-negative index patients to within-household TB transmission, and to identify risk factors that may influence transmission risk from these patients.

Design/Methods: We enrolled 4,044 microbiologically confirmed TB index patients and their 12,767 household contacts (HHCs) in Lima, Peru, between 2009 and 2012. HHCs were followed for 12 months to monitor TB transmission using tuberculin skin testing and to assess disease progression.

We used logistic regression to evaluate associations between index patient characteristics and HHC outcomes, including TB infection and incident disease.

Results: Among 1,134 child household contacts exposed to a smear-negative index patient, 241 (21%) were infected at baseline. Of the 465 contacts of any age who developed secondary disease during follow-up, 115 (25%) had been exposed to a smear-negative patient.

Among child household contacts of smear-negative index patients, baseline infection was more likely when the index patient was female (OR: 1.41, 95% CI:1.04–1.92), had diabetes (OR: 2.83 [1.11–7.21]), or came from a household with lower socioeconomic status (OR: 1.45 [1.04–2.02]).

Exposure to an index patient with a history of active smoking was associated with increased risk of developing secondary incident disease (OR: 3.49 [1.18–10.33]).

	Baseline Child HHC Infection			Secondary TB Disease

Socioeconomic Score Tertiles						
Lowest third	440 (39.3)	1.435 (1.049 – 1.964)	1.445 (1.035 – 2.018)	1163 (35.9)	1.402 (0.885 - 2.222)	1.279 (0.781 – 2.096)
Middle third	493 (44.0)	*(referent)*	*(referent)*	1413 (43.7)	*(referent)*	*(referent)*
Upper third	187 (16.7)	1.039 (0.677 – 1.595)	0.990 (0.630 – 1.555)	660 (20.4)	0.853 (0.456 – 1.597)	0.807 (0.420 – 1.547)

Conclusions: Smear-negative TB patients accounted for a quarter of within-household TB transmission in our study cohort. Risk factors for TST positivity among HHCs exposed to a smear negative patient included lower socioeconomic status and diabetes in the index patient. These findings highlight the need to consider smear-negative individuals in TB control strategies.

OA03-125-18 Smoked drug use drives tuberculosis transmission dynamics in a rural community in the Western Cape, South Africa

S. Malatesta,[1] N. Niemand,[2] S. Kulkarni,[3] M. Marin,[3] B. Mann,[2] S. Ghatti,[3] CR. Horsburgh,[4] T. Carney,[5,6] R. Warren,[2] M. Farhat,[3] L. White,[1] K. Jacobson,[7] [1]Boston University School of Public Health, Biostatistics, Boston, United States of America, [2]Stellenbosch University, South African Medical Research Council Centre for Tuberculosis Research, Cape Town, South Africa, [3]Harvard Medical School, Biomedical Informatics, Boston, United States of America, [4]Boston University School of Public Health, Epidemiology, Biostatistics, Global Health, Boston, United States of America, [5]South African Medical Research Council, Mental Health, Alcohol, Substance Use and Tobacco Research Unit, Cape Town, South Africa, [6]University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa, [7]Boston University Chobanian & Avedisian School of Medicine, Section of Infectious Diseases, Boston, United States of America
e-mail: samalate@bu.edu

Background: Smoked drug use may be an underrecognized contributor to *Mycobacterium tuberculosis* (Mtb) transmission. People who smoke drugs (PWSD) have elevated disease burden and contribute disproportionately to transmission due to greater infectiousness (smear-positive sputum, cavitary disease), shared smoking practices in poorly ventilated settings, prolonged periods of transmission potential from delayed diagnosis, more often being young men, and other social dynamics.

Design/Methods: We analyzed *Mtb* whole-genome sequencing data from 452 individuals diagnosed with pulmonary TB between 2017-2024 in a South African rural community. 399 were diagnosed at clinics (clinic-diagnosed), 53 were recruited via respondent-driven sampling (community-diagnosed) among PWSD (methamphetamine and/or methaqualone). We used a <2 single nucleotide variant threshold to define transmission clusters and summarized their size and composition.

We employed a machine learning approach (Naive Bayes with cross-validation) to estimate pairwise transmission probabilities that integrates genetic distance with host characteristics (spatial proximity, demographics, clinical data) and determines directionality from diagnosis date.

We estimated odds ratios and 95% confidence intervals for the contribution of host characteristics to identifying infectors in transmission pairs.

Results: 399 (88.3%) individuals were clinic-diagnosed of whom 180 (45.1%) were PWSD. All 53 community-diagnosed participants smoked drugs. Median participant age was 37 (IQR: 27-47) years, 283 (62.6%) were male, 130 (26.6%) had HIV, 158 (35.0%) had an incarceration history, and 175 (38.7%) had a history of TB. 163 (36.1%) participants linked across 53 transmission clusters; 22 (41.5%) clusters included ≥3 individuals. Most clusters contained PWSD (45/53; 84.9%).

Both PWSD that were clinic-diagnosed (aOR: 2.7, 95%CI: 1.6-4.5) and community-diagnosed (aOR: 5.2, 95%CI: 2.6-10.4) were more likely to be infectors (Figure 1).

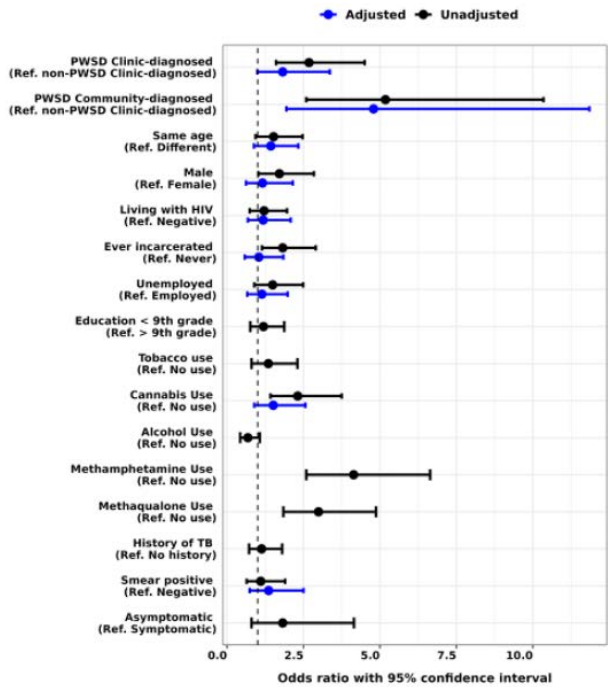

Figure 1. Associations between host characteristics and being an infector in direct transmission pairs.

Conclusions: In a high TB burden setting, PWSD significantly contributed to TB spread via increased odds of being an infector and high membership in transmission clusters. PWSD should be considered for prioritization for early screening and transmission interventions to reduce community transmission.

OA03-126-18 *M. tuberculosis* transmission dynamics in congregate settings: A genomic epidemiology study

K. Walter,[1] E. Ferreira Lemos,[2] A.P. Cavalcante Aires Alves,[2] G.F. Chaves Ferreira,[2] V. Maruyama Martins Coutinho,[2] B. Mathema,[3] J. Warren,[4] C. Colijn,[5] T. Cohen,[6] J. Croda,[2] J.R. Andrews,[7] [1]University of Utah, Epidemiology, Salt Lake City, United States of America, [2]Federal University of Mato Grosso do Sul, Medicine, Campo Grande, Brazil, [3]Columbia University Mailman School of Public Health, Epidemiology, New York City, United States of America, [4]Yale University School of Public Health, Biostatistics, New Haven, United States of America, [5]Simon Fraser University, Mathematics, Burnaby, Canada, [6]Yale University School of Public Health, Epidemiology of Microbial Disease, New Haven, United States of America, [7]Stanford University, Infectious Diseases and Geographic Medicine, Stanford, United States of America
e-mail: katharine.walter@hsc.utah.edu

Background: One barrier to intervening in the global tuberculosis (TB) pandemic is that it is unknown whether *M. tuberculosis* transmission largely occurs through repeated close exposures among few contacts or many shorter-term contacts. Identifying sources of transmission is particularly urgent in congregate settings with high incidence of infection.
Design/Methods: To identify drivers of *M. tuberculosis* transmission within a congregate setting with extremely high incidence of TB, we conducted genomic surveillance in a prison system in Central West Brazil. We whole genome sequenced *M. tuberculosis* isolates and collected detailed incarceration histories, including movements between and within prisons.
We investigated the relationship between exposures of differing proximity (cell, cell block, prison) and transmission risk, inferred by genomic clustering.
Results: We collected detailed incarceration histories for 595 individuals from whom we sequenced 561 high quality *M. tuberculosis* genomes. A month-long increase in exposure to an individual with TB within a prison cell increased the odds of pairwise genomic clustering by 7.4% (95% CI: 4.4-10.4%) and a six-month increase in exposure, by 54% (95% CI: 29.9%-82.5%). Most (89%; 528 of 595) individuals with TB had at least one potential week-long exposure in a prison cell to another individual with TB, and frequently many, with a median of 12 (IQR: 5-21) potential unique exposures to individuals in prison cells.
Frequent movements by the prison system create a highly connected contact network: individuals with TB were transferred a median of 5 (IQR: 1-17) times in the 12 months before diagnosis.
Conclusions: While close exposures within a prison were related to pairwise genomic clustering, most individuals with TB had multiple exposures to other individuals with TB due to frequent movements by the prison system. Our results support the urgent expansion of prison-wide mass

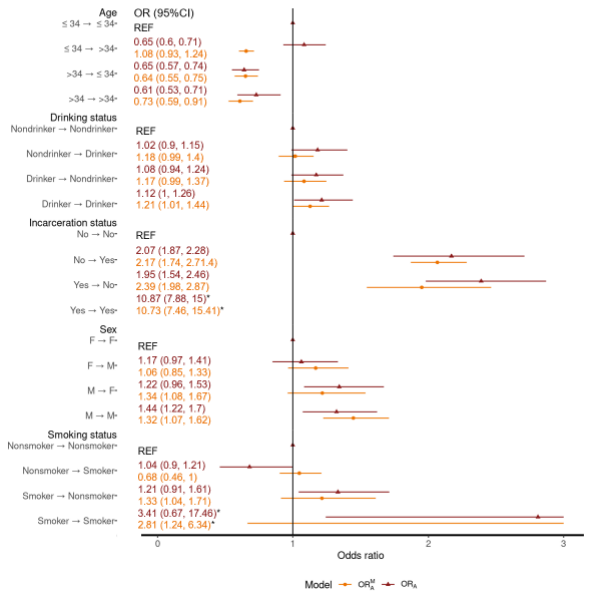
screenings, TB preventive therapy, and structural interventions to reduce transmission risk in prisons and other congregate settings.

OA03-127-18 Using whole genome sequencing and other metadata to estimate factors associated with tuberculosis transmission in Lima, Peru

A. Shapiro,[1] M. Brooks,[2] C.-C. Huang,[3] M. Murray,[4] H. Jenkins,[1] L. White,[1] [1]Boston University, Biostatistics, Boston, United States of America, [2]Boston University, Global Health, Boston, United States of America, [3]Harvard University, Medicine, Boston, United States of America, [4]Harvard University, Global Health, Boston, United States of America
e-mail: anshap@bu.edu

Background: A detailed understanding of tuberculosis (TB) transmission dynamics is necessary to interrupt the spread of disease. We develop a model to estimate adjusted odds ratios (ORs) of factors associated with genetic relatedness, defined by single nucleotide polymorphisms (SNP) differences obtained from whole genome sequencing (WGS), as a proxy for transmission.
Design/Methods: We build upon an existing model that estimates unadjusted ORs between genetic relatedness and pair-level features. The model uses an iterative algorithm to create a dataset approximating true transmission links inferred from SNP differences, shown in prior simulations to better capture transmission-covariate associations than genetic relatedness alone.
To calculate adjusted ORs, we integrated bootstrapped logistic regression within the iterative algorithm, addressing correlation from individuals appearing in multiple pairs. We applied this method to data from a cohort study in Lima, Peru, comparing results to ORs from logistic regression without the iterative framework.
Results: Amongst the 2,488 people diagnosed with TB in the study, we identified 2,481 possible transmission pairs out of 3,078,413 total possible pairs. Transmission pairs in which either the infector or infectee was younger than 35 or was incarcerated and in which both the infector and infectee were male had increased odds of transmission (Figure).
Point estimates from the iterative algorithm were similar to those from logistic regression but had larger confidence intervals, reflecting the adjustment for correlation in the data.
Conclusions: We designed a method to produce adjusted ORs that appropriately account for the correlation of pairwise genetic relatedness data and serve as an accurate proxy for the association of covariates and transmission. This method can be applied to any dataset with WGS and is a valuable tool to further our knowledge of risk factors associated with TB transmission.

Figure. Estimated adjusted naïve Bayes modified close genetic relatedness odds ratios (OR_A^M) and odds ratios estimated by a multivariate logistic regression model (OR_A) for the Lima, Peru cohort dataset. Both estimates are presented with 95% confidence intervals. *The value is out of scale and has not been included or entirely represented.



OA03-128-18 Comparative transmissibility of bacteriologically confirmed versus clinically diagnosed pulmonary TB at school setting: Implications for contact screening strategies

Y. Ren,[1] Q. Ruan,[2] F. Li,[3] L. Fei,[4] Y. Yang,[2] J. Li,[3] W. Zhang,[2] TB-YOUTH Study Group [1]Shanghai Sci-Tech Inno Center for Infection & Immunity, Clinical Research Departement, Shanghai, China, [2]National Medical Center for Infectious Diseases, Huashan Hospital, Shanghai Medical College, Fudan University, Department of Infectious Diseases, Shanghai, China, [3]Guizhou Center for Disease Control and Prevention, Institute for Tuberculosis Prenvention and Control, Guiyang, China, [4]National Medical Center for Infectious Diseases, Clinical Research Department, Shanghai, China

Background: Tuberculosis infection (TBI) remains a global health challenge. Current WHO guidelines prioritize preventive therapy for contacts of bacteriologically confirmed pulmonary TB (PTB) cases, assuming lower transmission risk from clinically diagnosed cases. This study evaluates this assumption.
Design/Methods: We analyzed data from the TB-YOUTH study (NCT06033807), including 256 PTB index cases (139 bacteriologically confirmed, 117 clinically diagnosed) and 14,786 school-based contacts. TBI was determined via IGRA (QuantiFERON®-TB Gold Plus). Primary outcomes compared TBI rates between contacts of bacteriologically vs. clinically diagnosed cases. Secondary outcomes included active TB (ATB) detection and trans-

mission determinants. Analyses used chi-square tests and generalized linear mixed models (GLMM) to account for clustering effects.

Results: Clinically diagnosed index cases demonstrated higher symptomatic manifestations (overall symptoms: p=0.023; cough: p=0.001; persistent cough >2 weeks: p=0.032) (Table 1). Crude TBI rate was marginally lower in contacts of clinically diagnosed cases in initial chi-square analysis (9.89% vs. 11.14%; *p*=0.01), but GLMM adjustment nullified this association (adjusted OR=1.05, *p*=0.65), with moderate clustering effects (ICC=0.11). Similarly, ATB detection differences (crude *p*=0.010) disappeared after GLMM adjustment with exceptionally high clustering effects (OR=0.94, *p*=0.91; ICC=0.80). Multivariable regression identified male index cases (OR=1.22, *p*=0.046) and prolonged cough (>2 weeks; OR=1.23, *p*=0.049) independently predicted higher transmission risk.

	Bacteriologically Confirmed (n=139)	Clinically diagnosed (n=117)	p
Age	17 [15, 19]	17 [15, 19]	0.381
Female Gender	78 (56.1)	62 (53.0)	0.708
Detected in Active case finding	72 (51.8)	63 (53.8)	0.841
Any Symptom	93 (66.9)	61 (52.1)	0.023
Cough	68 (48.9)	33 (28.2)	0.001
Sustained cough (duration > 2w)	49 (35.3)	26 (22.2)	0.032
Number of close contacts included	56 [50, 64]	56 [50, 63]	0.804

Table 1. Baseline characteristics of index cases
Data are in median [IQR] or n (%). P < 0.05 indicates significant statistical difference. W, week(s).

Conclusions: Our findings suggested that diagnostic classification (bacteriologically vs. clinically confirmed) did not predict TB transmission risk in schools after adjusting for clustering. High ICC values highlight the necessity of multilevel modeling in contact studies. Prolonged cough in index cases correlated with transmission, suggesting symptom-based interventions remain relevant.

These findings challenge the exclusion of clinically diagnosed cases from systematic prevention strategies, but still need to be validated by ATB incidence in prolonged follow-up.

OA03-129-18 Pairwise analyses of transmission among individuals with isoniazid-resistant and pan-susceptible tuberculosis using genomic and spatial data

H.-H.O. Lin,[1] Y. Lan,[2] P.-L. Lu,[3] C.-Y. Chiang,[4] T. Cohen,[2] H.-H. Lin,[1] [1]National Taiwan University, Institute of Epidemiology and Preventive Medicine, Taipei, Taiwan, [2]Yale University, Department of Epidemiology of Microbial Diseases, New Haven, United States of America, [3]Kaohsiung Medical University, Department of Laboratory Medicine and Infectious Disease Section of Department of Internal Medicine, Kaohsiung, Taiwan, [4]Wan Fang Hospital, Taipei Medical University, Division of Pulmonary Medicine, Department of Internal Medicine, Taipei, Taiwan
e-mail: olivialin0510@gmail.com

Background: The comparative transmission of drug-resistant and drug-susceptible strains of *M. tuberculosis* (*Mtb*) is a key determinant of the projected trajectories of tuberculosis (TB) epidemics.

Few analyses thus far have attempted to estimate and compare factors associated with transmission of drug-resistant and drug-susceptible *Mtb* circulating in the same population.

Design/Methods: We conducted whole-genome sequencing (WGS) using isolates from 3,796 (83%) out of total 4,565 culture-positive TB diagnosed between 2019 and 2023 in Kaohsiung, Taiwan. Genotypic isoniazid-resistant (INH-R) TB was defined using TB-Profiler, identifying 336 INH-R isolates carrying an isoniazid-resistance associated mutation and 3,077 pan-susceptible TB (DS-TB) isolates.

We used a hierarchical Bayesian regression model (implemented in the R package GenePair) to identify epidemiological, genomic, and spatial factors associated with each pair of TB cases belonging to the same putative transmission network (defined here using a threshold of no more than 12 single-nucleotide polymorphisms).

Results: Among pairs with DS-TB, closer spatial proximity, smaller age differences, and younger ages were independently associated with greater odds of being in the same transmission network.

Among pairs with INH-R TB, only closer spatial proximity was associated with greater odds of being in the same transmission network.

The Figure shows effect estimates for variables included in the model.

Conclusions: Our pairwise analyses suggest that person-to-person transmission dynamics differ by drug resistance status, highlighting the need for tailored approaches to TB prevention and care for individuals with *Mtb*.

Demographic and spatial factors appear to play a greater role in the transmission of DS-TB, warranting more targeted efforts in this population.

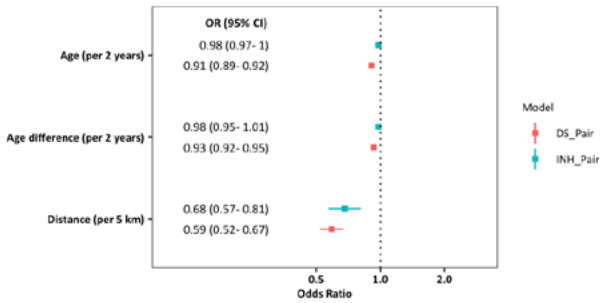


Figure. Odds Ratios for Age and Spatial Factors Associated with TB Transmission in INH-R and DS-TB Pairs.
Note: Age (per 2 years): sum of the ages of two patients per 2 years; Age difference (per 2 years): age difference per 2 years; Distance (per 5 km): spatial distance per 5 km.

OA04 TB and co-morbidities

OA04-130-18 TB multimorbidity and its impact on mortality amongst adults in South Africa: A prospective cohort study nested in a trial

G. Wood,[1] R. Byrne,[1] L. Lebina,[2] E. Worrall,[3] E. Webb,[4] P. MacPherson,[5] N. Martinson,[6] T. Wingfield,[1] [1]Liverpool School of Tropical Medicine, Centre for Tuberculosis Research, Liverpool, United Kingdom of Great Britain and Northern Ireland, [2]Africa Health Research Institute, Clinical Trials Unit, Durban, South Africa, [3]Liverpool School of Tropical Medicine, Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland, [4]London School of Hygiene and Tropical Medicine, Infectious Disease Epidemiology Department, London, United Kingdom of Great Britain and Northern Ireland, [5]University of Glasgow, School of Health & Wellbeing, Glasgow, United Kingdom of Great Britain and Northern Ireland, [6]University of the Witwatersrand, Perinatal HIV Research Unit (PHRU), Soweto, South Africa
e-mail: greta.wood@liverpool.ac.uk

Background: Tuberculosis (TB) multimorbidity- the co-existence of TB and another comorbidity within a single individual- is a major contributor to TB incidence and mortality. We investigated the prevalence and mortality of TB multimorbidity in South Africa.
Design/Methods: We conducted a prospective cohort study of adults ≥15 years with bacteriologically-confirmed pulmonary TB in two provinces in South Africa, nested within a cluster-randomised trial of household TB contact person investigations. We investigated five TB key comorbidities as defined by the World Health Organization: HIV, undernutrition, diabetes, smoking and alcohol use, and assessed all-cause mortality over 15 months using Cox regression. TB multimorbidity was defined as the presence of one or more concurrent TB key comorbidities in a person with TB.
Results: Of 1997 participants, 1896 (95%) had mortality data available at 15 months. Median age was 38 (IQR 29-48) years, 1203/1997 (60%) were male, and 86.2% (95% CI 84.6-86.6) had TB multimorbidity. TB multimorbidity peaked in participants aged 40-49 years (93% [90-95]), was more prevalent in men vs women (90% [88-91] vs 81% [78-84], p<0.001), and in urban vs rural areas (88% [86-90] vs 84% [81-86], p=0.005).
The prevalence of the five TB key comorbidities were HIV (54.7% [95% CI 52.5-56.9]), undernutrition (44.9% [43.3-47.7]), alcohol consumption (28.3% [26.3-30.3]), smoking (18.4% [16.7-20.2]), and diabetes (3.7% [2.9-4.6]).
Mortality was higher for participants with two (16.0% [13.0-18.8], HR 1.88 [1.20-2.95], p=0.006) and three or more (19.9%[14.9-24.6], HR 2.58 [1.56-4.24], p<0.001) TB key comorbidities, than those with no comorbidities (11.2% [7.17-15.0]) (Figure 1).

The population attributable fraction of TB multimorbidity on mortality was 57.1%.

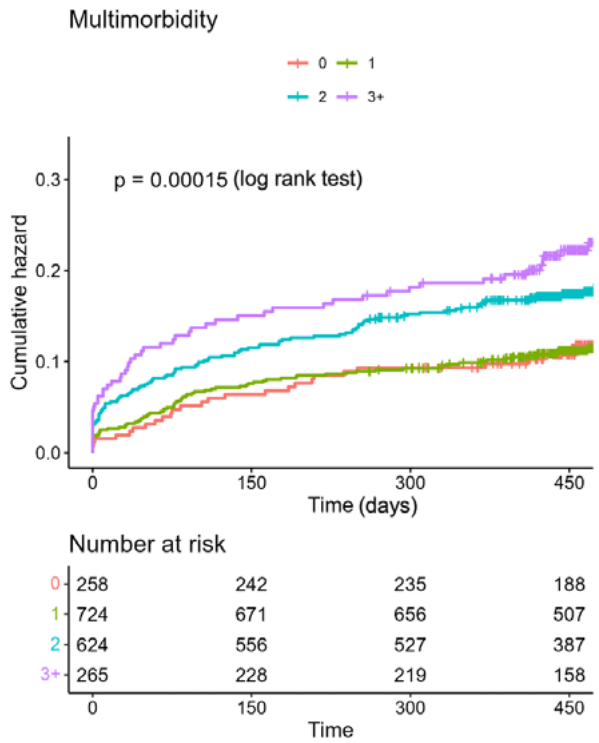

Figure 1.

Conclusions: TB multimorbidity is highly prevalent and a major contributor to TB mortality. People with TB should be routinely offered screening and management of comorbid conditions to reduce their risk of death.

OA04-131-18 Community-based, peer-led psychosocial support was associated with reduced tuberculosis stigma and depression among adults with tuberculosis in Indonesia: A prospective interventional cohort study

A. Fuady,[1] M.A.N. Haya,[1] F.F. Yani,[2] F. Agiananda,[3] M. Anindhita,[1] M. Haniifah,[1] A. Karnasih,[3] D.F.A. Haq,[1] E.R. Febriani,[2] F.R. Hardy,[1] T. Wingfield,[4,5] [1]Universitas Indonesia, Community Medicine, Faculty of Medicine, Jakarta, Indonesia, [2]Universitas Andalas, Pediatrics, Padang, Indonesia, [3]Universitas Indonesia, Psychiatry, Faculty of Medicine, Jakarta, Indonesia, [4]Liverpool School of Tropical Medicine, Clinical Sciences and International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland, [5]Liverpool School of Tropical Medicine, Centre for Tuberculosis Research Departments of Clinical Sciences and International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: ahmad.fuady01@ui.ac.id

Background: In Indonesia, our recent research demonstrated that 61% of people with tuberculosis (TB) experience moderate TB-stigma and 31% exhibit depression symptoms. Working with key multisectoral stakeholders, we co-developed a community-based, peer-led psychosocial support intervention.
This study evaluated the impact of the intervention on TB stigma and depression among adults with TB in Indonesia.
Design/Methods: A non-randomized, single-arm prospective intervention cohort studywas conducted in six primary health centers and two public hospitals in Depok and Padang cities from June 2024 to February 2025. All newly diagnosed individuals with drug-sensitive and drug-resistant TB, aged 15 years and above, were consecutively recruited. Participants were assessed at diagnosis, end of intensive phase (month-2), and continuation phase (month-6) for stigma, depression, and quality of life, using locally-adapted and validated tools including the Van Rie TB Stigma scale, PHQ-9, and EQ5D5L, respectively. All participants were offered a psychosocial support intervention consisting of individual counselling at baseline, and TB Survivor-led monthly group counselling until treatment completion. We applied McNemar and Cochran's Q tests to evaluate changes from baseline, Month-2 and Month-6.
Results: A total of 129 people (Depok=85, Padang=44) participated. At baseline, 74% (95%CI 65-82%) exhibited moderate TB stigma, primarily related to guilt and disclosure, which decreased to 43% (34-53%) at Month-2 and 21% (13-28%) at Month-6 (p<0.001). Mild to severe depression similarly decreased: 57% (35-72%) at baseline, 33% (20-47%) at Month-2, and 15% (6-23%) at Month-6 (p<0.001). Conversely, quality of life increased over time, with median (IQR) values rising from 0.84 (0.63-1.00) to 0.92 (0.83-1.00) at Month-2 and 1.00 (0.91-1.00) (p<0.001) at Month-6.

Conclusions: Community-based, peer-led psychosocial support, combining individual and monthly group counselling, has the potential to mitigate TB stigma and depression while improving quality of life among adults with TB in Indonesia. A randomised-controlled trial evaluating the effectiveness of the psychosocial support package is in preparation.

OA04-132-18 Association of *Helicobacter pylori* co-infection with tuberculosis disease severity: A cross-sectional study

J.B. Baluku,[1,2] M.M. Ichumar,[3] D. Zawedde,[2] M. Nabwana,[4] D. Nanyanzi,[5] Y. Wanda,[5] S. Namiiro,[1] B. Namanda,[1] E. Nabawanuka,[6] S. Kikomeko,[7] J. Mutesi,[7] S. Kiguli,[8] [1]Makerere University Lung Institute, Tuberculosis Research Group, Kampala, Uganda, [2]Kiruddu National Referral Hospital, Division of Pulmonology, Kampala, Uganda, [3]Kisenyi Health Center, Tuberculosis Clinic, Kampala, Uganda, [4]Makerere University John Hopkins University Research Collaboration, Data management, Kampala, Uganda, [5]Makerere Joint AIDS Program, HIV Care and Treatment, Kampala, Uganda, [6]Mulago National Referral Hospital, Department of Radiology, Kampala, Uganda, [7]Kiruddu National Referral Hospital, Division of Radiology, Kampala, Uganda, [8]Makerere University College of Health Sciences, Paediatrics and Child Health, Kampala, Uganda
e-mail: bbjoe18@gmail.com

Background: *Helicobacter pylori* (HP) has immunomodulatory effects and is highly prevalent among individuals with tuberculosis (TB), but its association with TB disease severity remains unclear. We assessed the association between HP infection and clinical, microbiological, and radiological TB severity. Secondarily, we explored factors associated with HP co-infection.
Design/Methods: We enrolled adults (≥18 years) with newly diagnosed, bacteriologically confirmed pulmonary TB from two public clinics in Kampala, Uganda. TB was confirmed using GeneXpert Ultra or smear microscopy. Participants completed a questionnaire, underwent physical examination, provided stool samples for HP stool antigen testing (SAT), and underwent chest X-rays imaging read by a radiologist.
Severe microbiological TB was defined as GeneXpert cycle threshold <16 or smear grade 3+; severe clinical TB as Bandim TBscore ≥8; and severe radiological TB as X-ray Timika score >71. We used modified Poisson regression to evaluate associations between HP and TB severity, adjusting for confounders.
Results: Of 200 participants, 67 (33.5%; 95% CI 27.3–40.4) tested positive for HP. Severe radiological TB was more frequent in HP-positive participants (34.8% vs. 22.1%, $p = 0.060$), as were severe clinical (14.9% vs. 11.3%, $p = 0.55$) and microbiological TB (40.0% vs. 33.8%, $p = 0.86$), though differences were not statistically significant. In adjusted analysis, HP was not significantly associated with severe clinical (aPR 1.17; 95% CI 0.53–2.60), radiological (aPR 1.51; 95% CI 0.94–2.42), or microbiological TB (aPR 1.14; 95% CI 0.80–1.63). HP infection was independently associated with rural residence (aPR 1.60; 95% CI 1.04–2.47), anorexia (aPR 1.71; 95% CI 1.01–2.90), and lower diastolic blood pressure (aPR 0.98; 95% CI 0.96–0.99).
Conclusions: HP co-infection was not significantly associated with TB severity, although a trend toward increased radiological severity was observed. HP infection was associated with rural residence, anorexia, and lower diastolic blood pressure.

OA04-133-18 Nasal host gene expression in adults with pulmonary tuberculosis and HIV in Uganda

N. Khambati,[1] K. Lopez Tamara,[2] L. Nakiyingi,[3] E. Nakabugo,[3] J. Ellner,[2] P. Salgame,[2] R. Song,[1] E.M. Bijker,[1,4] D. O'Connor,[1] W Evan Johnson,[2] [1]University of Oxford, Department of Paediatrics, Oxford, United Kingdom of Great Britain and Northern Ireland, [2]New Jersey Medical School, Rutgers University, Department of Medicine, Newark, United States of America, [3]Makerere College of Health Sciences, Department of Medicine, Kampala, Uganda, [4]Maastricht University Medical Centre, MosaKids Children's Hospital, Department of Paediatrics, Maastricht, Netherlands
e-mail: nisreen.khambati@paediatrics.ox.ac.uk

Background: Tuberculosis (TB) is a major cause of death in those with HIV, however diagnosis remains difficult. The first pathogen-host interaction in TB occurs in the upper airway and nasal samples are easy to collect. This study aimed to determine if nasal gene expression differs in TB disease, compare nasal gene profiles with blood and assess the performance of nasal and blood signatures in predicting TB.
Design/Methods: 40 adults with presumed pulmonary TB (PTB) and newly diagnosed HIV were consecutively enrolled in Uganda: 20 with active PTB disease (cases) and 20 without (controls). Nasal cells and blood were collected for RNA sequencing to identify differentially expressed genes (DEGs) and biological pathways. Receiver operating characteristic curves evaluated the performance of a classification model that used machine learning algorithms. Gene enrichment methods were applied to assess 59 published blood TB diagnostic signatures in the Ugandan blood and nasal datasets.
Results: 44 nasal DEGs and 238 blood DEGs were identified between TB cases and controls, with 3 DEGs common to both samples.
Figure 1 demonstrates the top DEGs. Amongst PTB cases, pathways related to the inflammatory response and innate immune system were downregulated in nasal samples and upregulated in blood. Proportions of immune cell

subtypes in nasal samples were not different based on TB status. Machine learning models trained using all 44 nasal DEGs had an area under the curve (AUC) between 0.85-0.93 for predicting TB, similar to models trained with the 238 blood DEGs (AUC: 0.83-0.95). 6/59 published blood signatures had an AUC>0.7 in the nasal dataset, compared to 46/59 in the blood dataset.

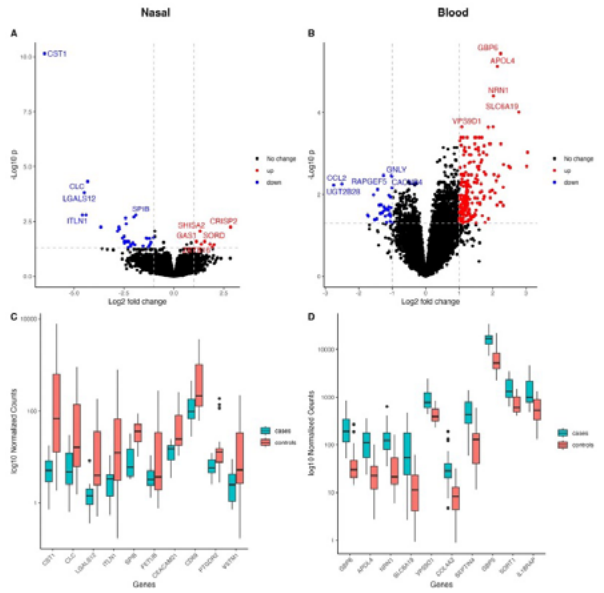

Figure 1: Top DEGs in PTB cases compared to controls
Volcano plot showing the effect size by the -log$_{10}$P value for nasal (A) and blood (B) samples. DEGs are highlighted in red or blue, with gene names shown for the top 5 downregulated and upregulated DEGs.
Boxplot of log transformed normalised counts for the top 10 DEGs for nasal samples (C) and blood samples (D).

Conclusions: This study suggests that there are distinct immune responses to PTB in the nose, compared with blood. Differences in nasal gene expression in adults with HIV who have PTB, versus those without PTB, highlight their potential as TB diagnostic biomarkers.

OA04-134-18 COVID-19 severity and risk of tuberculosis disease development within one year follow-up: A nationwide cohort study in Chile

S. Vargas-García,[1,2] M.E. Balcells,[1] E. Undurraga,[3,4] M.d.L. García-García,[5] L.A. Villarroel de Pino,[6] N. Vergara Magellas,[7] C. García Calavaro,[7] N. Escobar Salinas,[8]
[1]Pontificia Universidad Católica de Chile, Infectious diseases in adults, Santiago, Chile, [2]Universidad Autónoma de Ciudad Juárez, Institute of Biomedical Sciences, CuauhtémocMem, Mexico, [3]Pontificia Universidad Católica de Chile, Escuela de Gobierno, Santiago, Chile, [4]Research Center for Integrated Disaster Risk Management (CIGIDEN), Research Center for Integrated Disaster Risk Management (CIGIDEN), Santiago, Chile, [5]Instituto Nacional de Salud Publica, Center for Infectious Disease Research (Tuberculosis Unit), Mexico City, Mexico, [6]Pontificia Universidad Católica de Chile, Public Health, Santiago, Chile, [7]Ministry of Health of Chile, Department of Epidemiology, Santiago, Chile, [8]Ministry of Health of Chile, National Tuberculosis Control and Elimination Program, Santiago, Chile
e-mail: salvador.vargas@uacj.mx

Background: Severe COVID-19 causes profound immune dysregulation and pulmonary sequelae, which may heighten the risk to progressing from tuberculosis infection (TBI) to active disease. The use of corticosteroids and other immunomodulators in its management may further contribute to this progression.
However, the extent to which these factors influence the subsequent risk of developing an active tuberculosis (TB) remains uncertain.
Design/Methods: We conducted a nationwide retrospective cohort study in Chile, including all adults (≥18 years) with a PCR-confirmed SARS-CoV-2 infection between March 1, 2020 and October 31, 2022. Data were linked across five national health registries. SARS-CoV-2 infection severity was categorized as asymptomatic, non-hospitalized symptomatic, hospitalized non-critical, and hospitalized critical.
Participants were followed for up to 12 months. The outcome was the incidence of a newly notified TB. Adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs) were estimated using a parametric Weibull regression model, controlling for sociodemographic factors, SARS-CoV-2 vaccination status, and main comorbidities.
Results: Among 3,607,175 individuals with SARS-CoV-2 infection, 731 (0.03%) developed TB within a year. TB risk was significantly higher among all those hospitalized for COVID-19 —whether non-critical (aHR 8.19, 95% CI 6.17–10.88) or critical (aHR 7.75, 95% CI 5.41–11.09) — compared to individuals with asymptomatic SARS-CoV-2 infection. SARS-CoV-2 vaccination modified this association: unvaccinated individuals had an aHR of 13.40 (95% CI 9.77–18.38) versus 2.81 (95% CI 1.68–4.69) among those vaccinated. Tuberculosis risk nearly doubled

during the period when corticosteroid use for COVID-19 became widespread. Additional independent risk factors for TB included older age, male sex, migrant status, enrollment in the public healthcare system, and other chronic health conditions.

Table 2. Factors associated with active TB development in a SARS-CoV-2 infection cohort in Chile, 2020-2022. Comparative models: Selected model, stratum of vaccinated individuals, and stratum of unvaccinated individuals.

	Global model (n=3,667,175)				Vaccinated strata (n= 971,669)				Unvaccinated strata (n= 3,052,966)

Notes:CI: Confidence Interval [a] At least one (lung, kidney, asthma, liver disease). [b] At least one dose of CanSino vaccine or two doses of another type of vaccine prior to the identification of SARS-CoV-2.

Conclusions: Greater COVID-19 severity markedly increased the risk of developing TB during follow-up. These findings highlight the need for targeted TBI screening and preventive strategies among individuals recovering from severe COVID-19, particularly those with underlying comorbidities.

OA04-135-18 Biomarkers for diabetes mellitus (DM) and inflammation in people diagnosed with pulmonary tuberculosis (PTB)

F. Nabeemeeah,[1] T. Snyman,[2] J. George,[3] N. Crowther,[2] R. Chikwati,[2] T. Moloantoa,[1] P. Abraham,[1] K. Otwombe,[1] K. Hlongwane,[1] N. Mncube,[1] E. Variava,[4] N. Martinson,[1]
[1]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa, [2]University of the Witwatersrand, Chemical Pathology, Johannesburg, South Africa, [3]Univeristy of the Witwatersrand, Chemical Pathology, Wits Diagnostic Innovation Hub, Johannesburg, South Africa, [4]University of the Witwatersrand, Internal Medicine, Tshepong hospital, Johannesburg, South Africa
e-mail: nabeemeeahf@phru.co.za

Background: Biomarkers to accurately diagnose DM in people with TB (PWTB) are needed. Glycated haemoglobin (HbA1c) appears to over diagnose DM at TB disease onset. Fructosamine which measures glycated serum proteins may be an alternative. We report HbA1c, high-sensitivity C-Reactive protein (hsCRP) and fructosamine before TB treatment and one month after treatment completion.
Design/Methods: We enrolled a cohort of eligible adults(25 -65 years) with microbiologically confirmed PTB who had taken ≤5 doses of TB treatment. We purposively recruited three groups of PWTB:those without evidence of DM; those self-reporting prior DM, and those presenting with HBA1c≥6.5% or fasting glucose≥7mmol/l (characterised as dysglycaemic). All had HIV status ascertained with CD4 count and HIV viral load(VL) if living with HIV(LWH). Sputum was subjected to Xpert Ultra and mycobacterial culture. Proportions for categorical measures and medians (interquartile ranges) of biomarkers were determined by group.
Results: Of 76 participants(all positive Xpert MTB/Rif Ultra and most (88%) culture positive),54 had no DM,11 self-reported DM, and 11 were identified with dysglycaemia. Their median age was 37(IQR:31-45) years; 65% were male. 51% were LWH, their median CD4 count was 201cells/mm^3, 72% were on anti-retroviral therapy and 49% had VL<50 copies/ml. Median values for HbA1c, hsCRP and fructosamine at initiation of, and after TB treatment in those without DM were, respectively: 5.9% vs 5.5%, 106mg/L vs. 5.8mg/L , 232µmol/L vs. 271.5µmol/L; in those with DM: 11.7% vs.10.6% ,47.5mg/L vs 1.8mg/L ,491µmol/L vs. 443µmol/L ;and in the dysglycaemic group: 6.6% vs. 5.2% ,241mg/L vs. 5.9mg/L and 246µmol/L vs. 243.5 µmol/L. With TB treatment, HbA1c normalises in the dysglycaemic group and hsCRP approaches normal in the TB+DM group. Fructosamine levels in the TB+DM group are two fold those in the other groups at both timepoints.
Conclusions: Fructosamine appeared to identify diabetes in people with TB. Dysglycaemia as identified by HbA1c was transitory and normalised post treatment.

OA04-136-18 The impact of HIV on the phenotype and function of Mycobacterium tuberculosis-infected human alveolar macrophages

C. Kajanga,[1,2] D.V. Mhango,[1,3] A.P. Chirambo,[3,1] C. Mandalasi,[3,1] E.T. Chimbayo,[4,1] S. Mitini-Nkhoma,[1,3] A.M. Kamkwatira,[1] R.D. Malamba,[1] M. Manduwa,[1] D. Tembo,[1] H.C. Mwandumba,[1,3,5] [1]Malawi Liverpool Wellcome Research Programme, Infection Biology, Blantyre, Malawi, [2]Nottingham Trent University, School of Science and Technology, Nottingham, United Kingdom of Great Britain and Northern Ireland, [3]Liverpool School of Tropical Medicine, Department of Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland, [4]University of Glasgow, School of Infection, Immunity, and Inflammation, Glasgow, United Kingdom of Great Britain and Northern Ireland, [5]Kamuzu University of Health Sciences, Department of Medicine, Blantyre, Malawi
e-mail: ckajanga@mlw.mw

Background: People with HIV-1 (PWH) face a heightened risk of developing tuberculosis (TB) compared to HIV-1-uninfected individuals (HIV-). Pulmonary TB is the most prevalent form of TB in this population. Despite advancements like antiretroviral therapy (ART), which

has reduced HIV-associated pulmonary TB rates, PWH still faces a threefold greater risk of TB compared to HIV-infected individuals, indicating persistent deficiencies in *Mycobacterium tuberculosis* (*Mtb*)-specific immune responses in the lungs. We postulated that PWH have impaired early innate immune responses, making them more susceptible to TB disease.

Design/Methods: We conducted a study at the Malawi Liverpool Wellcome Research Programme (MLW) and the Queen Elizabeth Central Hospital in Blantyre, Malawi. Participants, including healthy HIV-uninfected individuals and asymptomatic PWH aged between 18 and 60 years, who underwent bronchoscopy to collect bronchoalveolar lavage (BAL) samples. We used a CDC1551 fluorescent reporter Mtb strain expressing mCherry for flow cytometry analysis to evaluate *Mtb* uptake by AMs. Surface immunophenotyping determined CD206 and HLA-DR expression, while intracellular cytokine staining assessed IL-6 and TNF-α production in *Mtb*-infected AMs.

Results: Among 34 participants (17 HIV-negative, 17 PWH, including 4 ART-naive) (28 females and 6 males), PWH had a median CD4 count of 511.0 cells/μl (range 113-841 cells/μl). PWH-derived AMs showed reduced CD206 expression (MFI 943) compared to HIV-negative individuals [(MFI 3878) (p=0.0001)] and diminished *Mtb*-specific IL-6 [(MFI 632.0 vs. 1664) (p=0.081)] and TNF-α [(MFI 3017 vs. 10386) p=0.0104)] responses. Despite ART, PWH AMs exhibited increased HLA-DR expression [(MFI 7049 vs. 3543) (p=0.0402)], indicating ongoing immune activation.

Conclusions: Our findings reveal HIV-associated downregulation of CD206 and increased HLA-DR expression on alveolar macrophages, indicating ongoing immune activation despite ART. Additionally, reduced IL-6 and TNF-α production suggests impaired early control of Mtb. This persistent dysregulation may underlie the elevated TB risk in PWH, even after effective ART.

OA04-137-18 Impact of glycemic control on multidrug-resistant tuberculosis treatment outcomes

R.P. Tampi,[1,2] C. Hewison,[3] U. Khan,[4,5] H. Huerga,[6] M. Bastard,[7] M.L. Rich,[8] M.F. Franke,[9] endTB

[1]Harvard University, Interfaculty Initiative in Health Policy, Boston, United States of America, [2]Harvard University, Center for Health Decision Science, Boston, United States of America, [3]Médecins Sans Frontières, Tuberculosis Working Group, Paris, France, [4]McGill University, Department of Epidemiology, Biostatistics and Occupational Health, Quebec, Canada, [5]IRD Global, TB Program, N/A, Singapore, [6]Médecins Sans Frontières, Epicentre, Field Epidemiology, Brussels, Belgium, [7]World Health Organization, Global Programme on Tuberculosis & Lung Health, Paris, France, [8]Partners In Health, Boston, United States of America, [9]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States of America
e-mail: rtampi@g.harvard.edu

Background: Multidrug-resistant tuberculosis (MDR-TB) presents a major challenge to global TB prevention and care efforts. Comorbid Type 2 Diabetes Mellitus (DM) has been associated with higher rates of unfavorable MDR-TB treatment outcomes. While mechanisms remain unclear, evidence suggests sustained glycemic control may improve treatment outcomes.

We estimated the total effect of controlled and uncontrolled diabetes at baseline on unfavorable treatment outcomes, hypothesizing that uncontrolled hyperglycemia explains unfavorable treatment outcomes among those with diabetes.

Design/Methods: We fit a generalized linear model with a logit link using data from the endTB observational study. Eligible participants were adults with a baseline diabetes diagnosis. Diabetes was classified, at enrollment, as controlled (hemoglobin A1c (HbA1c) <7%) or uncontrolled (HbA1c ≥7%). Unfavorable treatment outcomes were defined as a composite of death, treatment failure, and loss to follow-up (LTFU). Secondary analysis disaggregated LTFU from death and failure.

Results: Among 1,644 participants, 215 (13.1%) had diabetes at baseline (72 controlled and 143 uncontrolled) (Table).

		Unfavorable Outcomes		Death Among Unfavorable Outcomes		Treatment Failure Among Unfavorable Outcomes		LTFU Among Unfavorable Outcomes	
Diabetes Status at Baseline	N	N	Proportion (%)	Died (N)	Proportion (%)	Treatment Failure (N)	Proportion (%)	LTFU (N)	Proportion (%)
No Diabetes	1429	294	20.6	127	43.2	62	21.1	105	35.7
Uncontrolled Diabetes	143	37	25.9	15	40.5	3	8.1	19	51.4
Controlled Diabetes	72	15	20.8	12	80.0	1	6.7	2	13.3

The adjusted odds ratio (OR) for uncontrolled diabetes, versus no diabetes, and unfavorable MDR-TB treatment outcome was 1.27 (95% CI: 1.04, 2.29), while the adjusted OR for controlled diabetes was 0.74 (95% CI: 0.44, 1.06). Uncontrolled diabetes was associated with an outcome of LTFU (OR: 1.93, 95% CI: 1.12, 3.19) compared to no

diabetes. The adjusted OR for uncontrolled diabetes and death and treatment failure was 1.09 (95% CI: 0.66, 1.24) compared to those with no diabetes.
Conclusions: In this multi-country cohort, baseline uncontrolled diabetes was not associated with increased risk of death or treatment failure but was positively associated with LTFU. These findings suggest that a complex interaction of social, behavioral, and treatment factors - potentially contributing to both poor glycemic control and LTFU - may be the primary drivers of poorer MDR-TB outcomes, rather than purely underlying biological mechanisms.

OA04-138-18 Demonstrating integrated mental health screening during treatment of people-centered drug-susceptible tuberculosis (DSTB) service in Myanmar

A.P.S. Phoo,[1] K.Z. Thann,[1] D. Balasubramanian,[2] J. Farley,[3] [1]PATH, Myanmar Country Program, Yangon, Myanmar, [2]PATH, India Country Program, New Delhi, India, [3]PATH, Primary Health Care, Seattle, United States of America
e-mail: aphoo@path.org

Background and challenges to implementation: People with TB (PwTB) frequently face mental health challenges, including depression which can influence treatment outcomes. Integrating mental health support in TB care is critical for ensuring people-centered response. STOP TB Reach Wave 10 funded private provider interface agency for integrated service delivery project by PATH and Myanmar Health Assistant Association integrated Patient Health Questionnaire-9 (PHQ-9) depression assessment into drug-susceptible TB (DS-TB) service in two semi-urban townships in Myanmar, with assessments at treatment initiation andduring intensive phase.
Intervention or response: Health workers conducting PHQ-9 received structured 3-day training from mental health professionals and used validated Burmese-language PHQ-9 for people with limited literacy to ensure consistent understanding. Following TB education and counseling at treatment initiation, all PwTB starting treatment were screened for depressive symptoms using PHQ-9. A second assessment was conducted during the intensive treatment phase, after follow-up DS-TB adherence counseling. PwTB with mild symptoms (score <9) received regular counseling; PwTB with moderate or severe symptoms (score >9) were referred to a mental health specialist.
Results/Impact: Of 85 individuals (17-80 years), 85.9% had no depressive symptoms at baseline, improving to 88.2% at the second assessment. Mild symptoms declined from 14.1% to 11.8%. Notably, 10.6% improved from mild to no symptoms—75% of those initially with mild symptoms. Meanwhile, 8.2% shifted from no to mild symptoms, representing 9.6% of those with initially no symptoms. Most participants (81.1%) remained in the same category: 77.6% with no symptoms throughout, and 3.5% with persistent mild symptoms. No moderate or severe symptoms were reported at either time point.

	Initial Assessment % of Total (n=85)	Second Assessment % of Total (n=85)
No depressive symptoms (Score 0-4)	85.9% (n=73)	88.2% (n=75)
Mild symptoms (Score 5-9)	14.1% (n=12)	11.8% (n=10)
Transition	% of Total (n=85)	
Mild symptoms → no symptoms	10.6% (n=9)	
No symptoms → mild symptoms	8.2% (n=7)	
No symptoms → no symptoms	77.6% (n=66)	
Mild symptoms → mild symptoms	3.5% (n=3)	

Table 1: Changes in PHQ-9 status from initial to follow-up assessment.

Conclusions: Provision of integrated PHQ-9 screening in TB care is both feasible and valuable in supporting people-centered TB response. Counseling provided at key treatment stages may play a role in mitigating depressive symptoms during treatment. Scaling up mental health integration requires sustained investment in training, supervision, and linkage to further psychosocial services.

OA04-139-18 Disability is a risk factor for 1-year mortality after tuberculosis diagnosis in Korea

J. Min,[1,2] J.E. Park,[3] S.Y. Kim,[3] J.H. Park,[3] [1]The Catholic University of Korea College of Medicine, Department of Internal Medicine, Seoul, Republic of Korea, [2]Seoul St. Mary's Hospital, Division of Pulmonary and Critical Care Medicine, Seoul, Republic of Korea, [3]Chungbuk National University, Institutes of Health & Science Convergence, Cheongju, Republic of Korea
e-mail: minjinsoo@catholic.ac.kr

Background: We previously identified that people with disabilities have a higher risk of developing active tuberculosis. Building on this finding, we aimed to assess the effect of disability on 1-year mortality among people with tuberculosis.
Design/Methods: We conducted a nationwide population-based cohort study using the linked national registry databases in the Republic of Korea. From the National Disability Registration Database, we collected information on disabilities. The extracted information on disabilities was linked to variables selected from the National Health Information Database using the personal identification numbers.
Next, we established a link between these datasets and information regarding the causes of death from the cause-of-death statistics obtained from Statistics Korea. The primary endpoint was to compare 1-year mortality after tuberculosis diagnosis between people with and without

disabilities. Cox proportional hazard models were used to evaluate the hazard of 1-year mortality and explore related factors.

Results: Of the 317,597 enrolled participants with newly diagnosed active tuberculosis between 2008 and 2016, 33,712 (10.6%) had disabilities. Individuals with disabilities were significantly older (64.4±15.2 vs. 50.3±20.0) and predominantly male (64.2% vs. 55.2%) at the time of TB diagnosis. Individuals with disabilities had a higher incidence of all-cause mortality than those without disability (7.77 vs. 2.85 per 100,000 person-months). Disability was significantly associated with 1-year mortality (adjusted hazard ratio [aHR], 1.24; 95% confidence interval [CI], 1.19–1.29).

All-cause mortality also increased with age (aHR per 10 years, 2.06; 95% CI, 2.02–2.09) and was higher in males (aHR, 1.391; 1.84–1.98). Lower income levels and higher Charlson Comorbidity Index were also associated with increased mortality.

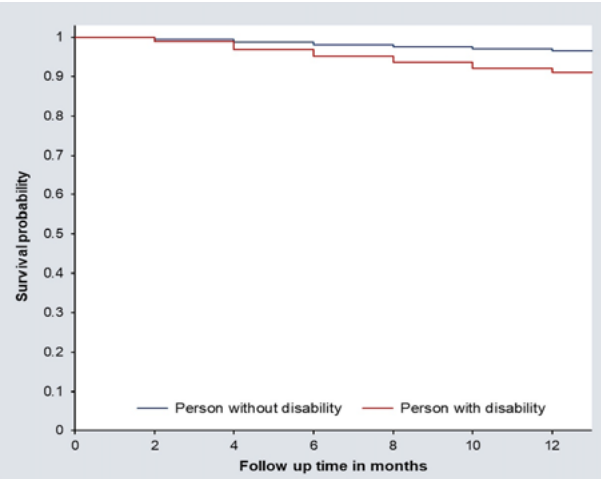

Figure. Survival rate Kaplan-Meier plots.

Conclusions: People with disabilities exhibit a higher 1-year mortality rate after tuberculosis diagnosis than those without disabilities. Tailored healthcare interventions and policies to improve anti-TB treatment outcomes for people with disabilities are necessary.

OA04-140-18 CD4 counts in HIV-negative participants in the RATIONS trial: The effects of gender and disease status

Background: CD4+ T cells play an essential role in protection from TB.CD4+ lymphopenia has been reported in patients with TB even without HIV infection. We report on baseline CD4 counts and predictors of CD4 lymphopenia in a subset of PwTB and their household contacts (HHC) at baseline within the RATIONS trial.

Design/Methods: We enrolled 268 participants (96/2800 PwTB, 172/6073 HHCs) using a convenience sample and estimated CD4 counts on a Beckman Coulter flow cytometer using standard protocols. None of the HHC were HIV positive; there were 6 PwTB with known HIV infection (0.3%). Underweight was a body mass index (BMI) <18.5 kg/m^2. We defined 2 thresholds for CD4 counts – low (< 500 cells/ul) and very low (< 300 cells/ul).

Results: Both PwTB and HHCs had a high prevalence of underweight, 82% of PwTB and > 33% of HHCs. The median CD4 counts in HHCs were lower than those reported for a healthy Indian population. Women HHCs had a median CD4 count of nearly 150 cells/µl higher than men HHCs despite lower weight, BMI, and hemoglobin. One in 4 HIV-negative HHC had low CD4 counts, and this proportion was lower in women compared to men.

Characteristics	Patients with TB (n=96)			p-value	Adult household contacts (n=172)			p-value
	Overall	Men (n=64)	Women (n=32)		Overall	Men (n=51)	Women (n=121)

Hb in g/dl, median (IQR)	10.6 (9.2, 11.9)	10.8 (9.2, 10.6)	10.4 (9.2, 11.2)	0.267*	11.7 (10.7, 13.1)	13.5 (12.6, 15.2)	11.3 (10.5, 12.0)	<0.00005*
CD4 cells/µl, median (IQR)	436 (292, 550)	406 (281, 536)	487 (320, 584)	0.095*	665 (501, 865)	583 (445, 722)	731 (551, 918)	0.0004*
% CD4 count <500/µl (95% CI)	66.7 (56.6, 75.5)	70.3 (57.8, 80.4)	59.4 (41.2, 75.3)	0.284§	24.4 (18.5, 31.4)	37.3 (24.9, 51.5%)	19.0 (12.9, 27.1)	0.011§
% CD4 count <300/µl (95% CI)	25 (17.3, 34.7)	28.1 (18.3, 40.6)	18.8 (8.4, 36.8)	0.317§	1.7 (0.56, 5.3)	1.96 (0.26, 13.20)	1.65 (0.41, 6.45)	0.888§

**Mann-Whitney U test; § Chi-squared test*

Over two-thirds of the PwTB at baseline had low CD4 counts, and a quarter of PwTB had very low CD4 counts. Overall, the predictors of low CD4 counts in the participants were age (aOR=1.03), male sex (aOR=1.99), and disease status (aOR=5.36), with a trend towards an association with low BMI in PwTB (aOR=2.72, p=0.088).
Conclusions: HHCs had lower CD4 counts than reference values for Indians, and a significant prevalence of low CD4 counts. Despite poorer nutritional parameters, women HHCs had significantly higher CD4 counts than men HHCs. Disease status was a predictor of low CD4 and very low counts despite HIV-negative status.

OA05 It takes a village: Improving prevention and detection of TB among children

OA05-141-18 Global, regional, and national burden of tuberculosis among children aged 0-14 years from 1990 to 2021: Results from the Global Burden of Disease Study 2021

L. Fu,[1] Y. Sun,[1] K. Liu,[1] S. Wei,[1] Y. Ning,[1] J. Du,[1] L. Li,[1]
[1]Beijing Chest Hospital, Office of the National TB Clinical Center, Beijing, China.
e-mail: jdu-sdu@163.com

Background: Tuberculosis remains a significant global public health challenge, particularly among children.
Design/Methods: Data on tuberculosis (drug-susceptible, MDR-TB, and XDR-TB) incidence and disability-adjusted life years (DALYs) among children aged 0-14 years in 204 countries and territories from 1990 to 2021 were extracted from the GBD 2021. Estimated annual percentage changes (EAPC) in the age-standardised incidence rates (ASIR) and DALY rates of tuberculosis, by age, sex, and socio-demographic index (SDI), were calculated to quantify the temporal trends. Spearman correlation to evaluate associations between tuberculosis burden and SDI.
Results: In 2021, there were an estimated 759,300 new tuberculosis cases among children globally, with an ASIR of 37·7 per 100,000 population. The global ASIR and DALY rates showed a declining trend from 1990 to 2021, with annual reductions of -2·61% (95%CI: -2·74 to -2·47) and -4·38% (-4·61 to -4·14), respectively.
However, regional disparities were evident, with Southern Sub-Saharan Africa had the highest ASIR (164·3 per 100,000) and DALY rates (1051·2 per 100,000). From 1990 to 2021, only High-income North America (EAPC=1·12, 95% CI: 0·61 to 1·64) showed an increasing trend in ASIR of tuberculosis.
Eight of the 21 GBD regions showed an increasing trend in ASIR of MDR-TB, with the largest increasing trend in Oceania (11·99,10·49 to 13·52), followed by Central Asia (9·76, 6·48 to 13·13) and South Asia (5·71, 3·10 to 8·38). A strong negative correlation was observed between tuberculosis burden and SDI, with low-SDI regions showing the highest disease burden.
Conclusions: Despite global declines in tuberculosis incidence and DALYs among children, significant regional disparities persist, particularly in Sub-Saharan Africa and regions with rising MDR-TB incidence. Targeted interventions are crucial for reducing the burden of tuberculosis and are indispensable for achieving global tuberculosis elimination targets.

OA05-142-18 Accuracy of Xpert MTB/RIF Ultra vs. liquid culture in induced sputum samples from children in a multicentric Brazilian study

M. Polese-Bonatto,[1] C. Nespolo de David,[1] I.T.S. Sartor,[1] T.R. Azevedo,[1] G.O. Zavaglia,[1] A.d.C. Robaina,[1] M.L. Tonini,[2] E.d.S. Alves,[3] D.M. Pelissari,[3] F. Dockhorn Costa,[3] M.C. Scotta,[1] R. Stein,[1] [1]Hospital Moinhos de Vento, Social Responsibility - PROADI-SUS, Porto Alegre, Brazil, [2]Brazilian Ministry of Health, Department of HIV/Aids, Tuberculosis, Viral Hepatitis, and STIs - DATHI, Brasília, Brazil, [3]Brazilian Ministry of Health, General Coordination for Surveillance of Tuberculosis, Endemic Mycoses and Nontuberculosis Mycobacteria/National Tuberculosis Program – NTP (Brazil), Brasília, Brazil
e-mail: renatotstein@gmail.com

Background: Culture remains the "gold standard" method for tuberculosis (TB) diagnosis, despite the long time for results. Diagnosis of TB in children is challenging because of nonspecific signs, paucibacillary disease, lack of expertise, and infrastructure for microbiological diagnosis. We evaluated the accuracy of Xpert MTB/RIF Ultra versus liquid culture in induced sputum.
Design/Methods: Cross-sectional study in 22 Brazilian sites. Children <15 years old were prospectively enrolled in two settings (hospitals and outpatient TB clinics) from December 2021 to March 2025.
All participants underwent induced sputum collection, and the same sample was analyzed by Xpert MTB/RIF Ultra and liquid culture (MGIT method).
Positivity of Xpert MTB/RIF Ultra was defined as detected (high, medium, low, very low, trace). Diagnostic accuracy was calculated using the epiR package.
Results: 2,262 participants were screened, and 1,792 included, with a median age of 3.2 (IQR 1.2-6.8). 1,472/1,792 (82.1%) had valid results, and 61/1,792 (3.4%) had culture contamination. 1,425/1,472 (96.8%) participants had negative TB results in both techniques, 23/1,472 (1.6%) were TB positive in MGIT and Xpert MTB/RIF Ultra (5 high, 4 medium, 8 low, 2 very low, and 4 trace detection), 16/1,472 (1.1%) had TB detection in Xpert MTB/RIF Ultra (4 very low and 12 trace) and were negative in MGIT, and 8/1,472 (0.5%) were positive in MGIT and negative in Xpert MTB/RIF Ultra.
Sensitivity was 74.2% (95% CI 55.4-88.1), and specificity was 98.9% (95% CI 98.3-99.4).
Conclusions: These partial results suggest that Xpert MTB/RIF Ultra using induced sputum samples may be a useful and faster alternative to MGIT in the diagnosis of TB in children.

OA05-143-18 Impact of the simple one step stool sample processing technique: The wellness on wheels truck experience in Ganjuwa Nutrition clinic, Bauchi state Nigeria

A. Abdullahi,[1] M. Tukur,[2] Z. Mangoro,[1] M. Bajehson,[2] T. Panda,[3] S. Mafwalal,[4] B. Odume,[5] N. Nwokoye,[6] O. Chukwuogo,[5] P. Ajiboye,[7] [1]KNCV Nigeria, Laboratory, Kano, Nigeria, [2]KNCV Nigeria, Programs, Kano, Nigeria, [3]KNCV Nigeria, Cepheid, Kano, Nigeria, [4]KNCV Nigeria, Programs, Bauchi, Nigeria, [5]KNCV Nigeria, Programs, Abuja, Nigeria, [6]KNCV Nigeria, Laboratory, Abuja, Nigeria, [7]KNCV Nigeria, Cepheid, Abuja, Nigeria
e-mail: adamuabdullahi@kncvnigeria.org

Background and challenges to implementation: In Nigeria, there are limited personnel trained in collecting appropriate respiratory specimens from those who cannot produce sputum especially children. Also, the number of facilities with TB molecular diagnostic machines is limited. KNCV Nigeria, in collaboration with the National Tuberculosis Control Program, implemented a modified simple-one-step (SOS), stool-based Xpert MTB/RIF method for diagnosis of TB in children who cannot expectorate sputum. We evaluated the impact of the mobile truck (Wellness on Wheels*)* mounted with Genexpert for childhood TB diagnosis.
Intervention or response: The wellness on wheels Mobile truck equipped with a digital x-ray coupled to an Artificial Intelligence software and Genexpert machine was deployed to MSF-supported Nutrition clinic at Ganjuwa, Ganjuwa LGA Bauchi state, Nigeria during the National Childhood TB testing week. Stool samples were collected from children presumed to have TB and analyzed using the Simple one-step stool processing method (SOS) and Xpert MTB/RIF Ultra testing.
The national childhood testing week is a weeklong activity dedicated to finding the missing TB cases particularly in children in the country. We analyzed data from this activity for the year 2024.
Results/Impact: During the week a total of 319 children were screened with 110 presumptive TB cases identified, a total of 110 stool samples were collected and processed using the Simple one-step method in May 2024 at Nutrition clinic Ganjuwa, Bauchi state with 3 (3%) Mycobacterium Tuberculosis (MTB) detected. All 3 diagnosed cases were DSTB and were enrolled on treatment.
Conclusions: The simple one step stool processing technique is an efficient and simple method that can improve yield from the Xpert based stool testing, we recommend continuous training and retraining of personnel for improved adherence to the SOP to ensure improved performance and better yield.

OA05-144-18 End-user perspectives on pediatric TB diagnostic processes in Uganda and Peru: A qualitative study

L. Pollmeier,[1] F. Held,[1] R. Calderon-Flores,[2] E. Nasinghe,[3] G. Bagenda,[4] L. Mujumbusi,[5] M. Joloba,[3] C. Zamudio,[2] A.R. Kekitiinwa,[6] R. Song,[7] N. Engel,[8] F. Basile,[9] [1]Maastricht University, Health, Medicine and Life Sciences- Global Health, Maastricht, Netherlands, [2]Universidad Peruana Cayetano Heredia, Instituto de Medicina Tropical Alexander von Humboldt, Lima, Peru, [3]Makerere University College of Health Sciences, Department of Immunology and Molecular Biology, School of Biomedical Sciences, Kampala, Uganda, [4]Makerere University, Department of Anatomy, Kampala, Uganda, [5]Medical Research Council/Uganda Virus Research Institute & London School of Hygiene and Tropical Medicine, Social Aspects of Health, Entebbe, Uganda, [6]Baylor College of Medicine Children´s Foundation, Department of Pediatrics, Kampala, Uganda, [7]University of Oxford, Department of Pediatrics, Oxford, United Kingdom of Great Britain and Northern Ireland, [8]Vrije Universiteit Amsterdam, Athena Institute, Network Institute, Amsterdam, Netherlands, [9]University of Oxford, Oxford Vaccine Group, Oxford, United Kingdom of Great Britain and Northern Ireland
e-mail: l.pollmeier@alumni.maastrichtuniversity.nl

Background: New, child-friendly sample types offer promise for decentralized and reliable pediatric TB diagnosis. However, little is known about their acceptability, feasibility, and equity implications.
This study explores the perspectives of healthcare workers, decision-makers, and caregivers regarding the sample collection processes for novel pediatric TB diagnostics in Uganda and Peru, aiming to identify barriers and facilitators to support their implementation and use at the point of care.
Design/Methods: Using qualitative methods, we conducted 51 in-depth interviews and 4 focus group discussions with caregivers of both children with TB, living with or without HIV/AIDS, healthcare workers, and decision-makers in Uganda and Peru, between May 2024 and March 2025. Thematic content analysis was used to analyze the data and identify key themes.
This study was nested within NOD-pedFEND, a diagnostic accuracy study.
Results: Participants emphasized the importance of clinical encounters, where healthcare workers ease caregivers' procedural fear through counselling. Familiarity with sample collection processes further enhanced acceptability. Although more invasive procedures like gastric aspirate and nasopharyngeal aspirate caused a higher emotional burden for both caregivers and providers compared to upper airway swabs and stool collection, they reported trusting the results more.
Invasive samples were perceived as more reliable, being collected from deeper within the body or areas where TB bacilli accumulate. Both caregivers and healthcare workers preferred same-day sample collection to avoid the challenges of home collection and the need for multiple hospital visits. Contextual and societal factors, including financial burdens, limited infrastructure, stigma, and low awareness, were identified as barriers to feasibility at primary healthcare level.
Conclusions: Findings were consistent across participant groups and countries. This study may help inform the implementation of new diagnostics by exploring acceptability, feasibility, and equity from an end-user perspective, while also pointing to the need for further research on pediatric TB barriers and facilitators in community-level settings.

OA05-145-18 Scaling impact: Enhancing childhood TB detection through monthly testing initiatives in Cross River State

A. Kewa,[1] O. Chukwuogo,[1] S. Useni,[1] C. Onwuteaka,[2] B. Odume,[1] [1]KNCV Nigeria, Technical Programs, Abuja, Nigeria, [2]KNCV Nigeria, Technical Programs, Calabar, Nigeria.
e-mail: akewa@kncvnigeria.org

Background and challenges to implementation: The National Tuberculosis and Leprosy Control Program instituted the National Childhood TB Testing Week to boost childhood TB case finding, which has proven to be an effective strategy for finding childhood TB cases in Nigeria.
However, outside of the testing week which happens every May, TB LON Cross River State has struggled and underperformed on this indicator only achieving 45% of their 2023 annual target.
Intervention or response: Given the success of Childhood TB Testing Week, the TB LON Cross-River team instituted a monthly Childhood TB testing exercise. Every third week of the month, community outreaches focus on screening children using strategies from Childhood TB Testing Week, such as increased awareness and social mobilization, targeted screening and testing in high-risk settings, and the use of innovative diagnostic tools, including stool testing. This was piloted in 6 Local Government Areas from July 2024 to November 2024.
Results/Impact: Post institution of the monthly testing exercises, 50 childhood TB cases were detected, from July to November 2024, representing 45.5% of all childhood TB cases recorded from January to November 2024. This reflects a marked improvement compared to the 38.2% recorded in the pre-intervention months (January–June 2024), which also included the National Childhood Testing Week.
Notably, 32% of all presumptive samples during this period were stool samples, and 44% of diagnosed cases were through stool testing — a significant rise from earlier months where stool testing was underutilized.

Figure.

Conclusions: Regular community outreach, modelled on successful strategies, can significantly improve childhood TB case detection, especially through innovative diagnostic approaches like stool testing.

OA05-146-18 Comparison of the National TB and Leprosy Program and World Health Organization criteria for pulmonary tuberculosis severity classification among children in Uganda

P. Wambi,[1] R. Castro,[2] B. Sweetser,[3] J. Nakafeero,[4] D. Atwine,[1] M. Sekadde,[5] A. Andama,[6,7] A. Katamba,[8,7] A. Cattamanchi,[3] E. Wobudeya,[9,4] D. Jaganath,[10]

[1]World Alliance for Lung and Intensive care Medicine in Uganda- Walimu, Pediatrics and Child Health, Kampala, Uganda, [2]University of California San Francisco, Division of pulmonary and critical care medicine, San francisco, United States of America, [3]University of California, Irvine, Division of Pulmonary Diseases and Critical Care Medicine, Irvine, Orange, United States of America, [4]World Alliance for Lung and Intensive care Medicine in Uganda- Walimu, Pediatrics and Child health, Kampala, Uganda, [5]Uganda National TB and Leprosy Control Program, Child and Adolescent Tuberculosis prevention and control, Kampala, Uganda, [6]Makerere University of College of Health sciences, Internal Medicine, Kampala, Uganda, [7]World Alliance for Lung and Intensive care Medicine in Uganda- Walimu, Research, Kampala, Uganda, [8]Makerere University of College of Health sciences, Medicine, Kampala, Uganda, [9]Mulago National Referral Hospital, Pediatrics and Child health, Kampala, Uganda, [10]University of California San Francisco, Division of Pediatric Infectious Diseases, San francisco, United States of America

e-mail: peterwambi1@gmail.com

Background: Implementation of the WHO severity criteria to shorten TB treatment for children has been challenging due to their dependence on chest X-ray (CXR). The Uganda National TB and Leprosy Program (NTLP) released broader criteria that may be able to compensate in settings with limited access to CXR.

Design/Methods: We analyzed data from children less than 15 years diagnosed with confirmed or clinical TB using NTLP guidelines from 2018-2023 in Kampala, Uganda. We applied three TB severity criteria:

1. WHO with CXR (CXR features of severe TB, hospitalized, severe acute malnutrition, or confirmed TB with high bacillary load [*i.e.,* smear-positive or Xpert-positive with medium, high or very high semi-quantitative grade and if less than 3 months old];
2. WHO without CXR, and;
3. NTLP (WHO without CXR criteria plus all children with HIV or confirmed TB).

We compared the accuracy of the NTLP and WHO without CXR criteria to the WHO with CXR criteria as a reference standard.

Results: Among 693 children included, median age was 2.6 years (IQR 1.2-5.1), 118 (17%) had confirmed TB, and 66 children (9.5%) were living with HIV. Using the WHO criteria with CXR, 29% (201) had severe TB (of whom 16.4% were living with HIV and 10.4% were paucibacillary).

Compared to the WHO with CXR criteria, the WHO criteria without CXR and NTLP criteria were 61% and 69.7% sensitive, respectively, and 98% and 81% specific, respectively (*Table 1.*)

	Sensitivity % (95% CI)[1]	Specificity % (95% CI)[1]	NPV % (95% CI)[1]	PPV % (95% CI)[1]
NTLP without CXR	69.7 (63 – 76)	81 (77- 84)	86.7 (77- 89.7)	60.1 (53.5 - 66.4)
WHO Criteria without CXR	61 (54-68)	98.4 (96 -99)	86.1 (83- 88.9)	94 (88.3- 97.2)

Acronyms and legend
CI: Confidence Interval; CXR: Chest X-ray; NPV: Negative Predictive Value; PPV: Positive Predictive Value; NTLP: National TB and Leprosy Program, Uganda.
1. In reference to the WHO criteria with chest X-ray.

Table 1: Accuracy of the NTLP criteria for severity classification in comparison to WHO criteria without CXR.

Conclusions: The NTLP criteria increased detection of children with severe TB that would have been missed by the WHO criteria without CXR, but at the cost of overtreating children with non-severe disease. Adjuvant tools are needed to guide TB severity for children in settings with limited access to chest X-rays.

OA05-147-18 Accelerating childhood TB case detection in Bangladesh: BRAC experience from effective implementation strategies

N. Kabir,[1] S. Reja,[1] S. Islam,[1] M.M.-U. Haque,[1] A. Islam,[1]
[1]BRAC, BRAC Health Program, Dhaka, Bangladesh
e-mail: nawrin.kabir1@brac.net

Background and challenges to implementation: Childhood Tuberculosis poses a substantial public health threat in a resource limited country like Bangladesh. The key challenges in child TB diagnosis include sub-optimal linkage to graduate practitioners and availability of pediatricians at peripheral facilities, lack of awareness, financial constraints faced by families. By March 2023, child TB cases detected in BRAC supported areas, represented only 3.4% of total detected TB patients, compared to the estimated incidence of 9% (Global Report 2024). Under the stewardship of National Tuberculosis Programme, BRAC executed some key strategies to mitigate the evolving gaps in child TB detection in the implementation areas.
Intervention or response: BRAC with the support of The Global Fund conducted orientations and workshops to strengthen linkage with graduate doctors, especially pediatricians emphasizing early detection, with a focus on clinical TB diagnosis among symptomatic children. Awareness campaigns were launched and we trained field staff and community health workers to help understanding the unique presentation of pediatric TB and refer to doctors for further evaluation. We enhanced providing social support (transport, diagnostic support for non-sputum sample & relevant tests) to symptomatic children of under-served families (low informal settlements, migrants, day laborers etc.) by third quarter 2023, for prompt diagnosis increasing linkage with pediatricians.
Results/Impact: Quarterly child TB case detection increased, from 1708 to 3049 and the proportion of child TB patients detected increased from 3.4% in Jan-Mar 2023 to 5.6% in Oct-Dec 2024. However, in 2024, 1921 child TB cases (presumptive positivity 19%) were detected from a total number of 10,152 child TB presumptive who were provided social support.

Year	Quarter	Total TB cases (New and Relapse)	Total no. of presumptive child TB	Total child TB cases detected	Proportion of child TB (%) among total TB cases
2023	Jan- Mar	50958	689768	1708	3.4
	Apr- Jun	51009	625234	1850	3.6
	Jul- Sep	52921	689640	2182	4.1
	Oct- Dec	52882	679109	2260	4.3
2024	Jan- Mar	53348	29889	2628	4.8
	Apr- Jun	55405	27975	2875	5.5
	Jul- Sep	56640	29917	2824	5.5
	Oct- Dec	60288	33502	3049	5.6

Table.

Conclusions: Programmatic strategies addressing the key challenges of identifying TB in children paved the way to continuous enhanced case detection in a high-burden country like Bangladesh to accelerate end- TB goals.

OA05-148-18 Safety, completion rate and rifapentine plasma concentration in Chinese children with 1HP for tuberculosis infection

W. Liu,[1] T. He,[2] S. Zhan,[1] H. Qin,[1] S. Lu,[1] W. Li,[2]
P. Zhang,[1] [1]The Third People's Hospital of Shenzhen, Department of Pulmonary Medicine and Tuberculosis, Shenzhen, China, [2]The Third People's Hospital of Shenzhen, Department of Pharmacy, Shenzhen, China
e-mail: 82880246@qq.com

Background: To assess the feasibility and safety of 1HP regimen in young Chinese children with tuberculosis infection, and to provide pediatric-specific evidence for extrapolating dosing strategies to children.
Design/Methods: An open-label, prospective, single-arm clinical trial was conducted among eligible participants (aged ≤ 14 years old). Completion rate, safety and Rifapentine concentrations of 1HP regimen were analyzed.
Results: 98.75% (79/80) of participants completed the treatment, with only one case (1.25%) in 6-14 year group of non-completion because of rash. The median duration of treatment was 28 days. 6.25% (5/80) experienced grade ≥3 adverse events (AEs), with no serious adverse events (SAEs) or deaths reported. The relationship between rifapentine concentration (mg/L) and time (days) in children stratified by age and weight demonstrated lowest rifapentine concentration in participants less than 2 years old and less than 15kg when compared to the other subgroups.

Table1. Basic characteristics of the participants.

Characteristic	Median[min，max] / (%)
Age (month)	43.0[6.0, 168.0]
Age (year)	3.6[0.5, 14.0]
Gender(male)	48(60.0%)
Weight(kg)	15.0[8.0, 73.0]
Height(cm)	102.0[68.0, 173.0]
BMI (kg/m^2)	15.0[10.4, 24.7]
BCG scars	80 (100)

Table 2. 1HP regimen completion status by sex and age group

	≤2years (n=20)		2-5years (n=40)		6-14years (n=20)		Total (n=80)
	Male (n=10)	Female (n=10)	Male (n=23)	Female (n=17)	Male (n=15)	Female (n=5)	
Treatment completed	10(100%)	10(100.0%)	23(100%)	17(100%)	15(100%)	4(80.0%)	79(98.75%)
Treatment not completed	0	0	0	0	0	1(20.0%)	1(1.25%)

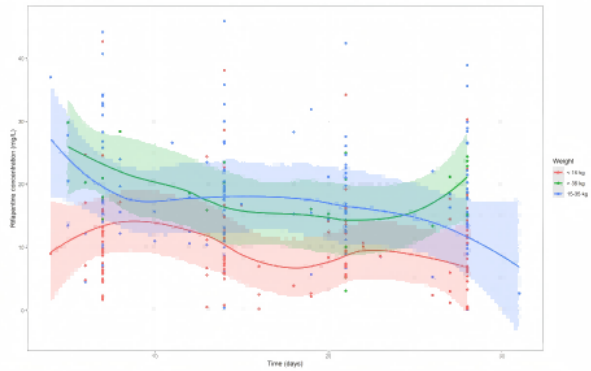

Figure 1. Rifapentine plasma concentration-time profiles across three weight-based pediatric subgroups.
The figure illustrates the relationship between rifapentine concentration (mg/L) and time (days) in children stratified by body weight: <15 kg, 15–35 kg, and >35 kg. Data points represent plasma rifapentine concentrations measured at serial time points post-administration. Pharmacokinetic parameters were calculated using non-compartmental analysis (NCA). Dashed lines indicate the median rifapentine concentration. Shaded areas represent 95% confidence intervals.

Conclusions: 1HP regimen is safe and feasible for young Chinese children with tuberculosis infection. Weight-based daily rifapentine (10-15 mg/Kg) might not be enough for young children, particularly for those younger than 2 years old and less than 15kg.

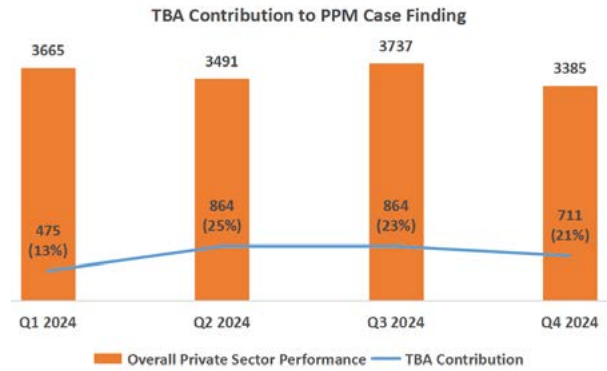
SHORT ORAL ABSTRACT SESSION (SOA)

SOA01 Maternal, child, and adolescent TB care: Prevention, diagnosis and treatment

SOA01-500-18 Integrating traditional birth attendants into TB disease finding: A culturally sensitive approach

H.U. Garba,[1] T. Aniagolu,[1] A. Ogar,[1] M. Bajehson,[2] A. Okoh,[3] M. Sheshi,[3] B. Odume,[3] M. Bathnna,[4] O. Adebayo,[4] E. Ubochioma,[5] J. Kimeu,[6] [1]KNCV Nigeria, Program, Kaduna, Nigeria, [2]KNCV Nigeria, Program, Kano, Nigeria, [3]KNCV Nigeria, Program, Abuja, Nigeria, [4]IHVN, Program, Abuja, Nigeria, [5]National Tuberculosis, Buruli Ulcer and Leprosy Control Program, Program, Abuja, Nigeria, [6]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Program, Geneva, Switzerland
e-mail: husman@kncvnigeria.org

Background and challenges to implementation: Traditional Birth Attendants (TBAs) serve as trusted healthcare providers in many communities, particularly in rural and underserved areas. Their strong rapport with women and families presents a unique opportunity to enhance tuberculosis (TB) case finding. In Kaduna State, KNCV Nigeria under the Global Fund Community - Public Private Mix (CPPM) Grant engaged and integrated TBAs into private-sector TB case detection intervention known as the Public Private Mix (PPM) to improve early diagnosis and treatment initiation. The PPM intervention leverages private healthcare providers reach and resources to enhance TB notification rates and improve access to quality care.
Intervention or response: A structured engagement model implemented from January to December 2024 involved training TBAs to recognize TB symptoms, educating them on counselling and stigma reducing strategies and sample collection to ensure linkage of presumed TB patients for diagnostic testing. The intervention leveraged on TBAs' cultural and social influence to address barriers such as stigma, misinformation, and poor TB service accessibility.
Results/Impact: The number of TB patients diagnosed via TBAs rose markedly in Q2 2024, totaling 864 TB patients (25% of private sector TB cases) compared to 475 TB patients diagnosed (13%) in Q1 2024. Contributions, however, experienced a small drop to 23% though the absolute number stayed same in Q3 2024, and 711 TB patients diagnosed (21%) in Q4 2024. Despite the fluctuation, TBAs regularly accounted for over 20% of TB cases identified in the private sector, underscoring their crucial role in case detection.



Conclusions: Integrating TBAs into TB case finding offers a culturally sensitive and community-driven approach to improving early diagnosis. Sustaining and scaling this approach requires continuous training, incentives, and collaboration with formal healthcare structures.
Strengthening referral linkages and monitoring TBAs' engagement has also been shown to further optimize their role in TB control efforts, ultimately reducing the disease burden in high-risk communities.

SOA01-501-18 Leveraging traditional birth attendants to integrate TB/HIV screening into maternal care in unconventional settings: Experience from Katsina State, Nigeria

H. Tilde,[1] H.B. Raji,[2] T. Adetiba,[2] R. Aimu,[2] O. Olupitan,[2] C. Mensah,[3] P. Dakum,[4] I. Lawrence,[5] C. Adesigbin,[6] O. Chijioke- Akaniro,[6] J. Ssekitooleko,[7] M. Zamzu,[7] [1]Institute of Human Virology Nigeria, Program Coordinating Unit (PCU), GF-NTHRIP, Kano, Nigeria, [2]Institute of Human Virology Nigeria, Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria, [3]Institute of Human Virology Nigeria, Office of the COO, Abuja, Nigeria, [4]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [5]KNCV, Programs, Katsina, Nigeria, [6]National TB and Leprosy Control Programme, Public Health, Abuja, Nigeria, [7]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Nigerian Country Team, Geneva, Switzerland
e-mail: htilde@ihvnigeria.org

Background and challenges to implementation: Despite efforts to combat tuberculosis (TB), HIV, and syphilis, challenges persist in reaching Pregnant Women (PW) in unconventional settings. In parts of Nigeria, the proportion of PW not attending antenatal care (ANC) is alarmingly high, 45% in Katsina, 35% in Kano and up to 85% in Kebbi.
To bridge this gap, the Institute of Human Virology Nigeria engaged Traditional Birth Attendants (TBAs), Mentor Mothers (MMs), and Community TB/HIV Workers (CTHWs) to screen all PW in these settings for TB, HIV, and syphilis and link them to health facilities offering ANC services.

This study evaluates the role of TBAs in optimizing screening of PW under the Global Fund Community Public-Private Mix (CPPM) project in Katsina State.

Intervention or response: A cross-sectional study was conducted from June 2024 to March 2025 to assess TB, HIV, and syphilis screening among PW not attending ANC in unconventional settings. All eligible PW encountered during Home-to-Home (H2H) active TB case search and those accessing care at Traditional Birth Homes (TBHs) were symptomatically screened for TB and tested for HIV and syphilis using dual rapid test kit. Data was collected from routine registers and analyzed. Positive results were reported as the screening outcome of each disease entity.

Results/Impact: From June 2024 to March 2025, a total of 26,138 pregnant women were screened during H2H and 8,320 at TBH. Among those tested, 15 women (0.057%) in H2H and 7(0.084%) in TBH were HIV-positive. Syphilis positivity was recorded in 11(0.042%) H2H and 3(0.036%) in TBH. For TB screening, 35(0.134%) women tested positive in H2H, while 8(0.096%) at TBH.

Conclusions: The engagement of TBAs in integrated TB/HIV/syphilis screening effectively expanded access to underserved PW in non-facility settings. This approach facilitated early detection, timely linkage to care, and highlighted TBAs' potential in community-based surveillance offering a scalable model for closing service delivery gaps in high-burden areas.

SOA01-502-18 Facility based screening for tuberculosis in pregnant and post-partum women in Papua New Guinea

P. Masta,[1] A. Vasiliu,[2] W. Ambano,[3] M. Kal,[3] G. Pukai,[4,1] F. Kupe,[5,4] K. Kiromat,[5,4] A. Sanaie,[6] T. Rahman,[6] A. Mandalakas,[7,8] H. Welch,[9,1] G. Mola,[1,10] [1]University of Papua New Guinea, Clinical Sciences, Port Moresby, Papua New Guinea, [2]Baylor College of Medicine, Pediatrics, Rouen, France, [3]The National Tuberculosis Program, Department of Health, Port Moresby, Papua New Guinea, [4]Paediatric Society of Papua New Guinea, Paediatrics, Port Moresby, Papua New Guinea, [5]National Capital District Provincial Health Authority, Paediatrics, Port Moresby, Papua New Guinea, [6]Stop TB Partnership, Innovations & Grants Team, Geneva, Switzerland, [7]Baylor College of Medicine, Pediatrics, Houston, United States of America, [8]Global Tuberculosis Fund, Pediatrics, Houston, United States of America, [9]Baylor College of Medicine, Pediatrics, Port Moresby, Papua New Guinea, [10]Port Moresby General Hospital, Obstetrics & Gynaecology, Port Moresby, Papua New Guinea
e-mail: walleyambano61k@gmail.com

Background: Papua New Guinea has both a high incidence of tuberculosis (TB) (432/100000) and a high fertility rate (4.2 children/woman). Women have an increased risk of TB during pregnancy and postpartum. The Port Moresby General Hospital (PMGH) is the only public labor & delivery center in the National Capital District, where the incidence of TB is estimated at 1,117/100,000 and oversees 15,000 deliveries yearly.

Design/Methods: From June 2023 to March 2024, active TB screening of women in the peri-partum period presenting for care at PMGH was implemented. Screening officers verbally screen women for symptoms of TB at strategic entry points including: antenatal clinic, labor and delivery ward, children's immunization clinic, and postpartum ward. Women with a positive symptom screen complete chest radiography and GeneXpert testing in the antenatal clinic. If diagnosed with TB, the women were linked to care, their baby initiated on TB preventive treatment, and the team conducted household contact investigation.

Results: During the initial nine months of project implementation, 9969 women completed screening in the antenatal clinic (4956/9969, 49.7%), labor and delivery ward (674/9969, 6.7%), and postpartum clinic (4339/9969, 43.5%). It is estimated that 37% of ante-natally booked women were screened. Among screened women, 471/9969 (47.2%) report symptoms consistent with TB, and 19.6% report having had contact with a person treated for TB in the past year, and 3% were living with HIV. The TB prevalence was estimated to be 1.8% (184/9969) and primarily consisted of pulmonary (52.7%; 97/184) and drug-susceptible TB (97.8%; 180/184); 90.4% of women initiated TB treatment.

Conclusions: Systematic screening (including radiology and GeneXpert testing) of women attending antenatal clinics, delivery wards, or postpartum clinics effectively improves TB case detection. Integration of routine TB screening with peri-partum care supports timely linkage to TB care and treatment, thereby reducing risk of poor outcomes for mothers and their families.

SOA01-503-18 Leveraging AI-powered predictive mapping to improve TB/HIV case identification among pregnant women in Nigeria

U. Atoi,[1] H. Bello Raji,[1] K. Ugwanyi,[1] E. Vincent,[1] T. Adetiba,[1] O. Olupitan,[1] A. Agbaje,[2] C. Mensah,[3] P. Dakum,[2] O. Chijioke-Akaniro,[4] A. Reilly,[5] M. Zamzu,[5] Global Fund NTHRIP Team [1]Institute of Human Virology Nigeria (IHVN), Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria, [2]Institute of Human Virology Nigeria (IHVN), Office of the CEO, Abuja, Nigeria, [3]Institute of Human Virology Nigeria (IHVN), Office of the COO, Abuja, Nigeria, [4]Institute of Human Virology Nigeria (IHVN), Public Health Department, Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Nigerian Country Team, Geneva, Switzerland
e-mail: tadetiba@ihvnigeria.org

Background and challenges to implementation: Nigeria bears a dual burden of TB and HIV, accounting for 14% of global pediatric HIV infections (~21,000 cases) in 20220, with only 44% ART coverage for PMTCT. In 2022, an estimated 479,000 TB cases occurred, however, 285,000 were notified underscoring major detection gaps, particularly among women and children.
This study evaluates the effectiveness of an AI-powered predictive mapping tool in improving TB/HIV case identification among Pregnant Women (PW).
Intervention or response: With support from the Global Fund, the Institute of Human Virology Nigeria (IHVN) deployed an AI-driven hotspot mapping tool to predict underserved communities with high concentrations of PW unlikely to access ANC or HIV testing. Integrated TB/HIV screening was incorporated into ongoing community-based TB case-finding in 7 states between Oct–Dec 2024.
The AI-tool guided community health workers to 28 priority Local Government Areas (LGA), using Google Maps for navigation and a digital-platform for reporting. Simple frequencies were calculated using MS Excel.
Results/Impact: During the AI-guided intervention (Oct–Dec 2024), 6,984 PW were identified across 28 LGAs. Of the 5,419 eligible, 99.2% were tested for HIV, yielding a positivity rate of 0.6%. This represents a 1.5-fold increase and 50% relative improvement in HIV case detection compared to the 0.4% yield during the pre-intervention phase (July–Sept 2024), which reached 33,120 women across 158 LGAs.
For TB, 1,216 presumptive-cases were identified and 909 evaluated, with 68 cases diagnosed (7.4% yield). This exceeded the pre-intervention yield of 6.9% (73 cases from 1,057 evaluated), reflecting a 1.09-fold increase and 8.7% relative improvement.
Conclusions: AI-powered predictive mapping improved TB and HIV case detection among PW despite covering 82% fewer LGAs. This targeted, data-driven approach offers a scalable solution for enhancing early diagnosis, optimizing resource use, and strengthening PMTCT and TB/HIV integration in high-burden, underserved settings. Future efforts should scale digital tools for broader public health impact.

SOA01-504-18 Preferences identified by key stakeholders for novel TB treatment regimens for pregnant and breastfeeding women in two high TB burden settings

Y. Hirsch-Moverman,[1,2] M.C. Castro,[3] C. Maramag,[4] J.P. Ferrer,[4] C. Berido,[5] J.A. Solon,[6] H.V. Madamba,[7] N. Vanqa,[8] W. Fillander,[8] G. Hoddinott,[9] A.C. Hesseling,[8] S.-A. Meehan,[8] [1]Columbia University, ICAP, New York, United States of America, [2]Columbia University, Epidemiology, New York City, United States of America, [3]Nutrition Center of the Philippines, Epidemiology and Data Analytics Unit, Muntinlupa City, Philippines, [4]Nutrition Center of the Philippines, Health and Nutrition Unit, Muntinlupa City, Philippines, [5]Nutrition Center of the Philippines, Health and Nutrition Unit, Cebu City, Philippines, [6]Nutrition Center of the Philippines, Nutrition Infection and Molecular Biology, Muntinlupa City, Philippines, [7]VSMMC Research Institute, Medical Specialist IV, Cebu City, Philippines, [8]Stellenbosch University, Desmond Tutu TB Centre, Department of Pediatrics and Child Health, Cape Town, South Africa, [9]The University of Sydney, School of Public Health, Faculty of Medicine and Health, Sydney, South Africa
e-mail: yh154@columbia.edu

Background: Pregnant women with TB have poor pregnancy and TB treatment outcomes, yet they are usually excluded from trials of novel therapeutic regimens, thereby limiting their TB treatment options. The Radiant-Moms study uses a discrete choice experiment (DCE) to examine preferences regarding novel shorter TB treatment regimens during pregnancy and postpartum among key stakeholders.
Design/Methods: As part of the DCE developmental phase, we identified an initial list of nine treatment and healthcare delivery attributes relating to TB treatment during pregnancy and postpartum: cost, wait time, treatment duration, side effects, safety, visit frequency, number of pills, taste, and risk for the baby. We conducted semi-structured in-depth interviews across two countries (South Africa and the Philippines) with 31 stakeholders (16 community influencers [CIs], 15 healthcare providers [HCPs]), to refine these attributes and understand how they may influence TB treatment decision-making and service delivery.
Results: There was agreement among CIs and HCPs on the importance of side effects, wait time, and visit frequency when designing TB treatment programs for pregnant and breastfeeding women. The additional attributes of risk for the baby, and treatment duration were high-

lighted by CIs and HCPs respectively. We added these attributes to our working list and refined language of the preliminary levels for each attribute. When asked to design the ideal TB treatment for women during pregnancy and postpartum, most participants suggested a shorter treatment (2-4 months) with fewer clinic visits. CIs in South Africa prioritized shorter waiting times, while those in the Philippines prioritized safety. We are now concluding similar qualitative work with pregnant and breastfeeding women.

Conclusions: Multiple TB treatment attributes were confirmed as likely important to pregnant and breastfeeding women's TB care preferences. There was some variability in stakeholders' anticipation of the likely most important attributes by country, though all attributes were coherent in both settings.

SOA01-505-18 Clinical mentoring to support the use of treatment decision algorithms for child TB diagnosis within a programmatic pilot in Mozambique and Zambia

E. Desselas,[1] A. Kachucka,[2] S. Manguele,[3] C. Mwiinga,[4] N. Lebrun,[5] N. Namuziya,[4] C. Mbate Mutemba,[3] B. José,[3] A. Mubanga,[2] J. Orne-Gliemann,[5] C. Chabala,[4] M. Bonnet,[1] Decide TB consortium [1]French National Research Institute for Sustainable Development (IRD), UMI 233 TransVIHMI, Montpellier, France, [2]Ministry of Health of Zambia, National TB and Leprosy Programme, Lusaka, Zambia, [3]Ministry of Health of Mozambique, National TB Control Program, Maputo, Mozambique, [4]University Teaching Hospital, School of Medicine, Department of Peadiatrics, Lusaka, Zambia, [5]University of Bordeaux, National Institute for Health and Medical Research (Inserm) UMR 1219, Research Institute for Sustainable Development (IRD) EMR 273, Bordeaux, France
e-mail: emilie.desselas@ird.fr

Background: Clinical mentoring can support introduction of clinically complex practices. We sought to implement and report on clinical mentoring for treatment decision algorithm (TDA) implementation for childhood TB at District Hospital (DH) and Primary Health Centre (PHC) level.

Design/Methods: The National TB programmes (NTPs) in Mozambique and Zambia are piloting the implementation of a comprehensive approach for improving childhood TB diagnosis and severity assessment for short course regimen within the Decide-TB project.

Following the training of healthcare providers (HCPs), onsite clinical mentoring visits were planned monthly for the first 3 months, supported by NTP facility mentoring guide. The performance of HCPs was assessed during bedside observations of TB screening, clinical examination, use of TDA, and disease severity assessment. Clinical case reviews were discussed in group meetings.

Results: As of March 2025, the first onsite clinical mentoring visit was conducted 6 to 8 weeks after the training in 28 facilities. A total of 62 HCPs (mean: 2.9 mentee per facility) were mentored. During bedside observations, most frequent areas identified for improvement included lack of systematic physical exam and recording of vital signs (26/28 facilities); and nutritional assessment (14/28 facilities). TB screening at entry points was not systematically done in 9/28 facilities, and 8/28 facilities were not assessing correctly for the TB screening questions.

Based on clinical case reviews, of 31 children assessed using the TDA, five were wrongly identified as presumptive TB and one was assessed with the wrong TDA. Immediate corrective actions focused on one-on-one bedside-teaching and orientation on TDAs in group meetings.

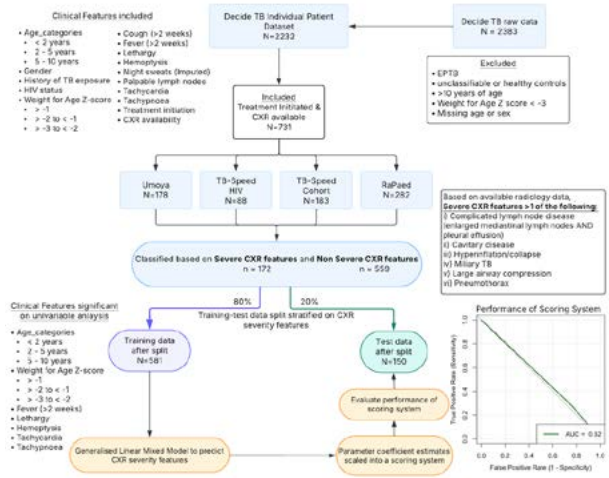
From 01/09/2024 to 03/03/2025	Mozambique District 1		Mozambique District 2		Zambia District 1		Zambia district 2	
Timing of visits since start of intervention (weeks)	W8-W13-W19		W6		W8-W13-W21		W6	
Health facility level and TDAs used	PHC (TDA B)	DH (TDA B&A)	PHC (TDA B)	DH (TDA B)	PHC (TDA B)	DH (TDA A)	PHC (TDA B)	DH (TDA B&A)
Number of facilities	5	2	5	1	6	1	6	2
Number of mentees: number, (mean for PHCs)	25 (5)	7	7 (1.4)	4	16 (2.6)	5	20 (3.3)	10
Number of cases discussed	28	3	0	0	6	2	2	4
Shortcomings in systematic screening (number of facilities)	0	1	3/5	1/1	1/6 (3 not reported)	not reported	2/6 (1 not reported)	1/2 (1 not reported)
Shortcomings in screening skills (number of facilities)	0	1	2/5 (2 not reported)	0/1	0/6 (5 not reported)	not reported	3/6 (1 not reported)	2/2
Physical exam & vital signs not assessed (number of facilities)	5/5 (vitals)	2/2 (vitals)	5/5	1/1 at OPD	6/6	1/1 OPD, and vitals for IPD	5/6	1/2 at OPD (1 not reported)
Nutritional assessment not systematically performed (number of facilities)	Not reported	Not reported	1/5	1/1 at OPD	4/6 (2 not reported)	1/1 at IPD	6/6	1/2 at OPD (1 not reported)

Conclusions: Clinical mentoring onsite visits following training are important to assess practices and propose corrective actions to reinforce capacities of HCPs to use TDAs at low level of health care. Vital signs and nutritional status assessment which are crucial for identifying TB presumptive children needed most of the support.

SOA01-506-18 Clinical predictors for radiological severe pulmonary tuberculosis in children: An individual participant data-analysis

A. Gupta,[1] L. Larsson,[1] P. Dodd,[2] M. Huyen Ton Nu Nguyet,[3] M. Palmer,[4] N. Mafirakureva,[2] M. d'Elbée,[3] J. A Seddon,[4,5] C. Chabala,[6] O. Marcy,[3] L. Olbrich,[1] M. Van de Zalm,[4]
[1]LMU University Hospital, Institute of Infectious Diseases and Tropical Medicine, München, Germany, [2]University of Sheffield, Sheffield Centre for Health and Related Research, School of Medicine & Population Health, Sheffield, United Kingdom of Great Britain and Northern Ireland, [3]University of Bordeaux, National Institute for Health and Medical Research (INSERM), Research Institute for Sustainable Development (IRD), Bordeaux, France, [4]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Cape Town, South Africa, [5]Imperial College London, Department of Infectious Disease, London, South Africa, [6]University of Zambia, Department of Paediatrics and Child Health, School of Medicine, Lusaka, Zambia
e-mail: akshita.gupta@med.uni-muenchen.de

Background: The World Health Organization has endorsed shorter treatment regimens for children with non-severe tuberculosis (TB), defined by radiological criteria, yet chest X-ray (CXR) is unavailable in many settings. We aimed to identify clinical features predictive of radiological severity of TB.
Design/Methods: We developed a large individual patient dataset (Decide-TB) from children recruited to RaPaed-TB, Umoya, and TB-Speed. Children eligible for treatment shortening and initiated on TB treatment with an expert-reviewed CXR were included. A logistic mixed-effects regression model was developed to predict CXR severity and diagnostic accuracy was evaluated on the 80-20 train/test stratified data split. Logistic regression coefficients were converted into clinically interpretable scores.
Results: 731 children were started on TB treatment and had available CXR data. The median age was 2.9 years (interquartile range: 1.3-5.6), 384 (53%) were male, and 172 (24%) children were classified with severe CXR features. Clinical features significant on univariable analysis ($p<0.157$ or <0.135 for variables with 1 or ≥2 degrees of freedom) included in the model were age, weight-for-age Z-scores, fever for >2 weeks, lethargy, haemoptysis, tachycardia, and tachypnoea.
On multivariable regression, children presenting with weight-for-age z-scores between -2 and -1 (adjusted odds ratio, aOR 1.6 95%CI 1.02-2.59), fever (aOR 0.6 95%CI 0.38-0.97), lethargy (aOR 1.6 95%CI 1.03-2.54), haemoptysis (aOR 3.0 95%CI 1.02-8.85) or tachypnoea (aOR 1.8 95%CI 1.04-3.25) were more likely to have severe features on CXR. We scaled the coefficient estimates for the parameters in the model, such that a score >10 constituted a sensitivity of ≥80% & specificity of ≥54% on the training dataset. This scoring system was evaluated on the test dataset for identifying non-severe CXR features and had a sensitivity of 72.3% (95%CI: 0.63-0.80), a specificity of 24.7% (95%CI: 0.11-0.40) (Figure1).



Conclusions: Clinical predictors alone at baseline had sub-optimal performance in determining radiological disease severity.

SOA01-507-18 Closing the gap in paediatric TB detection: Innovative approaches to improve case finding among children in Nigeria

Q. Ogbuji,[1] A. Uwajeh,[1] B. Nwaogu,[1] O. Onitiju,[1] A. Afolayan,[1] O. Olupitan,[2] A. Agbaje,[3] E. Ubochioma,[4] O. Urhioke,[5] M. Zamzu,[6] R. Aoife,[6] [1]Association for Reproductive and Family Health, TB & HIV, Abuja, Nigeria, [2]Institute of Human Virology, Nigeria (IHVN), Global Fund N-THRIP, Abuja, Nigeria, [3]Institute of Human Virology, Nigeria (IHVN), USAID TB-LON 3, Abuja, Nigeria, [4]National TB and Leprosy and Buruli Ulcer Control Programme, Global Fund Program Management Unit, Abuja, Nigeria, [5]National TB and Leprosy and Buruli Ulcer Control Programme, Child and Adolescent TB Unit FMOH, Abuja, Nigeria, [6]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Grant Management Division, Geneva, Switzerland
e-mail: nwaogu.b@arfh-ng.org

Background and challenges to implementation: According to the WHO 2024 Global TB reports, an estimated 1.3 million children worldwide developed tuberculosis (TB) and 161,000 children died of TB, making it a major cause of childhood mortality yet childhood TB remains underdiagnosed due to non-specific symptoms and challenges in sample collection. In Nigeria, 32,490 children were estimated to have TB, but access to paediatric TB screening and diagnostics remains limited, particularly in underserved communities. Innovative approaches are required to enhance childhood TB case detection, improve diagnosis, and achieve national notification targets.

Intervention or response: The Global Fund GC7 TB/HIV Integrated Project implements a multi-pronged strategy to improve childhood TB detection across six Nigerian states in 2024. Screening was enhanced at outpatient departments (OPDs), nutrition clinics, immunization sites, traditional birth attendants (TBAs), private medicine vendors (PMVs), and community pharmacies. Community-based TB outreaches targeted schools, orphanages, and slums. To improve diagnostics, the project scaled up stool-based GeneXpert testing and Chest X-rays, while Paediatric Digital X-ray (PDX) machines were introduced for better screening accuracy. The Mobile Application for Tuberculosis Screening (MATS) was deployed in private facilities to optimize detection.
Results/Impact: In 2024, 407,884 children were screened, with 53,062 identified as presumptive cases and 2,674 confirmed TB cases. Private facilities contributed 1,199 cases (45%), while community-based screening identified 1,475 cases (55%). Rivers and Nasarawa states recorded the highest confirmed cases. Childhood TB cases accounted for 6% of all TB cases diagnosed across GC7 implementation states.
Conclusions: The integration of innovative diagnostics, targeted outreach, and digital tools has improved paediatric TB detection under GC7. Progress has been made; however, achievements still fall short of the 10% national target. Expanding access to stool-based GeneXpert, strengthening community-based active case-finding, and improving sample transport networks will be critical in closing the detection gap and achieving national childhood TB notification targets.

SOA01-508-18 TB screening in the traditional initiation schools in the Leribe district of Lesotho

L. Maama,[1] L. Moipone,[2] L. Oyewusi,[1] [1]Ministry of Health, National TB and Leprosy Program (NTLP), Maseru, Lesotho, [2]Ministry of Health, Department of Disease Control, Maseru, Lesotho
e-mail: maama36@hotmail.com

Background and challenges to implementation: TB has been linked to traditional initiation schools in Lesotho; the country has a high TB incidence, and the National TB Program has set out to improve case finding and treatment, especially in congregate settings such as these schools, through community-based interventions and collaboration with the traditional initiation schools' owners.
We evaluated the impact of TB screening in 10 traditional initiation schools in Leribe district of Lesotho.
Intervention or response: Out of the 32 owners of traditional initiation schools in the Leribe district, we approached 10 of them to do TB screenings on all students enrolled in their institutions. For young Basotho men in Lesotho, traditional initiation schools, or „lebollo," are a significant cultural rite of passage. They prepare them for maturity by teaching them about their culture and responsibilities. Seasoned old men known as "basuwe run these isolated courses, which typically take place in mountains or "the bush,"" and they can range from a few weeks to six months.
A negative sequential TB screening approach was employed, and TB nurses and TB screeners used W4SS and CXR to perform the screening at entry, two months later, and at exit.
Results/Impact: Out of the 32 available traditional initiation schools in the district, 886 students were screened from 10 traditional initiation schools. Of the 886 individuals screened, 220 (25%) had presumed TB, and sputum samples were collected from all of them for laboratory investigation.
Of the 220 people investigated, 12 (5.5%) people were diagnosed with TB: 6 (50%) bacteriologically with Xpert MTB/RIF Ultra and 6 (50%) clinically.
Conclusions: Addressing the tuberculosis threat in congregate settings, particularly within traditional initiation schools, necessitates a multifaceted approach that respects cultural beliefs while prioritizing health. The inherent challenges posed by poor ventilation in these environments exacerbate the risk of TB transmission, highlighting the urgent need for targeted interventions.

SOA01-509-18 Community generated content to mitigate stigma: Telangana's youth led solution

S. Bollepogu,[1] R. A,[2] A. Singh,[3] J. Sangawar,[2] S. Chittiboyina,[4] [1]The Union, ACSM NTSU, Hyderabad, India, [2]National TB Elimination Program, Telangana, State TB Cell, Telangana, Hyderabad, India, [3]The Union, ACSM NTSU, New Delhi, India, [4]National TB Elimination Program, Telangana, State TB Cell, Telangana, Adilabad, India
e-mail: Bollepogu.Suresh@theunion.org

Background and challenges to implementation: India's greatest strength is its demographic dividend, with 27% of its population aged 15-29. This young population is key to innovation, entrepreneurship, and digital transformation. The stigma surrounding tuberculosis (TB) remains a major barrier in the fight against the disease—leading to delayed diagnosis, treatment dropouts, and poor patient care, which in turn fuels transmission and mortality. But can the youth offer a solution to this challenge?
Intervention or response: To understand stigma-related barriers, The Union, conducted focus group discussions (FGDs) in Telangana (January–April 2024) with a combination of urban and rural populations. Six groups-participants: students, married women, and workingmen,

providing insights on TB perceptions and possible solutions. Findings revealed that stigma places a heavy mental burden on TB patients and negatively impacts treatment adherence. Participants suggested that sharing success stories and doctor-led counselling through social media videos could normalize TB discussions and promote early diagnosis and treatment.

Based on these insights, a Short Film Contest was held across Telangana in collaboration with colleges and universities. Total of 45(~850 youth directly involved) short films were submitted, the jury announced the best three films from the submissions and awarded the cash prizes on the World TB Day 2024. Winning films were then screened for focus groups to assess their impact.

Results/Impact: 90% of participants showed improved TB knowledge after watching the films.

85% believed the content was engaging and impactful.

80% of those who once stigmatized TB patients said they now support them.

Telangana is utilizing these films in the outreach as the above results directly contribute to the TB elimination efforts.

Conclusions: Engaging youth as partners empowered them to create authentic, relatable content using storytelling. This approach proved effective in reducing stigma, fostering empathy, and promoting early diagnosis and treatment adherence—highlighting the potential of creative, youth-driven advocacy in public health programs.

SOA01-510-18 Differences in social networks of children and youth with and without incident TB infection in rural Uganda

E. Kakande,[1] B. Ssekyanzi,[1] R. Abbott,[2] W. Ariho,[3] J. Temple,[2] G. Lavoy,[3] G. Nattabi,[4] G. Chamie,[2] E. Charlebois,[2] M. Kamya,[5] L. Balzer,[6] C. Marquez,[2]
[1]Infectious Diseases Research Collaboration, Clinical Services, Kampala, Uganda, [2]University of California San Francisco, Division of HIV/AIDS, San Francisco, United States of America, [3]Infectious Diseases Research Collaboration, Data, Kampala, Uganda, [4]Infectious Diseases Research Collaboration, Laboratory, Kampala, Uganda, [5]Makerere University College of Health Sciences, Medicine, Kampala, Uganda, [6]University of California Berkeley, Division of Epidemiology and Biostatistics, Berkeley, United States of America
e-mail: rkakande@idrc-uganda.org

Background: Social network analysis can elucidate TB transmission dynamics by identifying person-to-person links and shared behaviors that increase TB risk. There are few studies examining social networks among children and youth.

Design/Methods: In the SONET study in 25 rural communities in Southwestern Uganda, we conducted QuantiFERON-Plus (QFT) testing on children/youth (aged 1-23 years) at baseline and one-year later. Among cases (QFT conversion from negative-to-positive) and age/location-matched controls (remained QFT negative), we administered surveys to elucidate social contacts.

We visualized the resulting egocentric networks, calculated egocentric network metrics (size, closeness, betweenness) and characteristics of people in their social networks (age, sex, TB infection) using t-tests and chi-square tests.

Results: Among the 3,290 SONET baseline-negative participants completing a follow-up QFT, 66 (2%) had incident TB. Among cases and eligible matched controls 60/66 (91%) and 579/601 (96%) completed the social-network survey in this nested study.

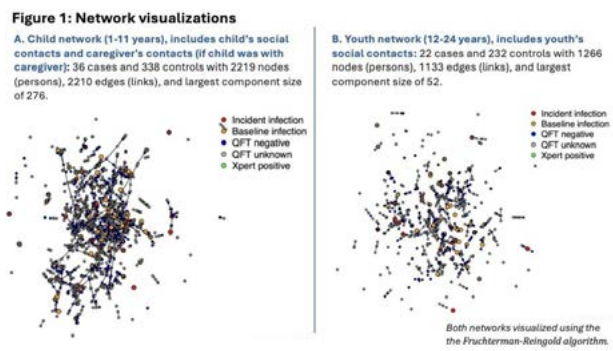


Figure 1 shows network for children (age 1-11 years) and youth (aged 12-23 years). Child cases (N=36) had similar network structures compared to controls (N=340) but were twice as likely to have a close contact with TB (31%

vs. 15%, p=0.03) and three-times as likely to have highly mobile contacts (28% vs. 9%, p<0.01). Youth cases (N=24) had significantly more contacts/network size (median 6 vs. 4; p=0.04) than controls (N=232) but similar network structure metrics otherwise. Youth cases also tended to have more close contacts with TB (17% vs. 7%, p=0.11) and highly mobile contacts (33% vs. 19%, p=0.09).
Conclusions: Children and youth with incident TB infection had significantly different social mixing patterns compared to controls, including more social contacts among youth, more highly mobile contacts and contacts with TB infection among children. Leveraging social-networks to enhance case-finding and identify children at higher risk for TB could be promising strategies warranting further study.

SOA02 Eyes on the Unseen: Leveraging data, tech, and community in finding the missing people with TB

SOA02-511-18 Reaching the undiagnosed: The contribution of active TB case finding campaign in Zambia

M... Mwanabeti,[1] A. Kachuka,[1] C. Kasapo,[1] L. Namonje,[1] M. Lupiya,[2] R. Chimzizi,[1] K. Mushota,[1] C. Chitalu,[1] E. Sinkamba,[3] C. Chabala,[4] A. Mubanga,[1] [1]Ministry of Health Zambia, National TB and Leprosy Program, Lusaka, Zambia, [2]Ministry of Health Zambia, Provincial Health Office-Lusaka, Lusaka, Zambia, [3]Global Fund Zambia, National TB and Leprosy Program, Lusaka, Zambia, [4]University Teaching Hospital, University of Zambia, School of Medicine, Department of Peadiatrics, Lusaka, Zambia
e-mail: mwanabetimary@gmail.com

Background and challenges to implementation: Active Case Finding (ACF) is a proactive approach that seeks to identify individuals with tuberculosis (TB) who may otherwise go undiagnosed. Despite achieving over 90% TB treatment coverage in Zambia in 2022 and 2023 , approximately 4,000 TB cases were missed in 2023. In early 2024, TB notifications declined.The National TB Programme, in collaboration with its partners, implemented two rounds of ACF campaigns in 2024 to strengthen TB case detection and maintain progress toward End TB Strategy targets.
Up until 2021, our treatment coverage was below 90%
Intervention or response: The first Active Case Finding campaign (June–August 2024) involved nationwide community and facility-level screening in high-burden hotspots through contact investigation, mobile diagnostic units (MDUs), and intensified screening. Simultaneously, health facilities were instructed to conduct routine TB screening at all service points. The second campaign, termed "Active Case Finding Reloaded" (September–December 2024), took a more targeted approach, focusing on health facilities that historically contributed 80% of national TB notifications. Facilities developed tailored microplans, supported by enhanced stakeholder engagement, virtual orientations, and training on data collection using Kobo Collect.
Results/Impact: The first Active Case Finding campaign contributed 13,367(28%) of Zambia's total notifications in 2024. The second campaign, implemented between September and December, accounted for 9,200 (60%) of the 15,334 notifications during that period of the annual total. Combined, both campaigns contributed 22,567 TB notifications, representing approximately 47.5% of the 47,186 total national TB notifications in 2024.
Conclusions: The dual Active Case Finding campaigns significantly improved TB detection by combining wide-reaching community outreach with targeted, data-driven

facility-based strategies. To sustain these gains, Active Case Finding should be integrated with broader public health efforts, and sustained funding is critical to achieve TB elimination goals. These results underscore the critical role of intensified Active Case Finding in improving TB detection.

SOA02-512-18 Reaching the unreached: India's 100-Day Drive to find every missing TB case

S. Malviya,[1] R. Rao,[1] U. Singh,[1] D. Panchal,[2] M. Deka,[2]
[1]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India
e-mail: dekam@rntcp.org

Background and challenges to implementation: India has significantly reduced its burden of missing tuberculosis (TB) cases—from an estimated 1.5 million in 2015 to 150,000 in 2024. As the country moves closer to its TB elimination target, the National Tuberculosis Elimination Program (NTEP) identified the need to intensify efforts to detect undiagnosed cases, particularly among vulnerable and asymptomatic individuals.
While active case finding has been a routine component since 2017, the scale and intensity required to reach the unreached necessitated a newer and more aggressive approach.
Intervention or response: NTEP launched a 100-day intensified campaign from December 2024 to March 2025 across 347 priority districts, selected based on high TB mortality, low testing rates, and estimated disease prevalence. The campaign augmented routine case finding through systematic community screening of vulnerable populations using a 10-symptom checklist and chest X-rays, followed by molecular testing for diagnosis. Concurrently, the campaign targeted the saturation of nutrition support through the Ni-kshay Poshan Yojana (direct benefit transfers) and the Ni-kshay Mitra program (community-led food support initiative). Active participation of community, public and private stakeholders was secured in the campaign.
Results/Impact: The campaign covered a population of 619 million, screening 93,238,574 individuals. Of these, 1,704,321 underwent NAAT, resulting in the detection of 140,262 TB cases among vulnerable populations. In total, 312,962 TB cases were notified across sectors during the campaign. Notably, 42% (132,200) of the TB cases detected were asymptomatic. Chest X-ray usage increased 33-fold compared to the same period in the previous year, while molecular testing rose 2.3-fold. The number needed to screen (NNS) was 665.
Conclusions: The campaign demonstrated that intensive community outreach, strategic use of radiological and molecular diagnostics, and multisectoral engagement can significantly enhance TB case detection. These learnings provide a replicable model for high-burden settings seeking to close remaining detection gaps in the path to TB elimination.

SOA02-513-18 Reaching the unreached: Leveraging community volunteers and color cards to enhance TB case finding and adherence in Ethiopia's pastoralist areas

Z. Trife,[1] G. Dessalegn,[2] H. Terefe,[2] D. Gelmecha,[3] B. Amer,[4]
[1]REACH Ethiopia, Monitoring, Evaluation and Research, Addis Ababa, Ethiopia, [2]REACH Ethiopia, Program management, Addis Ababa, Ethiopia, [3]REACH Ethiopia, M&E, Addis Ababa, Ethiopia, [4]REACH Ethiopia, Program management, Awash 7, Ethiopia
e-mail: zemedu2003@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge, with one-third of cases in Ethiopia undiagnosed or unreported annually. This issue is severe in pastoralist communities due to mobility, limited healthcare access, and low health-seeking behavior. Addressing these gaps requires culturally acceptable, community-driven interventions.
This study evaluates the effectiveness of engaging community volunteers in identifying missed TB cases, improving treatment adherence, and enhancing community participation in Ethiopia's pastoralist settings.
Intervention or response: A pilot intervention engaged 50 trusted community volunteers, including TB survivors, religious and clan leaders, women's association members, and community elders. Volunteers received three days of training on TB awareness, case identification, patient referral, and treatment adherence.
A specialized Color Card referral system, treatment monitoring tools, and IEC/BCC materials were introduced. Volunteers incorporated TB activities into social interactions, ensuring minimal disruption to their livelihoods. Dedicated personnel provided ongoing support and monitored the intervention's impact.
Results/Impact: Over nine months, volunteers screened 12,464 community members, identifying 1,103 presumptive TB cases, with 94.7% (1,104) tested using molecular diagnostics. Volunteers contributed 12% (69/575) of total TB case notifications, with a notification rate of 553/10^5 population—four times the regional target (139/10^5). This intervention contribute by 8% to increased annual case detection from 60% to 70%.
Additionally, 75 (13%) of notified cases received home-based adherence support. Seven drug-resistant TB (DR-TB) cases were detected, whereas none had been reported in the past two years. Qualitative findings highlighted in-

creased community awareness and engagement. One volunteer stated, *"Before this initiative, I didn't realize TB was so prevalent in our community."*

Conclusions: This community-led approach successfully identified missed TB cases, reduced costs, and improved treatment outcomes. Strengthening community engagement in TB programs, especially in pastoralist settings, is crucial for achieving End TB goals. Scaling up similar interventions can accelerate progress toward TB elimination in Ethiopia and beyond.

SOA02-514-18 Community involvement in active TB case finding in Indonesia: Two heads are better than one

B. Nababan,[1] T.T. Pakasi,[2] H. Diatmo,[3] G.B.L. Adhi,[2] S. Nadhila,[2] D.A. Subakti,[1] T. Hendrotomo,[4] Q.N. Salamah,[1] H. Paramaiswari,[1] R. Hidayat,[1] P. Hidayat,[1] P. Rahmadian,[1] [1]Consortium Penabulu-STPI, Principal Recipient of the Global Fund TB Community, Jakarta, Indonesia, [2]Ministry of Health Indonesia, Directorate of Communicable Disease, Directorate General of Disease Control, Jakarta, Indonesia, [3]Stop TB Partnership Indonesia, Tuberculosis, Jakarta, Indonesia, [4]Consortium Penabulu-STPI, Directorate of Communicable Disease, Directorate General of Disease Control, Jakarta, Indonesia
e-mail: betty.nababan@penabulu-stpi.id

Background and challenges to implementation: Community involvement in accelerating TB elimination by 2030 is one of Indonesia's national strategies for tuberculosis. The Penabulu-STPI Consortium, as the principal recipient of GF TB Community Cycle 7, describes our experience in engaging communities to actively find TB cases.

Intervention or response: This activity was carried out from January to December 2024 across 190 districts in 30 provinces in Indonesia. The implementation stages included national, provincial, and district coordination meetings involving TB programmers and stakeholders dan setting up the targets. In the role division, the community prepares cadres, while TB programmers handle TB services.

Cadre preparation involves updating modules, mapping and recruiting cadres, and providing training. The target for TB case finding includes contact persons of TB index cases through contact investigations, and individuals at risk through community outreach.

Cadres screen for TB symptoms and risk factors, refer individuals to health facilities and assist with sputum collection if necessary. Monitoring is carried out biweekly, with supervision in low-performance areas. Recording and reporting are conducted via a community information system, with results validated against the national TB information system.

Results/Impact: Of the 14,195 cadres trained, 10,222 (72%) conducted screenings across 190 districts in 30 provinces. Of the 5,162,167 contact persons/individuals at risk screened, 2,270,726 (44%) were referred to HFs, 1,628,852 (78%) were tested for TB, and 174,554 (11%) were diagnosed with TB, yielding a 3.4% TB rate.

Suboptimal referrals pose challenges due to high stigma, difficult geography, and issues with cadres' activity and coordination with HFs regarding feedback on referral results. The community contributed 29% (174,554/608,564) of the total TB cases reported in the national TB information system.

Conclusions: Community engagement is crucial in actively screening TB cases. However, effective coordination, strategic planning, and consistent monitoring are essential to ensure the optimal implementation of activities.

SOA02-515-18 Strengthening active case finding for tuberculosis advocacy in Chinese media: A practice-driven case study of communication interventions

Y. Zhang,[1] J. Shi,[2] H. Zhao,[1] Y. Xie,[1] Y. Geng,[1] X. Wang,[1] W. Zhao,[1] [1]Peking University, Center for Social Media Research, Beijing, China, [2]China International Communications Group, Academy of Contemporary China and World Studies, Beijing, China
e-mail: xiuli.wang@pku.edu.cn

Background and challenges to implementation: Recent report suggest that 50–70% of tuberculosis (TB) transmission occurs before a definitive diagnosis is made. In China, the median delay in seeking healthcare is 29 days, and many asymptomatic cases remain undetected. Although active case finding (ACF) is key to The End TB Strategy, mainstream Chinese media have paid scant attention.

This study aims to enhance the quality of media coverage on ACF in China, raising public awareness and supporting the goal of "end the global TB epidemic" by 2035.

Intervention or response: Initial exploratory interviews with 12 journalists from 11 media organizations were conducted to understand their views regarding ACF and to identify areas of confusion and reporting challenges. Based on these insights, 37 key media outlets (state-owned and commercial outlets) were selected for targeted interventions to ensure broad coverage and strategic influence. Tailored interventions were then implemented according to journalist profiles: for most journalists, seminars were held on key dates; senior reporters joined field media trips; early-career journalists participated in industry conferences; and all received ongoing support through updated media kits and access to CDC experts. Finally, the effectiveness of these interventions was assessed via media monitoring, in-depth interviews, and following-up surveys.

Results/Impact: Overall, 47 journalists published a total of 77 reports on ACF. Based on a follow-up survey of participating journalists (N=43), all respondents reported improved understanding of and willingness to report on ACF; 90.1% observed increases in the quantity and quality of reporting on ACF, and 79.1% of respondents believed that the engagement contributed to creating a more favorable environment for addressing the critical aspects of ACF. Further implications from in-depth interviews (N=12) were also revealed.
Conclusions: Overall, this media engagement effectively stimulated mainstream discourse on ACF and contributed to a supportive environment for TB elimination, underscoring the importance of accurate messaging, strategic timing, and strong government support.

SOA02-516-18 Systematic community TB screening using digital X-ray and live data monitoring to improve TB case findings in rural Lesotho

A.T. Andom,[1] R. Mahloane,[2] C. Mohloki,[1] J. Mokhohlane,[1] M. Ndayizigiye,[1] [1]Partners In Health Lesotho, Clinical, Maseru, Lesotho, [2]Partners In Health Lesotho, Strategic Information, Maseru, Lesotho
e-mail: mokurebi@gmail.com

Background and challenges to implementation: The 2019 Lesotho tuberculosis (TB) prevalence survey showed that symptomatic TB screening missed 70% of TB cases, while digital X-ray showed a sensitivity of 98% compared to culture. An innovative screening algorithm is needed to close the 58% of missing TB cases in Lesotho. This study aims to assess the outcome of TB screening using digital X-ray and risk factor screening at remote, hard-to-reach health centers.
Intervention or response: TB screening is based on symptoms, and there are no dedicated TB screeners at the health facilities in Lesotho. As a result, many TB cases were missed due to a less sensitive screening algorithm.
Results/Impact: In 2022, Partners In Health (PIH) implemented a revised TB screening algorithm. It also incorporated a digital x-ray with a computer-aided detection system (CAD), symptomatic and risk factor screening, and Geographic Information System (GIS) to identify community TB hotspots in seven hard-to-reach rural health facilities. PIH hired trained health workers in each health facility including a radiologist to provide timely feedback on the x-ray images. PIH introduced a live data-monitoring tool using an app called the TB Hunter system for timely monitoring of TB performance.
The intervention was assessed using descriptive analysis from June to July 2021 pre-intervention and June to July 2024 during intervention. Despite the decrease in screenings by 15% in 2024, TB case findings increased by 3.3 times during the intervention period. This is 93% of the annual performance target in 2024, while only 28% in 2021, based on the estimated national TB incidence of 664/100000 population and 89000 population in the catchment area of the health centers.
Conclusions: Implementing a sensitive TB screening algorithm with live data performance monitoring in remote, hard-to-reach health facilities was highly effective in improving TB detection. Investing in staff, systems (CAD, GIS), and stuff (digital x-rays, diagnostics) can improve TB detection.

SOA02-517-18 Leveraging a mass religious gathering for intensified tuberculosis case finding: Insights from the Maha Kumbh Mela, Prayagraj, India

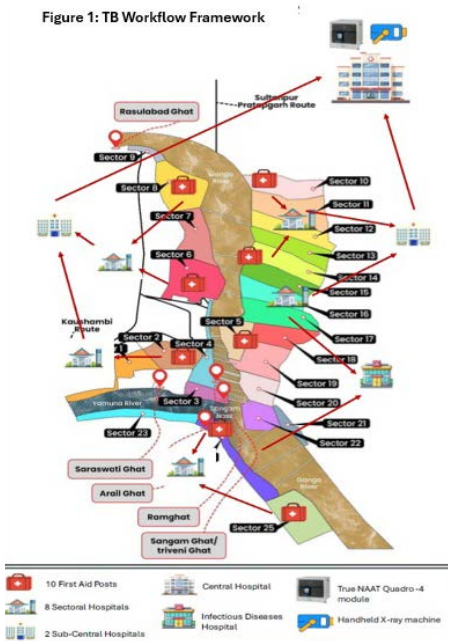
S. Bhatnagar,[1] R. Saxena,[1] V. Kumar VG,[2] S. Srivastava,[2] U. Mohan,[2] A. Rajeev,[2] K. Vijay,[2] S. Shukla,[2] S. Chandra,[2] U. Singh,[3] A. Bhardwaj,[4] A. Pandey,[5] [1]State Tuberculosis Cell, Uttar Pradesh, State Medical & Health Department, Lucknow, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [3]Central TB Division, Ministry of Health & Family Welfare, Govt. of India, New Delhi, India, [4]National Task Force, National TB Elimination Program, New Delhi, India, [5]State Medical & Health Services, State Medical & Health Department, Prayagraj, India
e-mail: kumarv@rntcp.org

Background and challenges to implementation: Maha Kumbh Mela(MKM), Prayagraj, Uttar Pradesh(UP), is world's largest gathering of religious pilgrims. It attracts diverse array of ascetics, saints, and pilgrims from various backgrounds every 12 years, spanning for 45 days. MKM provided a critical public health opportunity to enhance tuberculosis(TB) case detection among a mobile population. With support from UP government, large-scale targeted TB interventions were implemented in this unique congregate setting. By focusing on proactive planning, coordination, and use of digital tools, the study seeks to assess, potential impact of these initiatives on TB elimination efforts.
Intervention or response: Systematic planning established decentralized health services in MKM area (Figure-1), featuring health service delivery points at one central hospital, two sub-central hospitals, eight sectoral hospitals, and ten first aid posts in the MKM, which was visited by 10 million pilgrims daily. TB services were integrated at all delivery points and NAAT and portable X-ray units were made available for real time diagnosis.
Sample collection system was established comprising NTEP volunteers. Intensified TB Diagnostic and treatment algorithm under National TB Elimination Program were followed. Community engagement was bolstered

through 24×7 loudspeaker-announcements, visual-materials, and religious leaders' involvement. Data from Nikshay was analyzed to evaluate intervention's impact on TB care cascade from January 12 to February 26, 2025, using R version 4.2.3.

Results/Impact: 52,711 individuals were screened for TB (Figure-2). Of these, 1023 willing asymptomatic individuals were subjected to XRays, of whom 750 individuals found to have abnormal Xray were subjected to NAAT-testing with 726 symptomatic individuals identified during screening.

Overall, 1,476 NAAT evaluations were done, resulting in prompt management of TB presumptives. 1,650 individuals were successfully enrolled in the national Ni-kshay system for continued care and follow-up.



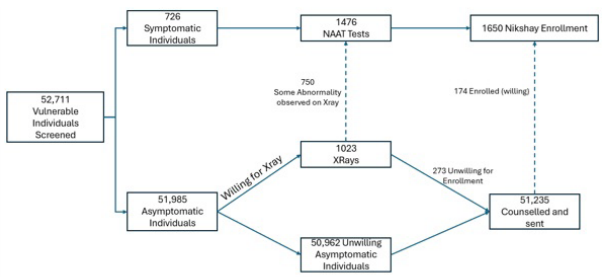


Figure 2: Flow of Beneficiaries during Kumbh Mela

Conclusions: MKM campaign showcased effectiveness of using large gatherings for disease surveillance and public health actions, emphasizing proactive planning, interdepartmental coordination, and digital integration for scalable TB interventions globally.

SOA02-518-18 Hidden no more: Community-led tuberculosis detection among street families in Kenya

S. Kitui,[1] A. Wanyonyi,[2] B. Ulo,[2] [1]Amref Health Africa in Kenya, Monitoring and Evaluation, Nairobi, Kenya, [2]Amref Health Africa in Kenya, Programmes, Nairobi, Kenya
e-mail: sharon.kitui@amref.org

Background and challenges to implementation: Despite progress in TB control, street families globally remain at high risk of infection due to poor living conditions, malnutrition, and limited access to healthcare. Kenya, categorized as one of 30 high TB burden countries, factors such as stigma, mobility, and financial constraints delay diagnosis and perpetuate transmission among this vulnerable group. The 2019 census recorded 20,101 street-dwelling individuals in Kenya, with urban areas, characterized by high population density and frequent interaction, experiencing a higher transmission rate than rural areas.

In response, Amref with support from Global Fund and in collaboration with its Sub recipients and National TB Programme, initiated a series of community-led TB outreach activities tailored to the unique needs of this population.

Intervention or response: From 2023 to 2024, five TB outreaches were conducted in Kisumu, Nakuru, Kitui, and Chuka—urban areas hosting around 10% of Kenya's street families. Community Health Promoters (CHPs), trusted by these communities, mapped hotspots and mobilized participants. Services were delivered on-site, including TB education, symptom screening using standard tools, chest X-rays, and where indicated, sputum collection and GeneXpert testing. Mobile data tools enabled real-time reporting. CHPs also supported contact tracing and follow-up to ensure treatment adherence and continuity of care.

Results/Impact: Symptomatic screening was conducted to a total of 1,326 individuals, 986 (74%) had TB symptoms. Chest X-rays were performed on 909 individuals, with 319 showing abnormalities warranting sputum tests. 46 people were diagnosed with TB (3.5% yield), higher than average outreach yields (1–2%). All were promptly initiated on treatment. CHPs provided consistent follow-up, supporting adherence and continuity of care.

Conclusions: A community-led, mobile model proved effective in improving TB detection and treatment among street families. This inclusive approach can be adapted to other vulnerable populations to close equity gaps in TB response.

SOA02-519-18 Active TB screening and case finding among individuals undergoing Methadone treatment at Ngara Methadone Clinic in Nairobi County, Kenya

E. Mueni,[1] L. Langat,[1] C. Ngunu,[1] R. Wangusi,[2] C. Macharia,[3] M. Kamau,[3] G. Kwamboka,[3] [1]County Government of Nairobi, Health, Nairobi, Kenya, [2]CIHEB, Health, Nairobi, Kenya, [3]Center for Health Solutions, Health, Nairobi, Kenya
e-mail: mlitswa03@gmail.com

Background and challenges to implementation: People who use drugs show a higher incidence and prevalence of tuberculosis than people who do not use drugs. For people who use drugs, exposure to *M tuberculosis* is amplified in environments such as places where drugs are used, dormitories and homeless shelters, police holding facilities, prisons, health-care centers such as methadone or HIV clinics, and rehabilitation centers, referred to as "institutional tuberculosis amplifiers".
In 2024, Nairobi recorded 140 tuberculosis (TB) cases among this population, with 7 cases (5%) involving clients enrolled in the methadone program. To address the notable prevalence of TB within this group, the County, had an active TB screening initiative specifically targeting clients at Ngara Health Center, one of Nairobi's largest methadone clinics.
Intervention or response: In March 2025, the County conducted a two-day tuberculosis screening initiative at Ngara Methadone Clinic. All clients attending the clinic for their daily methadone dose were sensitized about Tuberculosis screening. Those who consented underwent an initial digital chest X-ray. Those with abnormal chest X-ray findings were further assessed by clinicians and referred for Gene Xpert test.
Results/Impact: A total of 529 methadone clients received tuberculosis (TB) messages and counseling, comprising 452 (85%) males and 77 (15%) females. About 125 (24%) clients were screened for TB using digital X-ray, of which 113 (90%) were males. Of those screened, 109 (87%) clients (102 males and 7 females) had normal X-rays, while 16 (9%) clients (14 males and 2 females) had abnormal findings (score >60) and were subjected to gene xpert test. In total, 8 TB cases were diagnosed (5 bacteriologically and 3 clinically diagnosed), all of which were male.
Conclusions: Prioritizing individuals on methadone programs as a key and vulnerable group for TB is essential. This includes the development of an inclusive strategy and implementation of community-based interventions tailored to the needs of people who use drugs.

SOA02-520-18 Sensitivity and specificity of symptom-based screening among household contacts of tuberculosis patients in high TB burden countries

J. Nagudi,[1] Y. Hamada,[2] T. Ntshiqa,[1] G. Kubeka,[1] E. Nyanda Ntinginya,[3] J. Lalashowi,[3] M. Matete,[4] T. Mokitimi,[4] A. Copas,[2] M. Rangaka,[2] K. Velen,[1] S. Charalambous,[1]
[1]The Aurum Institute, Implementation Research Division, Johannesburg, South Africa, [2]Institute for Global Health, University College London, Global Health, London, United Kingdom of Great Britain and Northern Ireland, [3]National Institute for Medical Research, Tanzania, Medical Research, Daresalaam, United Republic of Tanzania, [4]Jhpiego, Monitoring, Evaluation and Research Division, Maseru, Monitoring, Evaluation and Research Division, Maseru, Lesotho
e-mail: jnagudi@auruminstitute.org

Background: Systematic screening for tuberculosis (TB) is essential in household contacts (HHCs) of persons with TB for case finding and ruling out active TB prior to TB preventive treatment. While symptom screening remains one of the WHO recommended screening tools, data on its accuracy in HHCs are limited. We evaluated the accuracy of symptom screening among HHCs in two high TB burden countries.
Design/Methods: The analysis included HHCs of index persons with microbiologically confirmed TB in South Africa and Lesotho, enrolled in the CUT-TB trial. The analysis was restricted to participants in the universal testing arm that provided sputum samples for GeneXpert ultra (reference standard) testing regardless of symptoms. Cough and other TB-related symptoms were assessed based on age group (Table).
We excluded contacts less than five years since they were required to provide sputum only if symptomatic.

	Screening tools	True Positive	False Positive	True Negative	False Negative	Sensitivity % (95% CI)	Specificity % (95% CI)
Overall (n= 1495)	Cough	5	112	1363	15	25,0 (8,7 - 49,1)	92,4 (90,9 - 93,7)
	*Any symptom	5	161	1314	15	25,0 (8,7 - 49,1)	89,1 (87,4 - 90,6)
<15 years (n= 425)	Cough	1	28	394	2	33,3 (0,8 - 90,6)	93,4 (90,6 - 95,5)
	Any symptom	1	63	359	2	33,3 (0,8 - 90,6)	85,1 (81,3 - 88,3)
≥ 15 years (n= 1070)	Cough	4	84	969	13	23,5 (6,8 - 49,9)	92,0 (90,2 - 93,6)
	Any symptom	4	98	955	13	23,5 (6,8 - 49,9)	90,7 (88,8 - 92,4)

*1329 contacts reported no symptoms, 140 contacts reported 1 symptom, 19 contacts reported 2 symptoms, 6 contacts reported 3 symptoms and 1 reported 4 symptoms. Any symptom refers to presence of any cough, fever, loss of appetite, wheezing, neck swelling or fatigue in contacts ≤ 15 years in Lesotho and ≤ 10 years and presence of any cough, fever, weight loss or night sweats for contacts >15 years in Lesotho and >10 years in South Africa

Table. Sensitivity and specificity of symptom-based screening among contacts of microbiologically confirmed TB patients.

Results: A total of 1495 contacts were included; 805 (53.8%) in South Africa and 690 (46.2%) in Lesotho. Contacts median age was 25 years (Interquartile range [IQR] 13-46 years) and majority were female (908 (60.7%)). TB was diagnosed in 20 (1.3%) contacts.
Any cough had a sensitivity of 25.0% (95% confidence interval [CI] 8.7-49.1%) and a specificity of 92.4% (95%CI 90.9-93.7%), while the presence of at least one symptom had a sensitivity of 25.0% (95%CI 8.7-49.1%) and a specificity of 89.1% (95%CI 87.4.2-90.6%). When stratified by age group, the results were similar (Table).
Reporting at least one symptom among contacts <15 years had a sensitivity of 23.3% (95% CI 6.8-49.9%) and a specificity of 90.7% (95%CI 88.8-92.4%) while contacts ≥15 years had a sensitivity of 23.5% (95% CI 6.8-49.9%) and a specificity of 92.0% (95%CI 90.2-93.6%).
Conclusions: When using a GeneXpert Ultra reference, symptom screening had low sensitivity among household contacts, substantially lower than estimates from the systematic review that informed current WHO guidelines.

SOA02-521-18 Impact of using the 10-symptom complex for tuberculosis (TB) screening on program indicators during the 100-day Intensified TB Case Finding campaign in Chandigarh, India

S. Singh,[1] R. Kumar,[1] U. Singh,[2] S. Chandra,[3] D. Agarwal,[4] P. Kapoor,[3] P. Kaur Samra,[3] C. Singla,[1] S. Agarwal,[5] M. Mohd.,[6] A. Bhardwaj,[7] [1]Government of Chandigarh, Dept of Health and Family Welfare, UT Chandigarh, Chandigarh, India, [2]Government of India, Ministry of Health and Family Welfare, New Delhi, India, [3]Government of India- WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [4]Government Medical College and Hospital, Sector 32, Department of Pulmonology, Chandigarh, India, [5]PGIMER, Treatment Support Centre, Chandigarh, India, [6]Government of Chandigarh, State TB Cell, Chandigarh, India, [7]National Task Force, Medical Colleges Task force, Chandigarh, India
e-mail: dhs_ut@yahoo.co.in

Background and challenges to implementation: The Union Territory (UT) of Chandigarh implemented the Government of India's 100-day intensified TB case-finding campaign, which aimed at active case-finding and community engagement, providing an opportunity to strengthen the National TB Elimination Program (NTEP) indicators within Chandigarh. During the campaign, the 4-Symptom screening tool (cough, fever, weight loss, and night sweats) was expanded to 10S (cough, fever, night sweats, haemoptysis, chest pain, shortness of breath, weight loss, loss of appetite, fatigue and swelling in the neck and other extrapulmonary symptoms).
The study aims to understand the effectiveness of this expanded 10-symptom screening tool on TB care cascade, among the vulnerable population.
Intervention or response: Chandigarh's National Tuberculosis Elimination Program (NTEP) implemented the 10-symptom screening tool under the 100-day intensified TB case finding campaign targeted to the vulnerable population. All medical officers, staff, and community volunteers were trained to identify ten TB symptoms. Three mobile vans equipped with AI-powered handheld X-rays conducted 178 camps over 100 days, ensuring comprehensive screening. Data from Ni-kshay, India's TB digital surveillance system, was analysed, comparing December 2023- March 2024 with December 2024- March 2025, to evaluate the effectiveness of the campaign on program performance.
Results/Impact: The expanded screening tool delivered significant outcomes in Chandigarh (*Table 1.*)

	Dec. 23 to March 24	Dec. 24 to March 25	% change
Presumptive cases identified and enrolled on Nikshay	9633	44570	+371%
Diagnostic tests conducted - X-rays	9467	21750	+130%
Diagnostic tests conducted – NAAT	5231	12195	+133%
Total case notification	2098	2321	+11%

Table 1: Key NTEP Indicators in Chandigarh.

The use of an expanded 10-S symptom complex has shown a significant increase in the identification of presumptive cases, NAAT, and X-ray utilization, thereby an overall 11% increase in case notification during that period ($p<0.05$).
Conclusions: The study indicates that broadening the symptom complex for TB screening can significantly enhance TB case identification and testing for TB in the high-risk vulnerable groups. By doing so, healthcare providers could enhance the accuracy of identifying individuals at risk for TB, leading to earlier diagnosis and treatment. This approach underscores the importance of comprehensive screening protocols in effectively combating the disease and reducing transmission rates.

SOA02-522-18 Enhancing TB case detection: A comparative study of AI-identified versus routine data-derived hotspots in Pakistan

A. Mahfooz,[1] A. Latif,[2] T. Reza,[3] S. Muhammad Asad Zaidi,[4] M. Wasim,[1] N. Nawaz,[2] F. Ali,[2] F. Emmanuel,[5]
[1]Center for Global Public Health, Pakistan, TB, Islamabad, Pakistan, [2]Mercy Corps, Pakistan, TB, Islamabad, Pakistan, [3]Center for Global Public Health, Pakistan, Public Health, Islamabad, Pakistan, [4]World Health Organisation, Public Health, Islamabad, Pakistan, [5]University of Manitoba, Canada, Institute of global public health, Winnipeg, Canada
e-mail: amna.mahfooz1@gmail.com

Background: Despite significant improvements in recent years for active case-finding (ACF) for tuberculosis (TB), a gap of 30% (205,864 missing TB cases) exists between case notification & expected incidence in Pakistan in 2023. Yields of ACF have been lower raising concerns about its effectiveness in programmatic settings.
The primary aim of this trial is to investigate whether using a geographically targeted approach supported by artificial intelligence (AI), MATCH-AI, can improve the yield of ACF in Pakistan.
Design/Methods: A stepped-wedge cluster randomized trial is being implemented across 65 districts in Pakistan to evaluate the effectiveness of AI versus routine targeting strategy for ACF. Data collection is ongoing, spanning from October 2023 to April 2025, with data for 14 months with 5000+ screening activities (camps) available and preliminary results can be presented. Site-selection for ACF in the intervention areas is guided using MATCH-AI software that models sub-district TB prevalence & identifies hotspots.
Control areas were selected using existing approaches for hotspot selection. The primary outcome measure is number of bacteriologically confirmed TB cases detected in both groups.
Results: Our preliminary results included data analysis of total 6190 camps, with 891 (locations for 1099 camps are not verified yet) camps on the intervention side & 4200 camps on the control side. The yield of bacteriologically positive cases across AI camp sites was 2.1% in comparison to 1.9% in camps selected through the conventional approaches.
A higher number of camp attendance was noticed in camps selected through conventional method with an average number of 69.2 ± 22 participants versus 67.3 ± 18.9 in the intervention camps.

		AI camps	Non-AI camps
1	Total Camps	891	4200
2	Total number of camp participants	60,001	290,748
3	Average number of camp participantss	67.3 ± 18.9	69.2 ± 22
3	Tests conducted on Xpert	9,661	41,527
4	Yield for Bacteriologically +ve cases	2.1%	1.9%
5	Detection rate/100,000 people	2082	1945

Table.

Conclusions: The trial, if proven successful, will help inform whether a targeted approach for ACF in high TB burden countries is effective & feasible. Hotspot identification using MATCH AI, could enhance TB case detection & lower the burden of missing TB cases in Pakistan.

E-POSTER SESSION (EP)

EP01 Next-gen technology for TB: Bridging the gaps in surveillance, diagnosis, and treatment

EP01-700-18 The use of technological innovation (MATS App) to improve TB case finding in PPM intervention: The Katsina State experience

A. Galadima,[1] I. Lawrence,[2] M. Sheshi,[3] M. Bajehson,[4] A. Okoh,[5] B. Odume,[6] M. Bathnna,[7] T. Adetiba,[8] O. Chijioke- Akaniro,[9] S. Dimang,[9] A. Reilly,[10] J. Kimeu,[10]
[1]KNCV Nigeria, Technical, Katsina, Nigeria, [2]KNCV Nigeria, Program, Katsina, Nigeria, [3]KNCV Nigeria, Private Sector, Abuja, Nigeria, [4]KNCV Nigeria, Program, Kano, Nigeria, [5]KNCV Nigeria, Technical, Abuja, Nigeria, [6]KNCV Nigeria, Executive, Abuja, Nigeria, [7]Institute of Human Virology, Nigeria (IHVN), Programme, Abuja, Nigeria, [8]Institute of Human Virology, Nigeria (IHVN), Technical, Abuja, Nigeria, [9]National TB and Leprocy and Buruli Ulcer Control Programme Nigeria, Program, Abuja, Nigeria, [10]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Geneva, Switzerland, Program, Switzerland, Switzerland
e-mail: agaladima@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains a significant public health challenge in Nigeria, particularly in Katsina State, where barriers to early diagnosis persist. KNCV Nigeria, with funding from Global Fund, is implementing the Public-Private-Mix (PPM) TB screening activities in Katsina state, taking services to the doorstep of the patients in the communities.
This study explores the impact of the Mobile Application for TB Screening (MATS App) on enhancing TB case finding in some selected facilities within the Public-Private Mix (PPM) intervention in Katsina State.
Intervention or response: This is a retrospective review of Program-level data for KNCV-implemented PPM TB screening activities for April,2024 and July, 2024 in Katsina State. The MATS App was deployed in selected PPM facilities across Katsina State in July 2024, and healthcare providers received comprehensive training on its usage. Data on TB case finding was gathered before and after the app's implementation for comparison.
Results/Impact: The introduction of the MATS App in July 2024 resulted in a marked increase in TB case finding. Quantitative analysis revealed a 171% increase in presumptive TB case identification and 391% increase in identified TB cases within one-month post-implementation as shown in the figure below.

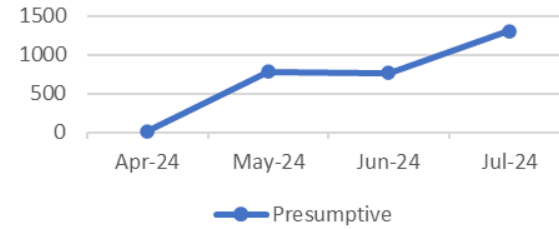

Figure. Presumptive TB identification trend.

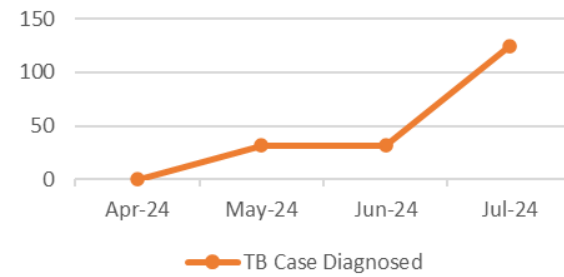

Figure. TB case notification trend.

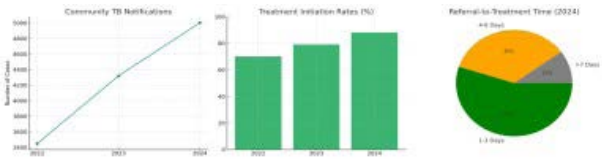
Conclusions: Deploying the MATS App Technology significantly improved TB case finding in Katsina State's PPM intervention. Its user-friendly interface improved efficiency in TB screening and real-time reporting capabilities streamlined TB screening and management processes.
This study underscores the potential of technological innovations like the MATS App to bolster TB control efforts in resource-limited settings. Expanding the use of such technologies across the PPM facilities in the state and other regions could further aid in the global fight against TB.

EP01-701-18 Leveraging health information systems to diagnose health system performance: Insights from the Global Fund PPM grant using CommTB in Katsina, Nigeria

P. Batur,[1] R. Abi,[1] [1]KNCV Nigeria, Programme, Katsina, Nigeria
e-mail: pshie@kncvnigeria.org

Background and challenges to implementation: In Katsina State, Nigeria, tuberculosis (TB) control efforts increasingly rely on the integration of community-level actors, particularly through the Public-Private Mix (PPM) model supported by the Global Fund. Central to this model is the deployment of the CommTB mobile application, used by Community-Based Organizations (CBOs) for community TB screening, identification, and real-time reporting. CommTB bridges data gaps between community TB activities and the national health system, enabling performance tracking and timely case management.
Intervention or response: This retrospective evaluation covers CommTB data from September 2023 to December 2024, collected by 3 CBO-s across Katsina State. CBOs used CommTB to document presumptive TB cases iden-

tified during outreach, referrals made, diagnostic confirmation, and treatment initiation. Data were extracted from the CommTB dashboard and cross-validated with state TB program records. Analysis focused on trends in community TB case notifications, referral-to-treatment turnaround, and system responsiveness.
Results/Impact: Community TB Case Notifications: Notifications increased by 45%, from 3,450 in 2023 to 5,003 in 2024.
- Referral-to-Treatment Efficiency: The average referral-to-treatment time dropped from 7 days to 3 days, driven by CBO-led navigation and CommTB alerts.
- Treatment Initiation Rate: Initiation improved from 70% in 2023 to 88% in 2024.
- Data Quality: CommTB-enabled reporting achieved over 90% completeness across key fields including symptom tracking, referral status, and treatment outcome.



Conclusions: The use of CommTB by community actors in Katsina has enhanced the visibility, responsiveness, and effectiveness of TB services under the GF PPM model. Real-time data from the field informs program decisions, accelerates linkage to care, and showcases the power of digital tools in decentralized TB surveillance.

EP01-702-18 IVRS-based cough tracking for early TB diagnosis among individuals purchasing cough syrups from local practitioners

G. Beri,[1] R. Kumar,[1] D. Parija,[2] P. Ambule,[2]
A. Shrivastava,[2] J. Parmar,[2] A. Heda,[3] B. Vadera,[4]
[1]Department of Health and Family Welfare, National Health Mission, Shimla, India, [2]Jhpiego, TB, Delhi, India, [3]Jhpiego, TB, Shimla, India, [4]USAID, TB, Delhi, India
e-mail: debadutta.parija@jhpiego.org

Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge, with many cases missed due to delayed care-seeking, misdiagnosis, and lack of timely referrals by local practitioners. In India Often the first point of contact, providers like chemists, traditional medicine (AYUSH) practitioners, and RHPs lack systems for tracking symptoms and making timely referrals results in missed chances for early TB diagnosis. Under the USAID-supported, JSI-led TIFA TCG grant, we're using IVRS (Interactive Voice Response System) to monitor individuals buying cough syrup and refer persistent cough cases for TB testing.
Intervention or response: The project uses the TB Mukt Himachal mobile app to record cough syrup distribution details, including the individual's name, age, mobile number, syrup type, and cough duration. This data generates a weekly line list shared with the IVRS team for two automated follow-up calls on Day 7 and Day 14.
The first call checks cough persistence and, advising testing for presumed TB cases. The second call follows up with untested individuals.
After second call, Non-responders and untested cases are referred to health workers for further follow-up. The primary outcome is the proportion of tested presumed TB cases, with secondary outcomes including IVRS responses, TB positivity, and completion rates.
Results/Impact: Between October and December 2024, the IVRS initiative tracked 35,348 individuals who received cough syrup from 6,464 local practitioners. Calls were connected to 21,486 (61%) individuals, with 5,821 (27%) responding to the first call about their cough status. Of those, 2,287 (39%) reported a persistent cough and were advised to test for TB. In the second call, 841 (36.8%) confirmed TB testing, and 48 (6%) were diagnosed with TB.
Conclusions: The IVRS initiative improved TB case finding with 6% positivity, but a 73% non-response rate calls for better engagement strategies.

EP01-703-18 Helping household TB contacts navigate the contact tracing cascade using a WhatsApp chatbot under South Africa's universal testing policy: Findings from Shesha

D. Mudzengi,[1] T. Ntshiqa,[1] Y. Hamada,[2] F. Ndebele,[1]
T. Mpanza,[1] F. Mboniswa,[1] G. Kubheka,[1] S. Hlope,[1]
M. Rangaka,[2] K. Velen,[1] S. Charalambous,[1]
[1]The Aurum Institute, Implementation Research Division, Johannesburg, South Africa, [2]University College London, Institute for Global Health, London, United Kingdom of Great Britain and Northern Ireland
e-mail: vamudzengi@outlook.com

Background: South Africa's universal TB testing policy requires that all household contacts of TB patients be tested microbiologically and, if eligible, start treatment or tuberculosis preventive therapy (TPT). While necessary, this policy increases the workload of community health workers (CHWs), who cannot feasibly follow-up every contact. To address this, we developed Shesha, a WhatsApp-based chatbot to deliver results, guide contacts through each step of the contact tracing cascade and enable them to self-report progress; placing more control in their hands.
Design/Methods: We developed Shesha over six-months in 2023 and implemented it for 19 months from September 2023. CHWs assisted only with registration during

first household visits. Thereafter, contacts engaged independently with Shesha on WhatsApp, receiving automated push messages to access their results, receive guidance, and report clinic visits, starting treatment and post-treatment activities.
We analysed chatbot data to assess engagement, TB test result receipt, and user-reported progression along the cascade.
We conducted qualitative interviews using the Unified Theory of Acceptance and Use of Technology (UTAUT) to explore perceived usefulness, ease of use, and behavioural intention.
Results: We approached over 445 contacts and enrolled 354. Among those not enrolled, 56% lacked WhatsApp-compatible phones and 41% were underage. Of the 354 enrolled, 315 (89%) opted in. Through Shesha, 236 (75%) received TB test results, 46 (15%) reported clinic visits, and 30 (10%) reported initiating treatment or TPT. Sixty-seven contacts gave reasons for not attending, including time constraints (31%), feeling healthy (16%), financial barriers (15%), work-related commitments (10%), childcare, and lack of nearby clinics (3% each).
Nineteen percent reported varied personal reasons. Interviews showed users valued receiving results, though many felt well and did not see a need for TPT.
Conclusions: Shesha demonstrated high early engagement and helped automate follow-up. However, limited downstream reporting reflected broader barriers to TPT uptake and the limits of self-reporting alone.

EP01-704-18 Innovative connectivity solution enhanced enrolment and management in Nigeria of people with drug-resistant TB and HIV in Nigeria

K. Jimoh,[1] D. Meshak,[2] E. Ubochioma,[3] O. Akaniro,[3]
[1]Connected Diagnostics Nigeria, Management, Abuja, Nigeria, [2]Connected Diagnostics Nigeria, Implementation, Abuja, Nigeria, [3]National TB and Leprosy Control Program, Program Management Unit, Abuja, Nigeria
e-mail: kagbaiyero@connecteddiagnostic.com

Background and challenges to implementation: Nigeria holds the highest burden of tuberculosis (TB) in Africa and ranks sixth globally among high TB burden countries. The country accounts for a significant portion of the global TB incidence and is also heavily affected by drug-resistant TB (DR-TB) and HIV-associated TB. The country relies on GeneXpert MTB/RIF machines to diagnose DR-TB at multiple clinical locations.
However, reporting TB testing results is lengthy due to continued reliance on paper records and slow data transit systems. The quality of results data is often poor, and subsequent program management decisions are not always timely or focused on priority needs.
Intervention or response: Nigeria relies on a cost-effective, innovative solution that sends GeneXpert diagnostic results to key health system actors instantly to enable quick enrollment of newly diagnosed patients in a DR-TB treatment program.
GxAlert is configured on GeneXpert systems, and connectivity is provided by local telecom to send encrypted data to the secure web-based GxAlert database in real time and with the capability to send diagnostic test results out to national programs, supervisors, clinicians, and patients via SMS text, email, and web dashboard or by connecting into existing M&E, patient record, or case management tools already in use.
Results/Impact: The proportion of DR-TB patients enrolled for treatment based on GxAlert messages received from 348 GeneXpert facilities jumped to 89% in January 2024 from only 70% enrolled in April 2022. This innovation has made it possible to get diagnostics results immediately back to clinicians and patients and improved the focus of diagnoses.
Conclusions: Using GxAlert SMS notification for GeneXpert testing suggests a scalable model for sustainability. Lessons learned include: Installation is done once and locally. Technology is kept simple as local telecom connectivity solutions are required and are readily available and affordable for GxAlert connectivity.

EP01-705-18 Reducing diagnostic delays through a radiology information system in Kirovohradska oblast, Ukraine

O. Pavlenko,[1] G. Gorenko,[2] M. Germanovych,[1]
A. Bogdanov,[1] G. Dravniece,[1] [1]PATH, STBCEU, Kyiv, Ukraine, [2]Kyrovograd Regional Phthisiopulmonary Medical Center, TB department, Kyrovograd, Ukraine

Background and challenges to implementation: In Ukraine, radiology workflows have traditionally relied on manual processes: images are shared via flash drives or radiologists travel to central facilities for X-ray interpretation. These same processes was used when conducting TB screenings with mobile X-ray in remote areas; interpretation was only possible once the team returned to the central facilities.
Further, Ukraine's health care system faces a shortage of experienced radiologists, leading to additional delays in X-ray interpretation and TB diagnosis.
Intervention or response: Since January 2025, the USAID-funded, PATH-led Support TB Control Efforts in Ukraine (STBCEU) project supported installation of a Radiology Information System (RIS) in the Kirovohrad TB facilities. The RIS provided centralized, cloud-based storage of X-ray images, allowing radiologists to access and interpret X-ray images remotely. It supported immediate image upload from any remote site, integration

with local and cloud-based medical information systems in DICOM format, and electronic result transfer to referring physicians. Family doctors could access images via QR codes or secure links. RIS also enabled comparison of X-ray with the radiological archive, reducing follow-up of patients with post-TB residual lung changes.

Results/Impact: Between January 31 and March 31, 2025, a total of 1,037 X-ray images were processed using the RIS. The average time required for a single doctor to interpret an X-ray was reduced to approximately 7 hours, compared to 96 hours per X-ray prior to the implementation of the RIS.

Additionally, the time needed to transmit results to the district level decreased to an average of 48 hours, down from an average of 432 hours before the introduction of the RIS.

Conclusions: The RIS implementation significantly streamlined the workflows of health care professionals. The system has facilitated both faster X-ray image processing and faster communication between health care providers, reducing delays in diagnosis and patient follow-up.

EP01-706-18 Prescription to notification: Digitizing drug sales in Uttar Pradesh

S. Shrivastava,[1] B. Shetty,[1] R. Washington,[1] A. Agnihotri,[1] Y. Kharkwal,[1] H. Himanshu,[1] A. Iyer,[2] R. Srivastava,[2] P. Shukla,[1] [1]India Health Action Trust, Tuberculosis, Lucknow, India, [2]India Health Action Trust, Information and Communications Technology, Lucknow, India
e-mail: bharatesh.shetty@ihat.in

Background and challenges to implementation: Tuberculosis (TB) remains a major public health issue in India, where many patients first seek care in the private sector. In 2018, Tuberculosis (TB) was declared a notifiable disease in India. Uttar Pradesh (UP), contributing 16% of India's population and 33% of Anti Tuberculosis Treatment (ATT) drug sales, reported over 0.6 million TB cases in 2023, while the India TB Prevalence Survey 2019 estimated nearly 1 million, revealing a large notification gap. Inconsistent manual and digital record-keeping practices pose additional barriers to accurate ATT sales tracking. A centralized digital application to resolve these issues was piloted in Lucknow.

Intervention or response: A web /mobile based app was deployed in the pharmacies to capture patient-level drug sales data. Pharmacists were trained at state and facility levels on accurate data entry and app adoption.

Primary data (December 2024-February 2025) from the app was cross-matched with the notification register (January 2023-February 2025) using mobile numbers and gender to identify individuals undergoing treatment but not notified. Field verification validated the findings.

Results/Impact:

1. Total 300 patient drug sales were recorded and data triangulation showed that 69% (207/300) of patients recorded in the app were not notified in Nikshay. Field verification confirmed that 32% (97/300) were not reported but were under treatment.
2. ATT drug sales were recorded 697 times, involving 28 distinct drug formulations and accounting for 16,702 tablets dispensed.

Distribution of ATT Drug Formulations Captured Through Pharmacy App

Drug Name	Drug_Generic_Name	Packaging						Quantity Sold (Tablets)
		1*1	1*10	1*2	1*3	1*4	1*6	
Akt 2 Tablet			70					70
Akt 3 Kit	Rifampicin (450mg) + Isoniazid (300mg) + Ethambutol (800mg)	60		72				132
Akt 4 Kit	Isoniazid (300mg) + Rifampicin (450mg) + Ethambutol (800mg) + Pyrazinamide (750mg)	71	199	35		113		418
Akurit-3 Tablet	Rifampicin (150mg) + Isoniazid (75mg) + Ethambutol (275mg)		1325					1325
Akurit-4 Tablet	Isoniazid (75mg) + Rifampicin (150mg) + Ethambutol (275mg) + Pyrazinamide (400mg)		1670					1670
Combunex 800 Tablet	Isoniazid (300mg) + Ethambutol (800mg)		75					75
Combutol 1000 Tablet	Ethambutol (1000mg)		1183					1183
Combutol 200 Tablet	Ethambutol (200mg)		60					60
Combutol 400 Tablet	Ethambutol (400mg)		310					310
Combutol 600 Tablet	Ethambutol (600mg)		589					589
Combutol 800 Tablet	Ethambutol (800mg)		1425					1425
Forecox Tablet	Isoniazid (150mg) + Rifampicin (225mg) + Ethambutol (400mg) + Pyrazinamide (750mg)		158				164	322
Macox Plus Tablet	Rifampicin (450mg) + Isoniazid (300mg)						48	48
P Zide 1000 Tablet	Pyrazinamide (1000mg)		700					700
P Zide 500 Tablet	Pyrazinamide (500mg)		949					949
P Zide 750 Tablet	Pyrazinamide (750mg)		1314					1314
Pyzina 1000 Tablet	Pyrazinamide (1000mg)		10					10
Pyzina 500 Tablet	Pyrazinamide (500mg)		90					90
Pyzina 750 Tablet	Pyrazinamide (750mg)		110					110
R-Cin 300 Capsule	Rifampicin (300mg)		115					115
R-Cin 450 Capsule	Rifampicin (450mg)		763					763
R-Cin 600 Capsule	Rifampicin (600mg)		52		197			249
R-Cin Capsule	Rifampicin (150mg)		90					90
R-Cinex 600 Tablet	Rifampicin (600mg) + Isoniazid (300mg)		290		1174			1464
R-Cinex Capsule	Rifampicin (450mg) + Isoniazid (300mg)		2038					2038
R-Cinex E Tablet	Rifampicin (450mg) + Isoniazid (300mg) + Ethambutol (800mg)		12				126	138
Solonex DT Tablet	Isoniazid (100mg)		345					345
Solonex Tablet	Isoniazid (300mg)		700					700
Grand Total		**131**	**14642**	**107**	**1371**	**113**	**338**	**16702**

Conclusions: The pharmacy app pilot shows promise in bridging TB notification gaps and provides useful insights into private-sector ATT drug prescribing practices and sales. Accurate identification of missing cases dependent on thorough data triangulation and field verification, as drugs are often bought by others on behalf of individuals on treatment.

EP01-707-18 Portable digital X-ray (PDX) screening as a catalyst for early multi-drug resistant TB detection among contacts in high-burden settings: A cross-sectional study from Katsina, Nigeria

I.T. Lawrence,[1] A.Y. Galadima,[2] P.S. Batur,[2] M. Sheshi,[3] A. Okoh,[3] B. Odume,[4] T. Adetiba,[5] A. Adekunle,[5] S. Dimang,[6] [1]KNCV Nigeria, Programmes, Katsina, Nigeria, [2]KNCV Nigeria, Technical, Katsina, Nigeria, [3]KNCV Nigeria, Programmes, Abuja, Nigeria, [4]KNCV Nigeria, Executive Management, Abuja, Nigeria, [5]IHVN, Programmes, Abuja, Nigeria, [6]NTBLCP, Programmes, Abuja, Nigeria
e-mail: ilawrence@kncvnigeria.org

Background: Multidrug-resistant tuberculosis (MDR-TB) remains a significant public health challenge, particularly in high-burden settings like Katsina, Nigeria. Traditional symptomatic screening methods often miss early or asymptomatic cases, leading to delayed diagnosis and ongoing transmission. Artificial intelligence (AI) aided portable digital X-ray (PDX) screening has emerged as a potential tool to enhance case detection. This study evaluates the effectiveness of PDX screening in enhancing MDR-TB case detection among close contacts of MDR-TB compared to symptomatic screening.
Design/Methods: A cross-sectional study was conducted among 587 close contacts of confirmed MDR-TB patients. Participants underwent both symptomatic and PDX screening. Those identified as presumptive cases were tested for MTB/Rif resistance using Gene Xpert or Truenat. The primary outcome measures were the number of drug susceptible tuberculosis (DSTB) and MDR-TB cases detected using each screening method. Data analysis included comparative proportions and percentage increases in case detection rates.
Results: PDX screening identified 145 presumptive cases (24.7%), compared to 98 cases (16.7%) via symptomatic screening. Confirmed TB cases were significantly higher with PDX screening (21 cases, 3.6%) than symptomatic screening (13 cases, 2.2%), representing a 61.5% increase. MDR-TB detection was markedly improved with PDX screening, identifying 15 cases (2.6%), compared to 6 cases (1.0%) through symptomatic screening— a 150% increase.
Conclusions: PDX screening demonstrated significantly higher yield in detecting both DSTB and MDR-TB among close contacts of MDR-TB patients, with a 61.5% and 150% increase in case detection, respectively, compared to symptomatic screening. These findings support the integration of PDX into contact investigation strategies to enhance early diagnosis and interrupt transmission in high-burden settings.

EP01-708-18 Designing a digital clinical decision support system to strengthen implementation of treatment decision algorithms for childhood TB in Zambia and Mozambique

C. Etoa Bekono,[1] E. Francisco,[2] M. Kabaso,[3] M. Mwanabet,[3] J. Ribeiro,[4] T. Simwanza,[3] C. Romao,[2] C. Kasungu,[5] E. Dessalas,[6] C. Roucher,[1] O. Marcy,[7] C. Khosa,[4] [1]University of Bordeaux, Bordeaux Public Health, Bordeaux, France, [2]Ministry of health Mozambique, Health Information, Maputo, Mozambique, [3]Ministry of Health of Zambia, National TB and Leprosy Programme, Lusaka, Zambia, [4]Instituto Nacional de Saoude, Polana Caniço Health Research and Training Center (CISPOC), Maputo, Mozambique, [5]Universty of Zambia, Pediatric Center of excellence (PCOE), Lusaka, Zambia, [6]French Institut of research and sustainable Development, UMI233-transVIHMI, Montpelier, France, [7]University of Bordeaux, National institute for Health and Medical Research (Inserm), Bordeaux, France
e-mail: celso.khosa@ins.gov.mz

Background and challenges to implementation: Digital tools such as clinical decision support systems (CDSS) could support the use of Treatment decision algorithms (TDAs) for childhood tuberculosis by healthcare workers. There is no data on design and implementation of a CDSS specifically tailored for TDA use in low- and middle-income countries (LMICs), where local workflows, infrastructure limitations, and integration with national health systems present unique challenges.
Intervention or response: As part of the Decide-TB project, a digital CDSS embedded within an electronic medical record (EMR) was co-designed by national TB programs (NTPs) in Zambia and Mozambique and research partners.
Researchers and NTP representatives identified essential data variables, and selected the system based on existing healthcare infrastructure. Iterative usability testing in real-world settings with healthcare workers—using the System Usability Scale and Think-Aloud protocols—helped assess the usability and shape key refinements.
Results/Impact: The tool included a 19 structured program stages EMR in DHIS2 Tracker with automated algorithm scoring, and built-in program rules to guide clinical decisions. It was deployed on tablets with offline functionality to support continuity in low-connectivity setting. Implementation was supported by structured training and real-time dashboards for supervision.
Usability testing and feedback from healthcare workers revealed that factors such as variability in digital literacy, limited access to devices, and non-intuitive design features of the DHIS2 platform influenced tool usability.
Adaptive support mechanisms, including continuous peer learning and WhatsApp-based data entry support, enhanced adoption and consistent use of the CDSS.

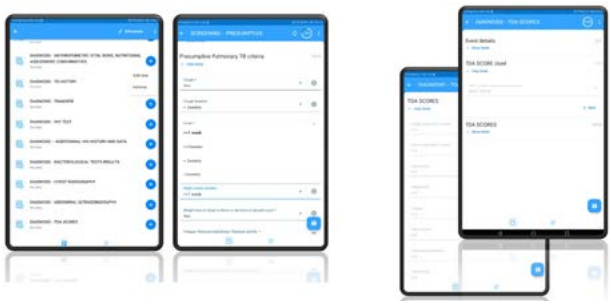


Figure. Illustrative screenshots: EMR/CDSS interfaces.

Conclusions: Developing digital CDSS tools to support TDA implementation in LMICs requires more than technological innovation; it demands stakeholder co-design, adaptation taking into consideration structural barriers such as electricity issues or internet issues and embedded capacity-building strategies adapted to the digital literacy of HCWs.

Addressing these factors holistically is crucial for digital CDSS tools to effectively enhance TDA uptake in LMICs.

EP01-709-18 Improving TB treatment outcomes through an interactive voice-based mobile health tool: Evaluation of the Call for Life tool in Karamoja, Uganda

T. Nsubuga,[1] H. Mackline,[2] F. Dhikusooka,[2] B. Picho,[1] M. Nabukenya-Mudiope,[1] S. Zawedde-Muyanja,[2] R. Obaikol,[3] [1]Infectious Diseases diseases, Health Systems Strengthening, Kampala, Uganda, [2]Infectious Diseases diseases, Research, Kampala, Uganda, [3]Infectious Diseases diseases, Academy, Kampala, Uganda
e-mail: tnsubuga@idi.co.ug

Background and challenges to implementation: The Call for Life (C4L) tool an interactive voice-based mobile health intervention providing daily treatment reminders, appointment alerts, and health tips via basic phones has been documented to improve TB and HIV outcomes in urban Uganda. The Karamoja, a remote region in northeastern Uganda, is home to nomadic pastoralist communities with limited access to healthcare, high mobility, and low literacy.

In 2020, the region's TB treatment success rate was only 48%, far below the national target of 85%. To address this, the USAID PACT-Karamoja Activity introduced the Call for Life (C4L) tool at five high volume health facilities to improve TB treatment outcomes. We evaluated the impact of this tool in this challenging setting.

Intervention or response: We conducted a retrospective cohort study in 13 health facilities in Karamoja. Five sites implemented the C4L tool; eight comparable sites served as controls. Patients were identified from the C4L database and TB clinic registers using systematic sampling.

The primary outcome was treatment completion. We used multivariable logistic regression with inverse probability weighting to adjust for confounders.

Results/Impact: We included 1,202 patients with drug-susceptible TB (601 users and 593 non-users) treated between September 2020 and August 2022. The majority (59.5%) were male. Median age was 38 years (IQR: 29–52); 64% had bacteriological confirmation, and 87.5% were HIV negative. C4L users had significantly higher treatment completion rates (92.2%) compared to non-users (83.8%), an 8.4 percentage point difference (95% CI: 4.71–12.02, $p<0.001$). Loss to follow-up was lower among users (1.3% vs. 8.8%). A higher proportion of C4L users had a documented sputum smear result at six months (97.0% vs. 76.0%, $p<0.001$).

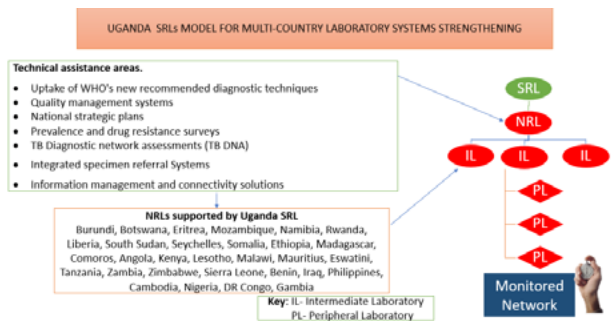
Conclusions: The C4L tool significantly improved TB treatment outcomes in a remote, high-burden setting.

EP02 Diagnostic networks in TB: Optimisation through innovation

EP02-710-18 A catalytic approach to strengthening laboratory systems through innovative solutions in technical assistance, training and capacity building: Case study of the Uganda Supranational Reference Laboratory

H. Ssentamu Nakato,[1] J. Namutebi,[1] [1]SRL- Uganda, Laboratory, Kampala, Uganda
e-mail: hasfa26@gmail.com

Background and challenges to implementation: Although tuberculosis is preventable and curable, it remains the leading global cause of mortality of a single infectious agent. The World Health Assembly endorsed the END TB strategy, but countries are far behind in achieving these goals. The glaring gaps require robust and coordinated innovative approaches to tackle the strategy's technical and programmatic needs. The Uganda National TB Reference Laboratory (NTRL) acquired the WHO Supranational Reference Laboratory (SRL) status in 2013 with a mandate to support laboratory networks across sub-Saharan Africa.
Intervention or response: Since 2013, the Uganda SRL expanded its highly skilled workforce coupled with facility infrastructure developments and the acquisition of advanced equipment. The NRLs in the region were supported through targeted technical assistance and mentorship. Developed an adult learning training program and a proficiency testing (PT) scheme. A laboratory information management system (LIMS) for TB laboratories and an integrated network connectivity solution were developed and availed in three languages. SRL personnel participated in Diagnostic network assessments for 5 Countries.



Results/Impact: Thirty highly qualified and competent SRL consultants are certified to offer technical assistance. An equipped state-of-the-art (BSL3) laboratory exists. Twelve countries can provide quality-assured TB Drug susceptibility testing. Three international accreditations were acquired (ISO15189, ISO17043 for 16 scopes, and ANSI/IACET for continual education and training with 23 courses). Sixteen countries were supported to develop and implement national strategic plans. Accreditation of fourteen NTRLs to ISO 15189 as well as PT provision to 25 countries. A web-based online system was developed to manage PT data. The TB LIMS and connectivity solutions were adopted by seven and two countries respectively.
Conclusions: The unique support model employed by the Uganda SRL has proved to be effective and relevant to achieve the END TB strategy objectives. The model can therefore be adopted for national laboratory networks, multi-country support projects as well as laboratory systems strengthening initiatives.

EP02-711-18 Moving from microscopy to nucleic acid amplification test: Leveraging diagnostic network optimisation to address challenges and strengthen TB testing in Jalandhar, India

G. Thori,[1] R. Bhaskar,[1] U. Singh,[2] V. Chopra,[3] S. Sharma,[4] S. Chandra,[5] P. Kapoor,[5] P. Kaur Samra,[5] P. Dhawan,[5] S. Singh Tomar,[5] R. Dadra,[6] [1]Government of Punjab, Ministry of Health and Family Welfare, Chandigarh, India, [2]Government of India, Ministry of Health and Family Welfare, New Delhi, India, [3]TB Hospital Patiala, Dept. of Chest and TB Diseases, Patiala, India, [4]Dayanand Medical College, Dept. of PSM, Ludhiana, India, [5]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [6]Government of Punjab, Department of Health and Family Welfare, Jalandhar, India
e-mail: kaurp@rntcp.org

Background and challenges to implementation: Jalandhar district in Punjab possesses promising potential to enhance its TB testing capacity by leveraging advanced diagnostic technologies. However, current challenges contribute to underutilization and a continued emphasis on microscopy over NAAT (Nucleic Acid Amplification Tests), with limitations related to human resources, sample transport, and workflow integration.
This study aims to assess the impact of the Diagnostic Network Optimization (DNO) initiative, which seeks to facilitate a smooth transition from microscopy services to NAAT and optimize the utilization of TB diagnostic resources in Jalandhar.
Intervention or response: Using 2024 as the baseline, data from Nikshay (India's web-based TB surveillance data system) was analysed across all diagnostic centres in the district. Key gaps identified were over-reliance on microscopy, low NAAT use (33.1% of capacity), suboptimal technical knowledge of the staff, and weak sample transport at several sites. To address these gaps, data-driven strategies were implemented from January–March 2025, including (i) upfront NAAT at microscopy-linked sites

(reserving microscopy for follow-up), (ii) staff reallocation to high-volume centres, (iii) NAAT machine relocation to high-demand sites, and (iv) streamlined sample transport via community health workers.
Post-intervention data (January to March 2025) was analysed using SPSS version 22. Parameters included (a) testing volumes, (b) NAAT utilization, and (c) Universal Drug Susceptibility Testing.
Results/Impact:

Indicator	2024 (Baseline)	January–March 2025	% Change
NAAT utilization against capacity	33.1%	94.3%	+61.2%
Average Monthly NAAT tests	505	1,610	+219%
Average monthly microscopy tests	101	80	−21%
Microscopy as follow-up	13%	16%	+3%
Universal drug susceptibility testing coverage	61%	73%	+12%

Table 1- Comparative data showing impact of DNO.

Conclusions: DNO exercise revealed critical gaps in TB care cascade, including underuse of molecular diagnostics, inefficiently used human resources, and weak sample transport. As NAAT adoption expands, institutionalizing data-driven DNO is extremely vital for adaptive, evidence-based planning to ensure equitable TB diagnosis.

EP02-712-18 Early lessons of - TB diagnostic network optimisation- to accelerate TB diagnosis in India

M. Das,[1] H. Vashistha,[1] R. Srivastava,[1] P. Singh,[1] S. Sangle,[2] B. Mishra,[3] S. Kumta,[4] A. Beri,[1] S. Chadha,[5]
[1]FIND, Medical, Delhi, India, [2]National TB Elimination Programme, State TB Cell-Maharashtra, Pune, India, [3]National TB Elimination Programme, State TB Cell-Bihar, Patna, India, [4]Bill and Melinda Gates Foundation (BMGF), Medical, Delhi, India, [5]FIND, Access, Geneva, Switzerland
e-mail: archana.beri@finddx.org

Background and challenges to implementation: Early and accurate diagnosis of TB is essential for achieving the global END TB targets. India contributes to one-fourth of global TB cases (~2.55 million). Though the country has prioritized molecular WHO-recommended rapid diagnostic (mWRD) tests for TB diagnosis, missing TB cases is still a concern. FIND is implementing 'TB Diagnostic network optimization' (DNO) initiative in India from 2024, supported by the Gates Foundation; in collaboration with National TB elimination programme (NTEP). We document the early findings of this initiative.
Intervention or response: FIND's TB DNO initiative is being implemented in all districts of Bihar and Maharashtra states of India, focusing on strengthening the TB diagnostic landscape. Under the project, geospatial analysis of TB diagnostic networks (including sample referral and transportation) is carried out and optimized networks are developed using routine NTEP data. Technical assistance (on-site assessment, training of laboratory personnel) is offered to facilities with mWRD devices. To determine the effect of DNO initiative on TB diagnostic tests, 30 districts were selected (based on TB notification; 18 from Bihar and 12 from Maharashtra). The mWRD test device performances (coverage, utilization) of years 2023 and 2024 were compared.
Results/Impact: In 2024, the mWRD devices per 100,000 population increased by ~133% (0.206 vs 0.480) compared to 2023. The mWRD tests increased by 97% (185,018 in year 2023 vs 364,926 in year 2024) and mWRD utilization improved by 45% from 2023 (29%) to 2024 (42%) (Figure 1). The optimized TB diagnostic models suggest a decrease in average distance and time between sample collection sites and mWRD facilities, once DNO suggestions are operationalized.

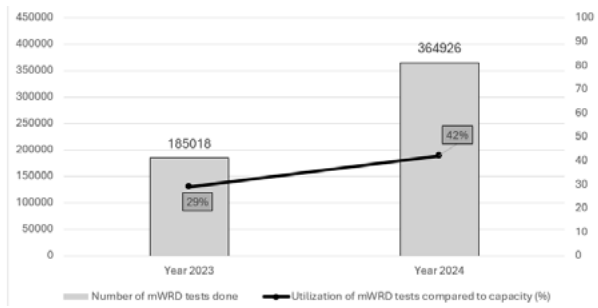


Figure 1. Utilization of molecular WHO-recommended rapid diagnostic tests under FIND'S DNO project, India, 2024

Conclusions: The TB DNO initiative shows promising insights for improving the TB diagnostic landscape of the country. Scaling up similar geospatial initiatives will help the country in meeting the END TB targets.

EP02-713-18 Optimising TB diagnostics: Evaluating the screening capacity and cost benefits of sputum pooling in PHC Masaka, Nasarawa State, Nigeria

M. Iwakun,[1] J. Bimba,[1] G.A. Bahuyak,[1] D. Atuwo,[1] B. Adeyanju,[1] G. Elias,[1] L. Shehu,[2] C. Adesigbin,[2] D.S. Makpa,[3] S. Kaka,[4] T. Wingfield,[5] V. Iem,[5] [1]Bingham University, Zankli Research Centre, Nasarawa, Nigeria, [2]National Tuberculosis Leprosy and Buruli Ulcer Conrol Programme (NTBCLP), Public Health, Abuja, Nigeria, [3]Nasarawa State Ministry of Health, Hospital Management Board, Medical Laboratory Services, Lafia, Nigeria, [4]Nasarawa State Primary Health Care Development Agency (NPHCDA), Primary Health Care, Nasarawa, Nigeria, [5]Liverpool School of Tropical Medicine (LSTM), Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: graciousbahuyak@gmail.com

Background: Tuberculosis (TB) remains a critical global health issue, particularly in resource-limited settings. While highly accurate, molecular diagnostic tools like Xpert MTB/RIF and Xpert MTB/RIF Ultra are costly, with cartridges priced at $7.97–$9.98. These expenses hinder large-scale testing, especially in low-income countries such as Nigeria, which faces one of the world's highest TB burdens. Limited resources significantly constrain diagnostic efforts, leaving many individuals unscreened. Sputum pooling offers a promising solution by allowing multiple sputum samples to be tested with a single cartridge, cutting costs and expanding diagnostic capacity.
This study evaluates and compares the screening capacity and cost-effectiveness of sputum pooling versus individual testing to optimize TB diagnostics.
Design/Methods: A cross-sectional study was conducted at PHC Masaka involving 523 presumptive TB individuals aged 15 years and above. Each participant provided two sputum samples, one for individual testing and pooling with Xpert Ultra, and the other for MGIT culture. Pools were formed with four samples per pool. Pools were formed with four samples per pool. Data was analyzed using STATA v15.1 to evaluate diagnostic efficiency, including the number of samples tested, cartridges used, MTB-positive cases detected, and cost savings.

Metric	Individual Testing	Pool Testing	Savings/ Additional
Samples Tested	503	131	1,516 additional Presumptives
MTB/RIF Ultra Cartridges Used	511 (including 3 repeats)	132 (including 1 repeat)	379 saved cartridges
MTB-Positive Cases Detected	33	26	
Increase in TB Presumptives Tested	N/A	N/A	201.4%
Cost of Saved Cartridges (379)	N/A	N/A	$3,020.63 (379 × $7.97 per cartridge)

Table 1: Impact of Pooling on TB Diagnostic Cost Savings, and Efficiency

Results: Result of 503 individual samples and 131 pooled samples were analyzed yielding 33 MTB-positives from individual testing and 26 MTB-positives from pool. Sputum pooling saved 379 cartridges, that can enable screening of 1,516 additional TB Presumptives—an increase of 201.4% in screening capacity. At $7.97 per cartridge, these savings amounted to $3,020.63.
Conclusions: Sputum pooling demonstrates substantial efficiency and economic benefits for optimizing TB diagnostics. This method expanded diagnostic capacity while achieving cost savings, supporting its feasibility in resource-limited settings. Careful implementation is necessary to address State/Regional TB prevalence and ensure adequate follow-up testing.

EP02-714-18 Diagnostic network optimisation: Increasing access and utilisation of molecular WHO recommended rapid diagnostics (mWRD) for TB Elimination in Uttar Pradesh, India

B.K. Shetty,[1] R. Washington,[1] P. Singh,[1] H. Himanshu,[1] Y. Kharkwal,[1] [1]India Health Action Trust, Programs, Lucknow, India
e-mail: bharatesh.shetty@ihat.in

Background and challenges to implementation: India contributes 26% of the global TB burden and Uttar Pradesh (UP) 20% of India's notified TB. Since 2021, the state of UP has substantially enhanced TB Case Notification. The utilization of molecular WHO recommended rapid diagnostics (mWRD) for confirmation of active TB disease was sub-optimal remained suboptimal.
Intervention or response: In 2024, India Health Action Trust (IHAT) working under the leadership of State TB Program initiated implementation of the Gates Foundation Diagnostic Network optimization (DNO) project.
The objective is to increase the coverage of mWRD among individuals with TB disease to 85%. IHAT mapped the mWRD machines by number, types functional modules, geolocation, capacity for testing, availability of human resource.
Evidence generated was shared with the state for actions including filling HR vacancies, ensuring equitable distribution of machines, test kits timely maintenance of devices/supportive equipment, and enhanced linkages with primary healthcare sites.
Results/Impact: The mWRD machines performing TB tests increased from 80% (725/898 in 2023) to 95% (882/926 in 2024). Population accessibility analyses determined that 77% had access to mWRD within 30 minutes driving distance. District average performance of tests increased from 47% (0.75M) to 74% (1.32M) of estimated annual capacity (1.8M). Equipment breakdown resolution within a week from 60% to 89%. Because

notification of TB cases increased from 6.2 M (2023) to 6.8 M (2024), the proportion of active TB diagnosed using bacteriological confirmation remained stable (40%) (274045/682092).

However, the proportion of bacteriological confirmation from mWRD vs smear improved from 31% (83598/253843) in 2023 to 48% (130640/274045) in 2024. Offer of mWRD among diagnosed increased from 54% (2023) to 60% (2024). Upfront of mWRD testing among presumptive TB increased from 17% (2023) to 26%(2024).

Year	Notification	Bacteriological Confirmation	Percentage	NAAT Testing among Bacteriological Confirmation	Percentage	Smear Testing among Bacteriological Confirmation	Percentage
2023	622950	253843	41%	83598	33%	116078	46%
2024	682092	274045	40%	130640	48%	82392	30%

NAAT Offered Among Notified TB cases

Year	Notification	Offered NAAT	Percentage
2023	622950	344763	54%
2024	682092	413874	60%

Table. Notification Bacteriological Confirmation (NAAT and Smear Testing) Data Source: Ni-KSHAY

Conclusions: UP's progress with expanding, utilization of mWRD diagnostics is significant but requires acceleration to achieve the national target of 85% of diagnosed TB offered an mWRD test.

EP02-715-18 Enhancing molecular testing for TB detection through diagnostic network optimisation: Implementation insight from the 100 days TB Campaign in Uttar Pradesh, India

S. Bhatnagar,[1] R. Saxena,[1] K. Dash,[2] U. Mohan,[3] A. Rajeev,[4] D. Baliga,[5] P.S. Preeti,[5] S. Srivastava,[5] S. Joshi,[5] S. Chandra,[4] U. Singh,[6] P. Singh,[7] [1]State Tuberculosis Cell, Uttar Pradesh, Lucknow, India, State Medical & Health Department, Lucknow, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, Bareilly, India, [3]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, Lucknow, India, [4]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [5]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, Delhi, India, [6]Central TB Division, Ministry of Health & Family Welfare, Govt. of India, New Delhi, India, [7]DNO Team (TB Project), India Health Action Trust, Lucknow, India
e-mail: mohanu@rntcp.org

Background and challenges to implementation: The Government of India launched a 100-day intensified TB campaign from December 2024 to March 2025 under the National Tuberculosis Elimination Programme (NTEP). This campaign aims to improve case detection, enhance TB prevention, and reduce mortality. In Uttar Pradesh, the state with the highest TB notifications, a diagnostic network optimization (DNO) exercise was implemented to boost molecular testing for TB detection. The study aims to assess the impact of this DNO exercise on increasing the number of molecular tests and daily utilization of Nucleic Acid Amplification Test (NAAT) services.

Intervention or response: TB detection centres with NAAT facilities were categorized based on daily utilisation capacity vis-à-vis workload. (i) High workload-low utilization, (ii) Low workload-low utilisation, (iii) High workload-high utilisation facilities. To optimize diagnostic operations, a multi-pronged strategy was conceptualised. Laboratory technicians were deployed from low workload to high workload centers, thereby extending NAAT operations from 8 hours to 16 hours. The study compared data of same period from last year (Jan–Feb 2024) with campaign-period data (Jan–Feb 2025) of this year. Data was sourced from Nikshay, India's web-based TB surveillance system. Key parameters included (i) number of NAAT tests conducted, (ii) machine utilisation rates, and (iii) TB notifications.

Results/Impact: The intervention led to a significant improvement in NAAT machine utilisation and testing output along with an increase in TB case notifications in the comparable study period (Figure 1). Statistical analysis using SPSS ver 22 also confirmed the association between network optimisation (increased NAAT testing) and increased TB notification ($p < 0.05$).

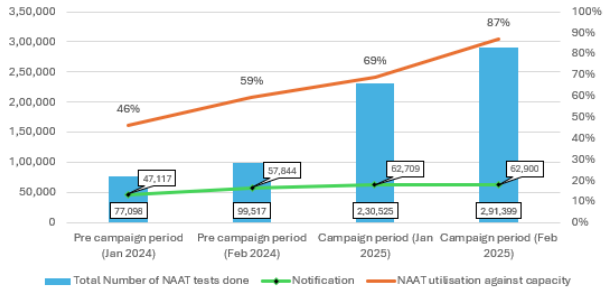

Figure 1. NAAT testing and utilization - Pre campaign & during campaign in Uttar Pradesh.

Conclusions: Diagnostic Network Optimization has significantly enhanced the molecular testing capacity and utilization rates in Uttar Pradesh. This scalable strategy is a replicable model for resource-limited high-burden states, contributing effectively to India's goals for tuberculosis elimination.

EP02-716-18 Impact of diagnostic network optimisation on TB diagnostic capacity and detection in high-burden setting: A comparative study from Delhi, India

D. Ashraf,[1] N. Saini,[1] D. Mani,[1] U. Singh,[2] S. Chandra,[3] T. Talukdar,[4] P.K. Yadav,[3] L. Aravindakshan,[3] M. Bhowmik,[3] Z. Siddiq,[5] N. Babbar,[5] K. Venkatesan,[3] [1]Government of Delhi, Department of Health & Family Welfare, Delhi, India, [2]Government of India, Ministry of Health & Family Welfare, Delhi, India, [3]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, Delhi, India, [4]Vardhman Mahavir Medical College & Safdarjung Hospital, Department of Chest Diseases and TB, Delhi, India, [5]Government of Delhi, Delhi State Health Mission, Delhi, India
e-mail: aravindanl@rntcp.org

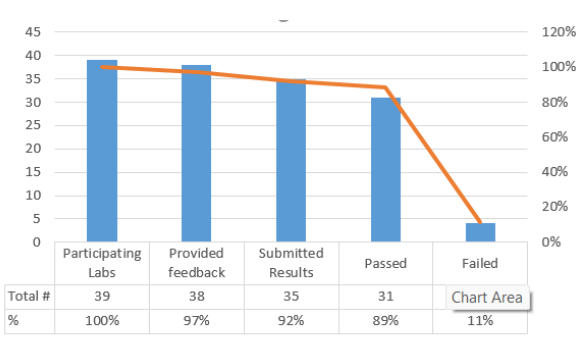
Background and challenges to implementation: Delhi, with tuberculosis (TB) prevalence rate of 747 cases per 100,000 population, is implementing upfront Nucleic Acid Amplification Test (NAAT) within framework of national TB program. However, progress is often impeded by suboptimal utilization of existing diagnostic infrastructure.
A Diagnostic Network Optimization (DNO) exercise was conducted during India's 100-day intensified TB case-finding campaign, aimed to evaluate and enhance utilization of NAAT infrastructure.
The study aims to conduct a comparative assessment of impact of DNO on utilization of existing NAAT capacity and detection of TB during two distinct periods: the pre-campaign phase (December 7, 2023, to March 24, 2024), and campaign phase (December 7, 2024, to March 24, 2025), without any capacity expansion.

Intervention or response: A state-wide assessment indicated that total of 1,266 NAAT could be conducted daily under full operational capacity.
This finding informed planning and implementation strategies, with interventions like
i. Redistribution of sputum samples as per optimal testing capacity,
ii. Improved availability of testing cartridges, and;
iii. Reassignment of laboratory technicians for additional work shifts.
These measures were designed to reduce testing backlog and maximize diagnostic yield within brief timeframe. A retrospective comparison was conducted utilizing data extracted from laboratory reports and Ni-kshay (India's digital TB surveillance system) and analyzed using SPSS ver22.
Results/Impact: During study period, NAAT utilisation increased from 25,801 tests to 66,462 tests (158%) and total TB diagnosed increased from 6,777 to 11,832 (75%). A two-proportion Z-test showed increase in proportion of TB cases diagnosed was statistically significant ($z = 28.76$, $p < 0.001$), indicating true improvement in case detection rather than random variation.
Conclusions: Delhi's proactive and targeted optimization of NAAT diagnostic capacity enabled significant increase in TB case-detection during 100-day intensified TB case-finding campaign. This model of leveraging existing diagnostic infrastructure through data-driven planning offers replicable approach for other high-burden urban settings in resource-limited scenarios.

EP02-717-18 A pilot study on external quality assessment using dried tube spot samples on the Truenat platform in Nigeria: Results and lessons learnt

R. Akpakpan,[1] J.O. Olabamiji,[2] K. Abba,[3] E. Ubochioma,[4] E. Emeka,[5] A. Tubi,[4] I. Ahmadu,[3] A. Agbaje,[6] B. Odume,[7] N. Nwokoye,[8] M. Emenoge,[9] T. Ibrahim,[10] [1]National Tuberculosis, Leprosy and Buruli Ulcer Control Program, Laboratory, Abuja, Nigeria, [2]Molbio Diagnostics Limited, International Sales, Lagos, Nigeria, [3]National Tuberculosis, Leprosy and Buruli Ulcer Training Centre, Laboratory, Zaria, Nigeria, [4]National Tuberculosis, Leprosy and Buruli Ulcer Control Program, Program Management Unit, Abuja, Nigeria, [5]Federal Ministry of Health, Medical Laboratory Science Division, Abuja, Nigeria, [6]Institute of Human Virology, Nigeria, Office of CEO, Abuja, Nigeria, [7]KNCV, Nigeria, Office of the CEO, Abuja, Nigeria, [8]KNCV, Nigeria, Laboratory, Abuja, Nigeria, [9]Weierstrass Michael Universal Solution Company Limited, Office of the CEO, Kano, Nigeria, [10]The Global Fund, CCM, Abuja, Nigeria
e-mail: ritainiobong@yahoo.com

Background and challenges to implementation: External Quality Assessment (EQA) is critical for ensuring the accuracy and reliability of diagnostic testing, particularly in decentralized settings. This pilot study aimed to evaluate the feasibility and performance of using Dried Tube Spot (DTS) samples for EQA in sites utilizing the Truenat platform for molecular diagnostics in Nigeria.
Intervention or response: A total of 39 sites participated in the pilot EQA program in March 2024(Q1). DTS panels were distributed to all sites, and participants were required to analyze the samples using the TrueNat system and submit their results. Performance indicators, including participation rate, result submission, pass/fail rates, and reported challenges, were assessed to determine the effectiveness of the approach.
Results/Impact: Out of 39 participating sites, 38 (97.4%) provided feedback, and 35 (92%) successfully submitted their results. Among those, 31 sites (89%) achieved a passing score, while 4 sites (11.4%) did not meet the required performance standards. Additionally, 3 sites (8%) reported challenges without submitting complete results, and 1 site (3%) did not provide any feedback. Importantly, all sites received their DTS panels, and no sites were excluded from the evaluation.



Conclusions: This pilot study demonstrates that DTS-based EQA is a feasible and effective approach for performance monitoring of TrueNat-based molecular diagnostics in Nigeria. The high participation and result submission rates indicate strong engagement, while the observed failure rates highlight the need for continued training and support. Scaling up DTS-based EQA could enhance quality assurance in molecular testing programs, contributing to improved disease diagnosis and surveillance.

EP02-718-18 Optimal utilisation of NAAT devices by strengthening population accessibility between NAAT labs and peripheral health centrers in Maharashtra, India

H. Vashistha,[1] S. Sangle,[2] M. Das,[3] P. Lakare,[1] M. Kolle,[1] A. Kadu,[4] P. Jadhav,[2] A. Debadwar,[2] P. Singh,[1] A. Beri,[1] S. Kumta,[5] S. Chadha,[6] [1]Foundation for Innovative Newer Diagnostics, Project Management, Pune, India, [2]State TB Cell, Administrative, Pune, India, [3]Foundation for Innovative Newer Diagnostics, Project Management, Delhi, India, [4]WHO, Public Health, Pune, India, [5]Gates Foundation, Tuberculosis, Mumbai, India, [6]Foundation for Innovative Newer Diagnostics, Access, Delhi, India
e-mail: drhimanshuvashistha@gmail.com

Background and challenges to implementation: Nucleic Acid Amplification Test (NAAT) devices have revolutionized the diagnosis of tuberculosis (TB) and other respiratory infections by offering rapid and accurate detection. However, their optimal utilization remains a challenge, particularly in resource-limited settings like India where population accessibility is constrained. This study aims to enhance the NAAT device utilization by strengthening population accessibility between NAAT labs and peripheral health centers (PHC). We utilize the Diagnostic network optimization (DNO) model that maximizes device throughput while minimizing patient turnaround time (TAT) in Maharashtra state.

S#	Parameters	MH Baseline model (Year 2023) - DMC to NAAT	MH Baseline (Year 2024) - DMC to NAAT	% Change in Baseline (2023 Vs 2024)
1	NAAT utilization Vs capacity (%)	NAAT Test - 4,94,329 Testing Capacity - 14,34,600 Utilization - 34.46 %	NAAT Test - 9,85,446 Testing Capacity - 21,58,200 Utilization - 45.66 %	NAAT test increased = 99.35% Testing Capacity increased= 50.4% Utilization increased = 32.5%
2	Average service distance (ASD) from PHC/SC to NAAT site	22.61 Km	12.57 Km	44.41%
3	Average time for sample transportation from PHC/SC to NAAT site (in minutes)	33.92 Min	18.86 Min	44.4%
4	Average sample transportation cost from PHC/SC to NAAT site	21,919.92 (INR)	16,857.51 (INR)	23.1%

Table.

Intervention or response: A geospatial analysis was conducted using software tools like Dxgeomap and ArcGIS with feeding in the data of TB prevalence taken from State TB cell and healthcare facility locations in all districts (36) of Maharashtra. Mapping was conducted based on 30-minute driving time to the nearby TB testing facility in the district.

Diagnostic network Labs were also assessed by conducting in person visits to DMC sites and linked NAAT labs, using predefined checklist based on evaluating the on-ground situation of sample transportation time, testing capacity, and result reporting turnaround.

Results/Impact: Baseline data analysis from year 2023 and 2024 (Table 1) indicate that implementing DNO approaches can reduce sample transportation delays from DMC to NAAT labs by up to 44.4%, improving timely diagnosis and initiation of treatment. Saturating NAAT devices in the state and linking the peripheral health centres to optimized hubs showing a 99.35% increase in NAAT tests, ensuring better utilization of NAAT devices and resulted in reduction of average service distance (ASD) by 44.41%.

Additionally, sample transportation cost was significantly reduced by 23.10%, facilitating affordable TB/DRTB management.

Conclusions: This DNO model enhances device utilization, reduces diagnostic delays, and improves early TB/DRTB detection. Future scalability of this approach requires integrated healthcare network, policy support, digital tracking systems, and investment in sample transport networks for efficient NTEP service delivery.

EP03 Childhood TB: Prevention and treatment for drug-susceptible and resistant TB

EP03-719-18 Optimising child-friendly TB prevention regimens: Qualitative insights from Ethiopian interest-holders

C. Mulder,[1] A. Bergman,[2] F. Mulatu,[3] R. Chaisson,[4] G. Churchyard,[5] A. Bedru,[3] D. Kerrigan,[6] N. Salazar-Austin,[7]
[1]KNCV Tuberculosis Foundation, TB Elimination & Health System Innovations, The Hague, Netherlands, [2]University of Virginia School of Nursing, Office of Nursing Research, Charlottesville, United States of America, [3]KNCV Ethiopia, KNCV Ethiopia, Addis Ababa, Ethiopia, [4]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States of America, [5]The Aurum Institute, The Aurum Institute, Johannesburg, South Africa, [6]George Washington School of Public Health, Department of Preventive Medicine, Washington, United States of America, [7]Johns Hopkins University School of Medicine, Department of Pediatrics, Baltimore, United States of America
e-mail: christiaan.mulder@kncvtbc.org

Background: The World Health Organization recommends short rifamycin-based tuberculosis preventive treatment (TPT) regimens in children. Attributes determining regimen acceptability remain poorly understood. We explored perceptions towards 3HP and 3RH among key informants recently engaged with TB prevention services in Ethiopia.

Design/Methods: Forty-seven in-depth interviews were conducted with caregivers of TB-exposed children, community health workers (CHWs), healthcare providers, and policy makers after the completion of the CHIP-TB trial, a programmatic, cluster-randomized trial designed to evaluate home-based TPT services delivered by CHWs.

We used thematic content analysis, using both a deductive and inductive approach, assessing acceptability based on palatability, ease of ingestion, dosing frequency, pill burden, adherence, side effects, and tolerability.

Results: Caregivers reported good palatability for both 3RH and 3HP, although some caregivers mentioned that their children vomited or wanted to spit out the medication. Dosing frequency was a crucial factor influencing acceptability, eliciting mixed responses—while all stakeholder groups acknowledged that weekly doses were easier to forget, targeted messaging and implementation strategies were employed to support adherence.

Conversely, 3RH daily dosing was considered burdensome and caregivers expressed difficulties forcing their children to take medication every day. Policy makers and providers demonstrated greater acceptance and preference for prescribing 3HP over 3RH, however, the higher number of loose pills per dose in the 3HP regimen was cited as a disadvantage, and the need for a fixed-dose,

child-friendly formulation was raised. Across both regimens, interest-holders reported generally mild side effects that did not result in treatment discontinuation.
Conclusions: While interest-holders generally preferred the 3HP regimen over 3RH for children due to its reduced dosing burden, they also highlighted the challenge posed by the higher number of pills per dose. Incorporating the preferences of children and their caregivers will be essential in developing child-friendly formulations that support better uptake, adherence, and improved treatment outcomes.

EP03-720-18 Effectiveness of strengthening frontline workers in enhancing TPT uptake among child contacts

A. Okungbure,[1] A. Agbaje,[2] C. Mensah,[2] P. Dakum,[2] O. Daniel,[3] A. Alege,[4] M. Pedro,[5] O. Akaniro,[6] S. Labaran,[6] R. Eneogu,[7] D. Nongo,[7] [1]Institute of Human Virology, Prevention, Care and Treatment, Lagos, Nigeria, [2]Institute of Human Virology, Office of the CEO, Abuja, Nigeria, [3]Institute of Human Virology, Prevention Care and Treatment, Ikeja, Nigeria, [4]Society for Family Health, Community, Ikeja, Nigeria, [5]Institute of Human Virology, Strategic Information, Ikeja, Nigeria, [6]National Tuberculosis Leprosy and Buruli Ulcer Control Program, Public Health, Abuja, Nigeria, [7]United States Agency for International Development, Office of HIV and TB, Abuja, Nigeria
e-mail: aokungbure@ihvnigeria.org

Background and challenges to implementation: The prescription and TPT uptake among child TB contacts (0–14 years) remains low, with declining trends over time. Supportive supervision revealed major gaps in contact tracers' capacity for identifying and managing eligible children. Strengthening frontline workers is crucial to improve timely TPT initiation and reduce TB incidence in this vulnerable group.
Intervention or response: In four Southwestern states of Nigeria, contact tracers under the Institute of Human Virology Nigeria (IHVN) were trained on effective counselling techniques, as well as the identification and mobilization of eligible child contacts (ages 0–14) for Tuberculosis Preventive Therapy (TPT). These trained personnel operate across designated public and private health facilities in 93 Local Government Areas (LGAs).
This capacity-building intervention was assessed by comparing TPT uptake among child contacts during two identical 12-month periods: October 2022–September 2023 (pre-training) and October 2023–September 2024 (post-training).
The study aimed to measure the impact of the training on TPT initiation rates in both public and private health sectors. Routine monitoring assessed the impact of training on TPT uptake indicators.
Results/Impact: Following the training intervention, TPT uptake among eligible child contacts (ages 0–14) showed a significant improvement. In private health facilities, enrolment increased from 28% in September 2023 to 61% in September 2024. Similarly, in public facilities, uptake more than doubled, rising from 25% to 56% over similar period.

CHILDREN CONTACT TPT UPTAKE 2023					CHILDREN CONTACT TPT UPTAKE 2024				
Age	0-4 yrs		5-14yrs			0-4 yrs		5-14yrs	
Facility type	CI-Private	CI-Public	CI-Private	CI-Public	Facility type	CI-Private	CI-Public	CI-Private	CI-Public
# of contacts eligible for TPT	581	2534	1770	9082	# of contacts eligible for TPT	720	3546	2131	11127
Facility type	CI-Private	CI-Public	CI-Private	CI-Public	Facility type	CI-Private	CI-Public	CI-Private	CI-Public
Total enrolled on TPT	240	105	419	2817	Total enrolled on TPT	474	2067	1252	6190
%	41%	4%	24%	31%	% improvement	66%	58%	59%	56%

Conclusions: Strengthening the capacity of the contact tracers significantly improved and increased TPT uptake in eligible children 0 - 14 years identified in the private and public health facilities. The observed increase in TPT uptake underscores the effectiveness of capacity-building interventions in enhancing pediatric TB prevention outcomes. These findings suggest that strengthening the skills of frontline health workers can substantially improve TPT coverage and contribute to more effective TB control in child contacts.

EP03-721-18 Closing the gaps in TB preventive therapy for under-6 child contacts in Enugu State, Nigeria: A 4-year review

J. Ikebudu,[1] R. Odo,[1] C. Onaga,[1] S. Madubuike,[1] [1]Ministry of Health, Department of Public Health and Disease Control, Enugu, Nigeria
e-mail: princessjoy7210@gmail.com

Background: Tuberculosis Preventive Therapy (TPT) is critical in reducing the risk of progression from latent TB infection to active TB disease, especially among high-risk groups like under-6 child contacts of TB cases. Despite its importance, TPT implementation in Nigeria remains suboptimal. This study assesses the 4-year trend (2015–2018) of TPT provision for under-6 child contacts in secondary and primary TB health facilities in Enugu State, Nigeria. The state has an estimated 5,383,817 population and 5 % case findings for children.
Design/Methods: A retrospective desk review of routine TB program data was conducted. Data were analysed using Microsoft Excel to derive counts, means, and proportions. The TB contact investigation cascade — 770 from identification to initiation of TPT—443 was evaluated.

Results: During the study period, 5,200 bacteriologically confirmed index TB cases were notified. A total of 770 under-6 child contacts were identified (an average of 0.1 child per index case), of which 660 were screened. Of those screened, 574 were eligible for TPT, and 443 were initiated on TPT. However, 327 children (13%) were lost across the cascade, from identification to TPT commencement—averaging 82 annually.
Additionally, 196 children (10%) were either not screened or found ineligible for TPT. Only 59 TB cases were notified in the 0–4 age group during the period. A steady increase in TPT coverage was observed from 2015 to 2018, with the highest number of contacts (268) identified and 131 initiated on TPT in 2018.
Conclusions: There is significant attrition of under-6 child contacts across the TPT cascade in Enugu State. Strengthening TB contact tracing, provider sensitization, mandatory and free chest X-rays for children, and integrating child TB indicators into routine reporting are essential. Improved tracking and caregiver engagement are critical to achieving global TB prevention goals.

EP03-722-18 Paediatric drug-resistant TB prevention in resource-limited settings: Mozambique's experience with levofloxacin prophylaxis

C.M. Mutemba,[1,2] I. Munyangaju,[3,2] B. José,[1,2] [1]Ministry of Health, National Tuberculosis Control Program, Maputo, Mozambique, [2]Mozambique National Paediatric TB Working Group, Paediatric TB, Maputo, Mozambique, [3]Barcelona Institute for Global Health, Clinical Research, Maputo, Mozambique
e-mail: cmbatemutemba@gmail.com

Background and challenges to implementation: Children exposed to multi-drug-resistant tuberculosis (MDR-TB) face high risks of disease progression. In 2021, Mozambique introduced a six-month levofloxacin-based TB preventive therapy (TPT). This operational evaluation analyses the programmatic cascade and treatment outcomes to inform TB elimination efforts.
Intervention or response: We conducted a national retrospective analysis of children (0–14) treated for MDR-TB infection from 2022–2024. Data from patient records, national TB registers, and monthly aggregated reports were analysed in Stata 18.0, covering the TPT cascade and outcomes. Eligibility followed National TB Program guidelines.
Results/Impact: During the period, 4,679 MDR-TB index cases were reported in Mozambique, with 1,437 child contacts (0–14 years) identified and 1,386 (96.4%) screened. Of these, 907 (65.4%) were eligible and initiated on Levofloxacin-based TPT, with annual uptake increasing from 63 (2022) to 443 (2023) and 401 (2024). Poisson regression confirmed a significant upward trend ($p < 0.0001$), with an estimated 81% annual increase. The cohort had a mean age of 7.2 years (SD ±3.9), 41.6% were female (n=377), and HIV co-infection was rare (0.2%, n=2), both cases on ART. Among the 907, 684 (75.4%) completed treatment, 148 (16.3%) were still on treatment, 53 (5.8%) lost to follow-up, 8 (0.9%) active TB, and 2 (<0.5%) died.
Limitations: Data quality was limited by inconsistent records and a 23.8% discrepancy between sources, potentially impacting cascade accuracy. Contextual factors (e.g., socioeconomic status, access barriers, adherence, or adverse events) that may influence outcomes, were not assessed. The retrospective design limited causal inference and implementation insights.

Total child contacts (0-14yrs) / MDR-TB index cases	**1,437 / 4,679**	
Total child contacts screened	1,386	96.4%
Total child contacts eligible for TPT	907	65.4%
Total child contacts initiated on TPT	907	100%
TPT Outcomes: Completed TPT	684	75.4%
Still on treatment	148	16.3%
Lost to follow-up	53	5.8%
Developed active TB	8	0.9%
Death	2	0.22%
Not evaluated	12	1.3%

Table 1: Levofloxacin-based TPT cascade, 2022-2024.

Conclusions: Mozambique's levofloxacin-based TPT program achieved high screening coverage (96.4%) and met WHO completion targets (>75%), showing feasibility in routine care. However, a 65.4% initiation rate (vs. WHO ≥90%) reveals gaps. Strengthening digital reporting, decentralising TPT to community-based level, and addressing knowledge gaps can reduce loss to follow-up and improve initiation.

EP03-724-18 Revolutionising childhood TB treatment: Programmatic implementation and rollout of the four-month shorter treatment regimen for drug-susceptible childhood TB in Zambia

A. Kachuka,[1] C. Chabala,[2] R. Chimzizi,[1] C. Chanda,[1] M. Kabaso,[1] C. Kasapo,[1] K. Zimba,[3] C. Kunda,[4] M. Nachamba,[5] M. Muyangana,[6] C. Mwiinga,[7] A. Mubanga,[8]
[1]Ministry of Health, National TB and Leprosy Program, Lusaka, Zambia, [2]The University of Zambia, School of Medicine, Department of Peadiatrics, Lusaka, Zambia, [3]United States Agency for International Development-Zambia, Clinical Care, Lusaka, Zambia, [4]Provincial Health Office, Public Health, Lusaka, Zambia, [5]Arthur Davison Children's Hospital, Paediatric Department, Lusaka, Zambia, [6]TBLON- Centre for Infectious Disease Research in Zambia, TB department, Lusaka, Zambia, [7]University Teaching Hospital, Children's hospital, Lusaka, Zambia, [8]Ministry of Health, National TB and Leprosy Program, Public Health, Lusaka, Zambia
e-mail: alankachuka@gmail.com

Background and challenges to implementation: Childhood tuberculosis (TB) has traditionally been treated using a six-month regimen, often associated with adherence challenges. In 2022, the WHO recommended a four-month Shorter Treatment Regimen (STR) for children with non-severe drug-susceptible TB (DS-TB). Zambia adopted the STR into its National Consolidated TB Guidelines to improve treatment outcomes.
Intervention or response: Zambia began a phased rollout of the STR in 2023, using an implementation framework that included training, mentorship, and data tools. The pilot covered Lusaka and Copperbelt provinces, involving 4 tertiary hospitals, 8 first-level hospitals, and 14 primary health centers. Nationwide rollout began in 2024, supported by hybrid training and mentorship. Data were collected through routine reports, facility surveys, and healthcare worker (HCW) interviews. Key indicators included treatment initiation, regimen adherence, adverse events, and HCW readiness.
Results/Impact: Between May 2023 and December 2024, over 2,000 HCWs were trained across 90 of 116 districts. In 2023, 26 pilot facilities reported 528 childhood TB cases, with 109 non-severe cases, of which 91% were initiated on STR. By June 2024, cumulative cases for 2024 rose to 706, with 71% of eligible non-severe cases started on STR. Following national rollout in mid-2024, 375 additional cases were diagnosed, with 75% of eligible children initiated on STR. By the end of 2024, 1,987 cases were reported, with 84% of non-severe cases receiving STR. HCWs demonstrated competence in differentiating non-severe from severe TB, contributing to high STR initiation rates. Challenges included training gaps, limited caregiver awareness, low HCWs confidence levels and inadequate Chest x-ray interpretation skills. Facilities with strong TB management systems integrated STR better.
Conclusions: Zambia's implementation of STR has proven feasible, acceptable, and sustainable. Key to its success are the integration into national guidelines, continuous mentorship, and a strong TB management system. The STR offers an opportunity for scaling TB treatment improvements in low- and middle-income countries (LMICs).

EP03-725-18 Urine biomarker assessment of adherence to TB treatment in children enrolled in a prospective cohort study in a high-burden setting

L. Njagi,[1] D. Onyango,[2] J. Mecha,[1] J. Githua,[1] M. Musyoka,[1] Y.-H. Hsu,[3] A. Kim,[3] N. Panpradist,[3] E. Maleche-Obimbo,[4] V. Nduba,[1] S. LaCourse,[5,6,7] D. Leon,[3]
[1]Kenya Medical Research institute, Center for Respiratory Disease Research, Nairobi, Kenya, [2]Kisumu County, Department of Health, Kisumu, Kenya, [3]University of Washington, Department of Bioengineering, Seattle, United States of America, [4]University of Nairobi, Department of Paediatrics and Child Health, Nairobi, Kenya, [5]University of Washington, Department of Global Health, Seattle, United States of America, [6]University of Washington, Department of Medicine, Division of Allergy and Infectious Diseases, Seattle, United States of America, [7]University of Washington, Department of Epidemiology, Seattle, United States of America
e-mail: njagi.lilian@gmail.com

Background: Tuberculosis (TB) treatment efficacy depends on adherence, but objective adherence data in children are limited. We report preliminary results from a diagnostic study that assessed children on TB treatment using caregiver reports and a urine dipstick that changes color when INH metabolites are detected within 48 hours of intake.
Design/Methods: Among children aged ≤15 who initiated standard 6-month treatment for drug-sensitive TB in a prospective cohort study in Nairobi, Kenya, with available urine samples, we assessed adherence using caregiver reports and urine dipstick tests during study visits corresponding to weeks 2, 4, 8, 16, and 24 of TB treatment. Optimal caregiver-reported adherence was defined as the reported ingestion of ≥80% of prescribed pills over all the visits. Consistent biomarker-confirmed adherence was defined as having a positive biomarker test at all visits. We compared caregiver-reported adherence with biomarker results and evaluated correlates of biomarker-confirmed non-adherence. We used generalized estimating equations to evaluate the correlates of negative biomarker tests at each visit.
Results: Among 188 children of median age 4.4 years (IQR 2.7, 7.1), 436 biomarker assessments were conducted (median 3 assessments (IQR 2, 4)/child). Biomarker-confirmed adherence was identified in 79.8% (348/436) of assessments. While 87.2% of caregivers (164/188) report-

ed optimal adherence, consistent biomarker-confirmed adherence was observed in 63.3% (119/188) children. Of 164 children with optimal caregiver-reported adherence, 94.9% (n=150) had at least one positive test, and 62.8% (n=103) had consistent biomarker adherence.
The concordance between caregiver-reported and consistent biomarker adherence results was 61.1% (kappa=-0.021, p=0.76). Caregiver reports of missed doses since the last study visit showed a trend for being associated with negative biomarker tests (risk ratio [RR] 0.71; 95% CI 0.49-1.01, p=0.059).
Conclusions: Biomarker-confirmed adherence was modest (63.3%) and differed substantially from caregiver-reported adherence (87.2%). Additional efforts are needed to support adherence, especially among children whose caregivers report missed doses.

EP03-726-18 Integrating paediatric drug-resistant TB into primary care: Mozambique's decentralisation strategy and its impact on detection

C.M. Mutemba,[1,2] I. Munyangaju,[3,2] B. José,[1,2] [1]Ministry of Health, National Tuberculosis Control Program, Maputo, Mozambique, [2]Mozambique National Paediatric TB Working Group, Paediatric TB, Maputo, Mozambique, [3]Barcelona Institute for Global Health, Clinical Research, Maputo, Mozambique
e-mail: cmbatemutemba@gmail.com

Background and challenges to implementation: Paediatric drug-resistant tuberculosis (DR-TB) is historically under-diagnosed and under-treated in high-burden settings due to limited diagnostic access and centralised care models. In 2017, Mozambique's National TB Program launched a national decentralisation strategy to improve paediatric DR-TB detection and access to care.
Intervention or response: We conducted a retrospective national program evaluation using routine surveillance data from 2017 to 2024.
The decentralisation strategy included three pillars: (1) health system integration of TB screening into Integrated Management of Childhood Illness (IMCI) protocols, nutrition programs, and mandatory screening for all children living with HIV (CLHIV) at follow-up visits, supported by training 4,372 frontline providers in paediatric TB screening and simplified diagnostic algorithms; (2) diagnostic expansion through Xpert MTB/RIF Ultra deployment to 120 sites, with standardised training in sample collection including stool-based testing and specimen referral systems; and (3) community-based detection through training 2,400 community health workers in household contact tracing.
Results/Impact: Paediatric DR-TB case notifications increased from 34 (3.6% of total DR-TB cases) in 2017 to 122 cases (8% of total DR TB cases) in 2023. Improvements were also observed in early case detection and access in rural areas, though quantitative data on time to diagnosis and treatment initiation were not captured.
Limitations: The evaluation used routine program data, which may be affected by reporting inconsistencies, data incompleteness, and misclassification. The lack of a control group limits causal inference, and variations in implementation fidelity across provinces were not systematically assessed.

Year	Total MDR TB cases	MDR TB cases 0-14 years	% MDR TB in children among total cases
2017	953	34	3.6%
2028	1206	60	5.0%
2019	1388	88	6.3%
2020	1364	95	7.0%
2021	1366	78	5.7%
2022	1441	100	6.9%
2023	1685	150	8.9%
2024	1533	122	8.0%

Table 1: Trends in Pediatric and Total MDR-TB case notification, Mozambique, 2017-2024.

Conclusions: Decentralising paediatric DR-TB services through health system integration, diagnostic expansion, and community-based approaches significantly improved case detection in Mozambique. This model offers a scalable framework for improving paediatric DR-TB outcomes and reducing inequities in similar high-burden settings.

EP03-727-18 Trends in the management and outcome of paediatric multi-drug-resistant TB in Namibia from 2013 to 2023: A review of national registry data

I. Burkhardt,[1] M. Iitana,[2] N. Ruswa,[3] H. Ekandjo,[4] M. Claassens,[4] E. Nepolo,[4] J. Seddon,[5,6] G. Günther,[7,4] [1]University Hospital of Bern, Division of Paediatric Infectious Diseases, Bern, Switzerland, [2]Katutura Intermediate Hospital, Department of Paediatrics, Windhoek, Namibia, [3]Ministry of Health and Social Services, National Tuberculosis and Leprosy Programme, Windhoek, Namibia, [4]University of Namibia, Faculty of Health Sciences and Veterinary Medicine, Windhoek, Namibia, [5]Stellenbosch University, Department of Paediatrics and Child Health, Cape Town, South Africa, [6]Imperial College London, Department of Gloabl Child Health, London, United Kingdom of Great Britain and Northern Ireland, [7]University Hospital of Bern, Department of Pulmonology, Bern, Switzerland
e-mail: burkhardt.ingrid@gmail.com

Background: Namibia has a high-burden of tuberculosis (TB) and childhood TB with multidrug-resistant (MDR) TB posing additional challenges. Recent advances led to the introduction of Xpert MTB/RIF as first-line diagnostic test and new and repurposed drugs for the treatment of

MDR-TB which are associated with favourable outcome.
Design/Methods: Retrospective review of Namibian national registry data from 2013 to 2023 of children aged 0-14 years with MDR-TB. National census data were used to estimate annual case notification rates (aCNRs).
Results: 217 episodes were available for analysis. The median age was 4 years (IQR 1-10). 120 (55.3%) were female and 21 (9.7%) were living with HIV. 168 (91.3%) were classified as MDR-TB with only 2 XDR and no pre-XDR cases. The aCNR increased by 75% from 1.2 in 2013 to 2.1 per 100,000 population in 2023. The treatment duration significantly decreased from a median duration of 19 months (IQR 19-23) to 11 months (IQR 9-13), respectively ($p < 0.001$). 98 individuals (59.4%) received a treatment regimen containing injectables, whereas 67 (40.6%) received an all-oral treatment regimen containing two or more WHO class A drugs and/or delamanid. By 2021 only all-oral regimens were used (fig. 1a). Outcome was unfavourable in 48 (23.9%) individuals and 18 (9%) died. The proportion of children with unfavourable outcome, and those who died, did not decrease over time (fig. 1b). There was no significant association between year of registration or treatment regimen and outcome.

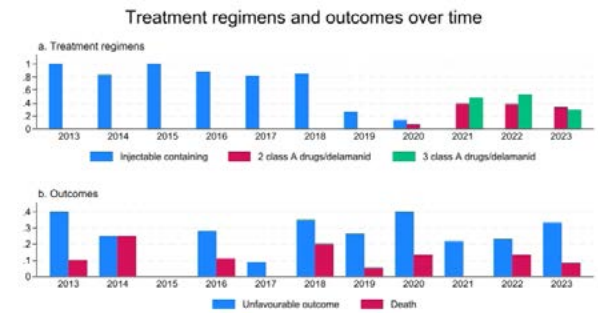


Figure 1: Panel a. shows the porportion of children who received standard regimens for multidrug-resistant tuberculosis containing injectables (blue), 2 class A drugs/delamanid (red) or 3 class A drugs/delamanid (green). Panel b. shows the proportion of children with unfavourable outcome (indluding death) (blue) and the proportion of children who died (red).

Conclusions: Whilst the proportion of children with unfavourable outcome and death are in keeping with internationally observed levels, both did not decrease over the study period despite the introduction of Xpert MTB/RIF in 2017 and new oral treatment regimens. Other factors along the paediatric MDR-TB care cascade potentially limiting the benefits of a rapid diagnosis of MDR-TB and newer treatment regimens should be assessed.

EP03-728-18 Pharmacokinetics and safety of clofazimine in children with rifampicin-resistant TB with novel dosing schedule

M. Boczar,[1] E. Nortier,[2] J.A. Hughes,[2] A. Garcia-Prats,[3] H. Draper,[2] J.-N. Van der Westhuizen,[2] A. Carelse,[2] A. Faraj,[1] E.M. Svensson,[1,4] A.C. Hesseling,[2] [1]Uppsala University, Department of Pharmacy, Uppsala, Sweden, [2]Stellenbosch University, Desmond Tutu TB Centre (DTTC), Department of Paediatrics and Child Health, Cape Town, South Africa, [3]University of Wisconsin-Madison, Department of Pediatrics, Madison, United States of America, [4]Radboud University Medical Center, Department of Pharmacy, Nijmegen, Netherlands
e-mail: milena.boczar@uu.se

Background: Clofazimine is a routinely recommended drug for rifampicin-resistant tuberculosis (RR-TB) treatment. CFZPK2 was a phase I/II study evaluating pharmacokinetics, safety and tolerability of clofazimine in children. The dosing schedule (Table 1) was modelled based on findings from the CFZPK1 study (Hughes et al, J. Infect. Dis., 2025). The study aim was to evaluate exposure and safety of the revised dosing schedule using a clofazimine tablet formulation.

WHO weight bands	Clofazimine dose	Dosing frequency
3 to < 5 kg	15 mg	Daily
5 to < 7 kg	20 mg	Daily
7 to < 10 kg	25 mg	Daily
10 to < 16 kg	40 mg	Daily
16 to < 24 kg	50 mg	Daily
24 to < 30 kg	75 mg	Daily

Table 1. Dosing schedule.

Design/Methods: Children receiving <12 weeks of routine RR-TB treatment were enrolled. Participants receiving clofazimine gel capsule formulations (Novartis) in routine care switched to a daily-dosed clofazimine tablet (Macleods) dispersed in water. Six pharmacokinetics samples were collected over 24 hours at 2 and 12 weeks on study. Data were analysed using population pharmacokinetic modelling including standard allometric scaling. Adverse events were monitored over the 12-week study period.
Results: Twelve children with median age 2.8 (range 0.6-8.2) years and median weight 12.1 (range 7.77-29.6) kg were enrolled. A published two-compartment model, with first-order absorption and elimination described the data well, but using a proportional error model. The median maximal concentration and time to maximal concentration was 1.08 (range 0.464-1.53) µg/mL and 8.17 (range 7.42-8.59) h, respectively. The predicted median weekly steady state area-under-the curve ($wAUC_{ss}$) was 107 (range 76.7-273) mg*h/L, while the predicted $AUC_{0-24h,week\ 2}$ and $AUC_{0-24h,week12}$ was 14.7 (range 4.23-45.2)

mg*h/L and 22.9 (range 10.0-34.0) mg*h/L, respectively. There were two severe adverse events (hepatotoxicity, skin hyperpigmentation) possibly related to clofazimine, but no clofazimine-related serious adverse events. There were five instances of QTcF prolongation of >460-<480 ms in three participants.

Conclusions: The median $wAUC_{ss}$ (107 mg*h/L) was closer to the previously defined adult target of $wAUC_{ss}$ (112 mg*h/L) than that reported in CFZPK1 ($wAUC_{ss}$ 163 mg*h/L). This suggests that the revised clofazimine dosing schedule is more appropriate for children with RR-TB but requires further evaluation.

EP04 Strenghtening laboratory systems for TB management

EP04-729-18 Operational challenges in TB laboratory networks: An analysis of delays in specimen processing and result reporting

J. Ogwu,[1] T. Adetiba,[2] E.J. Ikeh,[2] I. Ahmadu,[3] V. Ajuka-Patrick,[4] O. Olupitan,[2] C. Mensah,[5] P. Dakum,[6] R. Iniobong,[7] O. Chijioke- Akaniro,[7] J. Kimeu,[8] M. Zamzu,[8] GF NTHRIP Group [1]Institute of Human Virology Nigeria (IHVN), Laboratory, Abuja, Nigeria, [2]Institute of Human Virology Nigeria (IHVN), Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria, [3]National Tuberculosis and Leprosy Training Centre, Zaria, Laboratory, Abuja, Nigeria, [4]Institute of Human Virology Nigeria (IHVN), International Research Centre for Excellence, Abuja, Nigeria, [5]Institute of Human Virology Nigeria (IHVN), Office of the COO, Abuja, Nigeria, [6]Institute of Human Virology Nigeria (IHVN), Office of the CEO, Abuja, Nigeria, [7]National Tuberculosis, Leprosy and Buruli Ulcer Control, Public Health Department,, Abuja, Nigeria, [8]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Geneva, Nigerian Country Team, Geneva, Switzerland
e-mail: jogwu@ihvnigeria.org

Background: Efficient tuberculosis (TB) laboratory networks are critical for early diagnosis and treatment initiation. Despite Nigeria having one of the highest TB-burden globally with an estimated 452,000 incident cases in 2022, the country faces significant challenges in its diagnostic capacity, with only 30% of cases being detected through laboratory confirmation.

The fragmented nature of TB laboratory networks in Nigeria, characterized by inconsistent quality assurance systems and limited coordination between facilities, contributes to diagnostic delays. This study investigates delays in specimen processing and result reporting in TB laboratory networks in Nigeria.

Design/Methods: We abstracted time-stamped records from the Registers at the National Tuberculosis Reference Laboratory Centre Zaria covering January-December 2023 for Acid Fast Bacilli Smear Microscopy, culture, and drug susceptibility testing involving 2,347 specimens. Time-interval analysis and multivariate regression were performed using Stata version18.

Results: It was evident that there were delays in specimen processing. A median 12-day delay (IQR: 10-15) between collection and processing was experienced and 28% of specimens exceeded WHO recommended 7-day processing window.

With reporting delays, it was revealed that a median of 8-day delay (IQR: 7-10) post-processing and 22% discordance in critical result reporting times between urban and rural labs ($p<0.01$). Some of the causes of these delays included infrastructure gaps accounting for 42% of delays

(aOR=3.1, 95%CI:2.4-4.0), Staff-shortages increased processing time by 37% (p=0.003) and transportation challenges caused 2.8-day average delay per specimen.
Conclusions: This study highlights delays in specimen processing and reporting which can be addressed through a phased-intervention framework involving; immediate deployment of automated specimen tracking systems to minimize transportation delays, mid-term enhancement to rapid diagnostic capacity in high-volume laboratories, and long-term implementation of digital reporting platforms with real-time delay alerts.
These interventions can be integrated with targeted workforce expansion and continuous performance monitoring for sustained improvements in laboratory efficiency, diagnostic turnaround-time, and patient outcomes and satisfaction.

EP04-730-18 Strengthening TB diagnosis: Integrating new molecular platforms into South Africa's National TB Programme

P. Marokane,[1] M. Radebe,[1] L. Makubalo,[1] P. da Silva,[1] L. Scott,[2] W. Stevens,[2,1] [1]National Health Laboratory Service, National Priority Programme, Johannesburg, South Africa, [2]Wits Diagnostic Innovation Hub, University of Witwatersrand, Johannesburg, South Africa

Background: The National Health Laboratory Service (NHLS) has operated the Tuberculosis (TB) Molecular Programme for over a decade, initially utilizing the Cepheid GeneXpert platform with Xpert MTB/RIF and later Xpert MTB/RIF Ultra assays. Since its inception, the GeneXpert programme has processed over 27 million tests in 165 laboratories.
In 2021, following the World Health Organization's (WHO) recommendation to incorporate additional moderate-complexity molecular assays, the NHLS adopted a diversified diagnostic approach to enhance TB detection and drug resistance testing capabilities.
Design/Methods: As part of its diversification strategy, NHLS implemented a volume-based model for molecular diagnostics, introducing Roche's cobas MTB and cobas MTB-RIF/INH assays at eight high-volume sites, BD MAX MDR-TB at 74 sites, and GeneXpert Xpert MTB/RIF Ultra at 82 sites. The new assays detect both isoniazid (INH) and rifampicin resistance, crucial for optimizing TB treatment. Implementation included site assessments, instrument placement, staff training, and workflow changes. Clinical transition involved stakeholder engagement and updated TB diagnostic guidelines for smooth integration into routine care.
Results: The BD MAX MTB-MDR was implemented in November 2023, while the cobas MTB program was implemented later in May 2024 due to requirements for renovations and equipment relocation. To date, BD MAX MDR-TB has processed over 1 million tests, and the cobas MTB and MTB-RIF/INH assays have conducted over 300,000 tests, both assays reporting MTB detection rates of 6% and INH resistance ranging between 4% and 5%. Key lessons learned highlight the importance of change management, establishing communication channels to identify challenges early, and proactively addressing the complexities of evolving laboratory workflows.
Conclusions: The diversification of the TB Molecular Programme has enhanced diagnostic capacity, improved drug resistance detection, and aims to strengthen TB management within the national healthcare system.
Diversification requires change management to provide a structured approach for adapting new technologies, processes, and workflows to ensure smooth transitions.

EP04-731-18 Bridging turnaround time gaps inTB treatment initiation: Assessing the impact of Phygital training in corporate laboratory settings in India

V. Kurne,[1] S. Agarwal,[2] S. Pandey,[1] N. Sethi,[3] C. Thakur,[3] V. Abhishek Laxmalla,[3] M. Kumar,[1] N. Joshi,[1] [1]Hindustan Latex Family Planning Promotion Trust (HLFPPT), Health-TB & HIV, Noida, Delhi-NCR, India, [2]Hindustan Latex Family Planning Promotion Trust (HLFPPT), Health, Noida, Delhi-NCR, India, [3]Hindustan Latex Family Planning Promotion Trust (HLFPPT), Health-TB, Noida, Delhi-NCR, India

Background and challenges to implementation: Engaging the private sector, particularly corporate laboratories, is vital to closing the tuberculosis (TB) notification gap in India. To enhance real-time reporting, ensure data integrity, and strengthen public health linkages, a blended "phygital" (physical + digital) training program was developed and implemented.
This study evaluates its impact on laboratory performance and the turnaround time (TAT) for TB treatment initiation, contributing to the broader goal of TB elimination in India.
Intervention or response: Between November 2024 and March 2025, a structured training module was deployed across 11 corporate laboratory chains operating in 28 states. A total of 821 laboratory representatives from 437 laboratories—covering over 10,000 collection centers—were trained. The program focused on improving digital TB notifications through the Ni-kshay platform and enhancing compliance with Annexure 15A reporting protocols. A pre-post evaluation design was used, triangulating routine TB notification data with training records, documentation audits, and lab-level reporting indicators. Key outcome metrics included treatment initiation TAT, facility-appropriate PwTB enrolment, data completeness, and reporting timeliness. Statistical analyses were conducted using chi-square and paired t-tests ($p < 0.05$).

Results/Impact: Following the intervention, enrolment of PwTB at appropriate private facilities increased by 13% ($p < 0.05$). Median TAT from diagnosis to treatment initiation significantly decreased from 7 to 4 days ($p < 0.01$). Notable improvements were observed in data completeness and adherence to Annexure 15A, reflecting better linkage to early treatment. However, laboratories with high staff turnover exhibited slower improvements, underscoring the need for periodic refresher training.
Conclusions: The phygital training model demonstrated measurable improvements in TB notification practices and digital reporting compliance among private laboratories. Its scalable, adaptive design offers a promising pathway to enhance private sector accountability and expedite progress toward India's TB elimination targets.

EP04-732-18 Strengthening laboratory services for drug resistance testing of bedaquiline

N. Kumar,[1] S. Shanmugam,[2] R. Gopalaswamy,[3] S.K. Mohanvel,[3] L. Rajagopalan,[4] J. Kayesth,[4] A. Kamble,[1] U. Singh,[1] [1]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [2]ICMR-NIRT, Department of Bacteriology, Chennai, India, [3]ICMR-NIRT, Department of Bacteriology, Chennai, India, [4]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India
e-mail: kayesthj@rntcp.org

Background and challenges to implementation: A crucial component for the success of shorter, 6-9 months all-oral BPaLM regimen for the treatment of multidrug-resistant tuberculosis (MDR-TB) is the availability and accessibility of drug susceptibility testing (DST) for Bedaquiline (BDQ). To address this need, NTEP adopted a strategic approach aimed at strengthening laboratory infrastructure, building capacity, ensuring quality assurance, and establishing effective laboratory linkages for BDQ DST.
Intervention or response: Burden of drug-resistant TB (DRTB) was assessed State-wise, and capacity of existing certified laboratories was reviewed. To meet the estimated demand for DST among 63,936 MDR/RR-TB patients, gaps identified based on laboratory capacity, human resources, infrastructure, and equipment.To improve turnaround time for baseline BDQ DST and ensure geographic equity, potential laboratories in each State were evaluated. Expansion of BDQ DST was planned in phases for 62 laboratories, with a goal of at least one certified laboratory per State. Multiple laboratories were prioritized for high-burden and geographically large States.
Results/Impact: In Phase I, five National Reference Laboratories (NRLs) and 26 Culture and Drug Susceptibility Testing (CDST) laboratories were selected for capacity building. Hands-on training was conducted at SN-RL-NIRT, Chennai in November - December 2024. The programme division ensured timely supply of pure Bedaquiline drug powder to expedite the certification process. Standard Operating Procedures, diagnostic guidance, and certification protocols were disseminated to States. Continuous monitoring to ensure timely certification of laboratories to support the rollout of the BPaLM regimen.
Conclusions: Strategic implementation led to the expansion of BDQ DST services in 18 States, covering a significant proportion of the national DRTB burden. In Phase II, 17 additional laboratories identified extend services to eight more States. States with lower DRTB burden linked to certified laboratories in neighbouring States or to their respective NRLs. Until certification is achieved, patients initiated on BPaLM are linked to existing certified laboratories for baseline BDQ DST.

EP04-733-18 Diagnostic accuracy of SOS-Xpert Ultra on frozen stool samples for TB detection in rural Angola: Preliminary findings

P. Comella-del Barrio,[1,2,3] I. González-Farías,[1,4] A.N. Eugenio Etossi,[4] A. Zacarias,[4] J. Espinosa-Pereiro,[1,2] A. Sánchez-Montalvá,[1,2,5] M.T. Tórtola,[6] A. López-Suárez,[2,3] T. Sainz-Costa,[7,2] B. Santiago-García,[2,3] J. Martínez-Campreciós,[6,2] M.L. Aznar,[1,2] [1]Vall Hebron University Hospital, International Health Unit, Infectious Diseases Department, Barcelona, Spain, [2]Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red de Enfermedades Infecciosas (CIBERINFEC), Madrid, Spain, [3]Gregorio Marañón Research Institute, Gregorio Marañón Hospital, Pediatric Infectious Diseases Section, Paediatrics Department, Madrid, Spain, [4]Hospital Nossa Senhora da Paz, Infectious Diseases Department, Cubal, Angola, [5]Sociedad Española de Enfermedades Infecciosas y Microbiología Clínica, Grupo de Estudio de Micobacterias, Madrid, Spain, [6]Vall Hebron University Hospital, Microbiology Department, Barcelona, Spain, [7]Hospital La Paz, General Paediatrics, Department of Infectious and Tropical Diseases, Madrid, Spain

Background: In 2021, WHO endorsed stool testing for tuberculosis diagnosis in children using Xpert MTB/RIF Ultra (Xpert). The Simple One-Step (SOS) method offers a feasible approach in resource-limited settings, yet current protocols only validate fresh stool. In remote or low-resource areas, freezing stool before processing may be necessary due to delays from stockouts, equipment failure or transport limitations—yet current guidelines offer no recommendations for frozen specimens. We evaluated the diagnostic concordance of SOS-Xpert on frozen versus fresh stool in adults and children with presumptive TB in rural Angola.
Design/Methods: We report preliminary data from 46 patients (29 adults, 17 children) recruited at Nossa Senhora da Paz Hospital in Cubal. Each stool sample was divided into two aliquots (0.8 g or 2 mL, depending on con-

sistency per Bristol scale). One was tested fresh; the other frozen at -20 °C. Median freezing duration was 13 months (IQR: 12.4-15.5). Both aliquots were processed using SOS and analysed with Xpert.
In children, fresh stool served as an internal comparator. All had pulmonary TB-compatible symptoms; most had abnormal chest radiographs and started treatment based on clinical evaluation. In adults, respiratory Xpert results supported interpretation.
Results: Concordance between fresh and frozen stool results was high. In adults, frozen stool matched all Xpert-positive respiratory samples, which were also positive in fresh stool (sensitivity: 100.0%, specificity: 94.4%).
In children, sensitivity was 90.0% and specificity 85.7%. Three discordant cases were observed: two in children (one positive only in frozen, one only in fresh) and one in an adult (indeterminate in fresh).
This suggests potentially lower diagnostic yield in children, possibly related to the paucibacillary nature of disease and variability in stool composition.

Group	Frozen stool results	Fresh Stool result		
		Detected	Not detected	Indeterminate
Adults	Detected	11	0	0
	Not detected	0	17	1
Children	Detected	9	1	0
	Not detected	1	6	0

In adults, Xpert MTB/RIF Ultra on sputum was also available to support diagnostic interpretation. In children, fresh stool was used as the internal comparator. Discordant cases: CUA061, indeterminate in fresh, not detected in frozen; CUP017, detected in fresh, not detected in frozen; CUP090, not detected in fresh, detected in frozen ("Very Low").

Table 1. Comparison of SOS-Xpert Ultra results on fresh vs. frozen stoll samples (preliminary data)

Conclusions: Preliminary findings suggest that frozen stool processed with the SOS method shows high concordance with fresh samples and may be a practical alternative where immediate testing is not feasible.

EP04-734-18 Diagnostic performance of the FluoroType MTBDR assay for rifampicin and isoniazid resistance in routine laboratory setting

K. Kaapu,[1] I. Rukasha,[2,1] [1]University of Limpopo, Department of Pathology, Unit of Medical Sciences, Polokwane, South Africa, [2]National Health Laboratory Service, Microbiology, Polokwane, South Africa

Background: Rapid and accurate detection of *Mycobacterium tuberculosis* (M. tuberculosis) and its associated drug resistance is vital for timely treatment initiation. Recently FluoroType MTBDR was introduced, a novel molecular diagnostic test designed to detect resistance to rifampicin (RIF) and isoniazid (INH). This study aimed to evaluate the performance of the FluoroType MTBDR assay in a routine laboratory setting.
Design/Methods: 152 cryopreserved samples of drug-resistant and drug-susceptible isolates, all previously characterized using Genotype MTBDRplus were eligible for inclusion. The FluoroType results were then compared to those of Genotype MTBDRplus and GeneXpert MTB/RIF assays. Whole genome sequencing (WGS) results were available for 35 isolates and used to resolve discrepancies. WGS-based mutations were considered the final reference for determining resistance patterns in cases of discordant results. Sensitivity, specificity, negative predictive value, and positive predictive value were calculated to assess the diagnostic performance of FluoroType MTBDR.
Results: For the detection of resistance to RIF, FluoroType demonstrated a superior sensitivity of 100% (95% CI, 96-100) and a specificity of 92% (95% CI, 82-98), surpassing the performance of Genotype MTBDRplus. For the detection of resistance to INH, FluoroType achieved a sensitivity of 91% (95% CI, 77-98) and a specificity of 99% (95% CI, 95-100), both of which were higher than the corresponding values for Genotype MTBDRplus. These findings suggest that FluoroType MTBDR offers a highly accurate and reliable alternative to Genotype MTBDRplus for the detection of resistance to RIF and INH in *M. tuberculosis* isolates.
Conclusions: In conclusion, the FluoroType MTBDR assay demonstrated high sensitivity and specificity for detecting rifampicin and isoniazid resistance, outperforming Genotype MTBDRplus. Its superior diagnostic accuracy makes it a reliable alternative for routine laboratory settings, facilitating timely and precise tuberculosis drug resistance detection.

EP04-735-18 Deeplex Myc-TB-based single-nucleotide polymorphism(SNP) analysis of genetic diversity for *M. tuberculosis* strains in Eswatini

M. Ziyane,[1] D. Vambe,[2] M. Thunzini,[2] T. Dlamini,[3] C. Gascua,[4] L. de Araujo,[5] S. Dlamini,[6] G. Maphalala,[6] S. Ngwenya,[7] A. Kay,[2] S. Niemann,[5] [1]National TB Reference Laboratory, National TB Reference Laboratory, Mbabane, Eswatini, [2]Baylor College of Medicine Children's Foundation Eswatini, Clinical, Mbabane, Eswatini, [3]National TB Reference Laboratory, Laboratory, Mbabane, Eswatini, [4]Baylor College of Medicine Children's Foundation Eswatini, Laboratory, Mbabane, Eswatini, [5]Research Centre Borstel, Laboratory, Borstel, Germany, [6]Eswatini Health Laboratory Services, Laboratory, Mbabane, Eswatini, [7]National TB Control Program, Program, Manzini, Eswatini
e-mail: mangaliso.z@baylorfoundationeswatini.org

Background: Tuberculosis remains a major public health threat in Eswatini, driven by the transmission of highly resistant MDR-TB strains, including the *rpoB* I491F MDR MTBC outbreak clone circulating for over 30 years. These strains are resistant to first-line and several second-line drugs, highlighting the urgent need to break transmission

chains. This study examines *Mycobacterium tuberculosis* genetic diversity using Deeplex-based SNP analysis to understand evolutionary dynamics, and resistance mechanisms, helping to identify common lineages and drug resistance patterns in Eswatini.

Design/Methods: The research is conducted at the National Tuberculosis Reference Laboratory (NTRL) in Eswatini on over 200 samples from 2022 to 2025, included 233 samples in the final analysis. The Deeplex-Myc TB Kit was used to for Sequencing, and a web-based Deeplex pipeline was used for analysis to determine the resistance patterns and the genetic diversity.

Results: The results indicated a significant level of genetic diversity. Lineage 4 was found to be the most predominant, accounting for 79.8% (186/233) of the samples. However, the Deeplex Myc-TB kit accurately identified only 20% (38/186) of these Lineage 4 strains, with the Deeplex pipeline failing to delineate the remaining 80%, classifying them as lineage other than 4.9. Lineage 1 accounted for 8.5%, Lineage 2 for 5.5%, and Lineage 3 for 0.02%. The analysis suggested that Lineage 1 had a higher prevalence of MDR-TB and the most Pre-XDR cases (excluding those defined as „other than 4.9" category).

Category	Lineage1	Lineage2	Lineage3	Lineage4	Lineage6	No Lineage Specific	OtherThan4.9	Total
MDR	14	3	1	7		1	37	63
MDR+BDQ	2	1		1	2	1	67	74
nonMDR	1	6	2	23		3	22	57
preXDR	3	1					1	5
RR	0	1		2		2	2	7
S	0	1		5		1	12	19
XDR	0	0					6	6
(blank)	0	0				1	1	2
Total	**20**	**13**	**3**	**38**	**2**	**9**	**148**	**233**

Conclusions: The presence of various lineages, along with the indication of differing drug resistance profiles among them, underscores the genetic diversity of *M. tuberculosis* in Eswatini. The study concluded that due to the Deeplex kit's inability to fully distinguish Lineage 4, whole-genome analysis would be essential for a more comprehensive understanding of the genetic diversity.

EP04-736-18 Added value of Truenat as a first intention test for the detection of *M. tuberculosis* in the Democratic Republic of Congo

M. Aloni,[1,2] M. Kupa,[1] J.-F. Buteka,[1] L. Okenge,[1] S. Mbuyi,[3] M. Fina,[4] J.P. Malemba,[5] L. Mbulula,[5] R. Sentime,[6] F. Mukinda,[3] D. Muteteke,[4] M. Kaswa,[2] [1]DRC National Tuberculosis Control Programme, Laboratory, Kinshasa, Democratic Republic of the Congo, [2]University of Kinshasa, Faculty of Medicine, Kinshasa, Democratic Republic of the Congo, [3]DRC National Tuberculosis control Programme, Monitoring and Evaluation, Kinshasa, Democratic Republic of the Congo, [4]DRC National Tuberculosis control Programme, MDR TB Management, Kinshasa, Democratic Republic of the Congo, [5]DRC National Tuberculosis control Programme, NTP Management, Kinshasa, Democratic Republic of the Congo, [6]DRC National Tuberculosis control Programme, Pharmacy, Kinshasa, Democratic Republic of the Congo
e-mail: murielaloni@gmail.com

Background: Despite being highly preventable and generally curable disease, tuberculosis (TB) remains a major public health threat worldwide. The Democratic Republic of Congo (DRC) is among the 30 high-burden TB countries with an estimated incidence of 316 per 100,000 inhabitants. To reduce the incidence of TB in the country, it is essential to use innovative approaches. Beside GeneXpert, Truenat was recommended as a first intention rapid molecular diagnostic test by WHO rather than smear microscopy.

Design/Methods: Truenat was installed in 38 centres of diagnosis and treatment in four provinces (Kinshasa, Lualaba, Haut Katanga and Kasai Oriental) known to be hotspots for TB and MDR-TB. Given the higher presumptive burden in these provinces and limited coverage of Truenat, smear microscopy was also performed. Laboratory technicians were capacitated in installing and using Truenat machine.

Results: From 2022 to 2023, a total of 27 185 samples were tested using Truenat. 6 714 (24.7%) tested positive for *Mycobacterium tuberculosis (MTB)* (as compared to 18% positivity rate for microscopy). Of these, 493 (7.3%) were rifampicin resistant (RR).

Conclusions: Performing Truenat test was feasible and user-friendly in settings with limited resources and infrastructure. Truenat presented an additional value of identify more cases of MTB as compared to smear microscopy. These machines are expected to play an important role in identifying missing TB cases.

EP04-737-18 Operational performance of GeneXpert for TB diagnosis in West Java province, Indonesia: A public health evaluation

B.W. Lestari,[1] G. Nijman,[2] L. Shurianto,[3] S.N. Annisa,[3] I. de Boer,[2] I. Puspitasari,[3] S. Indriani,[3] B. Alisjahbana,[3] A.Y. Soeroto,[4] R. van Crevel,[2] P. Hill,[5] [1]Universitas Padjadjaran, Department of Public Health, Bandung, Indonesia, [2]Radboud university medical centre, Department of Internal Medicine, Nijmegen, Netherlands, [3]Research Center for Care and Control of Infectious Diseases, Padjadjaran University, Tuberculosis Working Group, Bandung, Indonesia, [4]Hasan Sadikin General Hospital, Department of Internal Medicine, Bandung, Indonesia, [5]University of Otago, Centre for International Health, Dunedin, New Zealand
e-mail: bony.wiem@unpad.ac.id

Background and challenges to implementation: GeneXpert is instrumental in tuberculosis diagnosis. Operational challenges are widely reported, but comprehensive evaluations of its operational performance are rare.
Intervention or response: We conducted health facility assessments in 40 community health centres with GeneXpert machines in West Java, Indonesia, and interviewed nurses, laboratory technicians, and program officers. We developed indicators and data collection tools using the World Health Organization GeneXpert implementation manual and Consolidated Framework for Implementation Research.
Results/Impact: GeneXpert has been implemented across the system with variable success. Several indicators scored below 75%, including nurse training (42%), technician's knowledge (68%), proportions of samples referred (67%), referred from private providers (2%), transported ≤1 day (61%), and tested in ≤1 day (72%), facilities with annual test volumes ≥3000 (16%), error rates ≤3% (46%), no result rates ≤1% (66%), absence of cartridge stockouts (72%) or machine module failure (37%), annual machine calibration (58%), stable power supply (0%) and adequate ventilation (60%). Barriers spanned multiple domains and layers. At CHCs, these included physical infrastructure, information technology, and a lack of (trained) human and material resources. Wider barriers involved local conditions (e.g. remote and difficult terrain, administrative processes), challenges with external organisations, insufficient funds, and large-scale events (e.g. active case finding). Continuous system adaptations and high staff motivation through proactive efforts and enthusiasm were key facilitators.
Conclusions: The Indonesian TB program has made significant progress in GeneXpert implementation. Residual challenges require multisectoral solutions and underscore the need to address real-world constraints in designing and implementing new TB diagnostics.

EP04-738-18 Blazing the trail of TB diagnosis in Nigeria: A journey that made sense

N. Nwokoye,[1] P. Nwadike,[1] I. Anaedobe,[1] Z. Mangoro,[1] M. Umoren,[1] S. Balogun,[1] V.-L. Ovoh,[1] T. Theodore,[1] O. Chukwuogo,[1] C. Ogbudebe,[1] S. Useni,[1] B. Odume,[1]
[1]KNCV Nigeria, Technical, Abuja, Nigeria
e-mail: nnwokoye@kncvnigeria.org

Background and challenges to implementation: Nigeria started the implementation of molecular WHO-recommended rapid diagnostic (mWRD) in 2011. Lessons learnt during project implementation demonstrated that adding more tools to the pool without strategic placement does not necessarily lead to more people being diagnosed. for improved diagnosis, the strengths and weaknesses of each tool should be evaluated and synergized with existing tools for optimal utilization. We reviewed the strategic deployment of molecular tools and diagnostic benefits over time.
Intervention or response: Nigeria experienced a huge evaluation gap despite the massive rollout of Xpert machines across 36 states. Poor machine utilization from power challenges, non-decentralization of testing to the community, primary health facilities, and the private sector where individuals first seek help were some identified reasons for the gap. To bridge the gap, KNCV Nigeria and the National TB program conducted a mapping of health facilities and devised a strategy on tool placement. TB LAMP was deployed to facilities with high workload and pervasive power issues owing to its solar system and high throughput. The 2-module Truenat instrument was deployed to primary health facilities with limited power supply, not necessarily facilities with high workload. Both tools were also prioritized for community active case finding due to their portable size. While Xpert remained in facilities with adequate power supply.
Results/Impact: A 4-year retrospective data analysis across the 14 KNCV-supported states showed a yearly increase in the number of persons with presumed TB and a steady decrease in evaluation gap from 35% in 2021 to 9% in 2024. The number of tests increased by 56.9% in 2024, consequently, the number of persons detected to have TB steadily increased over time.

Year	# Persons with presumed TB	Total Evaluated	Total cases identified	Evaluation gap	# Xpert Machines	#TB lamp Machines	#Truenat Machines
2021	862787	562237	51826	35%	184	11	28
2022	863915	664640	63136	23%	212	22	28
2023	1174903	987417	89518	16%	228	53	28
2024	1435395	1306955	113867	9%	236	83	28

Table 1: Distribution of diagnostics across 14 selected states and utilization over time

Conclusions: The results demonstrated that the strategic placement of diagnostics increased the utilization of machines, reduced evaluation gaps, and ultimately increased TB detection.

EP05 Childhood TB: Diagnosis and case-finding

EP05-739-18 Increase in TB diagnosis among children after implementing new WHO treatment decision algorithms in 5 sub-Saharan African countries

E. Briskin,[1] L.F. Nyikayo,[2] I. Barry,[3] A.M. Issa Soumana,[4] M.B. Abdullahi,[5] M. Namulwana,[6] M.M. Oumarou Farouk,[7] J. Mwanga-Amumpaire,[6] L. Moreto,[8] B. Schramm,[1] F. Nackers,[9] H. Huerga,[1] TB ALGO PED Study Group
[1]Epicentre, Field Epidemiology, Paris, France, [2]Médecins Sans Frontières, Operational Centre Barcelona, Malakal, South Sudan, [3]Médecins Sans Frontières, Operational Centre Brussels, Conakry, Guinea, [4]Epicentre, Research, Maradi, Niger, [5]Médecins Sans Frontières, Operational Centre Brussels, Maiduguri, Nigeria, [6]Epicentre, Research, Mbarara, Uganda, [7]Médecins Sans Frontières, West and Central Africa, Niamey, Niger, [8]Médecins Sans Frontières, Operational Centre Barcelona, Barcelona, Spain, [9]Epicentre, Research, Brussels, Belgium

Background: Almost half of children with tuberculosis (TB) go undiagnosed. In 2022, the World Health Organization (WHO) recommended two new treatment decision algorithms (TDAs) to facilitate TB case finding in children. We assessed the impact of TDAs implementation on TB diagnosis in Guinea, Niger, Nigeria, South Sudan and Uganda.
Design/Methods: In this pre-post research study the number of children under 10 years of age initiated on TB treatment, or with presumptive TB, over the total consultations or admissions of children of the same age, were retrospectively collected from routine programmatic sources 3-18 months prior to and following the introduction of TDAs in study sites. Comparisons of the TB treatment initiation rates before and after TDAs implementation were limited to the same calendar months year-over-year to control for potential seasonal effects.
Results: The percentages of children identified with presumptive TB increased from 11.4% (95%CI: 10.2 – 12.7) before TDAs implementation to 31.6% (95%CI: 30.0 – 33.1) after TDAs implementation in Nigeria and from 6.2% (95%CI:5.3 – 7.3) to 13.0% (95%CI:11.7 – 14.5) in South Sudan. The percentages of children initiating TB treatment increased in all sites after TDAs implementation (Table 1). Average proportional growth in percentage of children initiating TB treatment ranged from 1.2 fold in an inpatient therapeutic feeding center (Nigeria) to 5.0 in an outpatient cohort of children living with HIV (Guinea). Monthly fluctuations in case finding were observed, coinciding before TDA implementation with consultation and admission volumes, and with factors like the TDA focal person's presence, refresher training, and caseload changes afterward.

	Site-specific time periods		Children initiated on TB treatment over total consultations or admissions	
Site	Before algorithm implementation	After algorithm implementation	Before algorithm implementation % (95% CI)	After algorithm implementation % (95% CI)
Guinea	January 2023 – November 2023	January 2024 – November 2024	12/1363 0.9 (0.5 – 1.5)	61/1397 4.4 (3.4 – 5.6)
Niger	June 2022 - May 2023	June 2023 - May 2024	30/4804 0.6 (0.4 – 0.8)	106/4926 2.2 (1.8- 2.6)
Nigeria	January 2022 - December 2022	January 2024 - December 2024	234/8072 2.9 (2.6 – 3.3)	413/12,018 3.4 (3.1 –3.8)
South Sudan	January 2023 – November 2023	January 2024 – November 2024	42 / 2360 1.8 (1.3 - 2.4)	113/2294 4.9 (4.1 – 5.9)
Uganda	December 2022 – February 2023	December 2023 - February 2024	4/631 0.6 (0.2 - 1.6)	24/618 3.9 (2.6 – 5.7)

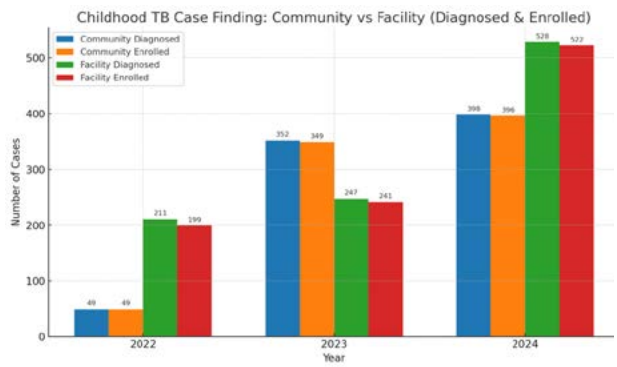
Conclusions: These results suggest that the WHO-recommended algorithms helped increase presumptive TB detection and TB diagnosis. The TDAs can be an important tool to close the gap of TB under-diagnosis in children. When TDAs are implemented, increased TB medication supply should be planned for.

EP05-740-18 Enhancing detection and enrollment of childhood TB through integrated community and facility-based approaches in high-burden settings: Lessons from two TB high-burden states in Northern Nigeria

G. Maren,[1] S. Omotayo,[2] K. Rimamtswab,[3] T. Bot,[4] J. Diara,[5] [1]KNCV Nigeria, Strategic Information Unit, Jos, Nigeria, [2]KNCV Nigeria, Strategic Information, Lafia, Nigeria, [3]KNCV Nigeria, Program, Jos, Nigeria, [4]KNCV Nigeria, Program, Jalingo, Nigeria, [5]KNCV Nigeria, Program, Makurdy, Nigeria

Background and challenges to implementation: Childhood tuberculosis (TB) remains a major public health concern in high-burden countries, with many cases going undetected due to non-specific symptoms, limited access to diagnostic tools, and poor linkage to care. Vulnerable populations such as children in slums, internally displaced persons (IDP) camps, Almajiri schools, and orphanages are particularly at risk. Addressing these challenges requires targeted, integrated interventions across both community and facility levels.
Intervention or response: Between 2023 and 2024, a combined strategy of targeted community outreaches and facility-based screening was implemented to enhance TB detection among children. The approach featured community testing weeks in schools, slums, IDP camps, Almajiri homes, and orphanages, focusing on children aged 0–14. Simultaneously, TB screening was integrated into

routine services at immunization clinics, Pediatric Outpatient Departments, Emergency Pediatric Units, and nutrition clinics.
Healthcare workers were trained on childhood TB screening, sample collection techniques (including stool and sputum), and clinical diagnosis. Linkage to care was enhanced through strengthened referral systems and structured follow-up processes.
Results/Impact: There was a significant increase in childhood TB case detection at both community and facility levels in 2023 and 2024 compared to 2022. Community-based interventions recorded a rise from 49 cases in 2022 to 352 in 2023 and 398 in 2024, while facility-based detection increased from 211 cases in 2022 to 247 in 2023 and 528 in 2024.



Conclusions: Integrating TB screening into both community outreach targeting children-focused groups and existing pediatric health services significantly improved childhood TB detection enrollment. The approach proved effective in reaching underserved populations and strengthening the continuum of care for children with TB.

EP05-741-18 Diagnostic accuracy of new treatment decision algorithms for TB in children: A multi-country diagnostic study

H. Huerga,[1] E. Briskin,[2] A. Arias Rodriguez,[2] B. Schramm,[2] M. Namulwana,[3] A.M. Issa Soumana,[4] L.F. Nyikayo,[5] I. Barry,[6] M.B. Abdullahi,[7] J. Mwanga,[3] F. Nackers,[8] C. Hewison,[9] TB ALGO PED Study Group [1]Epicentre, Field Epidemiology, Brussels, Belgium, [2]Epicentre, Field Epidemiology, Paris, France, [3]Epicentre, Research Centre, Mbarara, Uganda, [4]Epicentre, Research Centre, Nyamey, Niger, [5]Medecins Sans Frontieres, Operational Centre Barcelona, Malakal, South Sudan, [6]Medecins Sans Frontieres, Operational Centre Brussels, Conakry, Guinea, [7]Medecins Sans Frontieres, Operational Centre Brussels, Maiduguri, Nigeria, [8]Epicentre, Research, Brussels, Belgium, [9]Medecins Sans Frontieres, Operational Centre Paris, Paris, France
e-mail: helena.huerga@epicentre.msf.org

Background: New treatment decision algorithms for pulmonary TB in children include, in addition to laboratory testing, a score based on clinical, and where available, chest X-ray features. We assessed the diagnostic accuracy of these new algorithms as well as the diagnostic cascade in 5 sub-Saharan African countries.
Design/Methods: Prospective diagnostic study including children under 10 years with signs and symptoms of TB. Study sites included primary and higher health care facilities, nutritional centres, and HIV services in Guinea, Niger, Nigeria, South Sudan, and Uganda. Children were followed for 2 months. Reference standard was based on the international consensus definition for confirmed TB, unconfirmed TB and unlikely TB.
Results: Among 1864 participants enrolled, the median age was 1.7 years (IQR: 0.8-3.0), 851 (46.3%) were female, 1412 (76.9%) hospitalized, 1279 (69.6%) severely malnourished, and 203 (11.0 %) living with HIV (CLHIV). In total, 493 (26.8%) children were diagnosed with TB, 389 (78.9%) within one week of first assessment. Reasons for TB treatment were: 321 (65.1%) clinical or clinical-radiological algorithm score, 96 (19.5%) contact person with TB, 28 (5.7%) positive Xpert MTB/RIF, 33 (6.7%) positive TB-LAM. Among severely malnourished children, the main reason for TB treatment was the algorithm score (74.5%). A frequent reason for TB treatment was, among CLHIV, positive TB-LAM result (23.7%) and among children neither severely malnourished nor CLHIV, contact person with TB (48.7%). Among 1640 children, 333 (20.3%) had TB (of which 24% were confirmed) and 1307 (79.7%) unlikely TB, as per the reference standard. The algorithms sensitivity and specificity were 91.3% (95%CI 88.3-94.3) and 87.9 (95%CI 86.1-89.7), respectively.
Conclusions: The algorithms diagnostic accuracy was high. Clinical and clinical-radiological scores triggered most of the decisions to initiate TB treatment and highlight the importance of these assessments as part of a multi-faceted approach to diagnose TB in children.

EP05-742-18 Interpreting Xpert MTB/RIF Ultra trace-positive results in children: Experience from a large referral hospital

H.S. Schaaf,[1] H. van Deventer,[1] M. Mare,[2] C. Bosch,[1] H. Rabie,[1] A.C. Hesseling,[1] M.M. van der Zalm,[1] [1]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Cape Town, South Africa, [2]Tygerberg Hospital, Paediatrics and Child Health, Cape Town, South Africa
e-mail: hss@sun.ac.za

Background: Despite limited paediatric data, the World Health Organization recommends that children with Xpert MTB/RIF Ultra trace-positive results should be treated as having tuberculosis (TB), especially in high-burden settings. We evaluated children with Xpert Ultra trace-positive results only.
Design/Methods: Prospective routine-care microbiological surveillance including laboratory and clinical data were collected in children <13 years of age from March 2017 through February 2024 at Tygerberg Hospital, Cape Town, South Africa.

Characteristics of children 0-<13 years of age with trace-positive Xpert MTB/RIF Ultra	Number = 254 (%) or Median (Interquartile range)
Male sex	135 (53.1)
Weight for age (NCHS): <3rd centile	73 (28.7)
3-10 centile	46 (18.1)
Tuberculin skin test positive (≥10 mm)	30/61 (49.2)
Primary specimen type	
Respiratory samples (sputum, gastric aspirate, tracheal asp, BAL)	208 (81.9))
Pleural effusion	10 (3.9)
Cerebrospinal fluid	16 (6.3)
Lymph node fine needle aspirate	8 (3.1)
Tissue bone or synovial fluid	8 (3.1)
Other	4 (1.6)
When was antituberculosis treatment started	(n=223)
Before specimens taken	61 (27.4)
After specimens taken	162 (72.6)
Timing antituberculosis treatment initiated	
Before specimen obtained (n=59)	21 days (5 days-3 months)
After specimen obtained (n=150)	3 days (1 – 11 days)
Culture results	
Culture attempted	234 (92.1)
Culture not attempted	17 (6.7) (14 CSF; 1 stool; 1 asp; 1 tissue)
Culture contaminated	3 (1.2) (all BAL)
Number of negative mycobacterial cultures – median (IQR) and (range)	2 (1-3) (range 1-10)

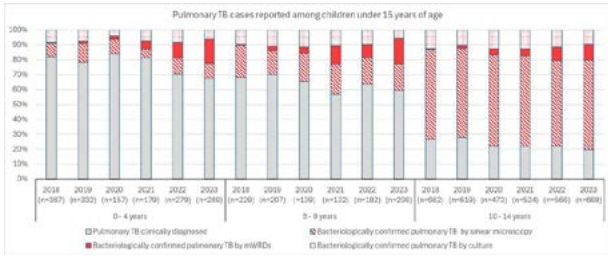
Results: Of 1373 children with microbiological results indicating *Mycobacterium tuberculosis*, 254 (18.5%) had only Xpert Ultra trace-positive results. Children's median age (IQR) was 27 (10-55) months; 11/246 (4.5%) were HIV-positive. TB contact was documented in 93/234 (39.7%) children; 73/254 (28.7%) were severely underweight-for-age. In 17 (6.7%; 14 cerebrospinal fluid samples) no culture was done in addition to molecular testing. Sixty-one (24%) children were on antituberculosis treatment (median duration 21 days; IQR 5 days-3 months) before specimens were obtained. Diagnoses assigned retrospectively were pulmonary TB only in 121 (47.6%; 89 non-severe disease), pulmonary and extrapulmonary TB (47; 18.5% – 16 TB meningitis [TBM]), extrapulmonary TB only (27; 10.6% – 10 TBM), unlikely TB or TB infection only (55; 21.7%), and likely laboratory mycobacterial cross- contamination (4; 1.6%). Treatment or TB preventive treatment was started or continued in 223 (87.8%); 31 (12.2%) children had no documented TB treatment or prevention. Six children died – all non-related to TB (Table)
Conclusions: Almost 80% of young children managed at a referral hospital with only Xpert Ultra trace-positive results were considered to have TB disease (half having severe TB), confirming that in high TB-burden settings, young children with Xpert Ultra trace-positive results should generally receive TB treatment. A smaller number could be treated for TB infection. Microbiological yield can possibly be improved by obtaining specimens before any TB treatment, and by requesting mycobacterial culture on larger volumes of cerebrospinal fluid specimens.

EP05-743-18 Impact of implementation of the molecular WHO-recommended rapid diagnostic test on bacteriological confirmation of pulmonary TB in children less than 15 years: A Peruvian cohort

V. Alarcon,[1] W. Solis,[1] D. Vela,[1] J. Tataje,[1] K. Guerra,[1] C. Bernabe,[1] C. Figueroa,[1] J. Acuache,[1] F. Mestanza,[2] P. Huaman,[1] M. Tovar,[3] [1]Ministerio de Salud, Dirección de Prevencion y Control de la Tuberculosis, Jesús María, Peru, [2]Hospital Nacional Docente Madre Niño San Bartolomé, Programa de Tuberculosis, Cercado de Lima, Peru, [3]Instituto de Investigación Nutricional, Direction of Research & Innovation, La MolinaPeru, Peru
e-mail: dir.investigacion@iin.sld.pe

Background: Peru is one of the 30 countries with a high burden of rifampin-resistant tuberculosis (MDR/RR TB) globally. The World Health Organization (WHO) has recommended the use of rapid molecular tests for diagnosing pulmonary tuberculosis since 2010, but implementation in Peru did not occur until 2018. This study aims to assess the impact of the molecular WHO-recommended rapid diagnostic test (mWRDs) on the pediatric population affected by TB in Peru.
Design/Methods: This observational operational research used a national TB program dataset from Peru's Tuberculosis Management Information System (SIGTB), the country's repository for diagnosed TB cases since 2018. Age groups followed WHO-recommended ranges for reporting TB in children and adolescents. Three categories of bacteriologically confirmed pulmonary TB were defined: (1) Confirmed by smear microscopy if positive, regardless of mWRDs or culture results; (2) Confirmed

by mWRDs if positive without a prior positive smear microscopy, regardless of culture results; and (3) Confirmed by culture if positive without prior smear microscopy or mWRDs evidence.
Results: Among children under 15, bacteriological confirmation was achieved in 49% (626/1278) of pulmonary TB cases in 2018, rising to 61% (715/1166) in 2023 (p<0.0001). Among confirmed pulmonary TB cases, mWRD-based confirmation significantly increased from 1.1% (7/626) in 2018 to 21.4% (153/715) in 2023 (p<0.0001). By age group in 2023, mWRDs confirmed pulmonary TB in 50% (47/94) of children aged 0–4 years, 42% (35/84) of those aged 5–9 years (p=0.3), and 13.2% (71/537) of children aged 10–14 years (p<0.0001). Children with MDR/RR-TB diagnosed by mWRDs accessed faster and more accurate second-line anti-TB treatment in a median of 9 days, compared to 26 days among those diagnosed through phenotypic testing (p<0.005).



Conclusions: The implementation of mWRDs has increased bacteriological confirmation of pulmonary TB and reduced the time to begin second-line anti-TB treatment among children under 15 years in Peru.

EP05-744-18 TB in teens: Risk factors for diagnostic delay and age-specific associations with disease severity

J. Wyda,[1] J.R. Tanzer,[2] B. Roman-Sinche,[3] L. Lecca,[4] S. Chiang,[5] [1]Brown University, Warren Alpert School of Medicine, Providence, United States of America, [2]Brown University Health, Biostatistics, Epidemiology, Research Design, and Informatics (BERDI) Core, Providence, United States of America, [3]Partners in Health in Peru, Programa de TB, Lima, Peru, [4]Partners In Health, Peru, Lima, United States of America, [5]Brown University - Warren Alpert School of Medicine, Pediatrics, Providence, United States of America
e-mail: justin_wyda@brown.edu

Background: Adolescents account for 12–17% of new tuberculosis (TB) cases globally, yet little is known about diagnostic delays in this age group. Delayed care may increase disease severity and community transmission, especially in settings with high TB burden.
Design/Methods: We analyzed data from a prospective study of 249 adolescents (ages 10–19) treated for rifampicin-susceptible TB at Ministry of Health centers in Lima, Peru, between September 2020 and August 2021. Variables were collected through clinical chart abstraction and a structured survey completed by participants 3–5 weeks after treatment initiation. Diagnostic delay was defined as self-reported time from symptom onset to diagnosis. We used K-means cluster analysis to group adolescents by psychosocial characteristics and examined associations between cluster and diagnostic delay using regression. We also assessed the age-stratified relationship between delay and sputum smear positivity in pulmonary TB.
Results: Median diagnostic delay was 22.5 days (IQR: 7.5–45). Cluster analysis identified three groups; the cluster characterized by the highest levels of poverty, substance use, and childhood trauma had the longest mean delay (44 days vs. 36 and 35 days for the other two clusters), though differences were not statistically significant. Longer diagnostic delays were associated with greater sputum smear positivity in both age groups, but this relationship was statistically significant only among younger adolescents (10–15 years), suggesting that delays lead to more severe disease at diagnosis and increased potential for transmission.

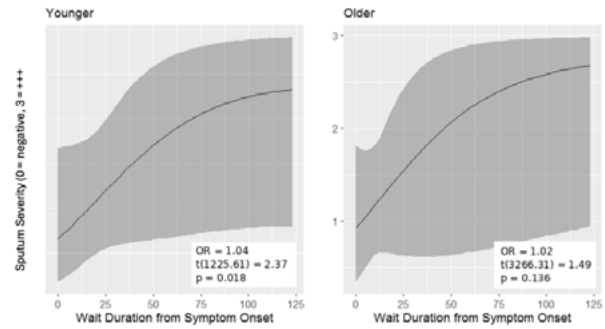


Figure: Sputum smear positivity vs. diagnostic delay. Sputum smear positivity was assessed on a scale of 0 (smear negative) to 3+, indicating the quantity of Mycobacterium tuberculosis visualized on acid-fast microscopy. Diagnostic delay is the number of days between the onset of symptoms and TB diagnosis. The older group, aged 15-19 (mean = 17.8), is distinguished from the younger group, aged 10-15 (mean = 14). The average age for Clusters A and B is 17.8, while for Cluster C, it is 14.

Conclusions: Social and structural factors—such as household instability, food insecurity, and substance use—may contribute to TB diagnostic delays in adolescents. Younger adolescents may be especially vulnerable to severe disease following delayed care. Adolescent-centered interventions that address psychosocial and structural barriers are critical to improving timely diagnosis and limiting transmission.

EP05-745-18 Incorporating paediatric TB surge in polio zero-dose community activities: Learnings from Kaduna State

V. George,[1] B. Odume,[2] G. Julius,[1] O. Chukwuogo,[2] M. Bajehson,[3] [1]KNCV NIGERIA, Technical, Kaduna, Nigeria, [2]KNCV NIGERIA, Management, Abuja, Nigeria, [3]KNCV NIGERIA, Technical, Kano, Nigeria
e-mail: vgeorge@kncvnigeria.org

Background and challenges to implementation: Pediatric tuberculosis (TB) is frequently underdiagnosed owing to ambiguous symptoms, restricted diagnostic availability, and inadequate integration of TB services within comprehensive healthcare systems. In Kaduna State, Nigeria, the identification of zero-dose children—those who had never been vaccinated—and the management of concealed pediatric tuberculosis loads presented a twin problem. Cultural obstacles, stigma, and inadequate infrastructure further impeded attempts to identify and treat tuberculosis in children.
Intervention or response: To rectify these deficiencies, KNCV Nigeria, supported by USAID financing, included pediatric TB surge initiatives into existing polio zero-dose community outreach efforts. This novel strategy utilized the extensive outreach of polio programs to screen children for tuberculosis, inform carers, and send suspected cases for testing. Community health workers and vaccinators received training to identify tuberculosis signs and enhance referral networks. Community involvement and lobbying facilitated acceptance and participation.
Results/Impact: The approach resulted in a significant increase in tuberculosis case detection among zero-dose youngsters. Presumptive pediatric tuberculosis cases rose from 3,365 in the second quarter to 5,413 in the third quarter (61%) and 7,625 in the fourth quarter (41%). Diagnosed tuberculosis cases increased from 146 in the second quarter to 272 in the third quarter (86%) and 371 in the fourth quarter (36%), with all confirmed patients commencing treatment. Referrals to diagnostic centers increased by more than 40%. The community's confidence and awareness of tuberculosis and immunization services have also enhanced. The results underscore the efficacy of utilizing polio outreach to improve pediatric TB diagnosis in marginalized groups.

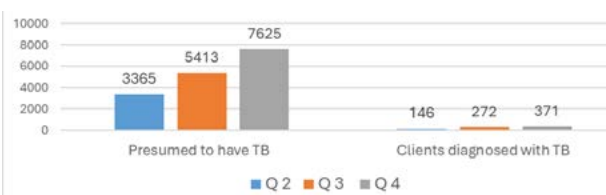

Fig. 1. Kaduna PPM pediatric cascade.

Conclusions: Incorporating pediatric tuberculosis case identification with polio zero-dose outreach is a viable and effective approach for enhancing tuberculosis diagnosis and healthcare accessibility. Expanding this strategy needs continuous financing, enhanced diagnostics, and resilient data platforms to sustain and amplify advancements in pediatric tuberculosis control.

EP05-746-18 Assessment of paediatric TB prevalence among Bacillus Calmette-Guerin vaccinated paediatric age group in Delta State Nigeria

E.E. Ajumuka,[1] W. Yekumah,[1] V. Edjobayire,[1]
[1]KNCV, Technical, Abuja, Nigeria
e-mail: docajumuka@yahoo.com

Background: Tuberculosis (TB) remains a major public health concern in Nigeria, particularly among children, who are more vulnerable to severe forms of the disease. Although the Bacillus Calmette-Guerin (BCG) vaccine is routinely administered to protect against TB, cases continue to emerge within vaccinated paediatric populations. In Delta State, where TB control efforts are ongoing, there is limited data on the prevalence of TB among children who have received the BCG vaccine.
This study seeks to assess the burden of paediatric TB within this group, aiming to better understand the vaccine's protective impact and identify potential gaps in prevention strategies.
Design/Methods: This was a retrospective descriptive study to assess the prevalence of tuberculosis among BCG-vaccinated children in Delta State, Nigeria. It involves analysis of immunization records in selected high burden facility (Ughelli, Warri, Agbor and Ekpan) over a 14 year period (January 2011 to January 2025) with paediatric TB cases diagnosed among the vaccinated over that same period (January 2011 to January 2025). These facilities provide routine TB diagnosis, treatment, and vaccination services.
The target population included children aged 0–14 years who were diagnosed with tuberculosis and had documented evidence of BCG vaccination.
Data were extracted from patient medical records, immunisation registers, and TB treatment registers. Extracted data were coded, inputted and analysed using SPSS version 25.
Results: General Characteristics of the Study Population: A total of 4,426 BCG-vaccinated children aged 0–14 years were randomly reviewed from immunization records across selected high burden health facilities in Delta State. Of these, 34 children (0.77%) were confirmed to have tuberculosis despite documented BCG vaccination status.
Conclusions: Though TB prevalence among BCG-vaccinated children was low, cases persist and as such, strengthening early detection, contact tracing, and vaccine impact monitoring is essential to close prevention gaps and improve outcomes for vulnerable children.

Age and Sex Distribution of TB Cases (n = 34)

Age Group (years)	Male	Female	Total	Percentage (%)
0–4	5	6	11	32.3%
5–9	7	6	13	38.2%
10–14	6	4	10	29.5%
Total	***18 (53%)***	***16 (47%)***	***34***	***100%***

Children aged 5–9 years had the highest prevalence of TB cases (38.3%), with a nearly equal distribution between male and female cases overall.

Type of TB Diagnosis Among Cases

TB Type	Number of Cases	Percentage
Pulmonary TB	32	94.0%
Extra-pulmonary TB	2	6.0%
Total	***34***	***100%***

Pulmonary TB was the most common presentation, accounting for 94%, while extra-pulmonary TB represented 6%.

Diagnostic Methods Used in Confirming TB

Diagnostic Method	Number of Cases	Percentage (%)
Clinical + Radiological	6	18%
GeneXpert MTB/RIF	26	76%
Smear Microscopy	1	3%
Clinical Diagnosis Only	1	3%
Total	***34***	***100%***

Among the 34 TB cases, 26 (76%) were diagnosed bacteriologically using gene Xpert

Treatment Outcome

Outcome	Number of Children	Percentage (%)
Cured	18	40%
Completed Treatment	10	42%
Lost to Follow-Up	2	6%
Died	2	6%
Ongoing Treatment	2	6%
Total	***34***	***100%***

Among the 34 TB cases, treatment success rate (combining cured and completed treatment) was 82%, while 6% were lost to follow-up and 6% died during treatment.

EP05-747-18 Predictors of paediatric TB disease in a pastoralist community, Turkana County, Kenya: A case-control study

J. Marcomic,[1] J. Kiplagat,[2] J. Ogoro,[3] L. Odeny,[1] A. Ahmed,[4] B. Ulo,[1] [1]Amref Health Africa in Kenya, Global Fund TB, Nairobi, Kenya, [2]Moi University, Medical statistics, Eldoret, Kenya, [3]Ministry of Health, National TB Program, Kenya, Kenya, [4]Ministry of Health, Field Epidemiology and Laboratory Training Program, Kenya, Kenya
e-mail: james.marcomic@amref.org

Background: Tuberculosis (TB) remains a significant global public health challenge, with 10 million cases and 1.6 million deaths reported in 2021. Children accounted for 11% of these cases and deaths. In Kenya, about 77,000 TB cases were reported, with pediatric TB making up 9.6% of cases and 4.8% of TB-related deaths. Turkana County, a predominantly pastoralist region, contributed to 19% of Kenya's pediatric TB burden. However, the specific drivers of high pediatric TB rates in this region remain unclear. This study aimed to identify predictors of pediatric TB in Turkana West Subcounty.
Design/Methods: An unmatched case-control study was conducted among children aged 0–14 years from January to May 2023. We randomly selected 106 pediatric TB cases from health facilities and enrolled 212 neighborhood controls. Data were collected using structured questionnaires covering socio-demographic, clinical, behavioral, and socioeconomic factors. Bivariate and multivariate logistic regression analyses were used to identify predictors of pediatric TB.
Results: Among 318 participants, 47% were male and 53% female, with a mean age of 5 years for cases and 6 years for controls. Children with a household TB contact in the past year had significantly increased odds of TB (aOR=21.09; 95% CI: 7.86–56.59). Previous hospital admission was also a significant predictor (aOR=3.26; 95% CI: 1.30–8.24). Caregiver alcohol use was strongly associated with TB (aOR=6.50; 95% CI: 2.41–17.53), while caregiver knowledge of TB prevention was protective (aOR=0.04; 95% CI: 0.01–0.12).
Conclusions: Pediatric TB in Turkana West is strongly linked to household TB exposure, hospital admissions, caregiver alcohol use, and lack of TB prevention knowledge. Targeted interventions focusing on caregiver education, improved healthcare access, and infection control can reduce pediatric TB burden in similar pastoralist settings.

EP05-748-18 Performance of the Fujifilm SILVAMP TB LAM II (FujiLAM II) assay in diagnosing childhood TB

S. Ayalew,[1,2] T. Wegayehu,[2] B. Wondale,[2] A. Piantados,[3] B. Tessema,[1] T. Seifu,[4] A. Berihun,[5] W. Tesfaye,[6] S. Neway,[1] A. Mihret,[1] [1]Armauer Hansen Research Institute, Mycobacterial and other Bacterial Disease Research Directorate, Addis Ababa, Ethiopia, [2]Arba Minch University, Department of Biology, College of Natural Sciences, Arba Minch, Ethiopia, [3]Emory University School of Medicine, Department of Medicine, Division of Infectious Diseases, Atlanta, United States of America, [4]Zewditu Memorial Hospital, pediatric, Addis Ababa, Ethiopia, [5]St. Paul Millennium Medical College, Pediatric, Addis Ababa, Ethiopia, [6]St. Piter Specialized Hospital, Pediatric, Addis Ababa, Ethiopia
e-mail: absosina2011@gmail.com

Background: Non-sputum tuberculosis (TB) diagnostics are urgently needed to improve childhood TB diagnosis, as current methods rely on sputum, which is difficult to obtain from children. This study evaluated the Fujifilm SILVAMP TB LAM II (FujiLAM II) for diagnosing TB in children.
Design/Methods: Children with TB (confirmed by GeneXpert Ultra MTB/RIF [Xpert Ultra] or clinically diagnosed) and healthy controls were recruited from hospitals and primary schools, respectively. Spot urine samples were tested using FujiLAM II. Sensitivity was assessed against a composite reference standard, Xpert Ultra results, and clinical diagnoses, while specificity was determined using healthy controls. FujiLAM II was compared to Xpert Ultra using McNemar's test. Odds ratios (ORs) with 95% confidence intervals (CIs) were calculated to evaluate sensitivity in key subgroups (HIV-coinfected, malnourished, and children under 5 years).
Results: Of 123 participants, 73 (59.3%) had TB (18 bacteriologically confirmed, 55 clinically diagnosed), and 50 (40.7%) were healthy controls. FujiLAM II showed an overall sensitivity of 19.7%, higher in confirmed cases (38.9%) than clinically diagnosed (13.2%). Sensitivity

varied by TB type: disseminated TB (30.8%), pulmonary TB (23.7%), and extrapulmonary TB (5.0%). Higher sensitivity was observed in children under 5 years (30.8%) vs. those above 5 (6.2%) (adjusted OR = 6.01; 95% CI: 1.20–30.09; p = 0.029), HIV-positive children (28.6%) vs. HIV-negative (19.4%) ($p > 0.05$), and malnourished children (26.8%) vs. those with normal growth (10.7%) ($p > 0.05$). Specificity was 100%. In children tested with both Xpert Ultra and FujiLAM II, sensitivity differences were not significant (34% vs. 26.4%; $p > 0.05$). Combining FujiLAM II with Xpert Ultra (positive if either test was positive) improved sensitivity to 47.2%.

Conclusions: FujiLAM II's child-friendly, rapid point-of-care approach shows promise for childhood TB diagnosis, particularly in children under 5 years, HIV-coinfected, or malnourished. With high specificity, it could serve as a valuable adjunct test.

EP06 Pregnancy: M. tuberculosis infection, TB diagnosis and treatment

EP06-749-18 Effect of gestational diabetes on interferon-gamma responses among pregnant women in India: Results of the PraGaTHi study

P. Raichur,[1] S. Naik,[2] P. Chebrolu,[3] V. Potphode,[1] M. Alexander,[4] V. Kulkarni,[1] P. Deshpande,[1] S. Tambe,[5] J. Mathad,[3] [1]Johns Hopkins Center for Infectious Diseases in India (CIDI), Johns Hopkins Center for Infectious Diseases in India (CIDI), Pune, India, [2]Byramjee Jeejeebhoy Government Medical College and Sassoon General Hopsitals, Obstretics and Gynaecology, Pune, India, [3]Weill Cornell Medicine, Center for Global Health, New York, United States of America, [4]Weill Cornell Medicine, Center for Global Health, New York, India, [5]Byramjee Jeejeebhoy Government Medical College and Sassoon General Hospitals, Obstretics and Gynaecology, Pune, India
e-mail: praichu1@jhu.edu

Background: HIV and diabetes mellitus (DM) are independent risk factors for Tuberculosis (TB) in non-pregnant populations. The effect of gestational DM (GDM) on TB immunology, particularly in women with HIV, is unclear.

Our previous work reported lower TB-specific immune responses in women with GDM, particularly in women with HIV on efavirenz-based antiretroviral therapy (ART). We sought to reassess this association with Dolutegravir-based ART.

Design/Methods: In the PraGaTHi study, pregnant women are screened for GDM using an oral glucose tolerance test (WHO 2013 cutoffs) and for TB Infection (TBI) using QuantiFERON-plus.

Among women with TBI, IFN-γ levels from TB1 and TB2 supernatant were compared between women with and without GDM. Linear regression models, adjusted for age, socioeconomic status, HIV, and Body mass index (BMI) assessed the impact of GDM on IFN-γ levels.

Results: Of the 109 (27%) enrolled women with TBI,35 (32%) had GDM, 25 (23%) had HIV, median age was 27 years (IQR 23.0 – 29.0) and median gestational age 20.4 years (IQR 16 - 23.6).

Women with TBI and GDM were older (28 vs 25.5 years, p=0.04), had higher median weight (69 vs 51 kg, p <0.001), BMI (28.9 vs 21.8, p <0.001) and were more likely to be multigravida (89% vs 70%, p 0.04), and HIV-negative (94% vs 69%, p=0.003) compared to women with TBI without GDM. GDM did not significantly affect IFN-γ in TB1 (0.78 vs 1.07, p >0.9) or TB2 (1.40 vs 1.58, p 0.5) tubes.

However, linear regression showed a trend of lower IFN-γ levels in women with GDM (p=0.1) (Figure 1).

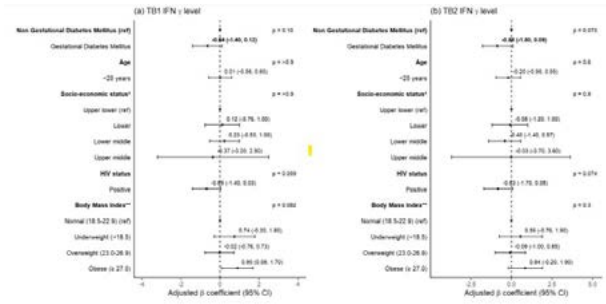

Figure 1: The association between Gestational Diabetes Mellitus and Tuberculosis (TB)1 (a) and TB2 (b) interferon-gamma (IFN-γ) levels among pregnant women with latent TB infection enrolled in Pune, India. Linear regression models adjusted for age, socio-economic status (SES), HIV status, and Body Mass Index (BMI) (ref, reference category). *SES categorised per modified Kuppuswamy scale; **WHO BMI categories for Asians.

Conclusions: Contrary to our previous findings, GDM did not significantly affect IFN-γ levels during pregnancy, regardless of HIV status, although a trend for lower levels was observed. Longitudinal studies will help determine whether GDM is a risk factor for maternal TB.

EP06-750-18 A multicentre, hospital-based survey of TB after in vitro fertilisation in China

X. Liu,[1] L. Xia,[1] [1]Shanghai Public Health Clinical Center, Fudan University, Department of Tuberculosis, Shanghai, China
e-mail: liuxuhui@shphc.org.cn

Background: In vitro fertilization (IVF) is increasingly popular for treating infertility. However, in regions with high tuberculosis prevalence, there are reports of fatal infections in tuberculosis patients who become pregnant through IVF, though clinical evidence remains limited.
Design/Methods: To systematically assess data on tuberculosis during pregnancy from multiple centers and clarify the association between the mode of conception and clinical outcomes, we retrospectively reviewed the conception mode and clinical information of pregnant tuberculosis patients using a multi-center medical electronic information system.
We investigated tuberculosis outcomes and fetal outcomes. The primary endpoints were the rate of critically ill maternal conditions post-tuberculosis development and maternal mortality within six months of treatment initiation.
Results: The study included 401 cases of tuberculosis during pregnancy from five infectious disease centers in China (2014-2023). Among these, 90 cases involved IVF, and 311 did not. Of the cases, 56% were bacteriologically confirmed, 44% were clinically diagnosed with negative bacteriological results, 97% had positive IGRA/TST results, and 1% were MDR/RR-TB.
The IVF group had a significantly higher proportion of critically ill cases (38% vs 13%, adjusted odds ratio [aOR]=5.8, P<0.001), with more severe complications such as hematogenous disseminated tuberculosis (86% vs 7%, P<0.001) and tuberculous meningitis (29% vs 6%, P<0.001), and worse fetal outcomes (miscarriage rate 24% vs 7%, P<0.001). There was no significant difference in maternal mortality between the IVF and non-IVF groups (2.2% vs 1.0%, P=0.684).
Conclusions: This study confirms that women who conceive through IVF are more susceptible to severe tuberculosis and experience worse perinatal outcomes. Therefore, it is essential to implement tuberculosis infection screening and prevention measures before undergoing IVF treatment.

EP06-751-18 Integrated TB screening in pregnant women during ANC: A study on early detection, TB treatment and pregnancy outcomes from rural India

K. Taluja,[1] M. Brouwer,[2] T. Garg,[3] R. Kumar,[4] S. Muni,[4] S. Bhagat,[5] B.K. Mishra,[6] G. Raikwar,[7] U. Aqil,[7] N. Nisha,[1] M. Kumar,[1] M. Bhardwaj,[1] [1]Innovators in Health(India), Operations, Samastipur, India, [2]PHTB Consult, M&E, Haren, Netherlands, [3]Stop TB Partnership, Innovations and Grants, Geneva, Switzerland, [4]IGIMS, Microbiology, Patna, India, [5]Government of Bihar, India, State Health Society, Patna, India, [6]Government of Bihar, State Health Society, Patna, India, [7]Government of India -WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, Delhi, India
e-mail: ktaluja@innovatorsinhealth.org

Background and challenges to implementation: Pregnant women (PW) are disproportionately vulnerable to TB. Due to limited access to non-Maternal and Neonatal Health services, including chest X-rays, TB often goes undiagnosed and untreated in this population. We studied the pregnancy and TB treatment outcomes of pregnant women who were screened, diagnosed, and treated for TB during their antenatal care (ANC), with the support of healthcare workers.
Intervention or response: We conducted screening for TB symptoms in pregnant women, aged 18-45 years of age attending ANC clinics from April 2023- December 2024. We facilitated presumptive PW for diagnosis through sputum or stool specimen testing. We encouraged PW with confirmed or clinically diagnosed TB to initiate TB treatment through usual care.
Results/Impact: We screened 30,646 pregnant women, aged 18-45 years (median age 22), from Begusarai and Samastipur districts of Bihar. 725 were found presumptive and 452 were tested either by stool or sputum for TB. Median turn-around time between screening and diagnosis of TB is 8 days with a range 1-72 days. We diagnosed 64 PW with TB and 62 started TB treatment. 2 PW did not wish to start their TB treatment. 53 PW (82%) had bacteriologically confirmed TB, either from sputum (92%) or stool (8%) specimen testing. 52 (83%) PW were successfully treated (cure and complete) for TB, 6 are on

treatment, 3 were lost to follow up for various reasons, 1 regimen changed. The pregnancy outcomes included 56 full-term deliveries with healthy babies, 1 miscarriage, 1 abortion and 4 still in their gestation period.
Conclusions: To enhance maternal and neonatal health in vulnerable areas, intensive case finding in PW can be integrated with ANC. Educating Healthcare Workers on TB symptoms during pregnancy and conducting early screening can facilitate timely diagnosis and treatment, and encourage institutional delivery. Respect for the women's choice towards decisions on treatment is crucial for acceptance.

EP06-752-18 Improving TB detection among pregnant women through community-based integrated TB/HIV screening in Southeast Nigeria: Early implementation results

C. Okoye,[1] J. Ilozumba,[2] W. Maya,[2] V. Ogbe,[2] O. Olupitan,[3] T. Adetiba,[3] O. Akaniro,[4] A. Adekunle,[3] M. Zamzu,[5] J. Ssekitooleko,[5] C. Adesigbin,[6] [1]Catholic Caritas Foundation of Nigeria, TB/HIV, Abak, Nigeria, [2]Catholic Caritas Foundation of Nigeria, TB/HIV, Abuja, Nigeria, [3]Global Fund N-THRIP, Institute of Human Virology, Nigeria (IHVN), TB/HIV, Abuja, Nigeria, [4]National TB and Leprosy Control Program, M&E, Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, GFATM, Geneva, Switzerland, [6]National TB and Leprosy Control Program, Program Unit, Abuja, Nigeria
e-mail: jilozumba@ccfng.org

Background and challenges to implementation: In many high TB burden settings, tuberculosis (TB) screening among pregnant women is often overlooked, resulting in missed diagnoses and contributing to adverse maternal and neonatal outcomes. Despite being a high-risk group, pregnant women are rarely included in routine active case-finding initiatives, partly due to low clinical suspicion and limited integration of TB screening within maternal health services. This study assesses the preliminary outcomes of a community-based intervention that integrates TB and HIV screening for pregnant women in Southeast Nigeria
Intervention or response: As part of the Global Fund TB/HIV Project, an integrated community-based screening initiative was conducted from January to December 2024 across Enugu, Ebonyi, Imo, and Abia States in southeastern Nigeria. The aim was to enhance TB and HIV case detection among pregnant women.
The intervention trained 370 Community Volunteers (CVs) and 576 Traditional Birth Attendants (TBAs). CVs conducted house-to-house visits and community outreaches to screen for TB symptoms, conduct HIV testing, and refer PW to Antenatal Care (ANC) services. TBAs integrated routine TB and HIV screening into their maternal care services at TBA facilities, embedding TB/HIV interventions within existing maternal health platforms.
Results/Impact: Over 12-month implementation period (January to December 2024), a total of 39,209 pregnant women were screened. 3,328 (9%) identified as presumptive TB cases, 13 TB cases diagnosed through molecular testing.11 pregnant women (85%) were initiated on treatment. A key implementation challenge was treatment hesitancy, with some pregnant women expressing fear that anti-TB medications might harm their unborn children, resulting in delays in treatment initiation.

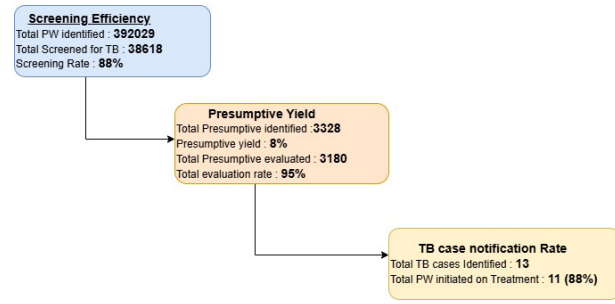

Figure. Result from TB screening of pregnant women (PW) January 2024 to December 2024.

Conclusions: Community-based integrated TB/HIV screening is an effective strategy for enhancing TB case detection among pregnant women in high-burden, low-access settings. However, to maximize uptake and ensure timely treatment, the model must incorporate targeted counseling interventions to address maternal concerns and promote confidence in TB treatment safety during pregnancy.

EP06-753-18 The effectiveness of integrating prevention of mother-to-child transmission (PMTCT) and TB screening services in Abia State, Nigeria

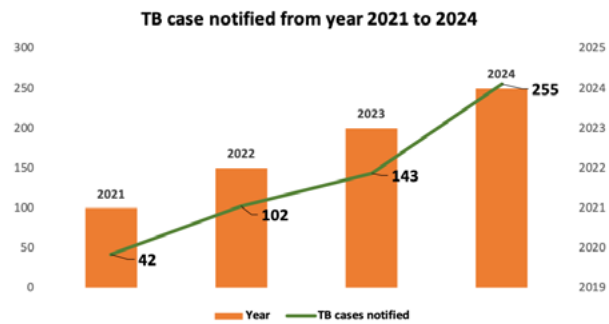
V.I. Ogbe,[1] M. Kuba,[1] J. Ilozumba,[1] C. Okoye,[1] W. Maya,[1] O. Adebayo,[2] T. Adetiba,[2] O. Olupitan,[3] C. Adesigbinfemi,[4] O. Chijioke-Akaniro,[4] J. Ssekitoleko,[5] R. Aoife,[6] [1]Catholic Caritas Foundation of Nigeria (CCFN), Program, FCT Abuja, Nigeria, [2]Institute of Human Virology, Nigeria (IHVN), Program management, FCT Abuja, Nigeria, [3] Institute of Human Virology, Nigeria (IHVN), Abuja, Nigeria, Program management, FCT Abuja, Nigeria, [4]National TB and Leprosy and Buruli Ulcer Control Programme Nigeria, Program management, FCT Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Geneva, Switzerland, Program management, Switzerland, Switzerland, [6]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Geneva, Switzerland, Program management, Geneva, Switzerland
e-mail: vogbe@ccfng.org

Background and challenges to implementation: Tuberculosis (TB), an infectious disease primarily affecting the lungs, poses a significant public health challenge, particularly in pregnant women who may also be at risk for HIV. Prevention of mother-to-child transmission (PMTCT) programs are designed to reduce the transmission of HIV from an HIV-positive mother to her child.
This study investigates the impact of integrating TB screening within PMTCT services in Abia State, Nigeria, focusing on improving TB case detection, enhancing maternal health outcomes, and addressing the intersection of TB and HIV.
Intervention or response: Descriptive statistics were conducted on data abstracted from community health records collected between July and December 2024. A total of 7,135 pregnant women were screened for TB, and 5,945 were tested for HIV. We used Microsoft excel to analyze the effectiveness of the integrated service delivery on TB case detection and subsequent treatment.
Results/Impact: Integration of TB screening into PMTCT services led to a significant increase in TB case detection among pregnant women. Among the 7,135 women screened for TB, 442 (6.2%) were identified as presumptive TB cases, sputum samples were collected for GeneXpert testing, and 6 (0.08%) were confirmed to have TB and initiated treatment.
In addition, 5,945 pregnant women were tested for HIV, with 81 (1.4%) testing positive and promptly enrolled in care. The integration of TB and HIV screening facilitated timely diagnosis and immediate linkage to treatment, ultimately improving health outcomes for both mothers and infants.
Conclusions: The integration of TB screening within PMTCT services significantly enhances TB and HIV case detection, enabling early diagnosis and timely treatment initiation. This approach strengthens maternal healthcare services and plays a pivotal role in reducing the burden of TB and HIV co-infection among pregnant women, ultimately improving health outcomes for both mothers and their infants.

EP06-754-18 Traditional birth attendants: Key allies in the fight against TB in hard-to-reach areas in Oyo State, Nigeria

O. Adedayo,[1] S. Akingbesote,[1] A. Agbaje,[2] A. Ricketts,[1] O. Daniel,[2] P. Dakum,[2] C. Mensah,[2] M. Pedro,[3] M. Toriola,[3] [1]Institute of Human Virology Nigeria, PCT, Ibadan, Nigeria, [2]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [3]Institute of Human Virology Nigeria, SI, Lagos, Nigeria
e-mail: olayinkacommy@gmail.com

Background and challenges to implementation: Traditional Birth Attendants (TBAs) remain key healthcare providers in rural areas, particularly in hard-to-reach communities. They serve as the first point of care for vulnerable groups, especially pregnant women, due to their accessibility, affordability, and cultural acceptance. With an estimated 62% of births occurring outside health facilities, TBAs play a crucial role in bridging healthcare gaps. In Oyo State, tuberculosis (TB) case notification had a 34% gap in 2021, highlighting the need for innovative interventions. This study explores the impact of engaging TBAs in TB service delivery, especially in rural areas.
Intervention or response: A total of 250 TBAs across five local government areas (LGAs) were trained and engaged to conduct TB symptomatic screening. Identified presumptive TB cases were referred for GeneXpert or Truenat testing, with chest X-rays conducted for those unable to produce sputum. TBAs received quarterly refresher training and financial incentives based on successful case referrals and treatment initiation. Each TBA used a standardised TB screening tool from the National Tuberculosis Programme, with data compiled by assigned Linkage Coordinators.



Results/Impact: From Q1 to Q4 2024, 14,209 individuals visited TBAs, of which 14,195 were screened for TB. This led to 2,221 presumptive TB cases (15.6%), all referred for laboratory evaluation. 255 TB cases (10.1%) were

confirmed, including 180 via GenXpert and 75 via chest X-ray. Additionally, 21 childhood TB cases (8.2%) were identified. TB cases identified through TBAs accounted for 5% of Oyo State's total TB cases in 2024, emphasising their role in early detection and referral.
Conclusions: Engaging TBAs in active TB case finding is vital for identifying missing TB cases, particularly in underserved communities. Strengthening collaborations between orthodox and alternative care providers enhances early TB detection and control.

EP06-755-18 Assessing blood-based TB transcriptomic gene signatures in pregnant women with bacteriologically confirmed and non-confirmed TB

N. Rakotosamimanana,[1] P. Ranaivomanana,[1] R. Ratovoson,[2] A. Razafimahefa,[1] C. Razafimahatratra,[2] [1]Institut Pasteur de Madagascar, Mycobacteriology Unit, Antananarivo, Madagascar, [2]Institut Pasteur de Madagascar, Epidemiology and Clinical Research Unit, Antananarivo, Madagascar
e-mail: rpaulo@pasteur.mg

Background: Tuberculosis (TB) is one of the leading causes of death in women of reproductive age.Widely available diagnostic tools often lack efficacy in pregnat women thereby resulting in missed diagnoses and leading to the death. Blood transcriptomic signatures have shown promise for TB testing especially as an alternative test practicable in populations that cannot produce sputum or who have paucibacillary disease.
Design/Methods: We propose to perform a prospective study to screen TB in pregnant women with transcrimtomic and routine tests. HIV-negative pregnant women presenting TB pulmunary symptoms were recruited from 17 healthcare facilities in Antananarivo, Madagascar. For each participant sputum were collected for acid-fast smear microscopy and Loweinsten-Jensen culture to identify the participants as active TB (pATB) and non-active TB pregnant women (pNTB). Venous blood were collected with PaxGene blood tubes to have RNA and QuantiFERON Gold Plus tubes to assess the TB infection status. The TB-scores generated from two signature sets Sweeney-3 and RISK6 were measured using qPCR.
Results: From April 2018 to August 2019, 34/276 pregnant women had TB bacteriologically confirmed TB. Significantly lower and higher relative expression respectively for DUSP3 ($p<0.01$) and GBP5 ($p<0.0001$) were observed in pATB compared to pNTB. A low Sweeney-3 TB-score was observed in pATB compared to pNTB ($p<0.0001$). RISK6 score shows a significative difference between pATB and pNTB ($p<0.0001$). From the ROC curve analysis, an AUC performance of GBP5 (AUC=0.77; 95%CI: 0.62-0.93), Sweeney-3 TB score (AUC=0.71; 95%CI: 0.55-0.87) and DUSP3 (AUC=0.64; 95%CI: 0.49-0.79). GBP5-TB score showed the best combination with a sensitivity and specificity ranging around 75.0% to 77.0 %, respectively.
Conclusions: While the two TB-gene signature showed slight difference between pregnant women with active and non confirmed pulmonary TB. The two gene signatures did not met the WHO Target product profile for screening tests for TB in our population.

EP06-756-18 TB treatment outcomes and safety among pregnant women and their infants

L. Chaisson,[1] S. Cox,[2] G. Gonzalez Perez,[3] I.D. Rusen,[4] S. Verkuijl,[4] K. Viney,[4] [1]University of California, San Francisco, UCSF Center for Tuberculosis, San Francisco, United States of America, [2]Johns Hopkins University, International Health, Baltimore, United States of America, [3]University of Illinois College of Medicine, Global Medicine, Chicago, United States of America, [4]World Health Organization, Global Programme on Tuberculosis and Lung Health, Geneva, Switzerland
e-mail: lelia.chaisson@ucsf.edu

Background: Pregnant and lactating women have historically been excluded from the majority of clinical trials on tuberculosis (TB) therapeutics, resulting in a lack of knowledge on the use of TB medicines for this population. We conducted a systematic review to evaluate TB treatment outcomes and safety for pregnant women.
Design/Methods: We identified studies reporting original data on TB among pregnant, postpartum, and/or lactating women published from January 2000–September 2024. We abstracted and pooled data to assess TB treatment outcomes (favorable vs. unfavorable); risk of adverse maternal outcomes (*e.g.,* death, pre-eclampsia, eclampsia); and risk of adverse fetal and neonatal outcomes (*e.g.,* preterm birth, low birthweight, TB, death) among pregnant women receiving TB treatment. We stratified analyses by country-level TB incidence and TB drug-susceptibility.
Results: In 22 studies reporting data on TB treatment outcomes, the pooled proportion with favorable outcomes was 79% (range 35%-100%) for drug-susceptible TB and 68% (range 49%-100%) for MDR/RR-TB. Unfavorable treatment outcomes were more common in high TB incidence settings.
In studies reporting data on maternal outcomes among pregnant women with TB (n=38), pooled mortality was 7.4% (range 0%-29%) for drug-susceptible TB and 8.2% for MDR/RR-TB (range 0%-13%) in high TB incidence settings. Incidence of pre-eclampsia ranged from 3.5%-8.9% and eclampsia from 0.7%-5.2%. In studies reporting data on fetal and neonatal outcomes (n=39), pooled incidence of stillbirth was 3.4% (range 0%-9.6%), preterm

birth was 32% (range 3.7%-70%), low birthweight was 35% (range 14%-64%), infant TB was 8% (range 0%-16%), and infant mortality was 6% (range 0%-9%) for drug-susceptible TB in high TB incidence settings (Table).

Outcome (number of studies included)	Pooled Proportion (Range)
IUD/Stillbirth (n=10)	3.4% (0% to 9.6%)
Spontaneous abortion (n=9)	4.1% (0% to 12.9%)
Preterm birth (n=11)	31.7% (3.7% to 70.0%)
Low birthweight (n=9)	35.4% (13.7% to 63.6%)
Small for gestational age (n=5)	28.3% (11.1% to 43.2%)
Infant TB (n=6)	8.0% (0% to 15.8%)
Infant death (n=4)	5.9% (0% to 8.6%)

Table. Adverse Neonatal and Infant Outcomes among Pregnant Women in Medium (100-300 cases per 100,000) or High (>300 cases per 100,000) TB Incidence Settings.

Conclusions: TB treatment outcomes varied widely among pregnant women, and TB in pregnancy was associated with a high risk of adverse fetal and neonatal outcomes, including preterm birth, low birthweight, and infant mortality. Adverse outcomes were most pronounced in settings with high TB incidence.

EP06-757-18 Rifampicin-resistant TB in pregnant and breastfeeding women: A review of national guidelines across high-burden countries

N. Hernandez-Morfin,[1] P. Phan,[2] N. Salazar-Austin,[1]
[1]Johns Hopkins University School of Medicine, Department of Pediatrics, Baltimore, United States of America, [2]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States of America.
e-mail: nataliahdezmorfin@gmail.com

Background: Pregnant and lactating women (PLW) have historically been excluded from tuberculosis (TB) treatment trials, leading to a lack of evidence-based guidelines for managing rifampicin-resistant TB (RR-TB) in these populations.
Despite recent advancements in TB treatment regimens, including newer all-oral, shorter-course options, PLW continue to receive prolonged and potentially more toxic treatments.
This study reviews national RR-TB guidelines across the high-burden RR-TB countries to assess the inclusion of specific recommendations for PLW, including guidance on diagnosis, treatment, monitoring, and breastfeeding.

Design/Methods: We conducted a policy review of national RR-TB guidelines in WHO's 30 high-burden RR-TB countries using systematic internet searches and outreach to key stakeholders. Data were extracted using a standardized form assessing screening, diagnosis, treatment regimens, clinical monitoring, and breastfeeding recommendations. Descriptive statistics were used to summarize findings.
Results: Among the 29 countries with available guidelines, all included at least one policy recommendation related to RR-TB in PLW. Only 52% specified a treatment regimen for pregnancy, while 38% provided guidance on individual drug safety. While 24% allowed the use of a 9-month all-oral regimen, an equal proportion explicitly prohibited it. Only 3% recommended or did not prohibit the use of the newer BPaL(M) regimen. Clinical monitoring recommendations were included in 28% of guidelines, with a minority specifying specialist involvement. Regarding transmission prevention to infants, 79% recommended continued breastfeeding using a mask. 11% of countries recommended postpartum separation under certain circumstances.

Recommendation:	N (%)
Specific RR-TB regimen recommended in pregnancy	15(52%)
No regimen specified, but drugs recommended	11 (38%)
No guidance provided	3 (10%)
9-month regimen	
Allowed	7 (24%)
Not allowed	7 (24%)
Do not specify duration of regimen	15 (52%)
BPaL/BPaLM	
Recommended	1 (3%)
Not prohibited	1 (3%)
Not recommended	9 (31%)
Delayed treatment start until 2nd trimester	11 (38%)
Pregnancy termination recommended (<20 weeks)	1 (3%)

Table 1. RR-TB treatment regimen recommended during pregnancy and lactation.

Conclusions: While high-burden RR-TB countries provide some guidance on TB management in pregnancy, there is substantial variability and inconsistency in recommendations. The limited inclusion of newer treatment regimens and inconsistencies in monitoring and breastfeeding guidance highlight an urgent need for more robust, standardized recommendations to ensure optimal care for PLW with RR-TB. Future research should prioritize the inclusion of PLW in clinical trials to generate evidence-based treatment guidelines.

EP06-758-18 Pharmacokinetics and safety of clofazimine in women treated for rifampicin-resistant TB during pregnancy and the postpartum period

J. Hughes,[1] F. McMorrow,[2] K. Brooks,[3] L. Fairlie,[4] A. Stek,[5] M. Mirochnik,[6] L. Wiesner,[7] K. George,[8] K. Knowles,[9] A.C. Hesseling,[1] E. Decloedt,[10] A. Eke,[11]
[1]Stellenbosch University, Paediatrics and Child Health, Cape Town, South Africa, [2]Harvard T. H. Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States of America, [3]Skaggs School of Pharmacy and Pharmaceutical Sciences, Department of Pharmaceutical Sciences, Aurora, United States of America, [4]University of the Witwatersrand, Wits RHI, Faculty of Health Sciences, Johannesburg, South Africa, [5]University of Southern California School of Medicine, Department of Obstetrics and Gynecology, Los Angeles, United States of America, [6]Boston University Chobanian and Avedisian School of Medicine, Department of Pediatrics, Boston, United States of America, [7]University of Cape Town, Department of Medicine, Cape Town, South Africa, [8]FHI 360, FHI 360, Durham, United States of America, [9]Frontier Science Foundation, Frontier Science Foundation, Amherst, United States of America, [10]Stellenbosch University, Department of Medicine, Cape Town, South Africa, [11]Johns Hopkins University School of Medicine, Department of Gynecology and Obstetrics, Baltimore, United States of America
e-mail: jhughes@sun.ac.za

Background: Clofazimine undergoes phase I liver metabolism by CYP1A2 and CYP3A4/A5, with phase II metabolism via UDP-glucuronosyltransferase enzyme systems. There are no published data on clofazimine pharmacokinetics during pregnancy, and safety data are limited.
We present pharmacokinetic and safety data from pregnant and postpartum women receiving clofazimine for treatment of rifampicin-resistant tuberculosis (RR-TB) in routine care in South Africa.
Design/Methods: This was a non-randomised, open-label, multicentre study to assess the pharmacokinetic properties of antiretroviral and related drugs during pregnancy and postpartum. Between 2017 and 2019, pregnant women receiving ≥2 second-line antituberculosis drugs in routine care were included. Participants were enrolled in the second or third trimester and had visits with intensive pharmacokinetic sampling at least once during pregnancy, and at 2-8 weeks postpartum. Pharmacokinetic parameters were estimated using non-compartmental methods and compared antepartum to postpartum (within participant) using geometric mean ratios (GMR) with 90% confidence intervals (CIs) and the Wilcoxon Signed-Rank Test for paired data.
Results: Eleven pregnant participants from South Africa, seven (65%) with HIV, were receiving clofazimine (100 mg daily) at enrolment, of which nine (82%) received clofazimine for >8 weeks prior to pharmacokinetic evaluation. Nine (82%) of the 11 women continued treatment postpartum. Peak plasma concentrations and area-under-the-concentration-time-curve exposures were higher in the third than the second trimester, but these exposures in the postpartum period were considerably lower than in pregnancy (Figure 1). Seven (64%) women and eight (73%) infants experienced severe adverse events during maternal RR-TB treatment, more likely related to co-morbidities and multidrug regimens than to clofazimine alone.
Conclusions: Clofazimine exposures during pregnancy were within the range previously reported among non-pregnant adult women receiving treatment for rifampicin-resistant tuberculosis. Maternal exposures in the two months after delivery were lower than during pregnancy, possibly due to hormonal changes and the effect on enzyme regulation and drug metabolism.

EP07 Measuring what matters: Prevalance, adherence and the human dimensions of TB care

EP07-759-18 Prevalence and trend of tuberculosis cases in tribal-dominated districts in India: A time series analysis

N. Mukherjee,[1] S. Basu Roy Choudhury,[2] P. Bhattacharya,[2] A. Versfeld,[3] [1]Manbhum Ananda Ashram Nityananda Trust (MANT), Centre for Public Health Resesrch at MANT, Kolkata, India, [2]Manbhum Ananda Ashram Nityananda Trust (MANT), Centre for Public Health Research at MANT, Kolkata, India, [3]Stop TB Partnership, Challenge Facility for Civil Society, Port Elizabeth, South Africa
e-mail: nirmalya@cphr-mant.org

Background: Tuberculosis remains the leading cause of death globally from a single infectious agent. India bears the highest TB burden, accounting for 27% of global cases. Despite this burden, limited research exists on TB prevalence among India's scheduled tribe population (104 Million), who have poor access to healthcare and are especially vulnerable due to social determinants such as poor malnutrition.
This study analyses the prevalence and trends in notified TB cases across tribal-dominated districts of India from 2021-2024.
Design/Methods: Quarterly data on TB notifications were extracted from Ni-kshay repository for the period January 2021 to December 2024 across Indian districts where scheduled tribe population exceeds 50%. A total of 90 such districts were identified, and TB notifications were aggregated by quarter. A seasonality index was computed to examine temporal variation, and trends were analysed using linear regression. The average annualized case notification rate (2021–2024) was calculated for each district to estimate prevalence, which was then mapped by state.
Results: Quarterly analysis of TB cases in 90 tribal-dominated districts showed seasonal variation, with highest notifications in the third quarter (index 1.08), suggesting a possible influence of climatic or socio-behavioural factors on TB reporting trends. A linear trend from 2021–2024 indicated a rising trajectory. The average ACNR was 144.63 per 100,000, significantly higher than the national average of 113 ($p < 0.05$). High-prevalence clusters were observed in 3 states, highlighting the need for targeted interventions.
Conclusions: While the analysis reveals seasonal and increasing trends in notified TB cases in tribal districts, it remains unclear whether these reflect true incidence patterns or seasonal shifts in healthcare access and reporting. This underscores urgent need for community-engaged research to investigate underlying socio-economic drivers and guide effective, context-specific responses.
Current top-down strategies risk missing large segments of vulnerable populations, necessitating more inclusive, participatory, and locally informed interventions.

EP07-760-18 Demographic and immunological patterns in tuberculosis infection: Insights from a hospital cohort of over 14,000 QFT-tested patients

P. Comella-del Barrio,[1,2] B. Miró,[3] L. Admella,[4] E. Ródenas-Alesina,[4,5,6] J. Espinosa-Pereiro,[1,2] M.L. Aznar,[1,2] J. Martínez-Campreciós,[1,2] M.T. Tórtola,[7] I. Ferreira-Gonzalez,[4,8] A. Sánchez-Montalvá,[1,2,9]
[1]Vall Hebron University Hospital, International Health Unit, Infectious Diseases Department, Barcelona, Spain, [2]Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red de Enfermedades Infecciosas (CIBERINFEC), Madrid, Spain, [3]Vall d'Hebron Research Institute, Statistics Unit, Barcelona, Spain, [4]Vall d'Hebron University Hospital, Cardiology Department, Barcelona, Spain, [5]Universitat Autonoma de Barcelona, Department of Medicine, Bellaterra, Spain, [6]Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red Enfermedades Cardiovaculares (CIBER-CV), Madrid, Spain, [7]Vall Hebron University Hospital, Microbiology Department, Barcelona, Spain, [8]Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red de Epidemiología y Salud Pública (CIBER-ESP), Madrid, Spain, [9]Sociedad Española de Enfermedades Infecciosas y Microbiología Clínica, Grupo de Estudio de Micobacterias, Madrid, Spain

Background: Tuberculosis infection (TBI) has been associated with chronic low-grade immune activation, a potential contributor to long-term health outcomes beyond tuberculosis. As part of a broader study investigating the link between TBI-driven immune activity and cardiovascular risk, we began by analysing the hospital's QuantiFERON-TB Gold (QFT) test database as an initial exploratory step. This analysis focused on patient-level interpretation of QFT results to identify demographic and clinical patterns relevant to persistent immune activation.
Design/Methods: We analysed 48,341 QFT test records performed in adults at a tertiary hospital between 2010 and 2023. After data cleaning and harmonisation, we include records with valid qualitative results and corresponding quantitative interferon-gamma values (Nil and antigen tubes). The final dataset included 14,342 unique patients. We described QFT positivity rates and explored associations with age, sex, and requesting clinical service. Nil tube values were analysed as a proxy for baseline immune activation.
Results: QFT was positive in 19.3% of cases, more frequently in men (22.8%) than women (15.6%). Positivity rose from 17% in ages 18–30 to 24% in those over 70. Highest positivity rates were observed in requests from

TB control, Infectious Diseases. Nil IFN-γ levels were higher in QFT-positive individuals (~0.5 IU/mL) than in negatives (~0.1 IU/mL; $p < 0.001$). Young men showed higher baseline IFN-γ than young women of the same age, a difference that waned over time (*Figure 1*).

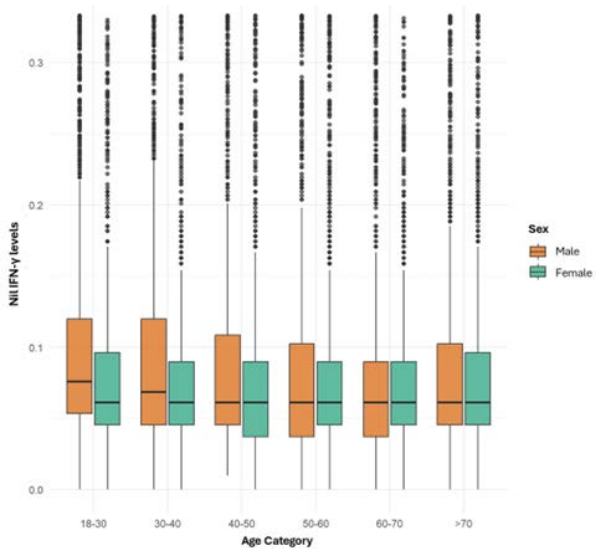


Figure 1. Baseline interferon-gamma levels (Nil tube) by age group and sex.

Conclusions: This large-scale hospital-based analysis supports the hypothesis that TBI contributes to persistent immune activation. The sex and age differences observed in IFN-γ levels may reflect variability in exposure to *Mycobacterium tuberculosis*, particularly in young men. These findings represent a profile of TBI in low incidence country and confirm progress toward understanding the long-term impact of TBI on cardiovascular health.

EP07-761-18 Sex stratified tuberculosis prevalence in low- and middle-income countries: Systematic review and meta-analysis

N. Swartwood,[1] N. Singh,[1,2] S.A. Mortazavi,[3] M.H. Can,[1] H. Cui,[1] D.K. Ryuk,[1,4] P. MacPherson,[3] K. Horton,[5] N. Menzies,[1] [1]Harvard TH Chan School of Public Health, Global Health and Population, Boston, United States of America, [2]NYU Grossman School of Medicine, Department of Population Health, New York City, United States of America, [3]University of Glasgow, School of Health & Wellbeing, Glasgow, United Kingdom of Great Britain and Northern Ireland, [4]Seoul National University College of Medicine, Department of Preventive Medicine, Seoul, Republic of Korea, [5]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland
e-mail: nswartwood@hsph.harvard.edu

Background: Men are at greater risk of tuberculosis (TB), have poorer access to care, and have worse TB outcomes than women in low- and middle-income countries (LMICs). We systematically identified survey-based sex-stratified estimates of TB prevalence in LMICs to investigate differences in TB prevalence by sex, and how this has changed over time.

Design/Methods: We searched multiple databases for publications which reported sex-stratified estimates of TB prevalence in LMICs and published between December 1, 2015, and February 29, 2024. We also included relevant surveys from a previous review, extending our study period to 2000–2024.

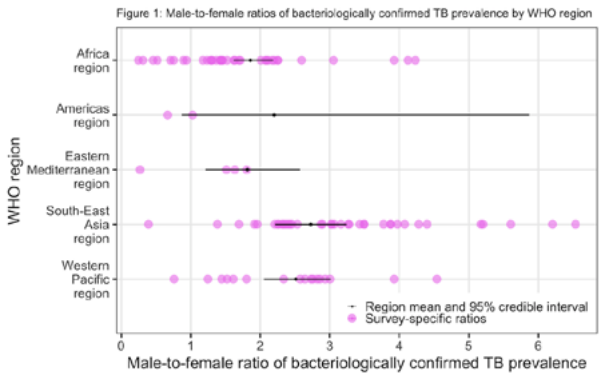
We fit multi-level Bayesian regression models to estimate TB prevalence for men and women, accounting for country- and survey-level random effects. We also estimated variation across World Health Organization (WHO) regions and annually.

Results: We screened 5,650 publications, reviewed full-text of 201 studies, and included 99 unique TB prevalence surveys (>4 million participants, 33 unique countries in five WHO regions) that reported sex-stratified bacteriological-confirmed TB prevalence in analysis.

Overall, TB prevalence was 444 [95% credible interval: 344, 605] per 100,000 among men and 201 [151, 278] per 100,000 among women, with a male-to-female prevalence ratio of 2.2 [1.9, 2.5].

All included WHO regions were estimated to have male-to-female prevalence ratios greater than 1.0–South-East Asia: 2.7 [2.2, 3.2], Western Pacific: 2.5 [2.1, 3.0], Americas: 2.4 [0.8, 5.5], Africa: 1.9 [1.6, 2.2], and Eastern Mediterranean: 1.8 [1.2, 2.6] (Figure 1).

Between 1994 and 2021, the male-to-female prevalence ratio increased with estimated male-to-female prevalence ratios of 1.9 [0.5, 5.1] in 1994 and 2.7 [1.4, 4.7] in 2021.



Conclusions: In LMICs, TB prevalence is substantially higher among men than women, with disparity likely widening. Understanding the individual, social, and health system determinants of this persistent gender differential is essential to maintaining an equitable path toward TB elimination.

EP07-762-18 Tuberculosis in prisons in Eastern Europe and Central Asia: A scoping review of prevention, diagnosis, and treatment interventions

A. Abdurakhmanova,[1] J. Cepeda,[2] S. Cox,[3] [1]Johns Hopkins University, BSPH, Health Leadership and Management concentration, Baltimore, United States of America, [2]Johns Hopkins University, BSPH, Epidemiology, Baltimore, United States of America, [3]Johns Hopkins University, BSPH, International Health, Baltimore, United States of America
e-mail: scox26@jhmi.edu

Background: Tuberculosis (TB) remains a major public health concern in prison systems across Eastern Europe and Central Asia (EECA), with prisons acting as amplifiers of TB transmission and drug resistance. Understanding TB care delivery across the criminal justice continuum is essential for improving health outcomes for incarcerated and recently released individuals.
Design/Methods: This scoping review maps evidence from original research studies published from 2010 to 2025 on TB interventions across the care cascade: TB preventive treatment (TPT), active case finding (ACF), diagnosis, and treatment.
The studies included were published in English or Russian and focused on incarcerated or previously incarcerated individuals in EECA countries. Databases searched included PubMed, Embase, and Web of Science. This care cascade was aligned with stages of the criminal justice continuum.
Results: We screened 206 articles, conducted full-text reviews for 103, and included 20. Most TB interventions were concentrated during incarceration. At intake, 7 studies reported symptom-based screening, but no other algorithms were described. During incarceration, 8 studies described periodic symptom-based screening, 3 had Xpert MTB/RIF and drug-susceptibility testing available onsite, and 13 reported offering treatment free of cost. Exit screening prior to release was rarely reported; only one study mentioned a small-scale intervention with no cases identified. Evidence was scarce for interventions after re-entry: only 1 paper discussed ACF, highlighting gaps in continuity of care. No study mentioned offering TPT to incarcerated or previously incarcerated people.

Table. TB interventions at each step of the TB care cascade available at each step of the criminal justice continuum in Eastern Europe and Central Asia*

	TB care cascade			
Criminal Justice Continuum	TB Preventive Treatment	Active case finding	Diagnostics	Anti-TB Treatment
During intake	None	Symptom-based screening n=7 papers	None	None
While incarcerated	None	Periodic symptom-based screening n=8 papers Annual (n= 3), bi-annual (n= 1), no frequency specified (n= 4)	On-site testing n=3 papers Xpert MTB/RIF (n=2), DST using MGIT and MTBDRplus (n=1)	On-site treatment (free of cost) n=13 papers
Prior to re-entry into community	None	Symptom-based screening n=1 paper	None	None
After re-entry into community	None	Symptom-based screening + incentives for sputum collection n=1 paper	None	None

*Data is summarized from 20 unique papers. Some papers described interventions at multiple care cascade steps.

Conclusions: While diagnostic and treatment interventions exist within prison walls, TB prevention and post-release continuity of care remain critically under-reported in the EECA region. Further research is needed on interventions that close these gaps, including expanding preventive therapy, standardizing exit screenings, and strengthening reintegration support. Improving linkage between penitentiary TB services and civilian health systems is essential to ensure that individuals released from incarceration can continue and complete their TB treatment without interruption.

EP07-763-18 Delays in uptake of global guidance for treatment of drug-susceptible tuberculosis case of Perú

J. Galarza,[1] C. Mitnick,[2] E. Osso,[2] A. Mendoza,[3] L. Lecca,[4] [1]University of Texas Health Science Center at Houston, Internal Medicine - Infectious Disease, Houston, United States of America, [2]Harvard University, Department of Global Health & Social Medicine, Harvard Medical School, Boston, United States of America, [3]Socios En Salud Sucursal Peru, Direccion de Programas, Lima, Peru, [4]Socios En Salud Sucursal Peru, Executive Direction, Lima, Peru
e-mail: jimmy.h.galarzacastillo@uth.tmc.edu

Background and challenges to implementation: Peru continues to struggle against TB, with the second-highest tuberculosis (TB) burden in the Americas. Innovations in TB treatment could improve the TB situation. The World Health Organization (WHO) has endorsed significant advances in updated guidelines, issued three times since 2010, with the latest update in 2022. We explored if Peru has integrated innovations from 2010 to 2023.

#	Summary of WHO recommendation	WHO (2010)	MINSA (2013)	WHO (2017)	MINSA (2018)**	WHO (2022)	MINSA (2023)
1	New patients with pulmonary TB should receive a regimen containing 6 months of rifampicin: 2HRZE/4HR	Strong recommendation High certainty of evidence	Agrees	Strong recommendation High certainty of evidence	Agrees	Strong recommendation High certainty of evidence	Agrees
2	Wherever feasible, the optimal dosing frequency for new patients with pulmonary TB is daily throughout the course of therapy	Strong recommendation High certainty of evidence	Does not agree	Strong recommendation High certainty of evidence	Does not agree	Strong recommendation High certainty of evidence	Does not agree
3	New patients with pulmonary TB may receive a daily intensive phase followed by a three-times weekly continuation phase [2HRZE/4(HR)3], provided that each dose is directly observed.	Conditional recommendation Moderate certainty of evidence	Agrees[&]	Withdrawn	Does not agree (retained)	Withdrawn	Does not agree (retained)
	3.1. New patients with pulmonary TB may receive a daily intensive phase followed by a three-times weekly continuation phase [2HRZE/4(HR)3], provided that each dose is directly observed in an HIV-prevalent setting	Conditional recommendation Moderate certainty of evidence	Agrees[&]	Withdrawn	Does not agree (retained)	Withdrawn	Agrees (withdrawn)
4	In all patients with drug-susceptible pulmonary TB, the use of thrice-weekly dosing is not recommended in both the intensive and continuation phases of therapy, and daily dosing remains the recommended dosing frequency	NA	NA	Conditional recommendation Very low certainty of evidence	Does not agree	Conditional recommendation Very low certainty of evidence	Does not agree
5	In new pulmonary TB patients treated with the regimen containing rifampicin throughout treatment, if a positive sputum smear is found at completion of the intensive phase, the extension of the intensive phase is not recommended	Strong recommendation High certainty of evidence	Does not agree	Strong recommendation High certainty of evidence	Does not agree	Strong recommendation High certainty of evidence	Does not agree
6	People aged 12 years or older with drug-susceptible pulmonary TB may receive a 4-month regimen of isoniazid, rifapentine, moxifloxacin and pyrazinamide (2HPMZ/2HPM)	NA	NA	NA	NA	Strong recommendation (new) Moderate certainty of evidence	Does not agree
	6.1. In children and adolescents between 3 months and 16 years of age with non-severe TB (without suspicion or evidence of MDR/RR-TB), a 4-month treatment regimen (2HRZ(E)/2HR) should be used	NA	NA	NA	NA	Strong recommendation (new) Moderate certainty of evidence	Does not agree
7	TB patients who are living with HIV should receive at least the same duration of daily TB treatment as HIV-negative TB patients.	Strong recommendation High certainty of evidence	Agrees*	Strong recommendation High certainty of evidence	Agrees*	Strong recommendation High certainty of evidence	Agrees
	7.1. ART should be started as soon as possible within two weeks of initiating TB treatment, regardless of CD4 cell count, among people living with HIV. Adults and adolescents / Children and infants.	NA	Agrees	Strong recommendation, low to moderate certainty of evidence: Adults / Adolescents. Very low certainty of evidence: Children and infants	Agrees	Strong recommendation, low to moderate certainty of evidence: Adults / Adolescents. Very low certainty of evidence: Children and infants	Agrees
8	In patients with tuberculous meningitis, an initial adjuvant corticosteroid therapy with dexamethasone or prednisolone tapered over 6–8 weeks[#] should be used.	NA	Preceded	Strong recommendation Moderate certainty of evidence	Agrees	Strong recommendation Moderate certainty of evidence	Agrees
	8.1. In patients with tuberculous pericarditis, an initial adjuvant corticosteroid therapy may be used.	NA	Preceded	Conditional recommendation Very low certainty of evidence	Agrees	Conditional recommendation Very low certainty of evidence	Agrees

* In Peru, the recommendation is for 9 months of daily treatment for HIV-coinfected, longer than the standard 6 months recommended for people not living with HIV.
** In 2018, parts of the Peruvian Norma were updated, but a full, new version was not reissued.
[&] It only applies the continuation phase in the Peruvian Norma.
[#] Different durations are recommended: 2-4 weeks in Peru and 6-8 weeks by WHO.
The recommendation: The use of fixed-dose combination (FDC) tablets is recommended [over separate drug formulations in the treatment of patients with drug-susceptible TB] was not included in the table due to format requirements, this recommendation was uptake by the Peruvian guideline since 2013.

EP07-763-18 Table.

Intervention or response: In this case study, we systematically compared each WHO recommendation to those contained in the contemporaneous guidance in Peru.
We categorize and report the number of concordant or non-concordant recommendations between those guidelines.
Results/Impact: Between 2010 and 2022, WHO issued 13 treatment recommendations for drug-sensitive TB (DS-TB), focusing on regimen composition, duration, formulation, administration frequency, adjustments for HIV-TB, and adjunctive therapies for extrapulmonary TB. Six of these recommendations are based on high-certainty evidence and remain in place.
By March 2023, Peru had adopted 6 of the 13 WHO recommendations. The country incorporated 67% of WHO's 2010 recommendations by 2013 and 67% of the 2017 guidelines by 2018. The two sets of guidelines align on regimen composition, particularly for people living with HIV, and on adjunctive therapies like antiretrovirals for HIV and corticosteroids for extrapulmonary TB, the latter adopted earlier by Peru than by WHO.
Conclusions: Our analysis shows that delays in adopting--or outright rejection of—the recommendations on duration could result in unnecessarily prolonged treatment, increased toxicity, significant inconvenience, and added burdens on the healthcare system.
Since 2010, more than 200,000 patients have been treated for TB in Peru under guidance that lags behind the global standard.
This is an ethical and public health failure. Systems for rapid review of emerging evidence and informed updates—and implementation—of guidance are critical to improve the quality of care for and reduce the burden of TB in Peru.

EP07-764-18 Integrated service delivery for tuberculosis: Assessing people-centeredness, sustainability, and effectiveness in wave 10 TB REACH interventions

J. Alonso,[1] M.I. Bakker,[1] A. Khan,[2] B. Kirubi,[3] J. Creswell,[4]
[1]KIT Royal Tropical Institute, Global Health, Amsterdam, Netherlands, [2]Independent, n.a., Chicago, United States of America, [3]Stop TB Partnership, Innovations and Grants, Stockholm, Sweden, [4]Stop TB Partnership, Innovations and Grants, Geneva, Switzerland
e-mail: julia.alodiam@gmail.com

Background: Global health interventions have historically focused on disease-specific programs to combat urgent health threats like the HIV and TB pandemics. While effective in mobilizing rapid responses, these vertical approaches have been criticized for being fragmented, inefficient, and unsustainable. Amid the rising burden of non-communicable diseases (NCDs) and the ethical imperative to provide human-rights-based care, integrated, people-centered strategies are gaining prominence. In response, TB REACH prioritized Integrated Service Delivery (ISD) in its Wave 10 funding cycle, supporting projects that combined TB services with care for other conditions.
Design/Methods: This mixed-methods study aims to characterize and evaluate the diverse case finding ISD models in 19 projects with multiple interventions across 14 countries running between Q1 2023 and Q4 2024. Project reports, quantitative data, a survey, and interviews were analyzed across three key impact areas of ISD theory: people-centeredness, sustainability, and effectiveness in TB case finding.
Results: Preliminary findings reveal four main approaches to ISD in Wave 10 projects. Most projects integrated TB screening into multi-disease community outreach (12 projects) or into existing services within health facilities (10 projects), such as maternal health or diabetes clinics. Only three projects screened or referred people with TB for additional health needs. Interestingly, five projects offered combined screening for TB and another condition within facilities. Although integration mostly involved screening and diagnosis, some interventions also targeted steps further down the care cascade, such as treatment initiation and adherence. Key challenges included care linkage due to barriers in access and treatment availability for conditions other than TB.
Conclusions: Early findings suggest ISD may improve convenience and access for people seeking care, but requires careful planning not to over-burden the health system and to ensure full care delivery for all health conditions. Final conclusions will align with the ISD theoretical framework upon study completion.

EP07-765-18 Temporal complexity in non-adherence to anti-tuberculosis treatment, a prospective cohort study in Tanzania

L. Tuwabunze,[1] K. Salim,[1] A. Liyoyo,[1] P. Paul,[2] S. Mpagama,[1] H.R. Stagg,[2] [1]Kibong'oto Infectious Disease Hospital, N/A, Sanya Juu, United Republic of Tanzania, [2]London School of Hygiene & Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland
e-mail: helen.stagg@lshtm.ac.uk

Background: Non-adherence to anti-tuberculosis (TB) regimens is not simplistic; rather, doses are missed in complex patterns. In a cohort of individuals being treated for rifampicin-sensitive pulmonary TB in Tanzania, we sought to examine the temporal complexity of how non-adherence changed across the treatment course and within a day, as well as the reasons for missed dose periods.
Design/Methods: 200 participants aged ≥18 years treated with the standard six-month regimen for drug sensitive TB were recruited March 2022-June 2023. Missed doses were measured using evriMED pillboxes and by pill count. Participant-declared reasons for up to three missed dose periods per month were collected. Patterns of missed doses- across treatment and within a day- and their reasons were visualised and described.
Results: Two participants died early in treatment, leaving 198 with missed dose data. Missed doses increased as time progressed. This was driven by early cessation of treatment (aka early discontinuation; median doses missed 0.0% in month 1 vs. 6.7% in month 6) from treatment, as opposed to doses missed sporadically (median doses missed 3.1% in month 1 vs. 4.1% in month 6). There was a median of one sporadic missed dose period (ranging between 0 and 42 doses in length) per participant. Out of all reported reasons for missed dose periods (Figure), 'forgot' or 'forgot and inconvenience' were the most common (59.6%).

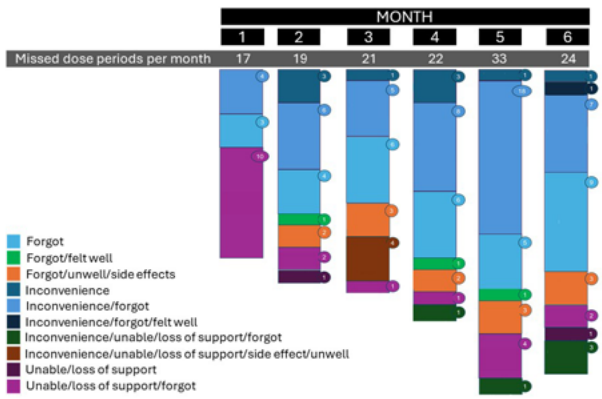


Figure. Reasons for missed doses across the treatment period.
The reasons for periods of missed doses (sporadic or early discontinuation) were reported for up to three missed dose periods per month by the participant. Numbers in circles/length of columns indicates the number of periods that occurred for that reason (or group of reasons) within a month. Multiple missed dose periods can be attributed to a participant in a particular month. If missed dose period spanned more than one month, it was reported across both months.

Conclusions: Non-adherence to anti-TB treatment is temporally complex, increases across the treatment course, and is the result of the intersection of multifaceted day-to-day events in an individual's life, with complicated implications for effective drug levels across the treatment course. This complexity substantially limits our ability to predict an individual's non-adherence at the start of treatment.
Joint first authors: Tuwabunze and Salim
Joint senior authors: Mpagama and Stagg

EP07-766-18 A comparison of adherence to tuberculosis treatment measured using self-report and urine testing amongst people with drug susceptible pulmonary tuberculosis (DSTB) in Johannesburg, South Africa

F. Munedzimwe,[1,2] R. Tomotomo,[1] A. Rachow,[3] M. Rassool,[4] L. Singh,[4] K. Velen,[5] S. Charalambous,[6,2] TB Sequel Network
[1]The Aurum Institute, Implementation Research Division, Johannesburg, South Africa, [2]University of the Witwatersrand, School of Public Health, Faculty of Health Sciences, Johannesburg, South Africa, [3]Klinikum of the University of Munich, Division of Infectious Diseases & Tropical Medicine, Munich, Germany, [4]Clinical HIV Research Unit, , University of the Witwatersrand,, Faculty of Health Sciences, Department of Internal Medicine, School of Clinical Medicine, Johannesburg, South Africa, [5]Foundation for Innovative New Diagnostics (FIND), Campus Biotech, Geneva, Switzerland, [6]The Aurum Institute, Global, Johannesburg, South Africa
e-mail: fmunedzimwe@auruminstitute.org

Background: Reliable adherence monitoring is essential for effective TB treatment and assessing the effectiveness of adherence-enhancing interventions yet no gold standard for measuring adherence exists. This study compared self-reported adherence to objective urine-based testing and identified predictors of non-adherence in a South African TB cohort.
Design/Methods: This cross-sectional study included people with DSTB recruited into the TB Sequel cohort between 07/2017-09/2019 in Johannesburg, South Africa. Adherence was assessed using self-reported missed doses and isoniazid urine testing at Month 2 (M2) and Month 6 (M6) using Isoscreen™ kits (GFC Diagnostics. Concordance was assessed using Gwet's AC. Diagnostic accuracy metrics (sensitivity, specificity, predictive values) were calculated. Multivariable logistic regression identified factors associated with urine-confirmed non-adherence.
Results: From 359 participants recruited in Johannesburg, 186 participants were included in this study. Over half, 110/186(59%) participants were male.
Self-reported adherence, defined as not missing any doses since the last study visit was high (95%(175/185) at M2 and 91%(170/186) at M6). Urine testing using kits that detect isoniazid, with its presence serving as a proxy for adherence, revealed lower adherence: 93%(172/183) at M2 and 79%(145/183) at M6. Concordance be-

tween self-report and urinalysis was high using Gwet's AC:0.88(95%CI:0.82–0.93) at M2 declining slightly to 0.69(95%CI:0.6–0.77) at M6. Self-report compared with urinalysis as the gold standard showed strong sensitivity (93% and 78%) and PPV(>91%), but poor specificity (9% and 25%) and NPV(<10%), indicating limited ability to detect non-adherence. In an adjusted logistic regression analysis, males were less likely to be non-adherent (aOR:0.23;95%CI:0.08–0.63p=0.004). Age, alcohol, education level and being on ART were not significantly associated with non-adherence.

	Proportion non- adherent	OR (95% CI)	p-value	aOR* (95% CI)	p-value
Age categories					
18-29	16%(9/34)	Per category increase -0.011 (-0.35-0.33)	0.95	Per category increase 1.08 (0.65-1.79)	0.76
30-39	28%(21/74)				
40-49	24%(12/50)				
50+	29%(50/28)				
Gender					
Female	20%(22/110)	Reference-Female 0.43 (0.22-0.83)	0.012	Reference-Female 0.24 (0.089-0.64)	0.005
Male	37%(28/76)				
Alcohol Use					
Non-drinkers	21%(15/72)	Per level increase 0.31 (0.19-0.51)	0.37	Per level increase 1.47 (0.76-0.65)	0.249
Moderate drinkers	33%(26/79)				
Heavy drinkers	26%(9/35)				
Education Level					
Low (No school or primary)	32%(8/25)	Per Level increase 0.97 (0.48-2.04)	0.93	Per level increase 0.13 (0.33-1.07)	0.067
Medium (Secondary/Highschool or vocational training)	25%(38/150)				
High (University & Higher)	36%(4/11)				
On Antiretrovirals (ART)		Reference-No		Reference-No	
Yes	54% (62/116)	1.00	0.99	0.38	0.701
No	46% (54/116)	(0.44-2.31)		(0.33-2.12)	

*Adjusted for age, gender, alcohol use, education level and ART

Table 1. Demographic and clinical factors associated with urine confirmed non-adherence.

Conclusions: Self-reported adherence overestimates adherence and fails to identify those at risk of treatment failure. Integrating objective adherence measures into TB programs may improve monitoring, enable early intervention, and support more person-centred care for better TB outcomes.

EP07-767-18 A theory-driven evaluation of the acceptability of a complex DRTB/HIV adherence intervention in South Africa

B. Seepamore,[1] J. Zelnick,[2] S. Tenza,[3] M. Girma,[4] J. Yushkov,[4] M. Zulu,[3] R. Perumal,[3] K. Naidoo,[3] R. Amico,[5] M.R. O'Donnel,[6] A. Daftary,[4] [1]University of KwaZulu-Natal, Social Work, Durban, South Africa, [2]Touro University Graduate School of Social Work, Social Work, New York, United States of America, [3]Centre for the AIDS Programme of Research in South Africa, CAPRISA MRC-HIV-TB Pathogenesis and Treatment Research Unit, Durban, South Africa, [4]York University, School of Global Health, Toronto, Canada, [5]University of Michigan, Department of Health Behavior Health Equity, Michigan, United States of America, [6]Columbia University, Department of Medicine, Division of Pulmonary, Allergy, and Critical Care Medicine, New York, United States of America
e-mail: seepamoreb@ukzn.ac.za

Background: Intervention acceptability is critical to uptake and scale-up. We evaluated acceptability in an ongoing randomized control trial (RCT) comparing the effectiveness of adherence strategies among people with DRTB-HIV.

Data collection and coding were guided by the theoretical framework of acceptability focusing on affective attitude, burden, ethicality, coherence, opportunity cost, perceived effectiveness, and self-efficacy,

Design/Methods: Between December 2023 to March 2025, in-depth interviews were conducted with 30 trial participants exposed to one of four study arms:

A. Enhanced standard of care (enhanced training and workflow);

B. Psychosocial support (A + individual counselling, support groups, transport assistance, trial reimbursement);

C. mHealth (A + electronic monitoring– Wisepill device, trial reimbursement), or;

D. Which includes all elements of A+ B+C).

Trained staff, multiple coders, and audit trails supported rigorous data collection, inter-rater reliability, and analytic confirmability.

Results: Participants were gender and age-diverse (16 females, median 36.5 years) and exposed to intervention A (n=6), B (n=7), C (n=9), or D (n=8). All reported that DRTB-HIV had disrupted their lives, arduous treatment, and increased dependency on others for emotional and material support. Stigma, income loss, and food scarcity were major concerns.

While they conveyed strong coherence and self-efficacy towards all interventions, specific components were differentially accepted (Table 1). (A): Short waiting times, staff compassion and respect, (B, D:) individual counselling, staff availability, peer support, and reimbursements (all arms) were considered the most valuable, least burdensome, ethically aligned, and confidence-bolstering. Affective attitudes toward psychosocial support (B, D), including staff relations (A), were strong.

Despite high coherence and self-efficacy toward mHealth (C), the device and follow-up calls were burdensome, diminishing acceptability. Innate treatment attributes, core to affective attitudes such as treatment length or job loss remained unaddressed.

Affective Attitude	Burden	Ethicality	Intervention Coherence	Opportunity Cost	Perceived Effectiveness	Self-Efficacy Effectiveness
How participants feel about the intervention	Amount of effort required to participate	Extent to which intervention good fit with individual values	Extent to which participant understands the intervention	Extent to which benefits, opportunities must be given up to participate	Extent to which intervention is likely to achieve its purpose	Confidence they can perform required behaviour
Motivated to complete treatment and	Disruption of everyday life (e.g. waking up to take meds)	Treated with respect, compassion and patience	Knowledge of the disease (DRTB), medication and side-effects	Loss of employment or work opportunities	Believe that they will be cured (DRTB)	Knows how to use the pillbox (understands dashboard)
Adherence being easier						
Appreciate the reimbursement and transport to the study site	Increased reliance on family and friends for support	Can depend on team/free to talk to staff	Study is to help people stay adherent, complete treatment, motivate, and learn about DRTB	Financial cost (travel, food)	The staff know what they are doing ("their things are straightforward")	Does not need reminders anymore, takes meds as instructed
Short waiting time	Carrying a pillbox (to visit or work)	Confidentiality (no label on pillbox)	Knows how to use the pillbox (understands dashboard)	Loss of relationships such as boy/girlfriend		Developed strategies to store/take meds (counts the pills)

Conclusions: Facility-level program enhancements and psychosocial support that align with patient values and ethics, imposed the least burdens and opportunity costs were most acceptable.

EP07-768-18 Digital DOTS's expansion for TB care in Brazilian municipalities: An operational analysis

A.L.T. Vinci,[1] N.M. Ribeiro,[1] W.O.B. Bernardi,[1] I.S. Oliveira,[1] B.F. Vigato,[1] M.E.P. Pelodan,[1] Y.M. Alves,[1] R.J. Rosa,[1] R.B.V. Tavares,[1] N. Zini,[1] I.C. Pinto,[1] R.A. Arcêncio,[1]
[1]Ribeirão Preto Nursing School - University of São Paulo (USP), Maternal-Infant Nursing and Public Health, Ribeirão Preto, Brazil
e-mail: altvinci@alumni.usp.br

Background: Tuberculosis (TB) remains a major public health challenge, especially in developing countries. Treatment adherence is essential for TB control, and digital technologies, such as Video Directly Observed Therapy (VDOT), offers a promising, patient-centered alternative that may improve adherence, outcomes, and reduce costs. In 2023, Brazilian government recommended a protocol for digital health use in TB treatment, but did not establish a particular technology, allowing municipalities to choose based on local needs. This study aimed to evaluate VDOT implementation in Brazilian municipalities and identify key implementation constraints.

Design/Methods: The study is being conducted in municipalities in São Paulo state, chosen by epidemiological criteria, including high TB incidence and loss to follow-up rates. VDOT allows video recording of medication intake via an Android application, allowing asynchronous supervision by healthcare professionals. Questionnaires were administered to individuals undergoing TB treatment. A descriptive analysis of participant profiles was performed, along with characterization of municipalities and challenges in implementing VDOT.

Results: VDOT has already been implemented in 6 of the 30 municipalities selected. Regarding the participants (n=23), the majority were male (73.9%), aged between 30 and 59 years (65.2%), self-identified as "pardo" (mixed race) (56.5%), had incomplete primary education (43.5%), worked in informal employment (30.4%) and earned less than the minimum wage (34.8%). The main constraints to expanding VDOT usage identified included management and professionals' changes due the election period, which delayed new municipalities' inclusion. Additional challenges involved heterogeneity in structure and processes in TB treatment, both across and within municipalities. Limited access to smartphone or Internet among individuals in treatment also restricted VDOT use.

Conclusions: The use of VDOT in TB treatment supervision has shown potential to improve adherence, especially in vulnerable populations, and, as study progress, more data will be available on the VDOT effectiveness and its impact on Brazilian public health.

EP08 TB treatment risks uncovered: Tackling adverse drug events and drug interactions

EP08-769-18 Drug–drug interactions between antiretroviral and anti-TB therapy in adults and children: A systematic review of pharmacokinetic and clinical outcomes

G. Aliska,[1,2,3] J.E. Marzuki,[4,5] R. Russilawati,[1,6]
[1]Universitas Andalas, Pharmacology and Therapeutics, Padang, Indonesia, [2]Dr M Djamil General Hospital, Clinical Pharmacology, Padang, Indonesia, [3]Universitas Andalas, Centre for Diagnostic and Research on Infectious Disease (PDRPI), Padang, Indonesia, [4]Universitas Surabaya, Pharmacology, Surabaya, Indonesia, [5]Ubaya Hospital, Clinical Pharmacology, Surabaya, Indonesia, [6]Dr M Djamil General Hospital, Departement of Pulmonology and Respiratory Medicine, Padang, Indonesia
e-mail: aliska@med.unand.ac.id

Background: Co-administration of antiretroviral therapy (ART) and anti-tuberculosis (TB) treatment is necessary in many HIV-infected individuals but presents major challenges due to drug–drug interactions (DDIs). Rifampicin and rifapentine, key components of first-line TB therapy, are potent enzyme inducers that can lower ART concentrations, especially among non-nucleoside reverse transcriptase inhibitors (NNRTIs) and protease inhibitors (PIs). Conversely, isoniazid may inhibit metabolism and increase toxicity risk.
This systematic review summarizes the pharmacokinetic and clinical outcomes of ART–TB co-treatment in both adults and children, with additional focus on pharmacogenetic variability.
Design/Methods: We reviewed 32 studies published through March 2025, including randomized controlled trials, cohort studies, and pharmacokinetic evaluations. Populations included HIV-infected adults and children receiving rifamycin-based TB therapy.
Outcomes assessed included antiretroviral plasma trough concentrations (Cmin), area under the curve (AUC), virologic suppression, and adverse events. Due to the heterogeneity of outcomes across studies, results were synthesized descriptively and stratified by ARV class (efavirenz, nevirapine, dolutegravir, PIs), age group, and genetic factors (CYP2B6, NAT2).
Results: Efavirenz showed stable exposure in most adult cohorts despite rifampin co-administration. However, up to 60% of children had subtherapeutic EFV levels. Nevirapine exposure was consistently reduced by rifampin and rifapentine, with lower concentrations associated with increased risk of virologic failure.
Dolutegravir required 50 mg twice daily to maintain effective exposure with rifampin, while rifabutin co-treatment often led to inadequate DTG and PI levels. Pediatric use of PIs with rifabutin was associated with neutropenia. CYP2B6 and NAT2 polymorphisms significantly influenced ART exposure and safety profiles.
Conclusions: This review highlights consistent pharmacokinetic risks across age groups and drug classes. Efavirenz remains the most robust ARV for adult TB co-treatment. Nevirapine and dolutegravir require careful monitoring or adjustment. Personalized ART guided by age and pharmacogenetics is essential to optimize TB–HIV outcomes.

EP08-770-18 Real-world challenges of 4-month rifapentine-moxifloxacin TB regimen: High hyperbilirubinemia in Thailand

T. Sanchat,[1] C. Chuchottaworn,[1] P. Sangsayunh,[1]
[1]Central Chest Institute of Thailand, Respiratory medicine, Muang District, Thailand
e-mail: sthanyanuch@gmail.com

Background: The four-month rifapentine-moxifloxacin (HPMZ) regimen has been endorsed as an alternative to the standard six-month tuberculosis (TB) treatment. While clinical trials have demonstrated its efficacy and safety, real-world data, particularly in Asian populations, remain limited. This study evaluates the effectiveness and safety of the HPMZ regimen in Thailand.
Design/Methods: This prospective study was conducted at the Central Chest Institute of Thailand from September 2023 to February 2025. Eligible participants were drug-susceptible TB (DS-TB) patients. The HPMZ regimen consisted of daily rifapentine 1200 mg, moxifloxacin 400 mg, isoniazid 300 mg, and weight-based pyrazinamide for eight weeks, followed by rifapentine, moxifloxacin, and isoniazid for nine additional weeks. Patients were monitored at scheduled visits, and adverse drug reactions (ADRs) were recorded.
Results: Eleven participants were enrolled, with a median age of 55 years and a median weight of 52.7 kg. The mean rifapentine dose was 21.38 mg/kg, Hyperbilirubinemia was the most common ADR, leading to treatment discontinuation in 90.91% of patients. Grade 3 hyperbilirubinemia occurred in 63.63%, with peak bilirubin levels averaging 3.12 mg/dL. Plasma concentration analysis revealed rifapentine overexposure, with two patients exceeding the reported mean Cmax of 48.25 μg/mL and 41.89 μg/mL.
Conclusions: The high incidence of hyperbilirubinemia suggests that the fixed 1200 mg rifapentine dose may not be suitable for lower-weight populations. These findings highlight the need for weight-based rifapentine dosing and standardized ADR management protocols before broader implementation. Future large-scale real-world studies are needed to assess further the safety, efficacy, and optimal dosing strategies of the HPMZ regimen in diverse populations.

EP08-771-18 The efficacy and safety of varying doses of linezolid in people with rifampicin-resistant TB

Y. Zhang,[1] F. Sun,[1] Y. Li,[1] W. Zhang,[1] [1]Huashan Hospital, Fudan University, Department of Infectious Diseases, Shanghai, China
e-mail: evelyncheung@126.com

Background: Linezolid is a critical component in rifampicin-resistant tuberculosis (RR-TB) treatment yet the optimal dosage and duration are unclear.
Design/Methods: Patients aged 16–75 years with pulmonary RR-TB susceptible to fluoroquinolone were prospectively enrolled and received three 9-month oral regimens with different linezolid doses (600mg daily for 9 months, 600mg daily for 2 months, 600mg daily for 2 months and then 300mg daily for 7 months). The background regimen contained bedaquiline, cycloserine, pyrazinamide, and a fluoroquinolone.
Adverse events of interest, namely peripheral neuropathy, myelosuppression and optic neuritis, were graded according to the Common Terminology Criteria for Adverse Events (CTCAE). Treatment outcome was consistent with the 2022 WHO guidelines.
This interim analysis only included patients who have completed treatment.
Results: Among 172 prospectively enrolled RR-TB patients, treatment success rates were 86.0% (49/57) with 600mg linezolid daily for 9 months, 77.2% (44/57) with 600mg for 2 months, and 84.5% (49/58) with 600mg for 2 months followed by 300mg for 7 months.
Severe anemia occurred in one patient (1.8%) receiving 600mg daily for 9 months, one (1.8%) receiving 600mg for 2 months and two (3.4%) receiving 600mg for 2 months followed by 300mg for 7 months (P = 0.999).
Peripheral neuropathy occurred in 6 patients (10.5%) receiving 600mg daily for 9 months, 3 (5.3%) receiving 600mg for 2 months and 3 (5.2%) receiving 600mg for 2 months followed by 300mg for 7 months (P = 0.563). Grade 3 and higher peripheral neuropathy was only reported in one patient (1.8%) receiving 600mg daily for 9 months and one (1.8%) receiving 600mg for 2 months. So far there has been no report of linezolid-related optic neuritis.

	600mg for 9m (n = 57)	600mg for 2m (n = 57)	600mg for 2m and 300mg for 7m (n = 58)	P value
Treatment success — no. (%)	49 (86.0)	44 (77.2)	49 (84.5)	0.417
Anemia of any grade — no. (%)	11 (19.3)	12 (21.1)	13 (22.4)	0.918
Anemia of grade 3 or higher — no. (%)	1 (1.8)	1 (1.8)	2 (3.4)	0.999
White blood cell decreased, any grade — no. (%)	10 (17.5)	6 (10.5)	5 (8.6)	0.307
White blood cell decreased, grade 3 or higher — no. (%)	1 (1.8)	0	0	0.663
Platelet count decreased, any grade — no. (%)	2 (3.5)	2 (3.5)	2 (3.4)	1.000
Platelet count decreased, grade 3 or higher — no. (%)	1 (1.8)	0	0	0.663
Peripheral Neuropathy, any grade — no. (%)	6 (10.5)	3 (5.3)	3 (5.2)	0.563
Peripheral Neuropathy, grade 3 or higher — no. (%)	1 (1.8)	1 (1.8)	0	0.549
Optic Neuritis — no. (%)	0	0	0	NA

Conclusions: Three different dosing strategy of linezolid achieved a high treatment success rate with few cases of severe myelosuppression and peripheral neuropathy.

EP08-772-18 NAT2 genotypes and clinical characteristics associated with liver injury in people with TB treated with first-line anti-TB therapy

I. Simapichet,[1] W. Imsanguan,[1] [1]Chiangrai Prachanukroh Hospital, Internal Medicine, Chiangrai, Thailand
e-mail: oilinthira.md@gmail.com

Background: Anti-tuberculosis drug-induced liver injury (AT-DILI) is a significant adverse effect associated with first-line anti-tuberculosis therapy, impacting 10–20% of patients and potentially contributing to early treatment failure. Genetic variations in *NAT2*, which influence the metabolism of isoniazid, play a crucial role in determining susceptibility to hepatotoxicity. Specifically, individuals with slow acetylator genotypes are at higher risk for AT-DILI.
This study investigates the clinical factors and *NAT2* genotypes status, associated with hepatotoxicity in patients undergoing treatment in Thailand.
Design/Methods: This retrospective cohort study was conducted at Chiangrai Prachanukroh Hospital, Thailand. The study included tuberculosis patients registered between 2022 and 2024 who had documented *NAT2* genotypes status. Data collected included demographic characteristics (age, gender, body weight), clinical factors (chronic hepatitis B and C infections), and laboratory findings (liver function tests two weeks after initiating therapy). Logistic regression analysis was used to identify associations between clinical predictors, *NAT2* genotypes, and the occurrence of AT-DILI.
Results: A total of 710 patients were included in the analysis, of whom 70 (9.9%) developed hepatotoxicity. Among all patients, 249 (35%) were identified as slow acetylators. The mean age of participants was 54.5 ± 16 years, with males comprising 64% of the study. Chronic hepatitis B and C infections were detected in 6.3% and 2.7% of patients.NAT2 slow acetylator status and chronic hepatitis C infection were significantly associated with an increased risk of AT-DILI with adjusted OR: 3.78 (95%CI : 2.20-6.50; $p < 0.05$) and adjusted OR: 3.57 (95%CI: 1.10–11.68; $p< 0.05$) respectively.

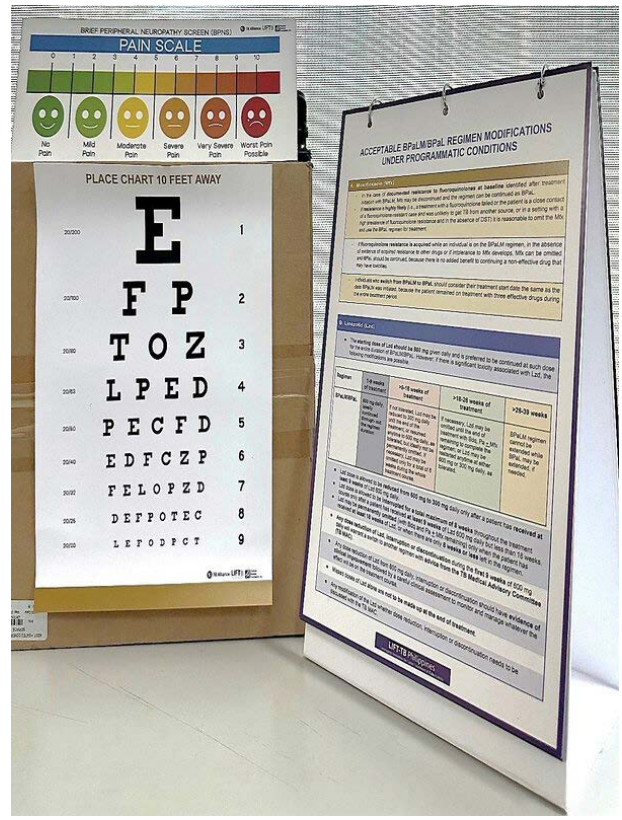
Variables	Adjusted Odds ratio	95%CI	P-value
NAT2 Slow acetylator	3.78	2.20-6.50	<0.05
Hepatitis C infection	3.57	1.10-11.68	<0.05
age ≥ 40	1.87	0.91-3.87	0.09
BW < 35	1.56	0.41-5.92	0.51
Female	1.54	0.90-2.67	0.11

Conclusions: This study shows *NAT2* slow acetylator genotypes and chronic hepatitis C infection as key risk factors for AT-DILI in tuberculosis patients treated with first-line anti-tuberculosis drugs. These findings emphasize the importance of genetic screening and close monitoring of liver function in high-risk populations to reduce treatment interruptions and improve therapeutic outcomes

EP08-773-18 Active TB drug safety of novel drug-resistant regimens: Challenges and solutions in a decentralised setting

M. Trono,[1] M.I. Quelapio,[2] I. Flores,[3] C. Malbacias,[4] M. Diachenko,[5] [1]Tropical Disease Foundation, Inc., LIFT-TB Project, Makati City, Philippines, [2]TB Alliance, Technical Assistance, Makati City, Philippines, [3]Jose B. Lingad Memorial General Hospital, TB DOTS Center, City of San Fernando, Philippines, [4]Department of Health (Philippines), Disease Prevention and Control Bureau, Manila City, Philippines, [5]TB Alliance, Market Access, New York City, United States of America
e-mail: docging1003@gmail.com

Background and challenges to implementation: Services for drug-resistant TB (DR-TB) have been recently decentralized to peripheral iDOTS facilities in the Philippines. Known for both its effectiveness and associated adverse events (AE) such as peripheral and optic neuropathy, and myelosuppression, the novel BPaLM regimen (Bedaquiline, pretomanid, linezolid, moxifloxacin) has been scaled up nationwide. aDSM implementation challenges were identified during 15 facility visits in 6 regions from June 2023 to June 2024, including weaknesses in: a) AE detection [absence of Snellen chart for visual acuity (VA) testing, space short of the required 20 feet, insufficient skills to properly perform the brief peripheral neuropathy screen (BPNS), VA and color vision tests, and interpret results]; b) AE management (lacking confidence to apply AE interventions endorsed by country guidelines, e.g., linezolid dose reduction, interruption or discontinuation at the correct timing); and c) AE recording and reporting (lacking monitoring sheets and malfunctioning electronic pharmacovigilance reporting platform).
Intervention/response: Interventions were targeted.
Intervention or response: Interventions were targeted to:
a) AE detection: provision of standard 20 feet and 10 feet Snellen charts, visual pain analogs, and actual demonstration of proper VA, color vision testing and BPNS;
b) AE management: provision of desk job aids/flip charts containing AE severity grading scales and guide to linezolid and regimen modification, and on-the-job clinical mentoring;
c) AE recording: creation of an aDSM monitoring sheet.

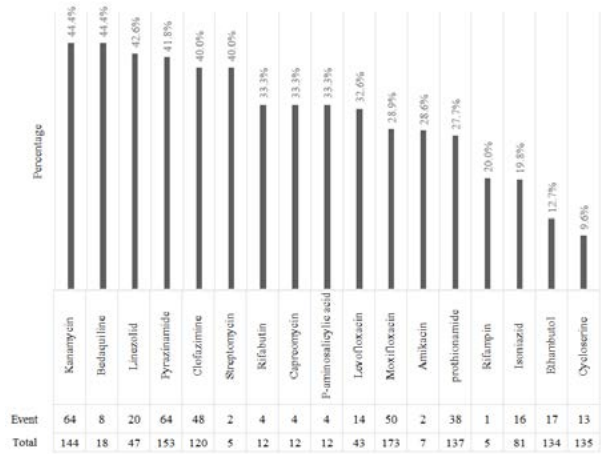


Results/Impact: AEs can become irreversible if addressed late, and can lead to treatment abandonment, if unmanaged. Health providers equipped with tools and training will make a key difference in the quality of life of patients, leading to better treatment outcomes.
Conclusions: aDSM is a critical component in the scale up of new regimens. Monitoring facilities captures real-world challenges in a decentralized setup. Targeted support through tools, teaching materials and mentoring are powerful means to impart skills and empower frontline health workers.

EP08-774-18 Adverse events in the treatment of rifampicin-resistant TB: Findings of comprehensive active drug-safety monitoring and management

R.C.-J. Lin,[1] C. Lin,[2] S. Chien,[3] Y.-W. Huang,[4] J. Lee,[2] C. Lee,[5] M. Yu,[5] C.-Y. Chiang,[5] [1]Taoyuan General Hospital, Ministry of Health and Welfare, pulmonary medicine, Taoyuan, Taiwan, [2]Tzu Chi General Hospital, Tzu Chi University, Division of Chest Medicine, Department of Internal Medicine, Hualien, Taiwan, [3]Chest Hospital, Ministry of Health and Welfare, chest medicine, Tainan, Taiwan, [4]Chang-Hua Hospital, Ministry of Health and Welfare, Chest medicine, Chang-Hua, Taiwan, [5]Wan Fang Hospital, Taipei Medical University, Division of Pulmonary Medicine, Department of Internal Medicine, Taipei, Taiwan
e-mail: dejavu1114@gmail.com

Background: Active tuberculosis drug-safety monitoring and management (aDSM) is recommended in the treatment of multidrug-resistant or rifampicin-resistant tuberculosis (MDR/RR-TB). We established and analyzed finding of comprehensive aDSM in Taiwan.
Design/Methods: We designed a treatment initiation form to capture characteristics of patients at baseline, a treatment review form to monitor symptoms, blood tests, QT intervals, and audiometry during treatment, and an adverse event report form for reporting severe adverse events (SAEs, grade 3 or more), serious adverse events and adverse events resulting in discontinuation of anti-TB drugs.
Severity of adverse events were categorized by using Common Terminology Criteria for Adverse Events (CTCAE) v4.03, and causality was assessed by using the World Health Organization – Uppsala Monitoring Centre (WHO-UMC) system.



Results: Of 333 MDR/RR-TB patients enrolled from May 2017 to February 2020, 329 (98.8%) had adverse events and 196 (58.9%) had SAEs during treatment. The top three SAEs were metabolism disorders (104, 31.2%), hearing impairment (102, 30.6%), and hepatotoxicity (64, 19.2%). Of 403 SAEs reported, 284 (70.5%) were classified as drug-related. The top five drugs associated with SAEs were bedaquiline (44.4%), kanamycin (44.4%), linezolid (42.6%), pyrazinamide (41.8%) and clofazimine (40.0%). Forty-four (13.2%) patients were hospitalized and 15 (4.5%) had prolonged hospitalization due to adverse events. One death was considered drug-related.
Conclusions: SAEs in the treatment of MDR/RR-TB were more frequent than previously reported and needed to be closely monitored and timely managed by systemic and comprehensive aDSM.

EP08-775-18 Cycloserine-induced neuropsychiatric toxicity in multidrug-resistant TB: Association with peak plasma concentration

J. Cheng,[1] K. Xu,[2] F. Pan,[3] G. Zhang,[1] R. Zheng,[4] [1]Zhejiang Hospital of Integrated Traditional Chinese and Western Medicine, pharmacy, Hangzhou, China, [2]Zhejiang Hospital of Integrated Traditional Chinese and Western Medicine, Tuberculosis, Hangzhou, China, [3]Zhejiang Hospital of Integrated Traditional Chinese and Western Medicine, Gastroenterology, Hangzhou, China, [4]Zhejiang Hospital of Integrated Traditional Chinese and Western Medicine, Pharmacy, Hangzhou, China
e-mail: zhengren0129@163.com

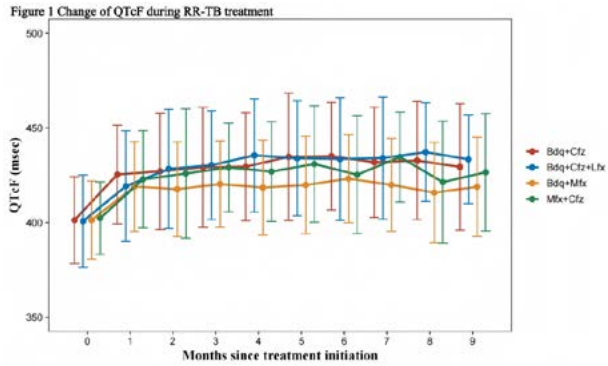
Background: Cycloserine (Cs) is a crucial anti-multidrug-resistant tuberculosis medication with significant clinical efficacy. However, its clinical application is limited by neuropsychiatric-related adverse drug reactions (ADRs).
Design/Methods: This study retrospectively evaluated the peak plasma concentration (C_{max}) of Cs and Cs-related neuropsychiatric ADRs, and analyzed the risk factors of developing neuropsychiatric ADRs. A multivariable ordinal logistic regression model was built to predict the incidence of neuropsychiatric ADRs.
Results: This study enrolled a total of 136 participants, with a cumulative incidence of neuropsychiatric ADRs of 12.5% (17/136). Patients with ADRs had significantly higher Cs C_{max} (26.50 mg/L vs. 18.11 mg/L, P=0.0003). The incidence of ADRs increased with higher Cs exposure, particularly when C_{max} exceeded 30 mg/L. Receiver operating characteristic analysis demonstrated the strong predictive value of C_{max} for neuropsychiatric ADRs. Notably, the predictive efficacy of the logistic regression model significantly improved after incorporating drinking history as a covariate, achieving a final predictive accuracy of 87.6%. The model demonstrated good calibration (Hosmer-Lemeshow test, P=0.563).
Conclusions: Cs C_{max} serves as a critical indicator for predicting Cs-related neuropsychiatric ADRs, with higher C_{max} correlating with an increased likelihood of neuropsychiatric ADRs. Dynamic monitoring of Cs C_{max} com-

bined with alcohol history assessment in clinical practice can enable accurate identification of high-risk populations for neuropsychiatric ADRs, thereby providing a scientific basis for developing individualized medication regimens and implementation of early interventions.

EP08-776-18 Incidence and severity of QTc prolongation associated with QT-prolonging drugs in rifampicin-resistant TB: Preliminary findings from a prospective cohort in China

Y. Zhang,[1] F. Sun,[1] Y. Li,[1] W. Zhang,[1] [1]Huashan Hospital, Fudan University, Department of Infectious Diseases, Shanghai, China
e-mail: evelyncheung@126.com

Background: Effective rifampicin-resistant tuberculosis (RR-TB) regimens often contain multiple QT-prolonging agents. It is important to understand the incidence and severity of QT prolongation in different drug combinations.
Design/Methods: Patients aged 16–75 years with pulmonary RR-TB were prospectively enrolled and received a 9-month oral regimen of a five-drug combination, comprising bedaquiline, linezolid, cycloserine, clofazimine, pyrazinamide, and a fluoroquinolone (moxifloxacin or levofloxacin). Electrocardiogram was conducted monthly, with QT intervals corrected using Fridericia's formula (QTcF). Prolonged QTcF was defined as >450 msec and significant QTcF prolongation was defined as a QTcF over 500 msec.
The relationship between specific drug combinations and QTcF prolongation was assessed with multivariable logistic regression analysis. Patients included in the current analysis have completed treatment and had at least two evaluable records of electrocardiogram.
Results: Among 549 RR-TB patients treated with 9-month oral regimens containing four QT-prolonging drug combinations, the distribution was: bedaquiline/levofloxacin/clofazimine (n = 167), bedaquiline/clofazimine (n = 137), bedaquiline/moxifloxacin (n = 157), and moxifloxacin/clofazimine (n = 88). QTcF prolongation occurred most frequently in the bedaquiline/levofloxacin/clofazimine group (50.3%), followed by bedaquiline/clofazimine (46.7%), moxifloxacin/clofazimine (43.2%), and bedaquiline/moxifloxacin (24.2%). Clinically significant QTcF prolongation was observed in 4.8% (8/167) of bedaquiline/levofloxacin/clofazimine recipients, 7.3% (10/137) of bedaquiline/clofazimine recipients, and 1.3% (2/157) of bedaquiline/moxifloxacin recipients.
Multivariable analysis demonstrated that three drug combinations increased risk of QTcF prolongation compared with the bedaquiline/moxifloxacin group: bedaquiline/levofloxacin/clofazimine (aOR = 3.132, 95% CI 1.927–5.090, P <0.001), bedaquiline/clofazimine (aOR = 2.707, 95% CI 1.632–4.491, P <0.001), and moxifloxacin/clofazimine (aOR = 2.375, 95% CI 1.341–4.209, P = 0.003). In contrast, a two-drug combination of QT-prolongers (aOR = 0.550, 95% CI 0.372–0.813, P = 0.003) reduced risk of QTcF prolongation compared to a three-drug combination.



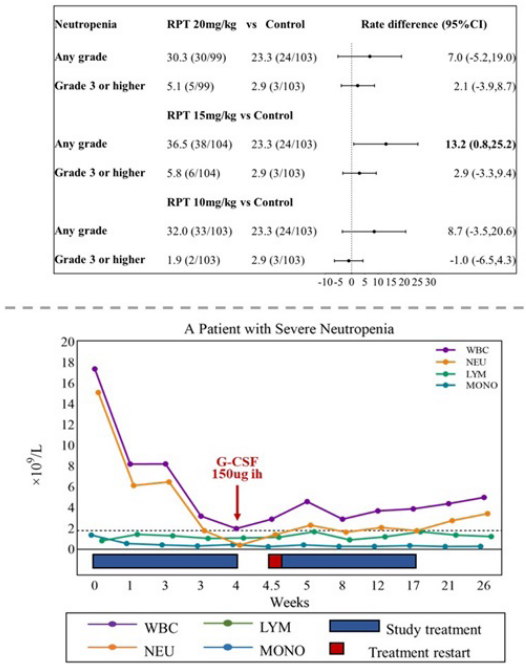
Conclusions: The current study showed the bedaquiline/levofloxacin/clofazimine group had the greatest QTcF prolongation risk, warranting enhanced monitoring in such drug combinations.

EP08-777-18 Impact of the high-dose rifapentine regimens for drug-susceptible TB on peripheral blood neutrophils: A noteworthy treatment-related adverse event

Y. Li,[1] L. Song,[1] Z. Feng,[1] S. Ge,[1] F. Sun,[1] W. Zhang,[1]
[1]Huashan Hospital, Fudan University, Department of Infectious Diseases, Shanghai, China
e-mail: y_li11@fudan.edu.cn

Background: Neutropenia was one of the most common adverse events during anti-tuberculosis treatment. This study aimed to evaluated the incidence of neutropenia with the use of 4-month regimen (2HPMZ/2HPM) for drug-susceptible tuberculosis.
Design/Methods: ORIENT trial (NCT05401071) was a multicenter randomized controlled trial in China to evaluate the safety of the high-dose rifapentine regimens, in which participants were randomly assigned to the control arm with the standard 6-month regimen (HRZE) or three investigational arms of 2HPMZ/2PMZ with rifapentine at different doses (10 mg/kg, 15 mg/kg, and 20 mg/kg). Complete blood count (CBC) was conducted at baseline, week 1, 2, 3, 4, 6, 8, 12, 17, 21, and 26 after treatment initiation. Neutropenia count decreased was recognized and graded according to *Common Terminology Criteria for Adverse Events version 5.0*. Incidence of neutropenia was compared between control arm and investigational arms using Pearson's $\chi 2$ or Fisher's exact test.
Results: A total of 409 patients were enrolled, with 103 in the control arm and 103, 104, 99 in the rifapentine 10, 15, 20 mg/kg arms, respectively. Neutropenia of any grade

occurred in 23.3%, 30.3%, 36.5% and 32.0% in the control arm and rifapentine 10, 15, 20 mg/kg arms, with significant difference between the control and the rifapentine 15 mg/kg arm (rate difference=13.2%, 95%CI: 0.8%-25.2%, P=0.038). There was no significant difference in grade 3 or higher neutropenia across four arms. One male patient in rifapentine 15 mg/kg arm experienced neutropenia of grade 4 (neutrophil count <0.5×10⁹/L). By discontinuing study medication and receiving a single subcutaneous injection of G-CSF, his neutrophil count returned to normal. Four days later, the original treatment regimen was reintroduced and the patient successfully completed treatment.



Abbreviations: LYM, lymphocyte; MONO, monocyte; NEU, neutrophil; RPT, rifapentine; WBC, white blood cell.

Figure1. Incidence of neutropenia in four arms and changes of complete blood count in a patient with severe neutropenia

Conclusions: A higher incidence of neutropenia was observed in rifapentine 15mg/kg arm, emphasizing the importance of close monitoring of CBC among patients receiving high dose rifapentine.

EP08-778-18 Five-year experience with anti-TB drug desensitisation in Singapore

E. Soh,[1] Y.Y. Ong,[2] X.R. Lim,[3] J. Tan,[3] S. Ho,[2] C.V. Choong,[1,4]
[1]Tan Tock Seng Hospital, National Tuberculosis Care Centre, Singapore, Singapore, [2]Tan Tock Seng Hospital, Pharmacy, Singapore, Singapore, [3]Tan Tock Seng Hospital, Rheumatology, Allergy and Immunology, Singapore, Singapore, [4]Tan Tock Seng Hospital, Respiratory and Critical Care Medicine, Singapore, Singapore

Background: Adverse drug reactions (ADR) to anti-tuberculosis (TB) medications pose significant treatment challenges, particularly in drug-susceptible TB where rifampicin (RIF), isoniazid (INH), and ethambutol (EMB) are cornerstone drugs. Desensitisation (both rapid and slow) is a strategy that may allow safe reintroduction of essential drugs.

We aimed to review the indications and outcomes of patients who underwent desensitisation at the National TB Care Centre, Singapore.

Design/Methods: We conducted a retrospective cohort study of patients who underwent TB drug desensitisation from 2020-2024. We collected data on the ADR experienced, which included mild allergic reactions, drug exanthem and severe hypersensitivity reactions such as Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS), Drug-Induced Hypersensitivity Syndrome (DIHS), and others. Desensitisation regimens were classified as rapid (completed within 3-5 days) or slow (over 5 days).

Outcomes were categorised as successful (completion without recurrence of hypersensitivity), partially successful (required modified desensitisation protocol), or failed (drug permanently discontinued).

Results: Fifty-one patients (median age 54.5 years (range 19-85 years), 62% female) underwent desensitisation. Amongst the 51 patients, there were 56 instances of desensitisation whereby 5 patients required desensitisation to 2 anti-TB drugs. RIF desensitisation (80.3%, n= 45) was the most common, followed by INH (17.9%, n=10), and EMB (1.8%, n=1).

ADR included mild allergic reactions (29.4%), drug exanthem (39.2%), DIHS (11.8%), DRESS (7.8%), Generalised Exfoliative Dermatitis (5.9%) and anaphylaxis (5.9%). Slow desensitisation protocol was done in 53.6% of cases, particularly for severe reactions.

Overall, successful desensitisation was achieved in 71.4% of patients, partial success in 12.5%, and failure in 16.1%. Rapid desensitisation was more frequently employed for mild reactions, while slow desensitisation was more often used in severe reactions with similar outcomes.

Conclusions: TB drug desensitisation is a viable strategy to retain key anti-TB drugs in patients with ADR, including severe hypersensitivity reactions, with reasonable success rates.

EP09 Training & education to end TB

EP09-779-18 Building resilience: Capacity building for front-line workers to provide integrated symptomatic TB and HIV testing services for pregnant women at informal settings in Nigeria

W. Mayah,[1] J. Ilozumba,[1] O. Ejim,[1] O. Adebayo,[2] M. Bathnna,[2] O. Urhioko,[3] M. Zamzu,[4] [1]Caritas Nigeria, TB Services, Abuja, Nigeria, [2]Institute of Human Virology Nigeria, N_THRIP Project, Abuja, Nigeria, [3]National Tuberculosis, Leprosy, and Buruli Ulcer Control Programme, TB Services, Abuja, Nigeria, [4]The Global Fund to Fight AIDS, Tuberculosis, and Malaria, Global Fund, Geneva, Switzerland
e-mail: wmayah@ccfng.org

Background and challenges to implementation: Integrating health services in informal setting such as Traditional Birth Attendants (TBAs) presents a unique opportunity to address the dual burden of tuberculosis (TB) and HIV in underserved communities. Frontline workers like the TBA focal persons, mentor mothers (MMs) and community volunteers (CVs) in these settings face significant challenges, including limited training, scarce resources, and disjointed service delivery systems, all of which impede effective screening and care.
Hence, this study was aimed at evaluating the outcome of the training on service delivery enhancements and maternal health outcomes, particularly for pregnant women in underserved communities.
Intervention or response: HIV testing using combo kit and symptomatic TB screening services training was conducted for 95 frontline workers (17 CVs, 27 MMs, and 51 TBAs) to provide these services across the 17 local government areas of Abia State, Nigeria between January 2024 and December 2024. Pre- and post-training assessments measured workers' knowledge, skills and confidence level.
Service delivery outcomes were tracked, including the volume of integrated screenings performed and the detection rates of TB and HIV cases among pregnant women. Data were abstracted from registers domiciled at the informal settings and analyzed using descriptive statistics on Microsoft Excel.
Results/Impact: Post-training assessments revealed an 85% increase in workers' knowledge of symptomatic TB and HIV testing services, with 90% reporting high confidence in conducting integrated screenings.
Out of the 8000 pregnant women screened symptomatically for TB and provided HTS, 442 were presumptives, 6 diagnosed and notified (referred from the TBAs to hub facilities).
Also, 7898 eligible pregnant women were tested and referred for ante natal care, 89 were reactive and referred to comprehensive treatment sites.
Conclusions: In all, the training successfully empowered frontline workers with the requisite knowledge to integrate symptomatic TB screening and HIV testing services for pregnant women in informal settings, bridging a critical gap in maternal health outcomes.

EP09-780-18 Enhancing TB knowledge among Alaramma (informal school teachers) in Kano State: Output assessment

J. Adizue,[1] S. Umar,[1] A. Yola,[2] J. Anyanti,[2] [1]Society for Family Health, Programs, Federal Capital Territory, Nigeria, [2]Society for Family Health, Program, Federal Capital Territory, Nigeria
e-mail: Jadizue@sfhnigeria.org

Background: Tuberculosis remains a major public health challenge, particularly among underserved and high-risk groups such as children in undergoing informal education through the '*Almajiri*' schools, where limited knowledge of TB contributes to delayed diagnosis and treatment. There are over 1,000 Almajiri schools in Kano State, with an average student population per school of about 150 students. These schools are poorly funded with non-existent regulations, which expose these students (Age 5- 17 years) to vulnerabilities including lack of access to health care services. A two-days capacity building session was held for informal School Teachers (*Alaramma)* who are the norm holders in the Almajiri system of education, to provide TB screening and referral for their students.
Design/Methods: The intervention adopted a multi-step approach involving advocacy, capacity-building, and monitoring. Key activities done were Tsangaya school leadership in the state for easy of implementation of the program. A desk review and mapping of Almajiri school in high TB-reporting local government areas was done, with selection followed by a two-day capacity building session for 100 Alaramma teachers, focusing on sensitisation with Low-literacy tools, screening, and referral.
Online platforms e.g. WhatsApp, was used for reporting and mentoring for the Alarammas. A framework for monitoring and evaluation was done to track progress and assess intervention impact.
Results: The intervention significantly improved TB knowledge among 100 trained Alarammas, with pre- and post-assessment results showing an increase from 35% to 97% on basic knowledge. **Three months** post-training (November 2024 to January 2025), key outcomes included: **8,011 children** sensitized on TB, **141 presumptive TB cases** identified evaluated, **11 confirmed TB cases** successfully linked to care.
Background and challenges to implementation: Tuberculosis remains a major public health challenge, particularly among underserved and high-risk groups such as children in undergoing informal education through the '*Almajiri*' schools, where limited knowledge of TB con-

tributes to delayed diagnosis and treatment. There are over 1,000 Almajiri schools in Kano State, with an average student population per school of about 150 students. These schools are poorly funded with non-existent regulations, which expose these students (Age 5- 17 years) to vulnerabilities including lack of access to health care services and shelter, and abuse (physical, Mental, Sexual). A two-days training program was done for Informal School Teachers (*Alaramma)* who are the norm holders in the Almajiri system of education, across school 10 local government areas in TB care cascade their students, thereby empowering community structures to take ownership.

Intervention or response: The intervention adopted a multi-step approach involving advocacy, capacity-building, and monitoring.

Advocacy visits to leadership of Tsangaya school for ease of project implementation. A desk review and mapping of Almajiri school within high TB-reporting local government areas was done, which was followed by a two-day intensive training program for 100 Alaramma teachers, focusing on TB education, screening, and referral using low-literacy materials.

Online platform i.e. WhatsApp, was established to foster timely feedback and provision of mentoring support for the Alarammas. A framework for monitoring and evaluation to track progress and assess intervention impact.

Results/Impact: The intervention significantly improved TB knowledge among 100 trained Alarammas, with pre- and post-assessment results showing an increase from 35% to 97% on basic knowledge. **Three months** post-training (November 2024 to January 2025), key outcomes included:

- **8,011 children** sensitized on TB.
- **141 presumptive TB cases** identified and referred for further evaluation.
- **11 confirmed TB cases** successfully linked to healthcare facilities for treatment.

Conclusions: Training the Alarammas, promotes TB awareness, screening, and referral services, expands health care for vulnerable children and supporting TB-affected students to access care thus strengthening community-based TB interventions to sustain long term gains beyond funded projects.

EP09-781-18 Integrating gender-related knowledge into the national medical training curriculum and healthcare workplace practices

Y. Kalancha,[1] L. Tonkonoh,[1] A. Daftary,[2] Y.C. Chorna,[3] T. Kiriazova,[4] I. Yelienieva,[5] Y.T. Terleeva,[6] O. Ushakova,[6] S. Myroniuk,[6] A. Vasylenko,[1] [1]TB Europe Coalition, N/A, Kyiv, Ukraine, [2]York University, Faculty of Health, Toronto, Canada, [3]York University, Department of Anthropology, Toronto, Canada, [4]Ukrainian Institute on Public Health Policy (Kyiv), n/a, Kyiv, Ukraine, [5]NGO Labor and Health Social Initiatives, n/a, Kyiv, Ukraine, [6]Public Health Center of the MOH of Ukraine, TB Management and Counteraction Department, Kyiv, Ukraine
e-mail: tonkonog@tbcoalition.eu

Background: Considering how gender roles and inequalities shape diagnosis, treatment and healthcare services access, addressing healthcare biases and practices are essential for people-centered TB care. While Ukraine's national TB treatment standards recommend gender-sensitive patient counseling, there is little understanding of how healthcare workers implement these approaches in practice.

Design/Methods: A qualitative study was conducted in four regions of Ukraine involving in-depth interviews with 15 national and 7 regional experts, ten focus group discussions with 80 healthcare workers of varying cadres. The study analyzed national gender-related legislation and medical education curricula. Data were triangulated and analysed to explore themes of gender awareness, workplace gender equality policies and practices, gender-sensitive care provision.

Results: 102 participants joined the study during 01.10.2024-05.11.2024. Gender considerations were reflected in the analysed documents, including references to gender-sensitive approaches (in educational curricula, TB counselling materials), but there was no recommended programming to support patients accessing gender-sensitive care or healthcare workers in providing it. Most healthcare workers acquired gender awareness through short, didactic, not universally available professional development workshops. They found the intermittent training lacked foundational knowledge and practical skills to address patients' gender-specific needs. They were concerned that without a structure, achieving gender equality in healthcare remains challenging. The gap could hinder access to care, treatment adherence, and advocacy for patients facing gender-related barriers.

This was key in TB programming and primary health care, as gender-related barriers can be high at the point of symptom presentation and testing. Addressing gender-related barriers in medical education is crucial beyond TB care, as they demonstrate impact across all health conditions.

Conclusions: Foundational gender-related health education and training, covering intersectionality between gender and other social determinants, should be fully

integrated into national medical training curriculum, post-graduation health workforce training programs to promote gender equality in the workplace and improve TB outcomes through gender-sensitive services.

EP09-782-18 Assessing the effect of a community-driven, gender-responsive TB initiative on TB-related knowledge and stigma: A controlled before-and-after interventional study in peri-urban communities, Nigeria

C. Ugwu,[1,2] C. Aneke,[2] N. Zoakah,[2] J. Bimba,[2,3] S.B. Squire,[4] T. Wingfield,[4] [1]Liverpool School of Tropical Medicine, UK, Clinical Sciences, Karu, Nigeria, [2]Bingham University, Zankli Research Centre, Karu, Nigeria, [3]Liverpool School of Tropical Medicine, UK, Clinical Sciences, Abuja, Nigeria, [4]Liverpool School of Tropical Medicine, UK, Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland

Background: Men account for more than two-thirds of TB cases in Nigeria and experience longer delays in accessing care and worse health outcomes than women. Our previous research identified major barriers to care, including TB-related stigma and limited TB knowledge.
With local multisectoral stakeholders, we co-developed a targeted intervention, implemented the intervention in peri-urban settings, and evaluated its impact on TB knowledge and stigma.
Design/Methods: Two intervention (IC) and two control (CC) cluster communities were selected by convenience. A Local TB Action Group (LTAG) was established in each IC, comprising key community members and leaders. ICs received men-led TB awareness campaigns and mobile X-ray-mediated TB screening in men's socio-cultural congregate settings for 6 months. CCs continued routine TB programme activities.
A baseline household survey assessing TB knowledge and stigma and a post-intervention survey were conducted across all clusters using locally validated data collection tools. Knowledge and Stigma were rated numerically on a 10-point and 44-point scale, respectively (higher scores equating to higher levels). Mixed-effects linear regression analyses were performed to evaluate the intervention's effect on TB-knowledge and stigma adjusted for covariates including education, employment, and socioeconomic status.
Results: Overall, 3,321 households were surveyed, 1,679 and 1,642 in the CCs and ICs, respectively. The intervention was associated with a significant average decline in stigma compared to the CCs (estimate: -24.46 [95% CI=-25.20 – -23.71], Table).
Similarly, TB-related knowledge significantly improved in the ICs with an estimate of +4.07 (95% CI=+3.746 – +4.392).

Table: mixed effects linear regression output for effect of intervention on TB-related stigma and knowledge

	Linear regression output for stigma score		
Effect	Estimate	Std. Error	95% CI
Community Intervention	0.954	1.611	−2.203 – 4.111
Time (End line)	−2.154	0.266	−2.676 – −1.633
Intervention * End line Interaction	**−24.457****	0.379	**−25.200 – −23.714**
	Linear regression output for knowledge score		
Effect	Estimate	Std. Error	95% CI
Community Intervention	−1.210	0.407	−2.007 – −0.413
Time (End line)	−0.679	0.116	−0.906 – −0.452
Intervention * End line Interaction	**+4.069****	0.165	**+3.746 – +4.392**

*Model setup: primary fixed effect variable="Cluster type*Time". Secondary fixed effect variables=sex, education, employment, and socio-economic status. Random effect variable=Cluster ID.

**Adjusted measures accounting for Sex, Education, Employment and Socio-economic status.

Conclusions: A community-led gender-responsive intervention improved knowledge and reduced TB-related stigma in vulnerable peri-urban settlements in Nigeria.

EP09-783-18 Overcoming language barriers and stigma in communication on TB: Using artificial intelligence (AI) for person-centred TB information for people from migrant populations

J. van Rest,[1] N. Jansen,[1] [1]KNCV Tuberculosis Foundation, TB Elimination & Health System Innovations, The Hague, Netherlands
e-mail: job.vanrest@kncvtbc.org

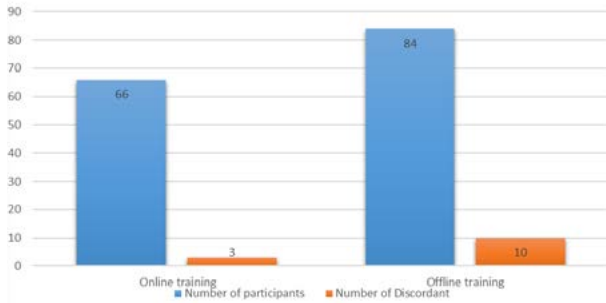
Background: TB has become an increasingly rare disease in the Netherlands, largely affecting people who reside - but were not born - in the Netherlands. Around 80% of all TB patients in 2023 were born in countries outside the Netherlands coming from 78 different countries.
Current tools to spread awareness and improve knowledge have largely centred on mass-media interventions such as videos or paper-based pamphlets.
Given recent advances in use of Large Language Models (LLMs), AI-enabled chatbots provide a highly interactive, personalized digital interface in a variety of languages, presenting a direct opportunity for improving knowledge of TB in a potentially cost-effective and scalable manner.
Design/Methods: We gathered relevant source materials to "train" the chatbot. The chatbot was deployed via web browser and WhatsApp. During a pilot phase, two groups of volunteers, TB professionals and general public, conversated with the chatbot in different languages on a variety of TB related topics such as TB and immigration, contact investigation, and TB screening. Survey data and chat conversations were analyzed and shared with pilot users during a focus group discussion.
Results: The language skills (grammar, spelling) were diverse with excellent rating in English and Dutch, but poorer rating in less common spoken languages (Tigrinya and Amharic).

The accuracy of responses were scored high for general TB information, but diverse for specific topics (TB screening, contact investigation).
A majority of the pilot users found the chatbot to be realistic and engaging, and that the responses were useful, appropriate and informative.
Conclusions: The use of an AI-enabled chatbot is perceived as an appropriate medium to provide information on TB. However, several components needs to be improved upon. As of early 2025, we are making significant improvements to the knowledge base of the chatbot and aim for deployment by the end of 2025.

EP09-784-18 Strengthening capacity for TB services: Effectiveness analysis of training methods, a comparative study

S. Tarin,[1] M.A. Shahed,[2] Z. Kabir,[3] Z. Nasreen,[3]
[1]National Tuberculosis Control Program, Training & Capacity building, Dhaka, Bangladesh, [2]Independent, Tuberculosis Expert, Dhaka, Bangladesh, [3]National Tuberculosis Control Program, Program, Dhaka, Bangladesh

Background and challenges to implementation: As digital transformation accelerates the debate between the effectiveness of online and offline training has gained significant attention. This study investigates and compares the effectiveness of these two training modes by examining core factors such as knowledge acquisition, skill development, learner engagement, and overall satisfaction. A comparative analysis was conducted using data collected from participants enrolled in structured online and offline "1 day training on mWRD EQA" among 150 participants organized by NTP Bangladesh. Each group underwent identical training content delivered through their respective platforms. Participant's performance was evaluated by comparison between the participant's result and the assigned values of the proficiency testing panel.
Intervention or response: Results showed that online training is highly effective in delivering theoretical knowledge, especially due to its flexibility of number of participants, reduced costing and the ability for learners at their own pace.
However, challenges such as reduced interaction, self-discipline issues, and limited hands-on experience. On the other hand, offline training demonstrated greater effectiveness in fostering interpersonal communication, collaborative learning, and real-time feedback. Participants in offline sessions showed stronger engagement levels and better performance in practical skill assessments, largely due to direct trainer support and structured learning environments.
Results/Impact: On evaluation of proficiency testing panel value of 150 participants 4.5% online batches and 11.9% from offline batches had the discordant result.



Conclusions: The analysis concludes that the effectiveness of training is not solely dependent on the mode of delivery but on how well the content, interactivity, and learner support are integrated. A blended training approach, combining the strengths of both online and offline methods, is recommended to maximize learning outcomes. This study provides valuable insights for educators, trainers, and organizations seeking to optimize their training strategies.

EP09-785-18 Digitally-enabled youth engagement model to *support HCWs to improve TB presentation to care in underserved urban slums of India*: The Take Charge Against TB program

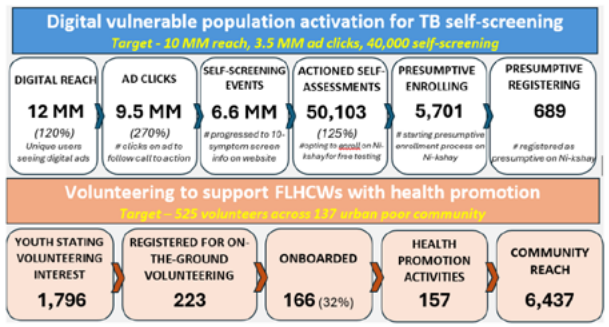
D. Balasubramanian,[1] R. Rao,[2] N. Kumar,[2] V. Garg,[2] N. Saini,[3] S. Sangale,[4] A. Rajesham,[5] K. Sayyad,[6] J. Chin,[7] A.-M. Ionescu,[8] P. Jha,[1] U. Singh,[2] [1]PATH, Infectious Disease, New Delhi, India, [2]Ministry of Health & Family Welfare, Government of India, Central TB Division, in the Department of Health, New Delhi, India, [3]Department of Health & Family Welfare, Government of Delhi, State TB Cell, National TB Elimination Programme, New Delhi, India, [4]Directorate of Health Services, Maharashtra, Public Health Department, Maharashtra, Pune, India, [5]Department of Health & Family Welfare, Government of Telangana, State TB Cell, National TB Elimination Programme, Hyderabad, India, [6]TB Alert India, Tuberculosis, New Delhi, India, [7]Johnson & Johnson, Global Health Equity, Singapore, Singapore, [8]Johnson & Johnson, Global Health Equity, Bucharest, Romania
e-mail: dbala@path.org

Background and challenges to implementation: Tuberculosis continues to pose significant public health challenge in India. Among urban youth, stigma, misinformation and limited knowledge discourages timely healthcare-seeking. To address these barriers, they should be empowered as TB services beneficiaries and active community change agents.
Intervention or response: The "Take Charge Against TB" program, with Johnson&Johnson Foundation support, was conceptualized and implemented through a dual activation approach—focusing on digital and on-the-ground mobilization of youth (18–34 years) from lower socio-

economic strata in Hyderabad, Pune, Delhi, in addition to frontline healthcare workers (HCWs) capacity building to accelerate early diagnosis and improve proactive presentation to care. To inform intervention design for youth, a digital baseline survey took place in advance of two-pronged mobilization strategy roll-out (social media messaging with call to action to undertake self-screening and follow-on testing alongside invitation to volunteer in their communities for health promotion).

Results/Impact: The knowledge, attitudes and practice (KAP) survey engaged 4.2 million youth, yielding 152,000 responses (3.6% response rate, male/ female ratio 77% - 23%). 35% were unaware that TB is curable, only 5% recognized all major TB symptoms, and 56% did not know TB diagnosis and treatment were free of cost. Additionally, 68% of respondents did not perceive themselves at risk for TB, 16% did not know of any action to take in case of symptoms and 42% expressed stigma associated perceptions towards other people living with TB. 12 million individuals were reached through social media, with 50,100 actioned self-assessments and nearly 1,800 stating interest to support HCWs with health promotion (of which 10% registered for onboarding and on-the-ground execution) (Figure 1).

Figure 1 – Impact of social media intervention under the Take Charge Against TB program*



** Take Charge Against TB program - a public health initiative by Johnson & Johnson, in collaboration with PATH and TBAlert India, partially funded by J&J India Community Impact and by Johnson & Johnson Foundation (registered charitable organization that reflects the commitment of J&J to create a world without health inequities by closing the gaps between communities and the care they need).*

Conclusions: Findings indicate significant KAP gaps about TB among urban poor youth and provide proof points for targeted health promotion interventions with actionable calls to action that improve proactive presentation to care.

EP09-786-18 Results from "Empowering frontline healthcare workers through holistic upskilling intervention on 3C's for underserved urban poor communities of India": The Take Charge against TB programme

D. Balasubramanian,[1] R. Rao,[2] N. Kumar,[2] V. Garg,[2] N. Saini,[3] S. Sangale,[4] A. Rajesham,[5] K. Sayyad,[6] J. Chin,[7] A.-M. Ionescu,[8] P. Jha,[1] U. Singh,[2] [1]PATH, Infectious Disease, New Delhi, India, [2]Ministry of Health & Family Welfare, Government of India, Central TB Division, in the Department of Health, New Delhi, India, [3]Department of Health & Family Welfare, Government of Delhi, State TB Cell, National TB Elimination Programme, New Delhi, India, [4]Directorate of Health Services, Maharashtra, Public Health Department, Maharashtra, Pune, India, [5]Department of Health & Family Welfare, Government of Telangana, State TB Cell, National TB Elimination Programme, Hyderabad, India, [6]TB Alert India, Tuberculosis, New Delhi, India, [7]Johnson & Johnson, Global Health Equity, Singapore, Singapore, [8]Johnson & Johnson, Global Health Equity, Bucharest, Romania
e-mail: dbala@path.org

Background and challenges to implementation: Frontline healthcare workers (FLHCWs) hold significant potential in expanding TB care by bridging critical gaps in reaching underserved populations to accelerate early diagnosis. Their strategic mobilization can be optimized through structured upskilling and clear scope of work deliverables.

Intervention or response: A capacity building intervention for FLHCWs (Accredited Social Health Activists, Auxiliary Nurse Midwives, medical officers, chemists, and informal care providers) in Hyderabad, Pune, Delhi, was developed addressing 3Cs (Competency development in screening & referral, Connection development for stigma eradication and Confidence development for community trust building) based on needs assessment as part of the "Take Charge Against TB" initiative, with Johnson&Johnson Foundation funding support.

A modular curriculum was developed with expert inputs from India Central TB Division and WHO, with iterative direct feedback from FLHCWs. The participatory approach ensured content was culturally relevant, linguistically accessible and practical.

Knowledge, attitudes and practices (KAP) improvement were assessed pre and post-training. FLHCWs received continued learning reinforcement, supervised mentorship and were monitored for TB referrals post-training.

Results/Impact: Between December 2024 and March 2025, 21 training events were conducted, covering 700 FLHCWs, with significant FLHCW KAP improvement. Post-training evaluations among 481 FLHCWs showed a mean KAP improvement of 12%, increasing to 87%, from 74.8% baseline. The biggest immediate change was in Attitudes (from 69% baseline to 86.9% post-training), followed by change in knowledge (from 86.5% baseline to

95.9%) and change in Practices (from 68.4% baseline to 78.2%). Within a month, 10% of trained FLHCWs (that previously had not taken such actions), initiated referrals for enrolling presumptive persons with TB, resulting in 128 individuals undergoing molecular diagnostic testing, with 9 confirmed persons with TB.

Component	Correct Pre-Test N - 562	Correct Post-Test N - 481	Pre-Post Difference	
			actual	% change
Knowledge	86.54%	95.91%	9.38%	11%
Attitude	69.31%	86.90%	17.60%	25%
Practice	68.43%	78.25%	9.82%	14%
	74.8%	87.0%	12.26%	16%

** Take Charge Against TB program - a public health initiative by Johnson & Johnson, in collaboration with PATH and TBAlert India, partially funded by J&J India Community Impact and by Johnson & Johnson Foundation (registered charitable organization that reflects the commitment of J&J to create a world without health inequities by closing the gaps between communities and the care they need).*

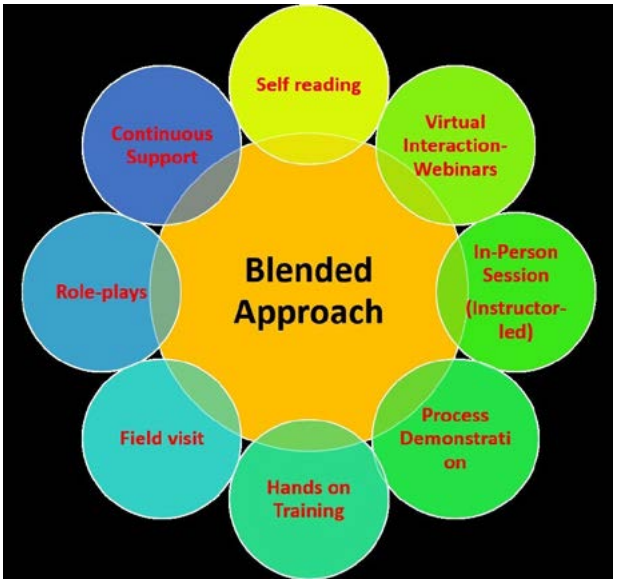
*Table 1. Improvement in frontline healthcare worker knowledge, attitude and practice survey under the Take Charge Against TB program**

Conclusions: Structured FLHCW upskilling improves TB KAP, even from relatively high baselines, leading to increased TB referrals and follow-on notifications. Integrating such interventions into national TB programs can further accelerate early diagnosis.

EP09-787-18 Effective capacity building for TB prevention and care: A modernised training approach for programme managers in India

A. Singh,[1] M. Mathew,[1] R. PS,[1] J. Jaju,[1] V. Garg,[2] A. Shah,[3] G. Gautam,[1] S. Ahmad,[1] N. Singla,[4] S. Gupta,[5]
[1]International Union against TB and Lung Diseases, TB, New Delhi, India, [2]Central TB Division, MoHFW, Govt of India, TB, New Delhi, India, [3]USAID, TB, New Delhi, India, [4]NITRD, Training, New Delhi, India, [5]NITRD, TB, New Delhi, India
e-mail: abhimanyu.singh@theunion.org

Background and challenges to implementation: Program Managers are critical to the success of National TB Program, providing leadership and oversight. However, their role is increasingly complex due to evolving program demands, frequent updates, and high staff turnover. Training needs are extensive—over 400 hours—spanning technical, managerial, and communication skills.
Traditional classroom models are inadequate, require long absences, affect service delivery, and don't cater to diverse learning needs. A scalable, resource-efficient approach is essential.
Intervention or response: To address this, a Modernised Training System (MTS) was developed and training operations optimized. Content was mapped to competencies and reorganized into blended modules—self-paced, instructor-led, practical, and field-based.



Knowledge-based modules were assigned for self-paced or virtual learning, while critical programmatic areas like case finding, TB prevention, and treatment were covered through interactive sessions. Field visits exposed managers to the care cascade—DR-TB wards, labs, AIC practices, and supervision. Communication skills were strengthened through role plays and peer learning.
This approach allowed program managers to attend in-person training for a limited time, focused on acquiring hands-on skills and practical experience, thereby optimizing both time and financial resources. Progress was tracked via quizzes and assessments.
Results/Impact: Standardized, modular training content was developed and rolled out with supporting SOPs and a detailed Trainer's Guide, enabling decentralized implementation across states. So far, 194 program managers have been trained. Average pre- and post-test scores improved from 58% to 72%, reflecting strong knowledge gains. Feedback indicated high satisfaction—78% rated content 8 or above, and 84% rated the overall experience 8 or above on a scale of 1 to 10.
Conclusions: The optimized training model for program managers under NTEP has successfully addressed challenges. The structured, blended, and flexible approach has enhanced the capacity of program managers while minimizing disruptions to service delivery—laying a strong foundation for sustained and effective TB control across the country.

EP09-788-18 TB training through Camparience (camping and experience) learning method: Engaging 20 young leaders across 18 regions in Indonesia in 2024

N.M. Hapsari,[1] I.M.P. Zein,[1] N. Nurliyanti,[2] H. Diatmo,[3] J.F. Faiz,[1] [1]Stop TB Partnership Indonesia, Communications, Jakarta Selatan, Indonesia, [2]Stop TB Partnership Indonesia, Program, Jakarta Selatan, Indonesia, [3]Stop TB Partnership Indonesia, Director, Jakarta Selatan, Indonesia
e-mail: iman.m@stoptbindonesia.org

Background and challenges to implementation: Youth, as dynamic community members and digital influencers, can drive TB awareness and advocacy**.** However, current training programs often use theoretical methods that lack real-world relevance. Experiential role-playing is needed to equip young leaders with practical insights and strategies to address TB challenges effectively

Intervention or response: To overcome the challenge of overly theoretical TB training, we implemented the Camperience program for 20 young leaders from 18 diverse Indonesian regions in September 2024. This training utilized the 70-20-10 human resource development framework, structuring learning into three interconnected components.

The 70% experiential learning component consisted of a 5-day simulation set in a fictional country, where participants navigated advocacy challenges with a government displaying limited commitment to TB. This immersive experience strengthened participants' competencies in policy engagement and strategic messaging. The 20% social learning element enabled peer-to-peer learning through activities such as organizing community-driven campaigns and conducting a simulated press conference to engage journalists.

The remaining 10% formal learning provided structured inputs from experts in public health, media engagment and advocacy. Through pre- and post-test, we quantitatively confirmed gains in knowledge and advocacy competencies. As a result, participants executed impactful media outreach and a creative protest, proving the training's practical success.

Results/Impact: The Camperience training enhanced TB advocacy skills, with pre-and post test results showing a p-value of 0.00, indicating a significant increase in knowledge. Participants also demonstrated strong commitment to their roles in the community by developing campaign and advocacy plans to their respective regions. The experiential, practice-based learning approach proved effective, although some participants faced challenges in connecting theory to practice.

Conclusions: Camperience training empowers youth as TB advocacy champions, revolutionizing public health engagement. We recommend its hands-on strategies for TB programs, readily scalable to ignite vibrant youth-led health movements worldwide.

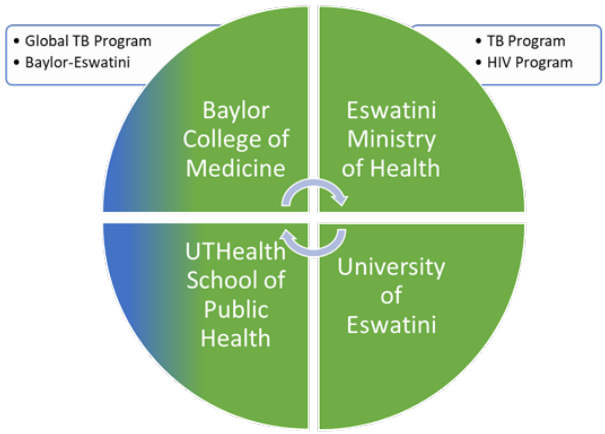
EP09-789-18 Bridging gaps in TB/HIV research: Empowering Eswatini's future scholars

K. Lockhart,[1] D. Vambe,[2] P. Dlamini,[3] T. Mathunjwa,[3] M. Shongwe,[3] N. Dlamini,[4] N. Dlamini,[4] A. Sikhondze,[4] A. Vasiliu,[1] A. Kay,[2] C. Cazier,[1] A. Mandalakas,[1] [1]Baylor College of Medicine, Global Tuberculosis Program, Houston, United States of America, [2]Baylor College of Medicine, Global Tuberculosis Program, Mbabane, Eswatini, [3]University of Eswatini, Faculty of Health Sciences, Mbabane, Eswatini, [4]Baylor College of Medicine Children's Foundation-Eswatini, Global Tuberculosis Program, Mbabane, Eswatini
e-mail: kai.lockhart@bcm.edu

Background and challenges to implementation: As of 2020, the University of Eswatini (UNESWA), the largest research university in the country, did not offer PhD programs to advance TB/HIV research.

Given the high incidence of TB/HIV, Eswatini faces a gap in research training capacity in pediatric populations. Baylor College of Medicine, the University of Texas Health Science Center at Houston (UT Health Houston), Baylor Foundation Eswatini, UNESWA, and the Eswatini Ministry of Health implemented the D43 Siyakhula Project in July 2021 to address this gap. Siyakhula builds local capacity by fostering collaborations between US-based faculty and local researchers.

Intervention or response: The D43 Siyakhula program, the only active D43 training program in Eswatini, trained two cohorts of short-term scholars in applied TB/HIV research in pediatric populations while offering support for pilot research projects. It also supports long-term doctoral students at UT Health Houston in transitioning to independent investigators, with these students also mentoring short-term scholars. Yearly surveys assess trainee satisfaction and knowledge to improve the program.



Results/Impact: Doctoral students studying health economics, biostatistics, and health policy are on track to completion and will return to Eswatini to apply these skills. Forty short-term scholars have been trained, 11 in the first cohort and 26 in the second. 37 of 40 (92.5%) submitted competitive TB/HIV research proposals, with 28 funded. One trainee secured external funding. Participants have published 10 peer-reviewed manuscripts and presented five abstracts at international conferences. The program improved training quality, with an increase in scholars reporting the knowledge gained will be useful in their roles from the first cohort (66%) to the second (71%).

Conclusions: This program builds training and research capacity for TB/HIV research in Eswatini through a collaborative model. The program has improved the training quality of scholars, underscoring its growing impact and potential to contribute to continued advancement of research and capacity-building efforts in Eswatini.

ABSTRACT PRESENTATIONS WEDNESDAY 19 NOVEMBER 2025

ORAL ABSTRACT SESSION (OA)

OA06 Genotypic and phenotypic resistance testing for TB

OA06-149-19 Phenotypic and genotypic resistance to key TB drugs in Mycobacterium tuberculosis isolates from endTB-Q participants

E. Ardizzoni,[1] A. Dippenaar,[2] W. Mulders,[1] L. Guglielmetti,[3] R. Calderon,[4] L. Chingisova,[5] F. Izmail,[6] N. Hirani,[7] N. Kursheed,[8] P. Rupasinghe,[1] C. Mitnick,[9] B.C. de Jong,[1]
[1]Institute of Tropical Medicine of Antwerp, Biomedical Science, Antwerp, Belgium, [2]University of Antwerp, Global Health Institute, Department of Public Health and Healthcare, Antwerp, Netherlands, [3]Medecins sans Frontieres, Medical Department, Paris, France, [4]PIH, Medical Department, Lima, Peru, [5]National Tuberculosis Reference Laboratory, Medical Department, Almaty, Kazakhstan, [6]National Tuberculosis Reference Laboratory, Medical Department, Johannesburg, South Africa, [7]National Center of Pulmonology, Medical Department, Mumbai, India, [8]Indus Hospital, Medical Department, Karachi, Pakistan, [9]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States of America
e-mail: eardizzoni@itg.be

Background: Acquisition of drug resistance (ADR) threatens successful treatment of drug-resistant TB. In the endTB-Q trial, 745 participants with rifampicin-,fluoroquinolone-resistant TB were randomized to the WHO standard regimen or 6-9 months experimental regimen containing bedaquiline, clofazimine, delamanid, linezolid (BDQ, CFZ, DLM, LZD). For participants culture-positive at ≥week 16 of treatment, we describe baseline and ADR, phenotypic resistance (pR) and variants in resistance-associated genes.
Design/Methods: Minimum-inhibitory concentrations (MICs) were determined using broth microdilution plates, with resistance defined as MIC>critical concentration (CC). Whole genome sequencing (WGS), performed on Illumina, was analyzed with TB-Profiler to report resistance-conferring variants (RAVs), or in their absence, for pR isolates, variants of uncertain significance.
Results: We analyzed 227 isolates from 32 participants. Of 11 who did not experience ADR, 2 were baseline-pR: one to CFZ (plus BDQ-MIC at CC) carrying an *Rv0678* RAV, and one BDQ+CFZ+DLM carrying an *atpE* and *ddn* RAV. Twenty-one participants showed ADR. Three with baseline pBDQ-R isolates, two with *Rv0678* RAVs and one wildtype (also throughout follow-up), experienced ADR to an additional drug. The other 18 (86%) participants developed pBDQ-R. For 14, RAVs were detected in *Rv0678* (n=11), *pepQ* (n=2) and *atpE* (n=1); four *Rv0678* RAVs were transient.
In the remaining 4/21, *Rv0678*-uncertain variants correlated with increased BDQ-MIC, three >CC (one preceding an additional *Rv0678* RAV) and one reaching the CC.
Five participants acquired pDLM-R: two with *ddn* RAVs, two wildtype and one with a transient low-frequency uncertain variant.
Three participants developed pLZD-R, one with an *rplC* RAV detected after pR emerged. WGS identified RAVs in 2/4 baseline pBDQ-R, 15/18 (83%) BDQ-ADR and 2/5 (40%) pDLM-ADR cases.

Conclusions: Most observed ADR included BDQ. WGS-identified RAVs could explain most pR cases, but not all, suggesting additional mechanisms of resistance. For two participants experiencing ADR, pR preceded acquisition of (hetero)resistant variants. Hence, longitudinal sequencing may enhance genotypic ADR detection.

OA06-150-19 Comprehensive analysis of mutations associated with rifampicin and isoniazid resistant tuberculosis in a high burden setting

J.M.W. Pinhata,[1] A.P. Brandao,[1,2] F.M.d.A. Ferreira,[1] S.M.d. Costa,[1] V.L.M.d. Silva,[1] L. Ferrazoli,[1] E. Chimara,[1] R.S.d. Oliveira,[1] [1]Adolfo Lutz Institute, Tuberculosis and Mycobacteriosis Laboratory, São Paulo, Brazil, [2]Oswaldo Cruz Foundation, Oswaldo Cruz Institute, Rio de Janeiro, Brazil
e-mail: juliana.pinhata@ial.sp.gov.br

Background: Adolfo Lutz Institute is the public health reference laboratory for tuberculosis (TB) diagnosis in the state of São Paulo, Brazil. Over 20,000 new TB cases are notified in São Paulo annually. Since there is limited information on TB molecular drug resistance in Brazil, the aim of this study was to describe the mutations associated with rifampicin (RIF) and isoniazid (INH) resistance in *Mycobacterium tuberculosis* complex (MTBC) isolates from TB patients in the state of São Paulo, between 2019-2021.
Design/Methods: Mutations in *rpoB, katG*, and *inhA* promoter in MTBC clinical isolates were detected using the GenoType MTBDR*plus* line probe assay (LPA). Inferred mutations by LPA underwent Sanger sequencing. Additionally, the prevalence of RIF-resistant (RIF-R), INH-resistant (INH-R), and MDR-TB was calculated.
Results: Among the 13,489 MTBC isolates with valid LPA results, 657 (4.9%) showed mutations. The overall prevalence of RIF-R, INH-R, and MDR-TB in São Paulo was 1.5%, 2.0%, and 1.2%, respectively.
A significant proportion of RIF-R isolates presented inferred *rpoB* mutations (89.1%), most of them being the borderline H445N. The *inhA* promoter C-15T mutation was predominant among INH-R isolates (52.8%).
Most of the MDR isolates presented the *rpoB* S450L+*katG* S315T1 mutations. Gene sequencing identified 8 isolates with mutations not included on the WHO catalogue (*rpoB* L430Lfs*10 [1290_1299del gagccaattc] (n=1), Q432R [1295 a>g] (n=1), Q432Hfs [1295_1304del aattaatgga] (n=1), M434Qfs [1300_1305del atggac] (n=1); *katG* with deletions (n=3) - the one tested on MGIT was INH-R; and *inhA* promoter c-20g (n=1), which tested INH-R on MGIT).
Phenotypic drug susceptibility testing revealed the 0.5 µg/mL critical concentration of RIF on MGIT still misses the *rpoB* borderline mutations L430P and H445N.
Conclusions: The findings emphasize the need for ongoing surveillance and the integration of molecular and phenotypic methods to ensure accurate detection and management of drug-resistant TB in our setting.

OA06-151-19 FreezeTB: A fast, reliable, economical tool to zap endemic tuberculosis using nanopore targeted next generation sequencing

T. Ness,[1,2,3] B. Inman,[2] J. Buttler,[2] G. Kovalenko,[4,2] A. Kay,[5,1] A. DiNardo,[1] A. Mandalakas,[1] E. Bortz,[2,3] [1]Baylor College of Medicine/Texas Childrens Hospital, Global Tuberculosis Program, Houston, United States of America, [2]University of Alaska, Anchorage, Biological Sciences, Anchorage, United States of America, [3]University of Washington, WWAMI Clinical Faculty, Anchorage, United States of America, [4]University of California Irvine, Population Health and Disease Prevention, Irvine, United States of America, [5]Baylor Clinical Center of Excellence, Global Tuberculosis Program, Mbabane, Eswatini
e-mail: tara.ness@bcm.edu

Background: Alaska has the highest incidence of Tuberculosis (TB) in the United States with disease disproportionately affecting Alaska Native/American Indian (AN/AI) populations and children under 14 years of age who account for almost a third of cases. With a case fatality rate of 8% during TB treatment and a quarter of TB cases lacking sputum culture to enable drug resistance testing, the FreezeTB initiative was launched to develop diagnostic tools tailored to meet the challenges of care in Alaska while being translatable to other settings.
Design/Methods: We sought to develop a rapid and cost-effective method for identifying drug resistant mutations in *Mycobacterium tuberculosis* using targeted next generation sequencing (tNGS). We designed a primer multiplex, amplification and barcoding protocol, and sequencing workflow for nanopore sequencers, including portable devices. We programmed an open-source (OS) software that detects mutations associated with drug resistance recognized by the World Health Organization. One hundred blinded *M. tuberculosis* isolates from Alaska (59 resistant, 41 pan-susceptible) were selected and underwent analysis with our lab and bioinformatic workflow, then compared to phenotypic drug susceptibility testing (pDST) using BACTEC MGIT 960.

Figure 1. Heat maps showing the results of 100 Alaska *M. tuberculosis* isolates, with results from phenotypic drug susceptibility testing (left) compared to results of FreezeTB targeted next generation sequencing (right), with each row representing an isolate. Phenotypic DST breakpoints are INH 0.1 µg/mL (reflex to 0.4 µg/mL if 0.1 µg/mL is resistant), RIF 1.0 µg/mL, EMB 5.0 µg/mL, PZA 100 µg/mL, and STR 1.0 µg/mL (LFX 1.0 µg/mL and MFX 0.25 µg/mL on request for isolates collected after 2022).

Results: Compared to pDST, FreezeTB workflow identified 80% of rifampin resistance (n=4/5), 74% of isoniazid resistance (n=37/50), 100% of streptomycin, ethambutol

and ethionamide resistance (n=9/9, 3/3, and 9/9 respectively) but only 14% of pyrazinamide resistance (n=1/7). FreezeTB is designed to detect resistance to fluoroquinolones, bedaquiline, pretomanid/delamanid, and linezolid, however no isolates had this resistance pattern. Using a portable sequencer, each sample was sequenced for under $35.

Conclusions: FreezeTB provides a one-day laboratory and bioinformatic workflow for sequencing *M. tuberculosis*; offering an OS software with graphical user interface and a laboratory workflow costing under $35 per sample. Freeze TB can accurately determine resistance for rifampin, isoniazid, streptomycin, ethambutol and ethionamide and is designed to detect resistance in newer drugs, such as bedaquiline and pretomanid.

OA06-152-19 One-day TB diagnosis and resistance mapping with BD MAX MDR-TB and ONT AmPORE assays

A. Golubov,[1] C. Corbett,[1] D. Sinitski,[1] O. Kabirov,[2] D. Allamuratova,[3] K. Sharma,[1] U. Antonenka,[1] M. Heiß-Neumann,[4] S. Hofmann-Thieland,[5] H. Hoffmann,[6,5]
[1]Institute for Microbiology and Laboratory Medicine / SNRL Gauting, Research and Development, Gauting, Germany, [2]National Tuberculosis Hospital Machiton, National Tuberculosis Reference Laboratory, Machiton, Tajikistan, [3]Republican Specialized Scientific Practical Medical Centre of Phthisiology and Pulmonology, National Tuberculosis Reference Laboratory, Tashkent, Uzbekistan, [4]Asklepios Lungenklinik, TB, Gauting, Germany, [5]SYNLAB Gauting, Laboratory for Microbiology and Molecular Biology, Gauting, Germany, [6]Institute for Microbiology and Laboratory Medicine / SNRL Gauting, Medical Microbiology, Gauting, Germany
e-mail: a.golubov@imlred.de

Background: The WHO has endorsed a broad range of molecular biological rapid diagnostic tests (mWRDs) for TB diagnosis and detection of key resistance markers for rifampicin and isoniazid. However, rapid tests for resistance markers are still lacking for drugs used in the BPaLM regimen. Targeted next-generation sequencing (tNGS) can detect resistance to all relevant anti-MDR-TB drugs with high accuracy, but challenges remain in sample availability and DNA extraction. We addressed this by combining the BD Max™ MDR-TB test with the AmPORE tNGS assay (Oxford Nanopore Technologies). This "One-Day Diagnostic Platform" (ODDP) enables comprehensive analysis from a single sputum sample within one working day.

Design/Methods: Spiked samples were created from native sputum and MTB strains with diverse resistance profiles. Clinical samples were collected from the Asklepios Pulmonary Hospital in Gauting, Germany, and the Republican TB Hospital in Machiton, Vahdat District, Tajikistan. Samples were first analyzed using the BD Max™ MDR-TB assay. DNA was then recovered from the instrument and processed with the ONT AmPORE tNGS assay. Discrepancies between BD Max™ and AmPORE were resolved by whole genome sequencing (WGS) using the Illumina platform. Statistical analyses were performed with Stata 16.0.

Results: The entire workflow was completed within an average of 8.5 hours (picture 1) , with the following time frame:
i. 0.25 h sample prep,
ii. 3 h BD Max™,
iii. 2.5 h multiplex PCR,
iv. 0.75 h library prep,
v. 1 h tNGS,
vi. 1 h data analysis.
Using a Ct value ≤28.0 as a threshold, 73% of clinical and 83% of spiked samples yielded resistance profiles covering ≥12 antibiotics. Only 8% and 10% of tNGS runs were unsuccessful, i.e., covering less than 12 antibiotics.

Time	Task	Equipment
8:00 – 8:15	Samples preparation	Work bench
8:15 – 11:15	BD Max™ MDR-TB and DNA recovery	BD Max™
11:15 – 13:45	Multiplex PCR for tNGS	Work bench, thermocycler
13:45 – 14:30	Barcoding and library purification	Work bench, thermocycler
14:30 – 15:30	Sequencing run	MinION
15:30 – 16:30	Data analysis	PC

Actual Work Day times (min)

Number of samples	Time to completion (hours)	Time to completion (minutes)
12	7.8	467
12	8.0	480
11	9.1	545

Conclusions: Integrating BD Max™ with ONT-based tNGS offers a rapid, accurate, and comprehensive diagnostic tool for MDR/XDR-TB, with potential for same-day results from a single sputum sample.

OA06-153-19 Targeted next-generation sequencing - A promising approach in the diagnosis of Mycobacterium tuberculosis and drug resistance

L. Shi,[1] P. Yi,[1] [1]The Affiliated Changsha Central Hospital, Hengyang Medical school, University of South China, Department of Tuberculosis, Changsha, China
e-mail: 124463122@qq.com

Background: Despite China's progress in tuberculosis (TB) diagnostics (62% bacteriological confirmation rate in 2022), unmet needs persist for rapid, comprehensive detection of Mycobacterium tuberculosis complex (MTBC) and drug resistance. Targeted next-generation sequencing (tNGS) offers simultaneous pathogen identification and resistance profiling, yet its clinical validation remains limited.

Design/Methods: This retrospective study analyzed 128 patients with suspected pulmonary TB (91 MTBC, 18 non-tuberculous mycobacteria [NTM], 19 non-mycobac-

terial infections) from Changsha Central Hospital (2021-2023). Bronchoalveolar lavage fluid (BALF) samples underwent parallel testing with tNGS, Xpert MTB/RIF, and mycobacterial culture. Diagnostic performance was assessed against composite clinical standards. Drug resistance concordance was evaluated using phenotypic drug susceptibility testing (DST) as reference.

Results: tNGS demonstrated superior sensitivity versus conventional methods: MTBC detection: 86.8% (79/91) vs. 61.5% for culture (p<0.001) and 59.3% for Xpert (p=0.002); NTM identification: 100% (18/18) sensitivity vs. 55.6% for culture, Turnaround time: 1.06±0.29 days vs. 34.26±17.92 days for culture (p<0.001); For resistance detection in 28 culture-positive cases, tNGS showed: 89.3% accuracy for rifampicin (100% sensitivity, 85% specificity), 100% concordance for levofloxacin resistance, Identified minority variants (e.g., rpoB L511P) missed by Xpert.

Conclusions: tNGS significantly improves diagnostic yield and speed for MTBC/NTM while enabling comprehensive resistance profiling. Its ability to detect co-infections and rare resistance mutations addresses critical gaps in conventional algorithms. Multicenter prospective studies are warranted to standardize tNGS implementation in TB diagnostic pathways.

OA06-154-19 Ai-enhanced detection of rifampicin or multidrug resistance in tuberculosis using MALDI-TOF lipid spectra: A novel approach to DST

M. Kang,[1] J. Whang,[1] J.S. Yang,[1] D.-e. Kim,[1] S. Kim,[2] L. Lee,[2] R. Nam,[2] J. Ko,[1] G.I. Lee,[2,1] [1]The Korean Institute of Tuberculosis, Center of Research and Development, Osong, Republic of Korea, [2]The Korean Institute of Tuberculosis, Center of Laboratory Medicine, Osong, Republic of Korea
e-mail: mg924192@gmail.com

Background: Tuberculosis (TB), caused by *Mycobacterium tuberculosis* (Mtb), remains a major global health concern. According to the WHO, 10.8 million cases were reported in 2023. Multidrug-resistant TB (MDR-TB), particularly rifampicin (RIF) resistance, poses serious treatment challenges. While MALDI-TOF has been utilized to detect antimicrobial resistance in other pathogens, its application to lipid analysis of Mtb is limited.

This study evaluates lipid profiles of drug-susceptible (DS) and rifampicin-resistant (RIF-R) or multidrug-resistant (MDR) strains using MALDI-TOF and machine learning to support improved drug susceptibility testing (DST).

Design/Methods: A total of 368 Mtb isolates (184 DS, 184 RIF-R or MDR) were collected from respiratory samples at the Korean Institute of Tuberculosis between 2022 and 2024. Lipids were extracted via autoclaving and chloroform:methanol (9:1) treatment. Spectra were acquired using the Autoflex-maX(Bruker) in positive reflector mode (300–3500 m/z) with DHB as the matrix. Peak presence within ±1.0 m/z was binarized, and chi-square analysis was used to select significant features, which were then applied to Random Forest, Logistic Regression, and Decision Tree models for classification.

Results: Eighteen candidate peaks were identified from spectral differences, with ten showing statistical significance ($p < 0.05$). Peaks at 599, 882, 996, and 1018 m/z were enriched in DS, while 810, 913, and 1519 m/z appeared more in RIF-R or MDR strains. The Random Forest model achieved an AUC of 0.786, with Logistic Regression and Decision Tree models showing similar performance (0.784 and 0.782, respectively).

Conclusions: This study demonstrates that MALDI-TOF lipid profiling, combined with machine learning, can differentiate DS from RIF-R or MDR Mtb strains based on distinct peak signatures, particularly in the 599, 810, and 1279 m/z regions.

Although lipid analysis requires several steps, it may serve as a rapid and informative complement to conventional DST, especially in cases of treatment failure or delayed response, ultimately supporting better clinical decision-making.

OA06-155-19 Diagnostic performance of Sanity 2.0 to detect resistance to rifampicin, isoniazid and fluoroquinolones among patients with TB

Y. Li,[1] Z. Feng,[1] X. Chen,[1] F. Sun,[1] W. Zhang,[1]
[1]Huashan Hospital, Fudan University, Department of Infectious Diseases, Shanghai, China
e-mail: fengzhdoct@163.com

Background: Effective tuberculosis (TB) management relies on prompt diagnosis of *Mycobacterium tuberculosis* (MTB) and timely detection of drug resistance to initiate optimum treatment regimens promptly. More molecular assay currently enables simultaneous detection of MTB and resistance to rifampicin (RIF), isoniazid (INH), and fluoroquinolones (FQ) are urgently needed. Sanity 2.0 is a novel integrated molecular test designed to address this gap. This study aimed to evaluate its diagnostic performance in clinical settings.

Design/Methods: Sanity 2.0 was evaluated using clinical specimens from patients with bacteriologically confirmed TB enrolled in two registered multicenter trials, INSPIRE (NCT05081401) and ORIENT (NCT 05401071). The sensitivity of Sanity 2.0 for MTB detection was evaluated. Sensitivity and specificity of Sanity 2.0 in detecting RIF, INH, and FQ resistance were assessed, using phenotypic drug susceptibility testing (pDST), whole-genome sequencing (WGS), Xpert MTB/RIF, and Xpert MTB/XDR as reference standards. Analyses were performed using R (version 4.3.1), with 95% confidence intervals (95% CI) calculated using the Wilson score methods.

Results: A total of 611 patients were recruited in this diagnostic study. MTB was detected in 563 of the specimens by Sanity 2.0, exhibiting a sensitivity of 92.1% (95% CI: 89.7–94.0) for detecting MTB. Taking the pDST results as the standard, the sensitivity for Sanity 2.0 detecting resistance to RIF, INH, and FQ was 100%, 91.7%, and 90.0%, respectively, with specificity of 85.3%, 95.9%, and 94.3%, respectively. Using NGS as reference, Sanity 2.0 achieved a 99.5% sensitivity for RIF resistance, 95.2% for INH, 93.6% for FQ, with specificity of 90.7%, 93.1%, 96.4%, respectively.

TABLE. Diagnostic performance of the Sanity 2.0 assay for detection of drug resistance compared with phenotypic drug susceptibility testing, whole-genome sequencing, Xpert MTB/RIF, and Xpert MTB/XDR assays.

Drug	Reference	No. of sample	No. of TP results	No. of FP results	No. of FN results	No. of TN results	Sensitivity(% [95% CI])	Specificity(% [95% CI])	Accuracy(% [95% CI])	PPV(% [95% CI])	NPV(% [95% CI])
RIF	pDST	201	183	19	0	110	100.0% (97.2 - 100.0)	85.2% (78.1 - 90.4)	94.5% (90.9 - 99.1)	90.5% (97.6 - 99.8)	96.5% (91.4 - 98.4)
INH	pDST	390	111	7	10	162	91.7% (85.5 - 95.5)	95.9% (90.7 - 98.0)	94.3% (87.5 - 93.8)	94.0% (90.5 - 98.4)	70.0% (70.0 - 85.8)
FQ	pDST	223	27	11	3	182	90.0% (74.4 - 96.5)	94.3% (90.1 - 96.8)	94.0% (90.4 - 96.6)	91.0% (83.5 - 95.4)	93.1% (91.7 - 97.2)
RIF	WGS	307	209	9	1	88	99.5% (97.4 - 99.9)	90.7% (83.3 - 95.0)	97.7% (95.9 - 99.3)	97.4% (91.2 - 99.8)	100.0% (99.6 - 100.0)
INH	WGS	327	159	11	8	149	95.2% (90.8 - 97.6)	93.1% (88.1 - 96.1)	94.1% (90.8 - 96.3)	94.1% (88.3 - 97.1)	94.2% (89.6 - 96.8)
FQ	WGS	308	98	10	4	206	91.6% (84.6 - 97.5)	96.4% (93.5 - 98.0)	95.1% (89.7 - 96.2)	71.1% (55.2 - 82.0)	98.4% (95.5 - 99.5)
RIF	Xpert-MTB/RIF	412	293	2	4	113	98.7% (96.6 - 99.7)	98.2% (93.8 - 99.5)	98.5% (96.1 - 98.2)	93.9% (92.3 - 97.8)	98.9% (93.9 - 99.8)
INH	Xpert-MTB/XDR	317	210	7	21	79	90.9% (86.5 - 94.0)	91.9% (84.1 - 96.0)	94.2% (91.1 - 96.1)	93.3% (88.8 - 96.4)	94.9% (90.3 - 97.4)
FQ	Xpert-MTB/XDR	315	81	8	15	234	87.1% (78.8 - 92.5)	96.7% (93.6 - 98.3)	93.9% (91.2 - 97.5)	85.3% (75.9 - 91.8)	98.5% (96.3 - 99.4)

RIF, rifampicin; INH, isoniazid; FQ, fluoroquinolones; pDST, phenotypic drug susceptibility testing; WGS, whole-genome sequencing; TP, true positive; FP, false positive; FN, false negative; TN, true negative; CI, confidence interval; PPV, positive predictive value; NPV, negative predictive value; CI, confidence interval.

Conclusions: Sanity 2.0 is a rapid, and user-friendly platform capable of detecting MTB and key drug resistance in a single step. It demonstrated good diagnostic performance and could potentially be an effective alternative as the initial test for rapid TB diagnosis and guiding individualized anti-TB treatment.

OA06-156-19 Improved internal quality control enhances accuracy of drug susceptibility testing in Eastern Europe and Central Asia

U. Antonenka,[1] O. Kabirov,[2] L. Turaev,[3] G. Kalmambetova,[4] N. Kampos-Rodriges,[5] H. Hoffmann,[1] [1]Institute of Microbiology and Laboratory Medicine, IML red, Gauting, Germany, [2]Republican TB Hospital Macheton, NRL, Dushanbe, Tajikistan, [3]Republican TB and Pulmonary Hospital, NRL, Tashkent, Uzbekistan, [4]National Tuberculosis Center, Department of Strategic Development and International Cooperation, Bishkek, Kyrgyzstan, [5]Public Health Center, NRL, Kyiv, Ukraine
e-mail: u.antonenka@imlred.de

Background: Accurate phenotypic drug susceptibility testing (pDST) is essential for tuberculosis (TB) treatment decisions. In 2019, Tajikistan's National Reference Laboratory (NRL) reported 55.9% false-resistant results for bedaquiline (Bdq).
We hypothesized that deviations in drug solution quality were not reliably detected using the WHO-recommended IQC based on a single critical concentration of M. tuberculosis H37Rv.
Design/Methods: Between 2018–2021, we implemented a harmonized MIC-based IQC protocol in four NRLs (Uzbekistan, Tajikistan, Kyrgyzstan, Ukraine) through on-site training and monitoring. MIC distributions were assessed using H37Rv (ATCC 27294) against multiple anti-TB drugs in BACTEC MGIT system. IQC was performed for each new drug solution lot using a 4-point MIC titration (mode ±1 and ±2). Equipment calibration and deviation response protocols were standardized. Data were analyzed to define reference MIC ranges and detect outliers.
Results: For Bdq, 75 IQCs showed a mode MIC of 0.25 mg/L in 80% of tests, with 97.3% within the 0.12–0.5 mg/L range. Other drugs (clofazimine, delamanid, linezolid, levofloxacin) showed similarly tight distributions. After MIC-based IQC implementation, re-testing of 129 isolates from Tajikistan NRL in 2022 showed 95.3% concordance with reference results, compared to 35% in 2019. False resistance dropped to 4.7%.
Conclusions: Our MIC-based IQC protocol provides a more discriminative and robust method to ensure pDST accuracy by detecting batch-specific errors in drug preparation.
The improved accuracy observed in partner laboratories supports the adoption of MIC-based IQC as a best practice, particularly for laboratories using new or repurposed anti-TB drugs. Global pDST quality assurance strategies should consider this approach.

OA06-157-19 Phenotypic drug susceptibility testing and genotypic characterization of Bedaquiline resistance among drug resistant *Mycobacterium tuberculosis* isolates

J.S. Michael,[1] Annie Sheeba V, Marilyn Mary Ninan, Manigandan V, Richa Gupta, Asha Frederick, Ranjani Ramachandran [1]Christian Medical College, Vellore, India, Clinical Microbiology, Vellore, India
e-mail: joymichael@cmcvellore.ac.in

Background: The new drugs bedaquiline, delamanid, and pretomanid have been approved for treating drug-resistant tuberculosis. The World Health Organization currently recommends the BPaL(M) regimen, which lasts 6-9 months, for managing drug-resistant tuberculosis.
This study aimed to perform phenotypic drug susceptibility testing (pDST) and identify mutations linked to bedaquiline (BDQ) resistance through whole genome sequencing (WGS).
Design/Methods: We conducted a prospective cohort study involving 298 drug-resistant Mycobacterium tuberculosis (MTB) isolates from patients visiting the respiratory medicine outpatient department at Christian Medical College, Vellore, and district TB centers across six districts in Tamil Nadu over the course of one year (2019-2023).
These isolates underwent phenotypic drug susceptibility testing (pDST) for bedaquiline using the BACTEC™ MGIT™ 960 system, following WHO guidelines. Additionally, whole genome sequencing (WGS) was performed on a subset of 150 isolates using the Illumina platform, followed by mutation analysis using BLASTIN.

Results: The study found a 7% prevalence of bedaquiline (BDQ) resistance. A total of 39 variants were identified across four candidate genes associated with BDQ resistance: Rv0678, mmpL5 (Rv0676c), pepQ, and Rv1979c. No mutations were observed in the Rv0677c, Rv1304, or atpE genes in any of the tested isolates. All isolates (100%) had at least one mutation in the Rv0676c gene.
Conclusions: This study identified the most common genetic variants linked to BDQ resistance from a tertiary care center in India. Larger studies across the country are necessary to explore the phenotypic and genotypic resistance profiles of BDQ and other drugs used in all-oral shorter regimens being introduced in India for the treatment of multidrug-resistant TB.

OA06-158-19 Determining the complete drug resistance pattern within a single day using a composite platform of BD-MAX™ MDR-TB and AmPORE TB with clinical samples

C. Corbett,[1] A. Golubov,[1] K. Venkatraman,[1] D. Sinitsky,[1] H. Hoffmann,[1] [1]IMLred GmbH, Research and Development, Gauting, Germany e-mail: Harald.Hoffmann@synlab.com

Background: Rapid drug susceptibility testing is critical for initiating an effective anti-tuberculosis (TB) regimen. Typically, the initial sputum sample from a patient is entirely consumed for TB diagnosis, with results limited to rifampicin (RIF) and isoniazid (INH) resistance. Utilizing DNA extracted from the BD-MAX™ system for targeted next-generation sequencing (tNGS) circumvents the need for a second sputum sample, enabling same-day reflex testing for up to 16 antibiotics.
This study aims to evaluate the feasibility of using BD-MAX™-extracted DNA from clinical samples for resistance profiling via tNGS on the AmPORE TB platform and to determine an optimal cycle threshold (Ct) value for BD-MAX™ that supports further tNGS analysis.
Design/Methods: Seventy-four clinical bacteriological confirmed TB-positive sputum samples were processed using BD-MAX™ per manufacturer instructions. The 7 to 10 µl left-over extracted DNA were applied to tNGS using the AmPORE TB assay for tNGS. The number of resistance-associated gene regions detected and their corresponding BD-MAX™ Ct values were assessed.
Results: Of the 74 clinical samples, 14 (19%) failed or had a indeterminate result on BD-MAX™ and were excluded from analysis with tNGS. Of the 60 samples with positivetNGS successfully sequenced resistance-associated gene targets for at least 12 antibiotics with 37(61.7%) samples; 73.0% of these had a BD-MAX™ IS6110/IS1081 Ct value of ≤28.0. tNGS failed for only 8.3% of samples with Ct values of ≤28.0 to produce ARPs covering at least 12 antibiotics. The targets most frequently successfully sequenced with tNGS were for Inh, Rif, fluoroquinolones, Lzd, Pza, Eto, and second-line injectables (see Table 1).

Table 1: Antibiotics (AB) corresponding to genes that were detected with tNGS using BD-MAX DNA that met antibiotic cutoff criteria for clinical sputum samples

Antibiotic	Number of samples when gene region for antibiotics not detected (for samples where at least 12 AB were detected) Clinical Samples (n=37)	Number of samples when gene region for antibiotics not detected (for samples where at least 1 AB is detected) Clinical samples (n=46)
Isoniazid	0	3
Rifampicin	0	3
Ethambutol	3	11
Pyrazinamide	1	7
Levofloxacin	1	3
Moxifloxacin	1	3
Bedaquiline	1	7
Linezolid	0	3
Clofazimine	3	12
Pretomanid	4	12
Delamanid	4	11
Streptomycin	1	7
Amikacin	0	4
Capreomycin	2	9
Kanamycin	2	9
Ethionamide	0	3

Conclusions: Integrating BD-MAX™ with AmPORE TB tNGS enables comprehensive antibiotic resistance profiling with results reported within a single day. A Ct-value of 28 provides a strong prognosis of successful downstream tNGS testing. This protocol enhances laboratory capabilities to rapidly deliver reliable, comprehensive resistance data facilitating immediate initiation of effective TB treatment regimens.

OA06-159-19 Evaluation of the BD MAX™ and COBAS® platforms for the detection of *Mycobacterium tuberculosis* and resistance to rifampicin and isoniazid in Peru

Z. Puyen Guerra,[1] M. Alarcón León,[2] E. Pacheco Ascencio,[1] S. Villar,[1] A. Vigo Tayro,[1] [1]Instituto Nacional de Salud, Laboratorio de Referencia Nacional de Micobacterias, Chorrillos, Peru, [2]Instituto Nacional de Salud, Laboratorio de Referencia Nacional de Micobacteria, Chorrillos, Peru e-mail: zpuyeng@gmail.com

Background: In 2021, the World Health Organization (WHO) recommended the use of moderate-complexity automated nucleic acid amplification tests (NAATs) for the detection of tuberculosis (TB) and resistance to rifampicin and isoniazid. NAATs are molecular techniques employed to identify and amplify specific nucleic acid sequences.
The objective of this study is to evaluate the diagnostic performance of the BD MAX and Cobas platforms using clinical samples from Peru.
Design/Methods: Various sputum samples stored at the "Laboratorio de Referencia Nacional de Micobacterias" (LRNM) in Peru were analyzed. Initially, all specimens underwent testing with GeneXpert Ultra, LJ culture, or the Genotype MTBDRplus line probe assay, following routine standard protocols. The remaining stored aliquots

were subsequently utilized to perform the BD MAX™ and COBAS® assays. Sensitivity, specificity, repeatability, and intermediate precision were determined for both platforms in the detection of pulmonary tuberculosis and resistance to rifampicin and isoniazid. The evaluation of both platforms was carried out at different times and using distinct sets of samples.

Results: The sensitivity and specificity of both the BD MAX™ and COBAS® platforms for the detection of Mycobacterium tuberculosis (MTB) were 100%, with no discordant results observed between the two assays. For the detection of rifampicin resistance, COBAS® demonstrated 100% sensitivity and specificity.

In contrast, BD MAX™ showed a sensitivity of 92.1% and a specificity of 96.34%. Regarding isoniazid resistance, both platforms exhibited 100% specificity; however, sensitivity was 94.7% for BD MAX™ and 97.01% for COBAS® (*Table 1*). Repeatability and intermediate precision tests yielded satisfactory results for both diagnostic platforms.

			Detected	Not detected	Total	Sensitivity % (95% CI)	Specificity % (95% CI)
			XPERT MTB RIF Ultra				
MTB	BD MAX	Detected	18	0	30	100 (78.12 – 99.49)	100 (82.87 - 99.23)
		Not detected	9	12			
			Cultivo LJ				
	Cobas	Detected	80	0	150	100 (95.42 – 99.93)	100 (93.52 - 99.57)
		Not detected	9	70			
			LPA (GenoType MTBDRplus)				
RIF	BD MAX	Detected	35	3	120	92.1 (77.52 – 97.94)	96.34 (88.04 - 99.05)
		Not detected	3	79			
	Cobas	Detected	62	0	120	100 (78.12 – 99.49)	100 (59.87 - 99.23)
		Not detected	0	58			
INH	BD MAX	Detected	54	0	120	94.7 (84.45 – 98.83)	100 (91.73 - 99.83)
		Not detected	3	63			
	Cobas	Detected	65	0	120	97.01 (89.66 – 99.46)	100 (91.58 - 99.83)
		Not detected	2	53			

Table 1. Diagnostic accuracy of BD MAX™ and COBAS® platforms (MTB, RIF and INH) from sputum samples of Peruvian patients with tuberculosis, during 2024.

Conclusions: The BD MAX™ and COBAS® assays proved to be effective tools for the detection of *Mycobacterium tuberculosis* and associated resistance to rifampicin and isoniazid in clinical samples from Peruvian patients.

OA07 Diagnosing and treating drug-resistant TB

OA07-160-19 Whole genome sequencing for new and repurposed anti-tuberculosis drugs among people with drug-resistant TB in the Philippines

D.J. Casalme,[1,2] M. Berioso,[1,2] J.A.R. Ganaden,[1,2] M.R. Macapagal,[1,2] F. Willis,[3] A. Kim,[3] A. Campbell,[4] J. Brust,[5] L. Tang,[6] B. Mathema,[6] NS. Shah,[7] M.T. Gler,[1,2]
[1]De La Salle Medical and Health Sciences Institute, Research, Dasmariñas, Philippines, [2]TB-HIV Innovations and Clinical Research Foundation Corp., Research, Silang, Philippines, [3]Emory University, Rollins School of Public Health, Atlanta, United States of America, [4]Emory University, Emory-Einstein TB Research Group, Atlanta, United States of America, [5]Albert Einstein College of Medicine & Montefiore Medical Center, Divisions of General Internal Medicine and Infectious Diseases, Bronx, United States of America, [6]Columbia University Mailman School of Public Health, Department of Epidemiology, New York, United States of America, [7]Emory University, Rollins School of Public Health and Emory School of Medicine, Atlanta, United States of America
e-mail: docasalme@tbhivicr.org.ph

Background: New anti-tuberculosis drugs developed in the past decade, combined with repurposed medications, have led to shorter, safer, and more effective regimens for treating multidrug-resistant TB (MDR-TB). Bedaquiline was fully rolled out in the Philippines in 2020, followed by the shortened BPaL/BPaLM regimens in December 2023. However, resistance to these drugs can emerge quickly and spread through transmission.

Design/Methods: We examined the prevalence and genomic correlates of resistance to new and repurposed anti-tuberculosis drugs in the Philippines using whole genome sequencing. We used baseline isolates from people newly enrolled in MDR-TB treatment during April 2019- April 2022 from Cavite province. Mycobacterium tuberculosis (MTB) strain lineage and genomic correlates of drug resistance were determined using whole genome sequence (WGS) analysis. MTB DNA was sequenced using paired-end WGS on the NovaSeq 6000, followed by bioinformatics analysis.

Results: Among 148 people with MTB genomic data, mean age was 43.6 years (SD± 14.6) and 72% were male. Lineage distribution showed 88% were lineage 1.2.1, 10% were lineage 4, and 2% were lineage 2. Only one (0.7%) had fluoroquinolone resistance (gyrA_D94G) and three (2%) had bedaquiline resistance (Rv0678). Isoniazid resistance mutations were found in 42% (62/148) of isolates, mainly katG_315T (55/62, 89%). Rifampicin resistance mutations were detected in 84%, primarily rpoB_S450L (68/125, 54%) and rpoB_H445Y (23/125, 18%). No WHO-graded resistance conferring mutations were found for delamanid, linezolid and pretomanid.

Conclusions: Resistance to new and repurposed anti-TB drugs remains low in the Philippines. Continued use of fluoroquinolones appears safe as resistance has remained low despite its programmatic use for MDR-TB since 2000. The high frequency of katG mutations suggests that high-dose isoniazid may not be suitable in MDR-TB regimens in the Philippines.

OA07-161-19 Targeted Nanopore sequencing for early detection of heteroresistance in *Mycobacterium tuberculosis*

A. Babu,[1,2] P. Ponnusamy,[1,2] P. Priyanka,[2] K. Ellappan,[3] M. Rastogi,[1,2] K. Vasudevan,[1,2] P.K. Selvam,[1,2] S. Vasanthaiah,[1,2] S. Sasidharan,[1,2] A. Pandey,[1,2,4] N.M. Joseph,[3] R. Verma,[1,2]
[1]Manipal Academy of Higher Education, School of Life Sciences, Manipal, India, [2]Institute of Bioinformatics, (IOB), Bangalore, India, [3]Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Microbiology, Pondicherry, India, [4]Mayo Clinic, Department of Laboratory Medicine and Pathology, Rochester, United States of America

Background: Heteroresistance, the co-existence of drug-resistant and drug-sensitive *Mycobacterium tuberculosis* (*M. tb*) strains, can lead to treatment failure, relapse, and resistance amplification. GeneXpert MTB/RIF Ultra may have low sensitivity for minority-resistant strains and does not report heteroresistance. Targeted sequencing may detect heteroresistance missed by routine diagnostics.
We compared GeneXpert Ultra and targeted Nanopore sequencing on samples spiked with H37Rv and multi-drug-resistant TB (MDR-TB) to quantify detection limits.
Design/Methods: We designed a 5'FAM- and 3'BHQ1-labeled molecular beacon probe targeting the *RD9* gene of *M. tb* for qPCR-based DNA quantification. A targeted Nanopore panel was developed to detect *rpoB, katG,* and *inhA* mutations linked to drug resistance. MDR strains were spiked into H37Rv at 10^6-10^2 dilutions. GeneXpert MTB/RIF Ultra cartridges were spiked with H37Rv:MDR at seven ratios (95:5, 90:10 to 40:60). Spiked ratios (99.5:0.5, 99:1, 95:5 to 40:60) at 10^6-10^2 dilutions were sequenced on MinION MK1c (R10.4.1, Q-score ≥9). In-house pipelines calculated coverage depth, performed variant calling, and analyzed heteroresistance.
Results: The targeted Nanopore panel showed 100% concordance with Illumina WGS in variant calling. High coverage depths were achieved for all markers, with a median of 17,359x (IQR: 11,162x–24,458x). GeneXpert MTB/RIF Ultra detected rifampicin resistance at ≥20% in 10^6–10^5 copies, ≥30% in 10^4 copies, but failed at 40% in 10^3 copies. Heteroresistance was undetected at 10^2 copies. Nanopore sequencing identified mutant alleles at all dilutions, including 0.5% frequency in 100 copies, with a median coverage depth of 438x, exceeding the 10x cutoff for accurate variant detection.

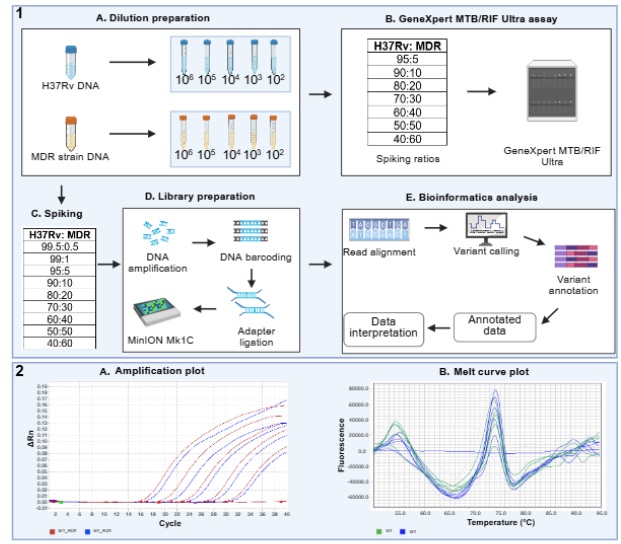


Figure: 1. Workflow schema for assessing heteroresistance in *M.tb* using GeneXpert MTB/RIF Ultra and targeted nanopore sequencing. **2.** Amplification plot and melt-curve plot obtained from the molecular beacon-based qPCR assay.

Conclusions: This study highlights the need for sensitive molecular diagnostics for early heteroresistance detection in *M. tb*. While GeneXpert MTB/RIF Ultra misses heteroresistance, Nanopore sequencing identified low-frequency resistant mutations, providing a cost-effective, scalable detection tool.

OA07-162-19 Assessing the performance of culture-free next generation sequencing for drug-resistant tuberculosis detection

I. Iannucci,[1] K. Moghaddasi,[1] F. Di Marco,[1] P. Miotto,[1] A.M. Cabibbe,[1] D.M. Cirillo,[1] The PORTB Consortium
[1]IRCCS San Raffaele Scientific Institute, Division of Immunology, Transplantation and Infectious Diseases, Milan, Italy
e-mail: iannucci.ilaria@hsr.it

Background: Targeted Next-Generation Sequencing (tNGS) of *Mycobacterium tuberculosis* (MTB) was approved by WHO for drug-resistant tuberculosis (DR-TB) diagnosis from respiratory samples. The new Deeplex Myc-TB XL (Genoscreen) provides extended target panel, including bedaquiline and pretomanid, matching the modern DR-TB treatment regimens. Still, whole-genome sequencing (WGS) may be preferred as it doesn't require target preselection and supports epidemiological surveillance. The new QIAseq xHYB MTB panel (Qiagen) enables whole-genome hybridization enrichment for direct WGS (dWGS) testing.
We investigated the limit of detection (LoD) and performance of tNGS and dWGS on 89 sediments from MTB-positive sputum samples collected within a TB vaccine trial with prevention of recurrence design.
Design/Methods: Ultra-Deep Microbiome Prep (Molzym) was used for DNA extraction and host DNA depletion. Real-time PCR was used to quantify MTB genome

copies (gc). Deeplex and QIAseq libraries were sequenced on Illumina systems. FASTQ files were analyzed using adapted MTBseq pipeline for detecting mutations relevant for drug resistance (DR) that were compared to WGS from corresponding isolates.

Results: Study samples showed broad quantification ranging from 1-10 (Ct 31-34), 10-100 (Ct 28-31), 100-1000 (Ct 25-28) to >1000 (Ct <25) gc/uL. Deeplex led to interpretable profiles for 86/89 (97%) samples (Ct 28.5±3.2).

Three samples had coverage depth <200x (Ct 32.6±2.8). QIAseq showed high quality dWGS (depth >30x, breadth >97%) for 53/89 (60%) samples (Ct 27.4±2.5), allowing transmission analysis.

Twelve samples (Ct 30.5±2.1) showed acceptable metrics (depth >20x, breadth >90%), whereas remaining (Ct 30.3±4.1) resulted in incomplete genome data.

Both assays demonstrated high (>98%) sensitivity and specificity for DR detection.

Conclusions: Culture-free dWGS allowed successful DR interpretation for 74% specimens. However, tNGS showed lower LoD (10 vs >100 total gc of dWGS) and stronger correlation with bacillary load.

Selecting between the two approaches based on bacillary loads would enable effective direct diagnostic sequencing from patient samples.

OA07-163-19 Multicentre study on the Mycobacterium tuberculosis H37Rv reference strain using a new EUCAST-AMST reference protocol developed for MIC-determination of bedaquiline, clofazimine, delamanid and pretomanid

J. Werngren,[1] F. Alcaide,[2] K. Klaos,[3] E. Svensson,[4] E. Borroni,[5] D. Cirillo,[5] T. Schön,[6] V. Gabro,[6] M.H. Hazbón,[7] S. Andres,[8] A. Aubry,[9] E. Cambau,[10] [1]Public Health Agency of Sweden, Department of Microbiology, Stockholm, Sweden, [2]Hospital Universitari de Bellvitge-IDIBELL, University of Barcelona, Microbiology Department, Barcelona, Spain, [3]Tartu University Hospital United Laboratories, Department of Mycobacteriology, Tartu, Estonia, [4]Statens Serum Institut International, Reference Laboratory of Mycobacteriology, Copenhagen, Denmark, [5]WHO collaborating Centre and TB Supranational Reference Laboratory San Raffaele Scientific Institute, Department of Mycobacteriology, Milan, Italy, [6]University Hospital in Linköping, Department of Clinical Microbiology, Linköping, Sweden, [7]Becton Dickinson, Microbiology Research & Development, Sparks, United States of America, [8]Reference Center for Mycobacteria, Research Center Borstel, Borstel, Germany, [9]Service de Bactériologie-Hygiène. AP-HP. Sorbonne-Université, Centre national de référence des mycobactéries et résistance des mycobactéries aux antibiotiques, Paris, France, [10]Service de Mycobactériologie spécialisée et de référence (CR 244) Laboratoire associé du Centre national de référence des mycobactéries et résistance des mycobactéries aux antibiotiques, Département des agents infectieux, DMU BioGem, APHP-Nord, Université de Paris, Inserm UMR 1137 IAME IMEA –Rez de chaussée, Hôpital Bichat Claude Bernard, Paris, France
e-mail: jim.werngren@folkhalsomyndigheten.se

Background: A multicentre study with nine EUCAST-AMST (European committee on antimycobacterial susceptibility testing) laboratories and the BD Microbiology R&D laboratory was performed using the new reference protocol developed by the EUCAST-AMST to test water-insoluble antituberculous drugs (ATTB). Bedaquiline (BDQ), clofazimine (CFZ), delamanid (DLM) and pretomanid (PA) MICs were determined to set the modal and MIC ranges of the M. tuberculosis (MTB) H37Rv strain.

Design/Methods: The ATTB stock solutions were prepared in 100% DMSO. The final DMSO concentration was 0.5 % in the broth microdilution assay. The MTB H37Rv strain was tested following the new EUCAST reference protocol. Test concentrations were for BDQ 0.008-1 mg/L, CFZ 0.016-2 mg/L, DLM 0.0005-0.06 mg/L and PA 0.016-2 mg/L. MIC was interpreted at the point both drug-free growth controls (GC100% and GC1%) were positive.

Results: For BDQ 175 MICs were generated, for CFZ 119, for DLM 252 and for PA 216. The MIC distribution range was 0.016-0.06 mg/L for BDQ, 0.06-1 mg/L for CFZ, 0.001-0.03 mg/L for DLM and 0.03-0.25 mg/L for PA. The

modal MIC was 0.03, 0.5, 0.004 and 0.12 mg/L for BDQ, CFZ, DLM and PA, respectively. The intra-laboratory reproducibility was high for BDQ (6/6 laboratories), DLM (8/9 laboratories) and PA (9/9 laboratories) with MICs within ± one dilution for >95% of observations, but lower for CFZ. Correspondingly, inter-laboratory reproducibility was high for BDQ (6/6 laboratories) but lower for DLM (6/9 laboratories), PA (7/9 laboratories) and CFZ (2/4 laboratories).

Conclusions: Ten laboratories, including nine within EUCAST-AMST, tested the MTB H37Rv strain with the new EUCAST reference protocol for MIC determination of water-insoluble ATTB. For most drugs, intra-laboratory reproducibility was high while inter-laboratory reproducibility was generally lower, but still with a well-defined modal MIC with ± one dilution range for BDQ, DLM and PA determined.

OA07-164-19 Baseline and acquired resistance-associated M. tuberculosis variants in BPaL-based regimens

S. Rofael,[1] C. Berry,[2] L. Elton,[1] P. Jolivet,[2] E. Kazounis,[2] T. McHugh,[1] P. Solanki,[1] B.-T. Nyang'wa ,[3] A. Bateson,[1]
[1]University College London (UCL), Centre for Clinical Microbiology, Division of Infection and Immunity, London, United Kingdom of Great Britain and Northern Ireland, [2]Médecins Sans Frontières, Public Health Department, London, United Kingdom of Great Britain and Northern Ireland, [3]Médecins Sans Frontières, Public Health Department, Amsterdam, Netherlands

Background: TB-PRACTECAL studied 24-week treatments consisting of bedaquiline, pretomanid and linezolid (BPaL), BPaL plus moxifloxacin (BPaLM) and BPaL plus clofazimine (BPaLC) for RR/MDR-TB in Uzbekistan, Belarus, and South Africa.

Design/Methods: Mycobacterium tuberculosis drug susceptibility testing (DST) (n=470) and minimum inhibitory concentration (MIC) (n=467) by BD-BACTEC™MGIT™ and whole genome sequence (WGS) (n=424) data were used to investigate the rates of baseline-resistance (BR) and acquired-resistance (AR) to moxifloxacin, bedaquiline, clofazimine, linezolid and pretomanid.

Results: At baseline, 62.8% were phenotypically MDR-TB, 4.9% RR, 18.3% Pre-XDR, and 0.9% XDR. The lineages observed were 72% Lineage2, 22% Lineage4, 0.9% Lineage3 and 0.7% Lineage1.

No BR was detected against linezolid, pretomanid or clofazimine. Moxifloxacin BR was detected in 19.6%(n=92/470), 70 of which showed low-level resistance (0.25<MIC ≤1mg/L). Bedaquiline BR was detected in 5/467 cases; one in South Africa caused by a known frame-shift mutation in mmpR5 (c.144dupC), and four in Uzbekistan, all with SNPs in mmpR5, of which three had a novel SNP p.Gly41Val.This novel SNP was detected five times, four baseline and one corresponding post-baseline sequence, all but one baseline isolate had an MIC=2mg/L (resistant). Of the bedaquiline BR cases, two completed treatment, one with BPaL and one with BPaLC and both had a successful clinical outcome; the other three were withdrawn due to resistance.

No AR to moxifloxacin, linezolid or pretomanid was observed. There were two cases of AR to bedaquiline/clofazimine; in one case a subpopulation (16%) emerged at week 41 with a frameshift in mmpR5 (c.138_139dupTG); in the other case AR to bedaquiline and clofazimine was observed phenotypically at week 54 but no sequence data was available. Both cases were relapses in the BPaL arm.

Conclusions: Baseline-resistance rates to all drugs in the BPaL-based regimens, except moxifloxacin, were very low. Acquired resistance was observed to bedaquiline and clofazimine, albeit at very low rates.

OA07-165-19 Association between pre-diagnostic fluoroquinolone exposure and acquired fluoroquinolone resistance in *Mycobacterium tuberculosis* in Shanghai, China: An EHR-based case-control study using whole-genome sequencing

L. Danni,[1] Z. Yangyi,[2] X. Biao,[1] [1]Fudan University, Department of Epidemiology, School of Public Health, Shanghai, China, [2]Shanghai Municipal Center for Disease Control and Prevention, Division of TB and HIV/AIDS Prevention, Shanghai, China
e-mail: 23211020060@m.fudan.edu.cn

Background: Fluoroquinolones (FQ) occupy a dual role in global health as both essential second-line antituberculosis (TB) agents and the most prescribed broad-spectrum antibiotics worldwide. However, the association between pre-diagnostic FQ exposure and acquired FQ-resistant TB has yet to be explored.

Design/Methods: This was a retrospective case-control study involving all culture-confirmed pulmonary TB cases reported in Shanghai, China from January 2022 to December 2023. Acquired FQ-resistant TB cases were identified through whole-genome sequencing (WGS) and compared with FQ-susceptible TB controls, which were randomly selected at a 1:1 ratio. Information regarding pre-diagnosis FQ exposure within 12 months prior to the TB diagnosis, was retrieved from the Shanghai Electronic Health Record (EHR) platform.

Results: FQ resistance was detected in 7.4% (260/3496) of all TB cases, with 93.5% (243/260) classified as acquired resistance. Among the patients with acquired FQ resistance, 17.3% (42/243) had received single FQ prescriptions and 42.0% (102/243) had received multiple prescriptions prior to TB diagnosis.

A multivariate logistic regression model revealed FQ exposure as the strongest resistance predictor: single prescription (aOR=4.31, 95% CI=2.37-8.04) and multiple

prescriptions (aOR=13.18, 95% CI=7.72-23.45). Restricted Cubic Splines (RCS) analysis illustrated a nonlinear dose-response relationship (Nonlinear: $P<0.0001$), with the probability of resistance increasing monotonically with the number of prescriptions.

Among the 784 FQ prescriptions dispensed to 144 FQ-exposed acquired FQ-resistant patients, prescriptions retrieved from non-designated tertiary hospitals for non-TB respiratory diseases, with an exposure interval of ≥61 days prior to TB diagnosis, were more prevalent in the FQ-resistant group (19.8%, 155/784, $P< 0.05$).

Characteristics	FQ-susceptible (N=243)	Acquired FQ-resistant (N=243)	OR (95% CI)	P value	aOR (95% CI)	P value

Table. Univariate and multivariate logistic regression on the risk factors of acquired FQ-resistance

Conclusions: A worrisome prevalence of FQ resistance among all TB cases in Shanghai, China was demonstrated, predominantly driven by acquired resistance. The dose-response relationship between pre-diagnostic FQ exposure and acquired resistance underscores the imperative need for judicious FQ use especially in respiratory infection therapy.

OA07-166-19 Baseline resistance to new and repurposed anti-TB drugs in the endTB-Q clinical trial

P. Rupasinghe,[1] A. Dippenaar,[2] L. Guglielmetti,[3,4,5] N. Barreda,[6] P. Thu Hang,[7] D. Thu Ha,[8] L. Chingisova,[9] N. Hirani,[10] A. Ashraf,[11] E. Ardizzoni,[1] C. Mitnick,[12,13,14] B. e-mail: prupasinghe@itg.be

Background: The endTB-Q trial (NCT03896685) included 324 participants with pulmonary, rifampin-resistant, fluoroquinolone-resistant tuberculosis (pre-XDR-TB), who were randomized to the WHO standard regimen for pre-XDR-TB or a 6-9 month experimental regimen.

Design/Methods: Minimum-inhibitory-concentrations (MICs) for bedaquiline (BDQ), linezolid (LZD), delamanid (DLM), and clofazimine (CFZ) were determined using broth microdilution (BMD). Phenotypic resistance (pR) was defined as an MIC greater than the critical concentration (CC). Whole-genome-sequencing (WGS) was performed on the Illumina platform. Genotypic resistance (gR) was defined as a WHO Category 1 or 2 resistance-associated mutation present at ≥3% allele frequency and mutations were classified as major/minor based on frequencies.

Results: Of the 324 participants, 266 (82.1%) had both baseline MIC and WGS data. Resistance to at least one drug was detected in 48 isolates (18.0%), with 19 (7.1%) showing both pR and gR. The highest overall resistance by any method was observed for CFZ (6.7%), followed by BDQ (4.9%), DLM (3.3%), and LZD (3.0%). The proportion of isolates showing both pR and gR was the highest for LZD (2.6%), followed by CFZ (2.2%), BDQ (1.9%), and DLM (0.8%). Isolates with pR-alone were most frequently seen with CFZ (4.5%), then DLM (2.6%), BDQ (1.9%), and LZD (0.4%).

Genotypic-only resistance was observed only for BDQ (1.1%). Most gR was due to major/fixed mutations; overall, minority variants were more common in BDQ- and

CFZ-resistant isolates. All LZD gR variants were fixed. Isolates from India (7.5%, gR+pR) and Pakistan (6.6%, gR+pR) had relatively high resistance rates; notably, all LZD-resistant isolates originated from India.

Drug	Resistant by	IN (n=119)	PK (n=90)	VN (n=22)[1]	PE (n=19)[1]	KZ (n=16)[1]	Total (n=266) (pR+gR)/ pR-only/ gR-only	Total (n=266) (pR+gR)+pR-only+gR-only

pR+gR: Resistance detected by both phenotypic and genotypic methods (Category 1 or 2 mutations present as per WHO mutation catalogue V2.0 + MIC > CC)
pR only: Phenotypic resistance only, MIC > CC gR only: Genotypic resistance only, Category 1/2 mutations present as per WHO mutation catalogue V2.0
[1] Small sample sizes, interpret with caution
[2] Minority: <50% allele frequency of resistance associated mutation
[3] Majority-fixed: >50% allele frequency of resistance associated mutation, fixed: 100% allele frequency
[4] One strain with majority and the other with minority drug-resistant populations
IN: India, PK: Pakistan, VN: Vietnam, PE: Peru, KZ: Kazakhstan, BDQ: bedaquiline, CFZ: clofazimine, LZD: linezolid, DLM: delamanid

Conclusions: These findings highlight the importance of baseline drug susceptibility testing, particularly in high resistance-prevalent settings. pR without gR may suggest gaps in our understanding of resistance mechanisms to new and repurposed anti-TB drugs. Minority variants may indicate early emergence of resistance, underscoring the need for rapid, sensitive diagnostics prior to treatment.

OA07-167-19 Baseline and emergent phenotypic pretomanid resistance in RR/MDR-TB patients in KwaZulu-Natal: Findings from the ADAP-TIV trial

R. Perumal,[1,2] S. Moodley,[3] C. Nimmo,[4] M. Zulu,[1] A. Wolf,[5] S. Ngema,[1] S. Rajagopalan,[6] M. Larsen,[6] K. Naidoo,[1] M. O'Donnell,[7,1] [1]Centre for the AIDS Programme of Research in South Africa, CAPRISA MRC-HIV-TB Pathogenesis and Treatment Research Unit, Durban, South Africa, [2]University of KwaZulu-Natal, Department of Pulmonology and Critical Care, Durban, South Africa, [3]Africa Health Research Institute, Microbiology, Durban, South Africa, [4]University College London, Department of Infection, Immunity & Inflammation, London, United Kingdom of Great Britain and Northern Ireland, [5]University of Columbia in the City of New York, Department of Epidemiology, New York, United States of America, [6]Albert Einstein College of Medicine, Department of Microbiology and Immunology, New York, United States of America, [7]University of Columbia in the City of New York, Department of Medicine, Division of Pulmonary, Allergy, and Critical Care Medicine, New York, United States of America
e-mail: mo2130@columbia.edu

Background: Bedaquiline and pretomanid have revolutionized treatment for rifampin-resistant/multidrug-resistant tuberculosis (RR/MDR-TB), but escalating drug resistance threatens their durability within RR/MDR-TB regimens. We evaluated baseline and treatment-emergent resistance to these drugs in a high-burden setting.

Design/Methods: ADAP-TIV is an adaptive, randomized clinical trial of adherence-support strategies in adults with RR/MDR-TB initiating treatment within a programmatic setting in KwaZulu-Natal, South Africa.

We analyzed phenotypic drug susceptibility testing (pDST) data of consecutively enrolled participants, focusing on those with culture-confirmed *Mycobacterium tuberculosis* (MTB) in the trial-designated laboratory.

MTB positivity was defined by growth in MGIT or solid media. Baseline resistance was assessed on a pre-treatment sputum sample, while emergent resistance was defined by new resistance in any sputum sample after treatment initiation. The critical concentration was defined at 0.25 μg/mL on 7H11 media for bedaquiline.

A conservative critical concentration for pretomanid of 0.25 μg/mL on 7H11 was assumed based on the lower WHO concentration for resistance in MGIT and published MGIT:7H11 MIC ratios. MGIT MIC testing and whole genome sequencing are in process.

Results: 357 consecutive RR/MDR-TB patients were screened, and 158 participants were enrolled. 93 (59%) had a positive MTB culture at baseline. Among these, 3 (3.2%) had baseline phenotypic resistance to pretomanid and 3 (3.2%) to bedaquiline; none had prior exposure to these drugs. Treatment-emergent resistance to pretomanid and bedaquiline (dual resistance) occurred in 2/29 (6.9%) participants with persistent culture positivity.

Timepoint	MTB-Positive Isolates n	Pretomanid Resistant n (%)	Bedaquiline Resistant n (%)	Dual Resistance n (%)
Baseline	93	3 (3.2%)	3 (3.2%)	1 (1.1%)
Month 2 or later	29	2 (6.9%)	2 (6.9%)	2 (6.9%)

Conclusions: Baseline and treatment-emergent resistance to bedaquiline and pretomanid were identified among patients receiving programmatic treatment for RR/MDR-TB with no prior exposure to these drugs. These results underscore the importance of upfront resistance detection to inform clinical decisions on drug selection and ongoing surveillance for resistance to novel drugs to guide public health responses. Routine, rapid phenotypic drug susceptibility testing for these novel agents is essential, especially in high RR/MDR-TB burden settings.

OA07-168-19 Bedaquiline, pretomanid, and linezolid resistance among rifampicin-resistant *M. tuberculosis* strains in South Africa

S.V. Omar,[1] R. Sobol,[2] L. Joseph,[1] R.M. Khouri,[2] L. Shrestha,[3] L. Tang,[2] F. Ismail,[1] F. Willis,[3] J.C.M. Brust,[4] T. Brown,[5] N.R. Gandhi,[3] B. Mathema,[2] [1]National Institute for Communicable Diseases, Centre for Tuberculosis, Johannesburg, South Africa, [2]Columbia University Mailman School of Public Health, Department of Epidemiology, New York, United States of America, [3]Emory University Rollins School of Public Health, Department of Epidemiology, Atlanta, United States of America, [4]Albert Einstein College of Medicine, Department of Medicine, Bronx, United States of America, [5]Boston University Chobanian & Avedisian School of Medicine, Department of Medicine, Boston, United States of America
e-mail: shaheedvo@nicd.ac.za

Background: The introduction of bedaquiline and pretomanid in combination with linezolid (BPaL) has transformed the fight against drug-resistant tuberculosis (DR-TB). We sought to characterize emerging resistance to this drug regimen in South Africa, which would pose a major obstacle for continued progress against DR-TB.
Design/Methods: All rifampicin-resistant *Mycobacterium tuberculosis* isolates programmatically underwent phenotypic drug-susceptibility testing (DST) for bedaquiline and linezolid; a subset also underwent DST for pretomanid. We conducted a prospective study of isolates from KwaZulu-Natal, Gauteng, Eastern Cape, and Free State provincial labs that were resistant by DST to any BPaL drug from 2023–2025. Enrolled isolates underwent minimum inhibitory concentration (MIC) testing for BPaL drugs and whole genome sequencing (WGS).
Results: We enrolled isolates from 456 individuals and obtained WGS from 339. Lineages 2 and 4 dominated. Sublineage 2.2.2 accounted for 31.6% (n=107) of all isolates and 64.8% of Eastern Cape isolates. At a 12 SNP cut-off, 44.5% (n=151) were clustered into 40 transmission clusters; 83 isolates in 33 clusters (24.5%) had identical *mmpR5* mutations. MIC results were available for 309 isolates; 273 (88.3%) were bedaquiline-resistant, 38 (12.3%) were linezolid-resistant, and 49 (15.9%) were pretomanid-resistant. 22.3% (69/309) of isolates were resistant to multiple BPaL drugs; 35 were resistant to bedaquiline and pretomanid, 27 were resistant to bedaquiline and linezolid, and 7 were resistant to all three.
We observed high-level phenotypic resistance in 3.3% of bedaquiline-resistant and 2.6% of linezolid-resistant strains (≥8µg/mL), as well as 35.4% of pretomanid-resistant strains (≥16µg/mL).
We identified 110 bedaquiline resistance-conferring mutations, mostly in *mmpR5* (n=99). The most common (65/273) was *mmpR5* E49fs. Among linezolid-resistant isolates, the most common resistance-conferring mutation was *rplC* C154R. No dominant mutation was detected among pretomanid-resistant isolates.

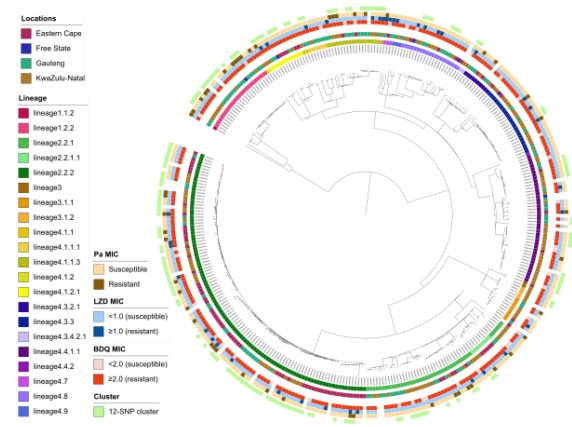

Figure: Phylogenetic tree of 339 study isolates. Drug resistance to bedaquiline (BDQ) was defined as MIC ≥2 µg/mL; resistance to linezolid (LZD) was defined as MIC ≥1 µg/mL; resistance to pretomanid (Pa) was defined as MIC ≥2 µg/mL for Lineage 1 isolates and MIC ≥0.5 µg/mL for Lineage 2, 3, or 4 isolates. All MIC testing was conducted using the MGIT method.

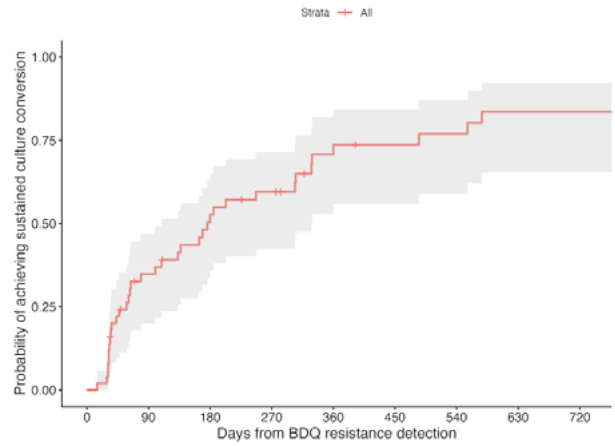
Background and challenges to implementation: The introduction of bedaquiline and pretomanid in combination with linezolid (BPaL) has transformed the fight against drug-resistant tuberculosis (DR-TB). We sought to characterize emerging resistance to this drug regimen in South Africa, which would pose a major obstacle for continued progress against DR-TB.
Intervention or response: All rifampicin-resistant *Mycobacterium tuberculosis* isolates programmatically underwent phenotypic drug-susceptibility testing (DST) for bedaquiline and linezolid; a subset also underwent DST for pretomanid. We conducted a prospective study of isolates from KwaZulu-Natal, Gauteng, Eastern Cape, and Free State provincial labs that were resistant by DST to any BPaL drug from 2023–2025. Enrolled isolates underwent minimum inhibitory concentration (MIC) testing for BPaL drugs and whole genome sequencing (WGS).
Conclusions: Among the studied isolates, nearly a quarter were phenotypically resistant to multiple drugs within the BPaL regimen. Transmission of bedaquiline-resistant strains warrants particular attention.

OA07-169-19 When treatment options narrow: Management of bedaquiline-resistant tuberculosis in Uzbekistan

M.J. Saunders,[1,2] E. Garsevanidze,[3] S. Allamuratova,[3] A. Ismailov,[3] M. Rekart,[3] N. Parpieva,[4] T Zinaida,[4] K. Safaev,[4] C. Gomez,[5] J.L. Alvarez,[1] N. Sitali,[6] A. Sinha,[1] [1]Médecins Sans Frontières, Manson Unit, London, United Kingdom of Great Britain and Northern Ireland, [2]City St George's, University of London, Institute for Infection and Immunity, London, United Kingdom of Great Britain and Northern Ireland, [3]Médecins Sans Frontières, Uzbekistan Mission, Nukus, Uzbekistan, [4]Ministry of Health, National TB Programme, Tashkent, Uzbekistan, [5]Médecins Sans Frontières, Uzbekistan Mission, Tashkent, Uzbekistan, [6]Médecins Sans Frontières, Medical Operations, Berlin, Germany

Background: Bedaquiline resistance is increasing globally, threatening effectiveness of short regimens for rifampicin-resistant tuberculosis. Limited data exist describing management strategies and clinical outcomes among people with bedaquiline-resistant tuberculosis.
Design/Methods: We did a retrospective cohort study of patients with bedaquiline-resistant tuberculosis in Karakalpakstan, Uzbekistan, from January 2017 until December 2024. Clinical and laboratory records were reviewed to describe drug resistance profiles, treatment regimens, and sputum culture results.
To characterise clinical outcomes, we measured time to sustained sputum culture conversion (SCC), and the proportion of patients who had tuberculosis-free survival (alive, and had completed treatment or were in care, and had SCC) 18 months after bedaquiline resistance was detected.
Results: We identified 56 patients with bedaquiline-resistant tuberculosis - 50 (89%) received treatment after resistance detection, and six (11%) did not, of whom four (67%) were known to have subsequently died.
Of those starting treatment, the median age was 41 years (interquartile range [IQR]=27-52), 32/50 (64%) were male, 29/50 (58%) were underweight (body mass index <18.5kg/m^2), 35/50 (70%) had fluroquinolone resistance, and 16/50 (32%) had not previously received bedaquiline.
The median treatment duration after bedaquiline resistance detection was 18 months (IQR=8.9-22), with bedaquiline prescribed for 42/50 (84%) patients for a median 5.6 months (IQR=2.2-13), imipenem for 33/50 (66%) for a median 8.1 months (IQR=4.4-11), amikacin for 25/50 (50%) for a median 7.9 months (IQR=4.4-11), and linezolid for 48/50 (96%) for a median 16 months (IQR=7.8-20). The median time to SCC was 176 days (IQR=58-485) (Figure).
Of 43 patients who had an assessable 18-month outcome, 24/43 (56%) had tuberculosis-free survival. 7/43 (16%) were alive and in care without SCC, 10/43 (23%) died, and 2/43 (4.7%) were lost to follow-up.



Conclusions: Management of bedaquiline-resistant tuberculosis in Uzbekistan required prolonged therapy, often with injectable agents, resulting in delayed culture conversion and poor clinical outcomes.

OA07-170-19 Safety and efficacy of an adaptive injectable-containing regimen for RR-TB: Results from the SHOORT trial in Niger

M.B. Souleymane,[1] T. Decroo,[2] A. Soumana,[3] A.-L. Cheikh Aboubacar,[3] I. Maman Lawan,[4] A. Yacouba,[5] A. Gagara-Issoufou,[5] I. Hamidou,[6] A. Ibrahim,[5] B. Catherine de Jong,[7] L. Rigouts,[7,8] A. Piubello,[9] [1]Damien Foundation, TB, Niamey, Niger, [2]Institute of Tropical Medicine, TB/HIV Unit, Antwerp, Belgium, [3]National Tuberculosis Programme, Coordination, Niamey, Niger, [4]Damien Foundation, TB, Maradi, Niger, [5]Université Abdou Moumouni de Niamey, Faculté des Sciences de la Santé, Niamey, Niger, [6]Université André Salifou de Zinder, Faculté des Sciences de la Santé, Zinder, Niger, [7]Institute of Tropical Medicine, Mycobacteriology Unit, Antwerp, Belgium, [8]University of Antwerp, Department of Biomedical Sciences, Antwerp, Belgium, [9]Damien Foundation, DR-TB department, Brussels, Belgium
e-mail: bachirsoul@gmail.com

Background: WHO recommends all-oral bedaquiline- and linezolid (LZD)-containing regimens for rifampicin-resistant tuberculosis (RR-TB). In Niger, high cure rates were previously achieved using an adaptive short treatment regimen (aSTR), with a second-line injectable drug (SLID) and LZD, where LZD replaced the SLID upon detection of ototoxicity with audiometric monitoring at baseline or during treatment. We evaluated the safety and efficacy of an all-oral (oSTR) versus aSTR in the SHOORT trial.
Design/Methods: Pragmatic trial, patients with fluoroquinolone-susceptible RR-TB were alternately assigned by alternate months to oSTR or aSTR (coin toss determined which regimen to be used first). Regression models

estimated the association between safety (grade 3-4 adverse events [AEs]) and efficacy (excluding loss to follow-up) of both treatment approaches.

Results: From April 2021 to December 2023, 296 patients (161 oSTR, 135 aSTR) were included. Baseline characteristics were balanced. In the aSTR group, 80/135 (59.3%) were switched to LZD due to baseline (n=60) or emerging (n=20) ototoxicity.

For the 20 patients with emergent ototoxicity, the median SLID duration before the switch was 2 months (IQR:1–3).

Grade 3–4 AEs occurred in 45/161 (28.0%) of oSTR vs. 18/135 (13.3%) aSTR patients (OR 2.90; 95%CI:1.55–5.65).

Anaemia (27 of 75 severe AEs), neurotoxicity (19), and hepatotoxicity (17) were more frequent with oSTR, while aSTR was associated with mild ototoxicity (grade 2 only) and nephrotoxicity (only one grade 3 case).

In the efficacy population, treatment success was comparable (79.0% [117/148] vs. 83.0% [103/124]; difference, 4.0%; 95%CI: -13.3-5.3; p= 0.4).

Unfavourable outcomes (death, treatment failure or relapse) occurred in 31 oSTR (27 deaths, 3 failures and 1 relapse) vs. 21 aSTR (19 deaths and 2 relapses) patients, with older age, HIV positivity, female sex, and low BMI increasing risk.

Safety population§	oSTR N = 161	aSTR N = 135	p-value
Severe grade 3-4 AE	45 (28.0%)	18 (13.3%)	0.002
Efficacy population	oSTR N = 148	aSTR N = 124	p-value
Favorable outcomes	45 (79.05%)	103 (83.06%)	0.7
Unfavorable outcomes	31 (20.9%)	21 (16.9%)	
Of which			
Died	27 (18.2%)	19 (15.3%)	
Failure	3 (2.0%)	0 (0.0%)	
Relapse	1 (0.6%)	2 (1.6%)	

§22 excluded: 21 losses to follow-up (10 oSTR, 11 aSTR) and 1 fluoroquinolone resistance detected a posteriori (oSTR)

Abbreviations: oSTR: all-oral bedaquiline linezolid containing short treatment regiment, aSTR: adaptive short treatment regimen, AE: adverse event.

Table 1: Safety and efficacy results of an all-oral versus an adaptive short treatment regimen

Conclusions: Short-term use of SLID with audiometric monitoring and selective LZD substitution is safer than long-term LZD exposure, without compromising efficacy.

OA08 Preventing TB by addressing the gap

OA08-171-19 Risk of immunological sensitisation to *MTB* and progression to incident TB disease in a high-burden setting

H. Mulenga,[1] S.C. Mendelsohn,[1] A. Fiore-Gartland,[2] A. Penn-Nicholson,[1] M. Musvosvi,[1] M. Tameris,[1] G. Walzl,[3] K. Naidoo,[4] G. Churchyard,[5,6,7] T.J. Scriba,[1] M. Hatherill,[1]

e-mail: humphrey.mulenga@uct.ac.za

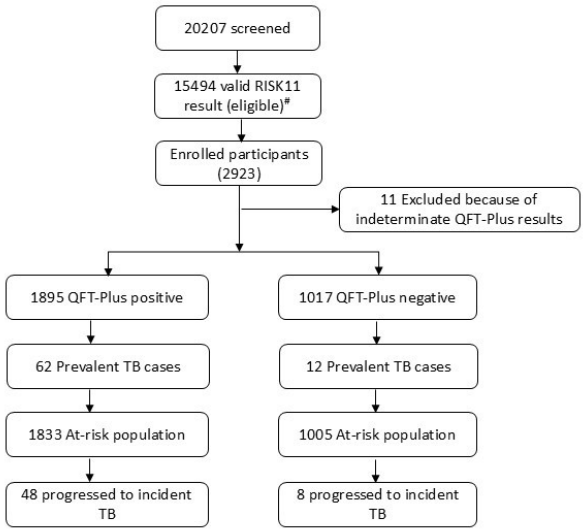
Background: Studies have shown that individuals immunologically sensitised to *Mycobacterium tuberculosis* (*Mtb*) have increased risk of progression to incident tuberculosis (TB) disease. We evaluated risk factors for *Mtb* sensitisation and progression to TB disease in a TB-endemic setting.

Design/Methods: Healthy HIV-uninfected adults (18-60 years) enrolled at five high TB incidence sites in South Africa were prospectively evaluated for *Mtb* immunological sensitisation with baseline QuantiFERON-TB Gold-plus. Participants were screened for microbiologically-confirmed TB (sputum liquid culture and/or Xpert Ultra positive) at baseline and during 15 months follow-up.

Multivariable logistic and Cox regression were used to evaluate risk factors for *Mtb* immunological sensitisation and progression to TB disease, respectively. Point estimates were adjusted with sampling weights to represent the screened population.

Results: Among 2912 participants evaluated, 63.4% (1895/2912) were *Mtb*-sensitised, of whom 1.8% (62/1895) had prevalent TB at baseline; 2.0% (48/1833) of those without prevalent TB progressed to incident TB. Among 1017 individuals who were not *Mtb*-sensitized, 0.6% (12/1017) had prevalent TB; 0.5% (8/1005) of those without prevalent TB progressed to incident TB (Figure 1). Risk factors for *Mtb*-sensitisation were increasing age (odds ratio; OR=1.02 per year, 95%CI 1.01-1.03), male sex (OR=1.34, 95%CI 1.08-1.67), smoking history (OR=1.31,

95%CI 1.05-1.64), prior TB (OR=2.20, 95%CI 1.40-3.47), and TB contact history (OR=1.4, 95%CI 1.08-1.83). *Mtb*-sensitisation (hazard ratio; HR=3.13, 95%CI 1.17-8.39) and smoking history (HR 2.34, 95%CI 1.03-5.29) were risk factors for TB progression; increasing body-mass index (BMI, kg/m^2; HR=0.89, 95%CI 0.82–0.97) was a protective factor.



Enrolment into the study was based on RISK11 status. RISK11 is an 11-gene signature for TB risk

Figure 1: Study flow diagram

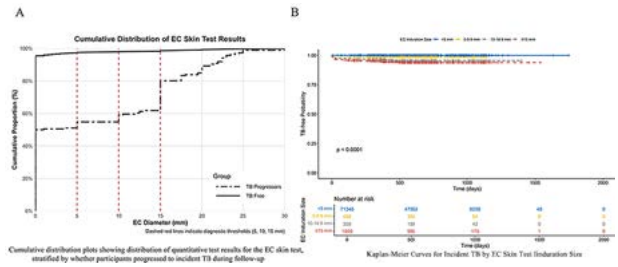
Conclusions: Compared to individuals who were not *Mtb*-sensitised, those who were *Mtb*-sensitised had a 3-fold risk of progressing to incident TB. Because this risk is highest in recently infected (first six months) individuals, a simple and rapid-test which distinguishes recent from remote infection is needed for targeted preventive therapy.

OA08-172-19 Predictive performance of the ESAT6-CFP10 skin test for incident TB: A prospective cohort study

P. Lu,[1] Q. Liu,[2] J. Wang,[1] [1]Nanjing Medical University, School of Public Health, Nanjing, China, [2]Jiangsu Provincial Center for Disease Control and Prevention, Department of Chronic Communicable Disease, Nanjing, China
e-mail: jmwang@njmu.edu.cn

Background: Recent international guidelines endorse Mycobacterium tuberculosis antigen-based skin tests, such as the ESAT6-CFP10 (EC) skin test, as alternatives to the tuberculin skin test (TST) and QuantiFERON-TB Gold In-Tube (QFT-GIT) assay. However, the EC skin test's predictive capacity for incident active tuberculosis (TB) remains unclear. We conducted a prospective cohort study to evaluate its performance in predicting TB disease.

Design/Methods: This study involved 73,761 students and teachers during a school TB outbreak. All participants underwent the EC skin test, with a repeat test offered 2-3 months later for initial negatives per national guidelines (not mandatory).
We assessed predictive performance by estimating hazard ratios (HRs) for TB incidence, comparing positive versus negative results across EC skin test thresholds. Incidence rates, rate ratios, sensitivities, specificities, and predictive values were calculated, stratified by induration sizes (<5 mm, 5–9.9 mm, 10–14.9 mm, ≥15 mm)
Results: Of 73,761 participants, 2,415 (3.3%) had latent TB infection (LTBI) at initial screening. Among 65,735 initially negative individuals, 659 (1.0%) tested positive in the second screening. Over 4 months to 4 years, 209 developed active TB (incidence: 166.08/100,000 person-years). Larger induration sizes correlated with higher TB risk (P<0.0001), per Kaplan-Meier curves and risk tables. Positive predictive values rose modestly with thresholds (initial: 4.7% at ≥5 mm, 5.8% at ≥15 mm; second: 5.2% at ≥5 mm, 7.3% at ≥15 mm).
Sensitivity decreased with higher thresholds (initial: 54.5% at ≥5 mm, 45.0% at ≥15 mm; second: 37.0% at ≥5 mm, 34.8% at ≥15 mm), while specificity improved (initial: 96.9% at ≥5 mm, 97.9% at ≥15 mm; second: 99.0% at ≥5 mm, 99.4% at ≥15 mm).



Cumulative distribution plots showing distribution of quantitative test results for the EC skin test, stratified by whether participants progressed to incident TB during follow-up

Kaplan-Meier Curves for Incident TB by EC Skin Test Induration Size

Conclusions: Higher EC skin test thresholds enhance positive predictive value but reduce sensitivity, underscoring the need for improved biomarkers or risk prediction models to refine TB prediction accuracy.

OA08-173-19 Differences in conversion and reversion rates of interferon gamma release assay in the elderly under different tuberculosis epidemic settings: A prospective quantitative study

W. Wang,[1,2] M. Zhang,[1,2] S. Chen,[1,2] P. Zheng,[3] Y. Zhang,[1,2] Q. Wu,[1,2] M. Jin,[4] B. Chen,[1,2] J. Jiang,[2,1] [1]Zhejiang Provincial Center for Disease Control and Prevention, Department of Tuberculosis Prevention and Control, Hangzhou, China, [2]Zhejiang Provincial Center for Disease Control and Prevention, Zhejiang Key Lab of Vaccine, Infectious Disease Prevention and Control, Hangzhou, China, [3]Huzhou Municipal Health Commission, Huzhou Municipal Bureau of Disease Prevention and Control, Huzhou, China, [4]Huzhou Center for Disease Control and Prevention, Department of Tuberculosis Prevention and Control, Huzhou, China
e-mail: jfwwang@cdc.zj.cn

Background: The burden of tuberculosis in the elderly is increasing. Comprehending the burden of latent tuberculosis infection and its variations in the elderly is conducive to developing more effective measures to end tuberculosis.
Design/Methods: From 2021 to 2024, a multi-center prospective observational study based on a cohort design was conducted in Zhejiang Province, China. At the end of one year following the baseline survey, a follow-up survey was implemented to monitor the alterations in the latent tuberculosis infection status of participants based on Interferon gamma Release Assay.
Results: A total of 3208 eligible older adults completed the **baseline(BS)**and **follow-up(FS)** surveys. The positive rate of latent tuberculosis infection at the BS and FS in the **high endemic setting(HES)** was both higher than that in the **low endemic setting(LES)**.
The Sankey diagram indicated that participants with a TBAg-Nil IFN-γ value ranging from 0.2 IU/mL to 0.7 IU/mL at baseline were more likely to undergo conversion and reversion at the follow-up.
The traditional-conversion rate and strict-conversion rate were 11.1% and 3.0% in the HES, which were higher than 5.6% and 1.5% in the LES. The strict reversion rate in the HES was 14%, which was lower than that in the LES (26%).
Compared with participants in the LES, participant in the HES had a higher risk of traditional-conversion (ARR: 2.32, 95%CI: 1.69-3.21) and strict-conversion (ARR: 2.20, 95%CI: 1.16-4.19), and a lower risk of strict-reversion (ARR: 0.5, 95%CI: 0.29-0.87).
Conclusions: The burden of latent tuberculosis infection and the risk of IGRA conversion among the elderly in high-endemic settings were higher than those in low-endemic settings. Hence, it is of great significance and urgency to enhance the active and early detection, standardized treatment of tuberculosis in the high-endemic setting.

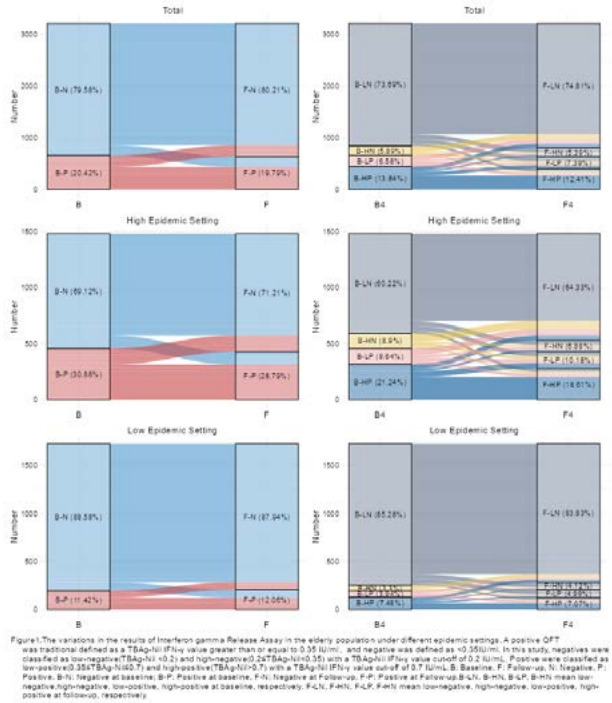


Figure1.The variations in the results of Interferon gamma Release Assay in the elderly population under different epidemic settings. A positive QFT was traditional defined as a TBAg-Nil IFN-γ value greater than or equal to 0.35 IU/mL, and negative was defined as <0.35IU/mL. In this study, negatives were classified as low-negative(TBAg-Nil <0.2) and high-negative(0.2≤TBAg-Nil<0.35) with a TBAg-Nil IFN-γ value cutoff of 0.2 IU/mL. Positive were classified as low-positive(0.35≤TBAg-Nil≤0.7) and high-positive(TBAg-Nil>0.7) with a TBAg-Nil IFN-γ value cut-off of 0.7 IU/mL. B: Baseline; F: Follow-up; N: Negative; P: Positive. B-N: Negative at baseline; B-P: Positive at baseline; F-N: Negative at Follow-up; F-P: Positive at Follow-up.B-LN, B-HN, B-LP, B-HP mean low-negative,high-negative, low-positive, high-positive at baseline, respectively. F-LN, F-HN, F-LP, F-HP mean low-negative, high-negative, low-positive, high-positive at follow-up, respectively.

OA08-174-19 Effect of community-based vs. clinic-based delivery of TB preventive therapy on TPT completion in South Africa: Outcomes from a randomized controlled trial (ThiPhiSA)

A.E. Shapiro,[1,2] S. Misra,[3] T. Madonsela,[3] K.K. Thomas,[1] C. Grabow,[1] M. Lenn,[1] J.F. Morton,[1] K. Reither,[4,5] L. Lynen,[6] A. van Heerden,[3,7] Z. Essack,[3,8] S. Bosman,[3] ThiPhiSA Study Group [1]University of Washington, Global Health, Seattle, United States of America, [2]University of Washington, Medicine, Division of Allergy and Infectious Diseases, Seattle, United States of America, [3]Human Sciences Research Council, Centre for Community Based Research, Sweetwaters, South Africa, [4]Swiss Tropical and Public Health Institute, Clinical Research Unit, Basel, Switzerland, [5]University of Basel, Medicine, Basel, Switzerland, [6]Institute of Tropical Medicine, Clinical Sciences, Antwerp, Belgium, [7]University of Witwatersrand, Medicine, Pietermaritzburg, South Africa, [8]University of KwaZulu Natal, School of Law, Pietermaritzburg, South Africa
e-mail: aeshapir@uw.edu

Background: There is a growing gap between people eligible for TB preventive therapy (TPT) and people receiving TPT in South Africa and globally. Community-based, multi-month TPT dispensing could reduce barriers to accessing TPT and improve completion for people with HIV (PWH) and close contacts of people with TB.
Design/Methods: We conducted a household-randomized, non-blinded trial of community-delivered TPT compared to standard clinic services in rural/peri-urban KwaZulu-Natal, South Africa (ThiPhiSA Study). Adults

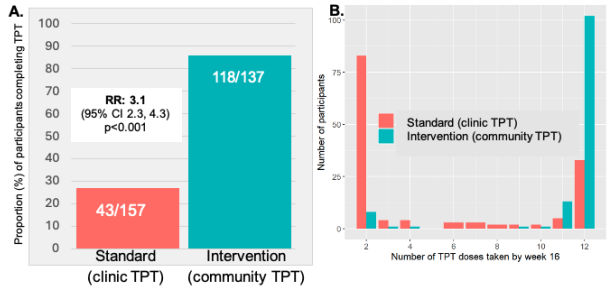
screening negative for TB through a community-wide screening program and eligible for TPT by South African guidelines were randomized 1:1 by household to Intervention: Immediate dispensing of 12 weeks 3HP at the community screening location or Standard: Dispensing 2 weeks 3HP and referral to their local public clinic to collect remaining 3HP per clinic refill schedule. Persons with contraindications for 3HP received 6H.

The primary outcome was TPT completion (defined for 3HP as taking 11 doses by 16 weeks) assessed by pill count and self-report. We used intent-to-treat analysis and estimated relative risks with modified Poisson regression.

Results: Between Feb-2024 to Feb-2025, 301 adults from 268 households were randomized: 211 (70%) female, median age 42 (IQR 35-51). 294 (98%) were PWH and 17 (6%) were household contacts of a person with TB. Eight people received 6H.

Compared to standard clinic care, community TPT delivery increased TPT completion (86% vs. 27%, RR=3.14, 95% CI: 2.32, 4.27). Standard arm participants took a median of 2 doses/weeks of 3HP (IQR 2-11) compared to median 12 doses/weeks (IQR 12-12) in the intervention arm. Five serious adverse events were reported (1 intervention/4 standard arm; none related).

Figure: **A)** Proportion of participants completing TPT by study arm; **B)** Distribution of number of doses of TPT (3HP) completed per participant, by arm, in the ThiPhiSA Study.



Conclusions: Community-based multi-month delivery of 3HP improved TPT completion for TPT-eligible persons in South Africa compared to requiring clinic visits for refills. Person-friendly approaches improving convenience should be adopted to decompress healthcare facilities and improve TPT coverage to meet TB prevention goals.

OA08-175-19 Bridging diagnostic needs in TB elimination: Evidence from a novel TB skin test SIILTIBCY using M. Tuberculosis specific antigens

U. Shaligram,[1] P. Kulkarni,[1] P. Nagarkar,[2] Z. Fneish,[3] R. Lothe,[1] D. Kapse,[4] M. May,[5] G. Nagar,[1] S. Polishwalla,[1] P. Singh,[1] T. Westera,[6] [1]Serum Institute of India, R&D, Pune, India, [2]Serum Institute of India, Regulatory Affairs, Pune, India, [3]Serum Life Science Europe, Clinical Research, Hannover, Germany, [4]Serum Institute of India, Clinical Research, Pune, India, [5]Serum Life Science Europe, Medical, Hannover, Germany, [6]Bilthoven Biologicals B.V., Marketing, Bilthoven, Netherlands
e-mail: teunie.westera@bbio.nl

Background: Tuberculosis (TB) remains a leading cause of infectious disease mortality worldwide. In the past decade, Europe has not met WHO End TB Strategy milestones, reflecting an urgent need for more accurate, accessible, and population-appropriate diagnostic tools. SIILTIBCY (Cy-Tb) is a novel skin test incorporating two recombinant *Mycobacterium tuberculosis*-specific proteins, rdESAT-6 and rCFP-10, designed to improve the specificity of intradermal TB testing. EMA marketing authorisation was granted in January 2025.

Design/Methods: The diagnostic performance and safety of SIILTIBCY were evaluated in a pooled analysis of seven clinical trials, including comparisons with the tuberculin skin test (PPD) and QuantiFERON-TB Gold (QFT).

Results: In participants with microbiologically confirmed TB, SIILTIBCY demonstrated a sensitivity of 76.8% (95% CI: 72.6–81.1), which was higher than QFT (68.0% [64.0-72.0]) and slightly lower than PPD (85.2% [81.6-88.8]). With 92.8% [90.2-95.5], specificity in TB-negative individuals was similar to PPD (90.7% [87.5-93.9]) and QFT (89.5% [86.3-92.6]).

Interestingly, in a BCG vaccinated sub-group, SIILTIBCY exhibited a higher specificity than PPD when a fixed induration threshold across all populations was used.

In the paediatric population, SIILTIBCY outperformed QFT in specificity (83.7% [76.5-90.8] vs. 72.3% [63.9-81.2]) and matched PPD (83.7% [76.5-90.8] vs. 85.1% [78.2-92.1]).

Across all populations, SIILTIBCY showed high post-test probabilities and a low false-negative rate. Together with the overall safety profile being comparable to PPD, this supports its utility in real-world settings.

Conclusions: Use of specific antigens, an easy application method, and a fixed induration threshold make SIILTIBCY a field-friendly and IGRA-like diagnostic alternative applicable across populations.

OA08-176-19 Clinical safety of levofloxacin for contacts of multidrug-resistant TB: Insights from the VQUIN trial

A.K.J. Teo,[1,2,3] Q. Li,[1] T. Duong,[4] N.Y. Pham,[5] C.B. Nguyen,[6] F. Garden,[7] T.-A. Nguyen,[8,9,10] V.L. Dinh,[11,12] B.H. Nguyen,[11,12] V.N. Nguyen,[13] G. Marks,[14,15] G. Fox,[1,2,14] VQUIN MDR-TB Trial Team [1]University of Sydney, NHMRC Clinical Trials Centre, Faculty of Medicine and Health, Sydney, Australia, [2]University of Sydney, The University of Sydney Institute for Infectious Diseases (Sydney ID) and the Centre of Research Excellence in Tuberculosis (TB-CRE), Sydney, Australia, [3]National University of Singapore, Saw Swee Hock School of Public Health, Sydney, Australia, [4]University College London, Medical Research Council Clinical Trials Unit, London, United Kingdom of Great Britain and Northern Ireland, [5]University of Sydney, The University of Sydney Vietnam Institute, Hanoi, Viet Nam, [6]Woolcock Institute of Medical Research, Woolcock Institute of Medical Research, Ho Chi Minh City, Viet Nam, [7]University of New South Wales, South West Sydney Clinical Campuses, School of Clinical Medicine, Sydney, Australia, [8]University of Sydney, The University of Sydney Institute for Infectious Diseases (Sydney ID) and the Centre of Research Excellence in Tuberculosis (TB-CRE), Ho Chi Minh City, Viet Nam, [9]University of Sydney, The University of Sydney Vietnam Institute, Ho Chi Minh City, Viet Nam, [10]University of Sydney, Sydney School of Public Health, Faculty of Medicine and Health, Ho Chi Minh City, Viet Nam, [11]National Lung Hospital, National Lung Hospital, Hanoi, Viet Nam, [12]Vietnam National Tuberculosis Programme, Vietnam National Tuberculosis Programme, Hanoi, Viet Nam, [13]Vietnam National University, Vietnam University of Medicine and Pharmacy, Hanoi, Viet Nam, [14]Woolcock Institute of Medical Research, Woolcock Institute of Medical Research, Sydney, Australia, [15]Burnet Institute, Burnet Institute, Sydney, Australia
e-mail: alvin.teo@aol.com

Background: The World Health Organization recommends a 6-month course of levofloxacin as TB preventive treatment (TPT) for rifampicin-resistant or multidrug-resistant TB (RR/MDR-TB) contacts.
This study aimed to assess the safety of levofloxacin for RR/MDR-TB contacts.
Design/Methods: We evaluated data from the VQUIN phase 3 trial in Vietnam, which compared 6-month daily levofloxacin with a placebo for treating *M. tuberculosis* infection in predominantly adult household contacts of people with RR/MDR-TB.
Descriptive analyses included event counts and exposure-adjusted-incidence rates (EAIR). EAIR is defined as the number of participants with an event divided by total person-years of exposure. We described the time to adverse events and treatment discontinuation using medians and interquartile ranges. Cox regression was used to describe the risk factors for musculoskeletal events.
Results: A total of 51 (10.4/100-patient-years) and 239 (61.3/100-patient-years) possible and probable drug-related AEs were reported in the placebo and levofloxacin arms, respectively (HR=5.40, 95%CI:3.79-7.70, p<0.001). In the levofloxacin group, 10/239 (4.2%) events were grade 3. The median time-to-AE was 25 days (IQR:7-49), and the median time-to-discontinuation was 90 days (IQR:61-181). Higher-grade AEs were associated with an increased risk of non-adherence and treatment discontinuation. Musculoskeletal events were the most common. Older age (HR=1.06, 95% CI: 1.00–1.13, p=0.036), being a current smoker at baseline (HR=2.51, 95% CI: 1.21–5.20, p=0.013), and consuming alcohol ≥4 times per week at baseline (HR=2.76, 95% CI: 1.24–6.14, p=0.013) were associated with a higher risk of musculoskeletal events.
Conclusions: Levofloxacin was safe for MDR-TB contacts, with very few adverse events greater than or equal to grade 3 reported. Most adverse events were mild to moderate, and musculoskeletal events were the most common. Close follow-up during the first month of treatment is crucial to monitor and manage any adverse events promptly.
Further research evaluating strategies to minimise musculoskeletal symptoms may improve treatment adherence and completion rates.

OA08-177-19 Adherence to weekly 3HP for TB prevention among TB contacts in Uganda: A cross-sectional study

A. Kityamuwesi,[1] M. Musoke,[1] L. Kunihira Tinka,[1] A. Nakate,[1] R. Madaya-Nambozo,[1] S. Muchuro,[2] S. Turyahabwe,[2] S. Matiku,[3] S. Zawedde-Muyanja,[1,4] A. Katamba,[1,5] L.J. Davis,[6,7] A. Cattamanchi,[8,9,10] [1]Uganda Tuberculosis Implementation Research Consortium, WALIMU, Research, Kampala, Uganda, [2]Ministry of Health, National TB and Leprosy Division, Kampala, Uganda, [3]New Dimension Consulting (NEDICO), Research, Dar es Salaam, United Republic of Tanzania, [4]Infectious Diseases Institute, Research, Kampala, Uganda, [5]Makerere University College of Health Sciences, School Of Medicine, Kampala, Uganda, [6]Uganda Tuberculosis Implementation Research Consortium, WALIMU, Research, New Haven, United States of America, [7]Yale School of Public Health and Yale School of Medicine, Epidemiology of Microbial Diseases & Pulmonary, Critical Care, and Sleep Medicine, New Haven, United States of America, [8]Uganda Tuberculosis Implementation Research Consortium, WALIMU, Research, Irvine, United States of America, [9]Division of Pulmonary and Critical Care Medicine, San Francisco General Hospital, University of California San Francisco, San Francisco, United States of America, [10]Division of Pulmonary Diseases and Critical Care Medicine, University of California Irvine, Orange, United States of America
e-mail: akityamuwesi95@gmail.com

Background: Adherence to self-administered weekly isoniazid and rifapentine (3HP) for tuberculosis preventive therapy (TPT) remains poorly understood. We objectively assessed 3HP adherence among contacts of persons with TB enrolled in a person-centered household contact investigation program.

Design/Methods: A cross-sectional adherence study was embedded within a larger before-and-after intervention study evaluating a person-centered household contact investigation strategy at 26 health facilities in Uganda.
The strategy involved: standardized educational booklets; task-shifting of contact investigation to community health workers (CHWs); and a community health rider service to transport CHWs, contacts, sputum samples and TPT refills between homes and health facilities. Between October and November 2024, we conducted unannounced home visits within 24 hours of a scheduled dose for contacts receiving 3HP at six facilities.
Consenting participants self-reported adherence and provided urine samples for isoniazid metabolite testing using IsoScreen. Non-adherence was defined as a negative IsoScreen urine test result. Generalized linear models with robust errors were used to identify factors associated with non-adherence.
Results: Overall, 23.1% (64/277) of participants were non-adherent. Non-adherence was notably higher among females (28.7%), people living with HIV (35.0%), alcohol users (29.2%), and non-household contacts (41.7%). In adjusted analyses, females (aPR=2.03, 95% CI: 1.25–3.28, p=0.004), non-household contacts (aPR=3.58, 95% CI: 1.67–7.68, p=0.001), and participants initiated on 3HP without latent TB infection testing (aPR=1.94, 95% CI: 1.25–3.02, p=0.003) were more likely to be non-adherent. Non-adherence progressively increased from 17.1% at weeks 2-3 to 29.3% at weeks 10-12 (p=0.029). Key barriers to adherence included fear of side effects (63.6%) and difficulty remembering to take medication (20.9%), while personal motivation (49.6%) and education on 3HP benefits (39.7%) facilitated adherence.

Characteristic	Categories (n)	PR (95% CI)	p-value	aPR (95% CI)	p-value
Sex	Female	1.81 (1.12-2.93)	0.02	2.03 (1.25-3.28)	0.004
Relationship to index person with TB	Non-household (12)	1.87 (0.92-3.80)	0.08	3.58 (1.67-7.68)	0.001
TB infection test result	Positive (160)	1			
	Negative (43)	1.28 (0.68-2.42)	0.44	1.27 (0.89-2.42)	0.464
	Not tested (74)	1.86 (1.18-2.95)	0.01	1.94 (1.25-3.02)	0.003
Time since start of 3HP	2-3 weeks (99)	1		1	
	4-6 weeks (62)	1.41 (0.76-2.62)	0.28	1.60 (0.84-3.06)	0.156
	7-9 weeks (58)	1.51 (0.81-2.79)	0.19	1.61 (0.83-3.13)	0.167
	10-12 weeks (58)	1.71 (0.95-3.08)	0.08	2.02 (1.07-3.79)	0.029

Conclusions: Despite home-based care, non-adherence to 3HP was substantial. Objective adherence monitoring, targeted gender-sensitive counseling, TB infection testing, and proactive side-effect management are essential components of 3HP delivery to enhance adherence outcomes.

OA08-178-19 Implementing intervention strategy framework to enhance TB preventive treatment in Mansa District of Punjab, India

R. Bhaskar,[1] G. Thori,[1] U. Singh,[2] S. Chandra,[3] V. Chopra,[4] S. Sharma,[5] P. Kapoor,[3] P. Kaur Samra,[3] P. Dhawan,[3] N. Sood,[6] A. Bhardwaj,[7] V. Chaudhary,[8] [1]Government of Punjab, Ministry of Health and Family Welfare, Chandigarh, India, [2]Government of India, Ministry of Health and Family Welfare, New Delhi, India, [3]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [4]TB Hospital Patiala, Dept. of Chest and TB Diseases, Patiala, India, [5]Dayanand Medical College, Dept. of PSM, Ludhiana, India, [6]Government of Punjab, Department of Health and Family Welfare, Mansa, India, [7]National Task Force, National TB Elimination Program, Chandigarh, India, [8]Government of Punjab, Department of Health and Family Welfare, Chandigarh, India
e-mail: kaurp@rntcp.org

Background and challenges to implementation: Several studies have identified key areas for improvement in uptake of Tuberculosis Preventive Treatment (TPT), such as enhancing drug supply consistency, increasing awareness among healthcare providers and strengthening screening and follow-up systems. An assessment conducted in Mansa district during 2024-2025 led to an intervention strategy framework aimed at effectively enhancing TPT implementation and contributing to better health outcomes in community.
Intervention or response: Figure 1 shows cascade of intervention strategy framework. This was rolled out in Mansa district in three phases over 16 weeks from December 2024- March 2025.

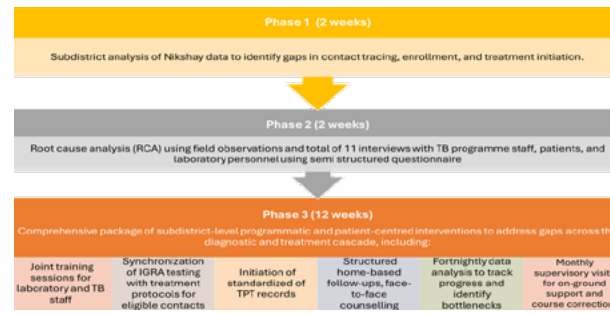


Figure 1: Intervention Strategy Framework for Improving TPT Uptake in Mansa District, India

Post-intervention outcomes, including enrollment, initiation rates, and time to treatment, were compared to Q1 2023 and Q1 2024. Data from Nikshay (India's digital TB surveillance system) was analysed using SPSS version 22, with appropriate statistical tests.
Results/Impact: RCA identified fragmented diagnostic workflows, non-standardized TPT documentation, missed Nikshay entries, and unclear accountability for test-to-treatment linkage as systemic barriers. Targeted interventions in Q1 2025 led to significant improvements

over Q1 2024 and Q1 2023. TPT enrollment increased from 30.8% (n=76) in Q1 2023 and 25.7% (n=66) in Q1 2024 to 65.8% (n=578) in Q1 2025 ($p = 0.02$). TPT initiation rose from 30.8% (2023) and 25.7% (2024) to 65.2% (2025, $p < 0.01$). Among household contacts aged ≥5 years, initiation increased from 24.4% (2023) and 22.7% (2024) to 61.5% in 2025 ($p < 0.01$). For children under 5, initiation improved from 68.6% (2023) and 62.1% (2024) to 91% in 2025 ($p = 0.02$). Median diagnosis-to-treatment time decreased from 7 to 2 days.

Conclusions: The study strongly recommends implementing data-driven interventions to tackle operational and behavioural gaps while enhancing TPT uptake. This includes staff training, home-based follow-ups, timely diagnostic feedback, and regular data reviews. These components collectively address challenges associated with scaling up TPT effectively.

OA09 Finding TB in key vulnerable populations

OA09-179-19 Optimising TB detection through diagnostic intensification: A case study from Baran, Rajasthan

P. Soni,[1] T. Patni,[2] S. Meena,[3] R. Gupta,[4] B. Meharda,[2] M. Rathore,[4] K. Paliwal,[1] V. Mishra,[4] S. Chandra,[4] U. Singh,[5] [1]Directorate of Health and Family Welfare, Government of Rajasthan, Department of Health and Family Welfare, Jaipur, India, [2]Kamla Nehru State TB Training and Demonstration Centre, Department of Health and Family Welfare, Government of Rajasthan, Ajmer, Rajasthan, India, [3]Directorate of Health and Family Welfare, Government of Rajasthan, Department of Health and Family Welfare, Baran, India, [4]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [5]Ministry of Health & Family Welfare, Govt. of India, Central TB Division, Delhi, India
e-mail: rakshag@rntcp.org

Background and challenges to implementation: District Baran in Rajasthan faces challenges in Tuberculosis (TB) detection due to limited diagnostic access and a high proportion of socioeconomically vulnerable populations. Although National TB Elimination efforts are in place, early detection remains inadequate.

This study aims to evaluate a targeted diagnostic intervention from December 2024 to March 2025 to enhance TB screening coverage and improve molecular testing efficiency among vulnerable groups.

Intervention or response: A comprehensive intervention was launched, incorporating microplanning and vulnerability mapping to target high-risk areas and populations. Mobile diagnostic units equipped with handheld digital X-ray and NAAT platforms (CBNAAT/Truenat) were deployed to optimize the diagnostic network. Resource mobilization ensured uninterrupted logistics and staff availability. Community-based intensified screening aligned with identified vulnerability clusters was conducted.

Programmatic data from Ni-kshay (India digital TB surveillance system) were analysed to evaluate (i) the proportion of the vulnerable population screened, (ii) microbiological testing patterns, and (iii) daily utilisation of NAAT modules.

Data were extracted from *Ni-kshay*, (India's digital TB surveillance system), and Comparative assessment was done for same cohort previous year using SPSS ver 22.

Results/Impact: Between December 2024 and March 2025, 2,07,884 individuals were screened achieving 228% (triple) coverage. Of the total symptomatic positive, 76% of microbiological tests were conducted using nucleic acid amplification tests (NAAT). Daily NAAT utilization was 69% of the available testing capacity, which is over 200 % more than previous year ($p<0.05$) reflecting significantly improved operational efficiency in molecular diagnostics.

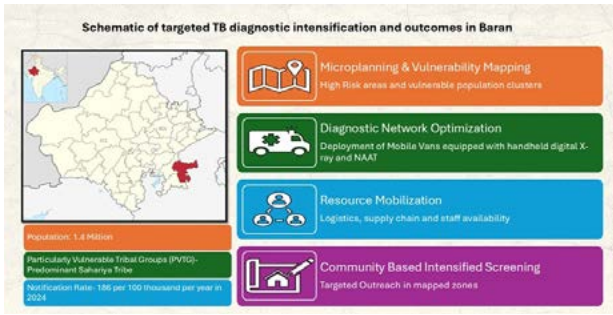

Figure.

Conclusions: The intervention demonstrated significant improvements in TB case-finding metrics in Baran, with exemplary screening coverage and optimal utilization of molecular diagnostics.
These findings highlight the value of tailored, resource-sensitive strategies in aspirational districts to enhance TB detection among underserved populations.

OA09-180-19 TB in an urban slum: Collecting community stories to improve awareness and screening of TB in the Philippines

A. Solaiman,[1] E. Venables,[2] M.R. Roxas,[1] R. Castro,[3] C. Hewison,[2] F. Hossain,[4] [1]Médecins Sans Frontières, Medical Department, Manila, Philippines, [2]Médecins Sans Frontières, Medical Department, Paris, France, [3]Manila Health Department, Health Department, Manila, Philippines, [4]Médecins Sans Frontières, Medical Department, Tokyo, Japan

Background and challenges to implementation: Effective health promotion is key to successful tuberculosis (TB) care. However, engaging with communities about TB screening, prevention and treatment in a participatory way can be challenging, particularly in densely populated, impoverished areas. TB misconceptions and rumors can hinder successful health messaging.
Intervention or response: Médecins Sans Frontières (MSF) implemented the Story of Change methodology in Tondo, an urban slum in Manila, Philippines. An innovative approach implemented by MSF globally uses storytelling to create and communicate health promotion (HP) messages. Between July-September 2024, community members shared TB stories through a process of participatory listening and exchange. Stories were analyzed and grouped into themes then combined into one fictional story to integrate into community engagement and HP activities.
Results/Impact: Personal stories collected increased the understanding of challenges and experiences faced by communities in relation to TB screening and treatment.
Shared stories included experiences of TB-related stigmatization, discrimination and isolation, fears of screening and receiving positive results, people who struggled to access health-care services or take their TB treatment and people not wanting treatment because of a lack of perceived illness.
Once diagnosed, most patients, despite the initial distress, accepted treatment to prevent TB transmission to their household members and friends, highlighted the importance of support networks, and shared stories of how those who had completed TB treatment had a renewed commitment to a healthier lifestyle.
The final story includes the experiences of several people, focusing on the importance of family support during TB screening, treatment and diagnosis.
Conclusions: The Story of Change methodology enabled understanding of firsthand community members experiences which contributed to the development of participatory, culturally relevant HP and community engagement. Community-driven methods in overcoming barriers to TB prevention and care are important.
Expanded use of storytelling can enhance TB-related communication via contextualised, relatable health messages and improve TB screening uptake and reduce stigmatization.

OA09-181-19 Improving finding TB among vulnerable populations using portable digital X-ray (PDX) machine: Experience from Kano State correctional centres

S. Bashir,[1] M. Bajehson,[1] H. Baffa,[1] O. Chukwuogo,[2] B. Odume,[2] M. Tukur,[1] G. Zephaniah,[3] L. Innocent,[4] [1]KNCV Nigeria, Programme, Kano, Nigeria, [2]KNCV Nigeria, Programme, Abuja, Nigeria, [3]KNCV Nigeria, Monitoring and Evaluation, Kano, Nigeria, [4]KNCV Nigeria, Programme, Katsina, Nigeria
e-mail: sbashir@kncvnigeria.org

Background and challenges to implementation: Tuberculosis remains a global health challenge with Nigeria ranking first in Africa and 6th globally in terms of TB burden. Correctional centres are high-risk environments for TB transmission due to overcrowding, poor ventilation, and limited access to healthcare. Inmates in correctional centres face substantial barriers in accessing TB diagnosis and treatment, often resulting in delayed diagnosis and poor treatment outcomes.
This study explores the implementation of active TB case finding among inmates in Kano correctional centers using CAD4TB (Computer aided detection for Tuberculosis) AI-screening PDX machine designed to facilitate early case detection.
Intervention or response: This study was conducted in Kurmawa and Goron Dutse correctional centers in Kano State, Nigeria, targeting all inmates in the facility. To enhance early TB detection, KNCV Nigeria deployed PDX machine with artificial intelligence software, CAD4TB. The case-finding strategy involved active screening where all consenting inmates underwent WHO 4-symptom

screening and digital chest X-ray. Those with CAD4TB scores above 34 provided sputum samples for TB-LAMP or Truenat testing, while individuals unable to produce sputum or those with negative molecular test results symptoms were further evaluated for clinical diagnosis. Diagnosed TB cases were enrolled on treatment.
Descriptive statistics were used to analyze and present the results of screening conducted between January and December 2023.
Results/Impact: A total of 5,338 (100%) Inmates were screened for TB, 390 (7%) presumptive for TB identified, and all of them were evaluated (100%) using TB Lamp or Truenat machines, 57 (15%) TB cases were diagnosed and 100% of the diagnosed cases were enrolled on TB treatment.

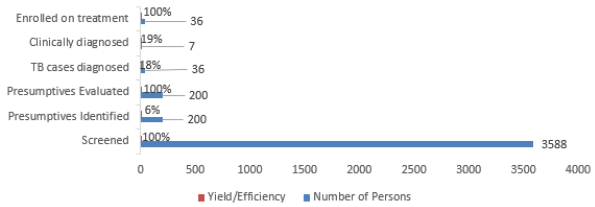

Figure. Graphical representation of the TB screening data for 2023 at the Kurmawa & Goron Dutse correctional centres using the PDX machine.

Conclusions: The comprehensive TB case finding strategy using the PDX machine with CAD4TB AI and treatment programme implemented in Kano correctional centres resulted in improved TB case detection and treatment outcomes among inmates. By leveraging existing social networks and cultural capital, we recommend a similar approach across all vulnerable populations in the country.

OA09-182-19 From evidence to policy: Prioritising TB key and vulnerable populations (KVPs) in Tanzania for strategic investment

R.A. Khaji,[1] V.M. Kabwebwe,[2] A. Tarimo,[3] [1]SHDEPHA+, Health and Program management, Kahama Municipal Council, United Republic of Tanzania, [2]SHDEPHA+, Administration and Governance, Kahama Municipal Council, United Republic of Tanzania, [3]National Tuberculosis & Leprosy Programme (NTLP), TB Care and Prevention services, Dodoma, United Republic of Tanzania
e-mail: rabiabeid@gmail.com

Background and challenges to implementation: Despite significant efforts, Tanzania continues to experience high TB incidence, with an estimated 128,000 new cases and 18,100 deaths annually. Hard-to-reach populations often invisible in surveillance systems bear a disproportionate burden of disease. In 2024, Tanzania's National TB and Leprosy Programme (NTLP), in collaboration with SHDEPHA+ and civil society, conducted a national prioritization of TB Key and Vulnerable Populations (KVPs) to inform a targeted size estimation and mapping strategy and align with the Global Plan to End TB.
Intervention or response: A two-day national roundtable was convened in May 2024, engaging 20+ multisectoral stakeholders including ministries, civil society organizations, and community representatives. Twenty KVP groups were scored across six vulnerability domains: environmental, biological, behavioral, legal, socio-cultural, and economic. Scoring was conducted in small groups using a consensus-based framework adapted from the Stop TB Partnership's Data for Action Guide. Final scores were validated in plenary sessions and used to categorize risk levels.
Results/Impact: Eight KVPs were identified as high-risk, with average vulnerability scores ranging from 57% to 79%. These groups included people who use drugs, urban/rural poor, artisanal miners, fisherfolk, refugees and migrants, prisoners, homeless/nomadic populations, and people living with HIV. Five additional groups including children, elderly, healthcare workers, and those with chronic illnesses were categorized as medium risk. Findings revealed overlaps, stigma, and gaps in service access across these groups. Stakeholders emphasized the need for targeted, data-informed interventions tailored to each group's specific vulnerabilities.

Key and Vulnerable Population	Average Risk Score (%)
People who use drugs (PWUD/PWID)	79%
Urban and rural poor (slums)	78%
Artisanal miners	74%
Homeless and nomadic populations	68%
Migrants, refugees, and IDPs	65%
Fisherfolk	64%
People living with HIV (PLHIV)	63%
Prisoners and detainees	57%

Table 1: TB KVP prioritization

Conclusions: This participatory and evidence-based process resulted in a national KVP prioritization framework that enhances programmatic equity and accountability. It informed policy direction for TB KVP mapping and future interventions. The approach demonstrated that targeting TB in Tanzania must be intersectional responding to social, legal, and environmental determinants and must be grounded in community voice, inter-sectoral action, and data.

OA09-183-19 Invisible populations, visible impact: Reaching nomadic and hard-to-reach populations through community TB interventions in Northern Nigeria

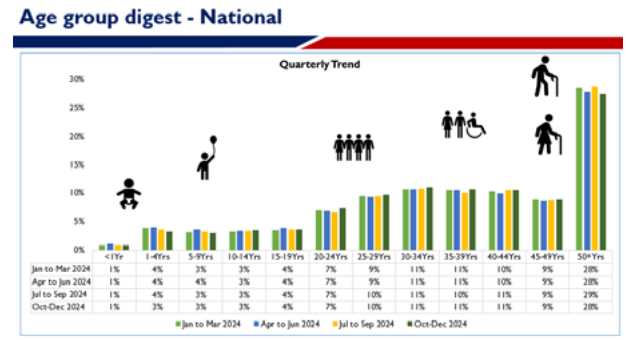
E. Vincent,[1] T. Adetiba,[1] C. Adesigbin,[2] E. Ubochioma,[2] M. Zamzu,[3] J. Ssekitooleko,[3] O. Olupitan,[4] A. Agbaje,[4] O. Adebayo,[1] C. Mensah,[4] P. Dakum,[4] R. Dickson-Nze,[5]
[1]Institute of Human Virology Nigeria, Prevention, Care and Treatment, Abuja, Nigeria, [2]National Tuberculosis, Leprosy and Buruli Ulcer Control Program, Program Coordinating Unit, Abuja, Nigeria, [3]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Department, Geneva, Switzerland, [4]Institute of Human Virology Nigeria, Program Coordinating Unit, Abuja, Nigeria, [5]Institute of Human Virology Nigeria, Strategic Information, Abuja, Nigeria
e-mail: aagbaje@ihvnigeria.org

Background and challenges to implementation: Northern Nigeria harbors a significant burden of undiagnosed tuberculosis (TB), particularly among nomadic, pastoralist, and geographically isolated communities. These populations often remain invisible to routine TB programs due to mobility, stigma, and weak health infrastructure. This abstract presents the outcomes of a targeted community-led TB active case finding intervention implemented under the Global Fund-supported N-THRIP project.
Intervention or response: Community-based organizations (CBOs) were engaged in January 2024 to implement home-to-home and outreach TB screening campaigns in hard-to-reach communities across 64 Local Government Areas in Borno, Adamawa and Taraba States, areas with a significant nomadic population. Special outreach models included use of mobile diagnostic vans, evening and weekend screenings, and collaboration with traditional leaders and nomadic gatekeepers. TB screening, testing, and treatment initiation data were extracted and disaggregated by population type and location.
Results/Impact: From January to December 2024, TB screening across targeted nomadic communities in these three states led to 8,695 confirmed diagnoses from 86,647 presumptive cases identified from the 277,048 individuals screened, yielding a detection rate of 3.1% and a **Number Needed to Screen** (NNS) of 32, slightly below the national average of 42. Among nomadic populations, culturally tailored approaches including Fulani mobilizers and local-language messaging helped foster trust and participation. Despite logistical challenges such as poor road access and weak network coverage, adaptive planning and collaboration with local actors ensured smooth implementation. Impressively, 99.9% of all diagnosed cases were promptly linked to care and started treatment at nearby public facilities.
Conclusions: This intervention demonstrates that with context-specific strategies, community systems can effectively identify TB cases among populations historically excluded from formal health systems. Investing in locally adapted models, leveraging traditional structures, and optimizing last-mile logistics can transform TB case finding in underserved populations and accelerate progress toward TB elimination in fragile settings.

OA09-184-19 Integrating TB screening and treatment into social protection programmes to enhance early detection and access to care

M. Mwesige,[1,2,3] H. Luzze,[1] N. Modi,[1] M.G. Nabukenya Mudiope,[2] T.J. Nsubuga,[2] M. Ocero Ogola,[4] E.E. Nsiimenta,[1] E. Mbabazi,[5] S. Muchuro,[2] [1]Ministry of Health, National Tuberculosis and Leprosy Program (NTLP), National TB and Leprosy Program, Kampala, Uganda, [2]Infectious Disease Institute (IDI), Health Systems Strengthening, Kampala, Uganda, [3]Makerere University, School of Public Health, School of Public Health, Kampala, Uganda, [4]Ministry of Gender, Labour and Social Development, Expanding Social Protection Programme, Kampala, Uganda, [5]Office of the Prime Minister Prime, Minister's Delivery Unit (PMDU), Kampala, Uganda
e-mail: mathiusmwesige1@gmail.com

Background and challenges to implementation: Globally, Uganda ranks among the 30 high-burden TB-HIV countries, with 88,869 reported TB patients in 2024, compared to an estimated annual burden of 940,000. Among older individuals aged over 50, tuberculosis presents a significant challenge, accounting for 28% of national notifications in 2024, despite those aged over 60 constituting only 9.2% of the total population. Individuals over 60 years are at a heightened risk of developing TB due to weakened immune systems, comorbidities with non-communicable diseases, malnutrition, and limited access to healthcare.



Intervention or response: In June 2024, National TB and Leprosy Programme in collaboration with USAID Local Partner Health Services, Acholi, and PACT Karamoja, strategically partnered with Expanded Social Protection Programme of the Ministry of Gender, Labour, and Social Development to integrate Tuberculosis care services into the Social Assistance Grant for the Elderly (SAGE) programme. SAGE staff were oriented on tuberculosis to enhance their awareness of the disease and to integrate

tuberculosis care services into SAGE operations. The trained staff members became change agents and mobilised beneficiaries for tuberculosis screening during the SAGE pay points.
Results/Impact: 980 SAGE beneficiaries from 15 payout points in the Acholi and Karamoja districts were sensitised and screened for tuberculosis. Among these 980 beneficiaries, 530 (54%) were identified as presumptive and provided a sputum sample for testing, under WHO-recommended molecular testing.11 individuals were found to be TB-positive, including one (1) patient with multidrug-resistant TB. Tuberculosis screening and testing at the SAGE pay points yielded a positivity rate of 2.1%, significantly higher than the national average of 0.2%. All patients were referred for TB treatment at the nearest health facility, ensuring prompt access to appropriate medical interventions.
Conclusions: Integrating tuberculosis screening into social protection programmes enhances early detection and access to care. The significant positivity rate emphasises the need for expanded, targeted interventions to improve tuberculosis control among elderly populations.

OA09-185-19 Associations between community venue-time and incident TB infection among children and youth in rural Uganda

R. Abbott,[1] E. Kakande,[2] B. Ssekyanzi,[2] W. Ariho,[2] G. Nattabi,[2] J. Temple,[1] G. Chamie,[1] E.D. Charlebois,[1] M. Kamya,[2] L.B. Balzer,[3] C. Marquez,[1] [1]University of California, San Francisco, Medicine, San Francisco, United States of America, [2]Infectious Disease Research Collaboration, N/A, Mbarara, Uganda, [3]University of California, Berkeley, Biostatistics, Berkeley, United States of America
e-mail: Carina.Marquez@ucsf.edu

Background: Estimates suggest that most TB infections are acquired outside the home. Yet, data on where children/youth acquire TB are sparse and needed to guide age-specific case-finding. In SONET, a longitudinal cohort of children/youth 1-24 years in rural Southwestern Uganda, we sought to evaluate whether (1) incident TB infection was associated with time in community-based venues and (2) certain venue-types were associated with incident TB.
Design/Methods: The SONET incidence cohort included participants who had a negative QuantiFERON-Plus (QFT) at baseline and a repeat QFT one-year later. Incident TB infection (case) was defined as QFT conversion from negative to positive. Cases and a random sample of controls completed a social-spatial network (SN) questionnaire, asking about time spent in community-based venues. For children <12 years, we surveyed the primary caregiver. By case-control status, we compared (1) median total monthly-hours spent in community-based venues, restricting the caregiver network to only when they brought the child with them, with a Wilcoxon rank-sum test; and (2) number of named venues by case-control status with a t-test.
Results: From June 2023-June 2024, 3,290/4,961 (66.3%) baseline QFT-negative participants completed a follow-up QFT. Among them, 66/3,290 (2.0%) had incident TB infection, 60/66 (90.9%) completed the SN questionnaire plus 579 controls. Overall, there was no difference in median monthly-hours spent in community-based venues comparing cases and controls, but a significant difference was seen within males ages 12-24 (median 78.1 hours/month vs. 43.3 hours/month, respectively, p=0.05). Cases/their caregivers named significantly more video halls than controls (p=0.03) and more bars (p=0.06), particularly when restricted to males (p=0.01).

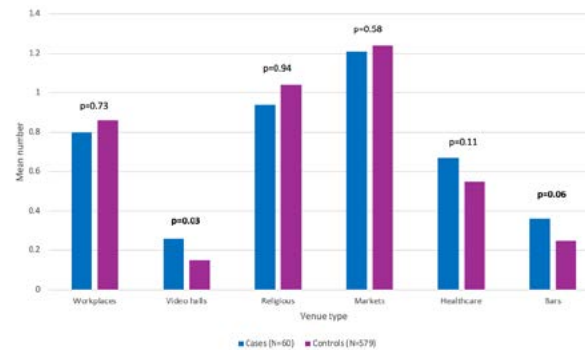


Figure 1. Mean number of venue-type by case-control status (min 0; max 3).

Conclusions: In this cohort, venue-types emerged as potentially high-yield for active case-finding, particularly for males, for whom community-based exposures may play a larger role. These data can help inform novel community-based screening programs and are among the first to highlight video halls as a key venue for youth.

OA09-186-19 Paradigm of ending TB in special populations in Kano State

S. Ibrahim,[1] M. Tukur,[1] M. Bajehson,[1] B. Odume,[2] [1]KNCV Nigeria, Program, Kano, Nigeria, [2]KNCV Nigeria, Program, Abuja, Nigeria
e-mail: ibrahimsaidat06@gmail.com

Background and challenges to implementation: Ending TB among special populations requires a multifaceted approach, including targeted screening, improved access to diagnosis and treatment. According to WHO, correctional centres are considered reservoirs facilitating TB and multidrug-resistant TB transmission within their walls and to the community at large. Overcrowding significantly hinder TB prevention and care among these special group of people that are vulnerable to TB transmission, exacerbated by other unfavourable living condi-

tions within the settings, access to care is also hindered as they are not stable with inmates having variable durations of stay. We present results of TB active case finding services among inmates in correctional centers in kano state, Nigeria.

Intervention or response: A retrospective observational study was conducted in 2022 under which KNCV Nigeria implemented the Portable Digital X-ray (PDX) intervention. The PDX initiative was rolled out across seven states, with Kano State deploying 2 machines.

This intervention aimed to facilitate active TB case finding among inmates, Goroundutse and Kurmawa are the 2 federal correctional centres in Kano having over a thousand inmates who are transient stays, and its implications for ending TB through chest X-ray screening, GeneXpert testing, and prompt linkage to care

Results/Impact: A total of 2,608 individuals were screened using PDX. Of these, 211 were identified as presumptive TB cases and evaluated accordingly. TB was confirmed in 11 individuals using GeneXpert, while 36 were diagnosed via chest X-ray findings. Translating to a total of 47 inmates were enrolled.

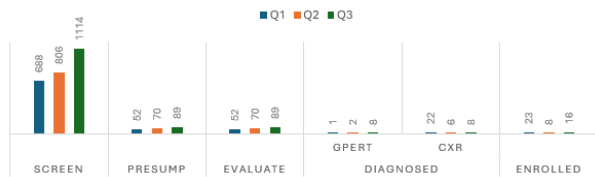

Figure. TB cascade for PDX screening in Kurmawa & Goron Dutse correctional centres Q1-Q3 2022.

Conclusions: The PDX intervention significantly improved TB case detection in correctional centres, enabling early diagnosis and treatment in a population that is typically underserved showcasing the potential of innovative tools and targeted interventions to close existing TB care gaps in special populations.

Sustaining and scaling up such programs is essential to disrupt TB transmission in closed settings and reduce public health risk both within and beyond prison walls.

OA09-187-19 Addressing the gap: TB preventive treatment implementation in people with silicosis in Brazil

F.A. Dias e Sanches,[1,2] F.L. Romero Vega,[3] J.N.d. Barros Silva,[3] F. Dockhorn,[3] [1]Federal University of Rio de Janeiro, Tuberculosis Research Center, Rio de Janeiro, Brazil, [2]Piquet Carneiro University Policlinic, Governance and Compliace and Infection Prevention and Control comission, Rio de Janeiro, Brazil, [3]Ministry of Health, Brazil, National Tuberculosis Program, Brasília, Brazil
e-mail: sanches@hucff.ufrj.br

Background: People with silicosis have a 2.8 to 39 times higher risk of developing tuberculosis compared to the general population, making preventive care essential for this vulnerable group.

Design/Methods: To analyze the implementation of tuberculosis preventive treatment (TPT) among people with silicosis in Brazil, identifying gaps and regional disparities to strengthen integrated public health interventions. Methodology: We analyzed nationwide data through the Brazilian Ministry of Health Notifiable Diseases Information System (Sinan, Pneumoconiosis Silicosis 2006-2024) and the Latent Tuberculosis Infection System (IL-TB (2018-2024)).

Statistical analyses included standardized morbidity ratios (SMR), chi-square tests, odds ratios (OR), quantification of the implementation gap, multiple logistic regression, and population attributable fraction (PAF) for TPT among people with silicosis across different regions and municipalities.

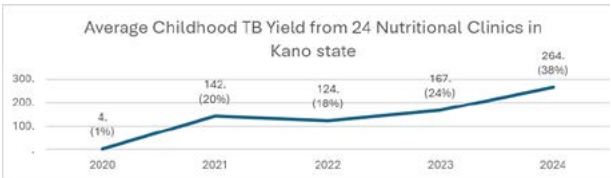
Results: Among 2,784 people reported with silicosis, only 39 people (1.4%) with both TB and silicosis were documented, and additionally just 179 people with silicosis (6.4%) received TPT. The observed TB-silicosis representation corresponds to an SMR of 0.50 (95%CI: 0.36-0.69), indicating potential underdiagnosis. Regional disparities were highly significant ($\chi^2 = 78.6$, $p<0.0001$), with municipalities in the South region being 6.20 times more likely (95% CI:3.57-10.79) to implement TPT than the Southeast, despite the latter having higher silicosis prevalence. Municipalities with occupational health services had significantly higher implementation rates (OR = 3.76, 95% CI: 2.83-4.98).

Conclusions: The significant disparity between the burden of silicosis and TPT implementation represents a missed opportunity for disease prevention. Our findings support the need for integrated care pathways between occupational health services and infectious disease services, with targeted interventions in municipalities with higher silicosis prevalence. Policy recommendations include shared care protocols, mandatory ILTB screening for all people with silicosis, regional training programs, and strengthening surveillance systems to reduce the deadly combination of tuberculosis and silicosis among Brazilian workers exposed to silica dust.

OA09-188-19 Leveraging on nutritional clinics to improve childhood TB detection in public health facilities: Kano State experience

G. Zephaniah,[1] B. Mamman,[2] A. Dikko,[2] O. Chidubem,[1] C. Ogoamaka,[3] K. Nigeria,[3] [1]KNCV Nigeria, Strategic Information (SI), Kano, Nigeria, [2]KNCV Nigeria, Technical, Kano, Nigeria, [3]KNCV Nigeria, Management, Kano, Nigeria
e-mail: gzephaniah@kncvnigeria.org

Background and challenges to implementation: Nigeria is one of the countries with the highest TB burden globally, and childhood TB is a significant part of this. Studies indicate that pulmonary tuberculosis is the most common form in children, and clinical diagnosis based on symptoms, contact history, and radiological findings is crucial for younger children that are unable to produce sputum. And the underlying factors for TB in children includes poor health infrastructure, poverty, malnutrition and lack of awareness.
Intervention or response: KNCV Nigeria through the USAID Funded TB LON 1&2 Project has trained health care workers on screening and identification of a presumptive TB case, referral for evaluation and linkage to TB treatment. Each facility has a TB screener at the Nutritional Clinic who conduct health talk on signs and symptoms of TB in children. While the physicians armed with the prerequisite knowledge on clinical features of TB in children, identify and referred presumptive for free chest X-ray provided by KNCV Nigeria and the TB cases diagnosed with any of the diagnostic tools available were enrolment on TB treatment immediately.
Results/Impact: Kano state has a total of 60 Children Nutritional Clinics spread across 44 LGAs of the state and KNCV is conducting TB Screening in 24(40%) of this facilities in 14 LGAs and from January 2020 – December 2024, a total of 364,075 attendees were recorded, and 295,769(81%) children were screened for signs and symptoms of TB, while 20,643(7%) identified as presumptive for TB, 16,680(81%) evaluated for TB using Genexpert machine, and a total of 703(4%) were diagnosed to be positive for TB and 673(96%) of them were enrolled on TB treatment.



Conclusions: The achieved result from the intervention clearly shows that a scale up of TB screening in all the nutritional clinic across the state will increase childhood TB case finding in Kano state.

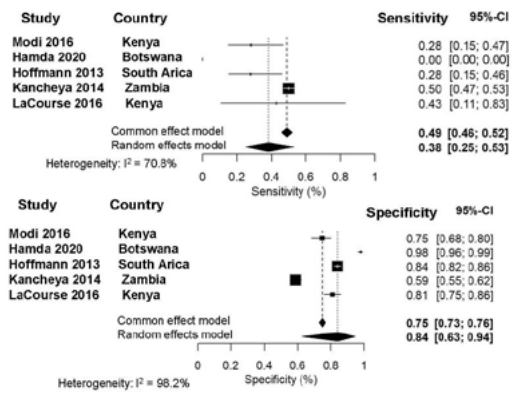
OA10 Just the two of us: The continuum of maternal and early childhood TB

OA10-189-19 Systematic review of TB screening and diagnostic tools for pregnant and postpartum women

S. Cox,[1,2] S. Verkuijl,[3] K. Viney,[3] G. Gonzalez-Perez,[4] L. Chaisson,[5,6] [1]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States of America, [2]Johns Hopkins University, Center for TB Research, Baltimore, United States of America, [3]World Health Organization, Global Programme on Tuberculosis & Lung Health, Geneva, Switzerland, [4]University of Illinois College of Medicine, Medicine, Chicago, United States of America, [5]University of California, San Francisco, UCSF Center for Tuberculosis, San Francisco, United States of America, [6]University of California, San Francisco, UCSF Institute for Global Health Sciences, San Francisco, United States of America
e-mail: scox26@jh.edu

Background: Over 200,000 pregnant women are estimated to develop tuberculosis (TB) each year. However, the performance of screening and diagnostic tools for TB infection (TBI) and TB disease (TBD) in this population is not well understood. We conducted a systematic review to synthesize evidence on the performance of TBI and TBD screening and diagnostic tests in pregnant and postpartum women.
Design/Methods: We searched PubMed, Web of Science, and Embase from January 2000 to September 2024 for articles reporting data on TBI and TBD screening and/or diagnostic tests among pregnant, postpartum, and/or lactating women. Two reviewers conducted title/abstract and full-text reviews.
We abstracted data to calculate:
1. number needed to screen (NNS), defined as the inverse of the proportion with TB detected;
2. kappa statistic for test agreement, and;
3. diagnostic accuracy (sensitivity and specificity).
Analyses were stratified by HIV status and peripartum stage.
Results: Of 6,168 articles screened, 53 were included. For TBI, interferon-gamma release assay (IGRA) yield was generally higher than TB skin test (TST) yield [weighted mean NNS range: 3-7 vs. 5-9; n=29 studies]. In 5 longitudinal studies, IGRA yield remained higher than TST yield across peripartum stages, regardless of HIV status. Pooled kappa for TST/IGRA ranged from poor to moderate (0.07 to 0.60; n=13 studies). Among pregnant women with HIV, pooled sensitivity of symptom-based screening was 38% (95% CI: 25-53) and pooled specificity was 84% (95% CI: 63-94) [Figure; n=5 studies]. Xpert MTB/RIF for TB screening showed higher accuracy (pooled sensitivity: 63% [95% CI: 25-90]; pooled specificity: 99% [95% CI: 83-100]; n=2 studies).

Figure. Sensitivity (top panel) and specificity (bottom panel) of symptom-based screening among pregnant women living with HIV, relative to microbiological reference standard.



Conclusions: For TBI screening among pregnant and postpartum women with and without HIV, IGRA is likely to detect more TBI than TST. Performance of symptom-based screening and Xpert for TBD was suboptimal. Data was limited for pregnant women without HIV and for other TBD screening and diagnostic tools.

OA10-190-19 Maternal TB infection risk in pregnant women living with HIV

L. Pretorius,[1] T. Van Der Byl,[1] T. Beattie,[2,3] S. Ginindza,[3] J. Moodley,[4] V. Govender,[5] T. Moloantoa,[6] M. Van Schalkwyk,[7] T. Nielson,[8] S. LaCourse,[9] J. Mathad,[10] R. Chaisson,[11] Dolphin Moms Team [1]The Aurum Institute, Clinical Research, Tembisa, South Africa, [2]Utrecht University, Department of Interdisciplinary Social Sciences, Johannesburg, South Africa, [3]The Aurum Institute, Clinical Research, Johannesburg, South Africa, [4]The Aurum Institute, Clinical Research, Durban, South Africa, [5]The Aurum Institute, Clinical Research, Pretoria, South Africa, [6]Perinatal HIV Research Unit - PHRU, Clinical Research, Klerksdorp, South Africa, [7]FAMily Centre for Research with Ubuntu (FAMCRU), Clinical Research, Stellenbosch, South Africa, [8]The Aurum Institute, Clinical Research, Klerksdorp, South Africa, [9]University of Washington, Department of Epidemiology, Washington, United States of America, [10]Weill Cornell Medicine, Obstetrics and Gynecology, Manhattan, United States of America, [11]Johns Hopkins University, Epidemiology and International Health, Baltimore, United States of America
e-mail: lpretorius@auruminstitute.org

Background: Women are at greatest risk of Tuberculosis (TB) during pregnancy and immediately postpartum. The World Health Organization recommends TB preventive therapy (TPT) for pregnant people living with HIV (PLHIV) in high-burden settings. We assessed prevalence and risk factors of TB infection (TBI) among participants enrolled in the DOLPHIN Moms trial.
Design/Methods: Dolphin Moms is a Phase II open-label multi-centre randomized controlled trial across three sites in South Africa. Pregnant PLHIV(≥18 years) with, singleton pregnancies at 20–34 weeks gestation, virally suppressed on at least 4 weeks of DTG-based antiretroviral therapy were randomised to receive one month of daily isoniazid and rifapentine (1HP) or three months of once-weekly isoniazid and rifapentine (3HP). TBI testing was performed with (QuantiFERON-TB Gold plus). Logistic regression was used to identify baseline factors associated with maternal TBI. Variables with a p-value<0.20 in the univariate analyses were included in a multivariable model and adjusted for age.
Results: 215 pregnant PLHIV (n_{1HP}=89 ; n_{3HP}=126) were tested for TBI. Baseline TBI prevalence was 42.33% (91/215, 5 indeterminate, 1 missing) and similar in both 40.45%(1HP) and 43.65% (3HP) arms. In univariable analyses, earlier gestational age, higher median CD4, previous alcohol, and tobacco use was associated with TBI. However, in multivariable analyses only higher CD4 and tobacco use remain relevant. Refer to Table 1.

Characteristic		IGRA result			Univariable		Multivariable	
		Positive, N=91 n (%)	Negative, N=118 n (%)	Total	OR (95% CI)	p-value	OR (95% CI)	p-value
Age	Median (IQR)	33 (28-36)	31 (28-35)	32 (28-36)	1.018 (0.968-1.071)	0.490	1.035 (0.978-1.095)	0.237
Gestational age - categories	20 - 26 weeks	48 (52.7)	43 (36.4)	91 (43.5)	ref 0.521		ref	
	26 – 34 weeks	43 (47.3)	74 (62.7)	117 (56.0)	(0.298-0.909)	0.022	0.598 (0.325-1.101)	0.099
CD4	Median (IQR)	755 (639-915)	647 (454-806)	696 (522-845)	1.002 (1.001-1.003)	<0.001	1.002 (1.001-1.004)	<0.001
Reported tobacco use	Never	70 (76.9)	104 (88.1)	174 (83.3)	ref 2.229		ref 2.385	
	Yes	21 (23.1)	14 (11.9)	35 (16.7)	(1.062-4.676)	0.034	(1.027-5.54)	0.043
Reported alcohol use	Never	59 (64.8)	59 (64.8)	152 (72.7)	ref 2.018		ref 1.524	
	Yes	32 (35.2)	32 (35.2)	57 (27.3)	(1.089-3.738)	0.026	(0.763-3.047)	0.233

Table 1: Baseline factors for maternal TBI risk evaluated

Conclusions: We found a high prevalence of TBI among pregnant women, with multiple risk factors for TBI, underscoring the need for data on shorter TPT regimens in this population. Alcohol and tobacco use may be associated with maternal TBI. Counselling of Pregnant PLHIV on tobacco use and alcohol consumption is needed.

OA10-191-19 Cytokine profiles in pregnant women from India and South Africa stratified by presence of TB or latent TB across pregnancy stages

V. Kulkarni,[1,2] M. Alexander,[3] F. Nabeemeeah,[4] N. Gupte,[1,2] S. Naik,[5] F. Swanepoel,[4] P. Deshpande,[1,2] V. Potphode,[1,2] S.k. Tambe,[5] A. Gupta,[6] N. Martinson,[4,7] J. Mathad,[8] PARTHISA Study team at BJGMC-JHU CRS, Pune, India and PHRU, Johannesburg, South Africa
[1]Byramjee-Jeejeebhoy Government Medical College-Johns Hopkins University Clinical Research Site, Clinical Research, Pune, India, [2]Center for Infectious Diseases in India, Johns Hopkins India, Clinical Research, Pune, India, [3]Weill Cornell Medicine, Center for Global Health, USA, Pune, India, [4]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa, [5]Byramjee-Jeejeebhoy Government Medical College & Sassoon General Hospitals, Department of Gynecology and Obstetrics, Pune, India, [6]Johns Hopkins University, School of Medicine, Division of Infectious Diseases, Baltimore, United States of America, [7]Johns Hopkins University, School of Medicine, Medicine, Baltimore, United States of America, [8]Weill Cornell Medicine, Center for Global Health, USA, New York, United States of America
e-mail: vkulkar2@jhmi.edu

Background: Tuberculosis (TB) adversely affects pregnant women. Previous studies showed that pregnancy-related immune changes decrease TB-specific interferon-gamma (IFN-γ) responses. We analysed other cytokines across pregnancy stages to evaluate their ability to discriminate TB groups.
Design/Methods: Pregnant women were enrolled in India and South Africa (SA) and stratified by IFN-γ Release Assay (IGRA), HIV and TB disease status. Eight cytokines (IFN-α, IFN-β, IFN-γ, IL10, IL4, IL6, IP10, TNF-α) measured from plasma using Luminex at antepartum, delivery, and postpartum. Differences in inflammatory response and cytokine discriminatory ability across TB groups and pregnancy stages were analysed using a random effects univariate model that reflects longitudinal changes.
Results: Of 103 enrolled participants who contributed 439 samples (India 174 and SA 265), 27 had active TB disease; 47 were IGRA positive, and 29 IGRA negative with no TB. Median age was 28 (IQR 24-33) years, gestational age 19.3 (IQR 15.6-22.6) weeks, 42/103 (41%) living with HIV, with median CD4 573 cells/mm^3 (IQR,426-857) and 83% with viral load <200 copies/ml. Pairwise comparisons showed that all cytokines except IFN-β had significant differences between active versus latent TB ($p \leq 0.001$) and active versus no TB ($p<0.05$). With any TB (active or latent) vs no TB, IFN-α, IL10, IL4, IL6, IP10, and TNF-α were significantly elevated, while IFN-γ was significantly low. Random effects model for different cytokines across pregnancy and postpartum showed that IL10 (p=0.03) and IL6 (p=0.02) remained significantly higher in women with any TB versus no TB at delivery. Postpartum, IFN-β (p=0.004) was significantly higher in any TB versus no TB. Thus, distinguishing latent from active TB and any TB from no TB.

Table 1: Comparison of cytokines between TB groups

Cytokines	Active TB vs No TB		Latent TB vs No TB		Active TB vs Latent TB	
	Slope difference (95% CI)	p value	Slope difference (95% CI)	p value	Slope difference (95% CI)	p value
IFN alpha	0.38 (0.13, 0.63)	**0.003**	0.01 (-0.20, 0.22)	>0.9	0.37 (0.15, 0.60)	**0.001**
IFN beta	-0.94 (-3.1, 1.2)	0.4	-0.61 (-2.5, 1.3)	0.5	-0.33 (-2.3, 1.6)	0.7
IFN gamma	-2.7 (-4.7, -0.70)	**0.01**	1.2 (-0.59, 3.0)	0.2	-3.9 (-5.8, -2.1)	**<0.001**
IL10	0.51 (0.16, 0.86)	**0.004**	-0.09 (-0.39, 0.22)	0.6	0.60 (0.28, 0.91)	**<0.001**
IL4	11 (6.2, 15)	**<0.001**	0.12 (-3.8, 4.1)	>0.9	11 (6.5, 15)	**<0.001**
IL6	7.2 (2.0, 12)	**0.01**	-0.51 (-5.0, 4.0)	0.8	7.7 (3.0, 12)	**0.001**
IP10	15 (9.0, 22)	**<0.001**	0.41 (-5.2, 6.1)	0.9	15 (9.3, 21)	**<0.001**
TNF alpha	1.2 (0.25, 2.0)	**0.01**	-0.54 (-1.3, 0.25)	0.2	1.7 (0.88, 2.5)	**<0.001**

Table 1 shows the pairwise cytokine comparison between Active TB versus No TB, Latent TB versus No TB, and Active versus Latent TB using a Random effects univariate model that reflects longitudinal changes at all pregnancy stages ie, antepartum, delivery, and postpartum. The slope difference with 95% confidence intervals and p value are considered significant when <0.05.

Conclusions: Our study identified significant variations in cytokine levels across different TB groups and pregnancy stages, underscoring their potential as diagnostic markers for TB disease and infection in this high-risk population. However, further validation is needed in this context.

OA10-192-19 An assessment of guideline implementation for TB screening among pregnant women living with HIV using linked population data in the Western Cape, South Africa

R. Dinkele,[1,2] F. Phelanyane,[1,2] M. Smith,[1,2] M. Kubjane,[3] V. Mudaly,[4] A. Heekes,[1] T. Jacobs,[2] J. Euvrard,[1,2] M.-A. Davies,[1,2] A. Boulle,[1,2] E. Kalk,[1] [1]University of Cape Town, School of Public Health, Cape Town, South Africa, [2]Health Intelligence Directorate, Western Cape Department of Health and Wellness, Cape Town, South Africa, [3]University of the Witwaterstrand, Wits Health Consortium, Johannesburg, South Africa, [4]University of Cape Town, Department of Medicine, Cape Town, South Africa
e-mail: emma.kalk@uct.ac.za

Background: Pregnancy increases the risk of tuberculosis disease (TB), a leading cause of non-obstetric maternal death among pregnant women living with HIV (pWLHIV). In 2019, South African guidelines recommended that all pWLHIV receive GeneXpert-MTB/RIF (GXP) sputum testing. Using routine electronic public service health data consolidated in a health information ex-

change, we aimed to assess the implementation of GXP screening among pWLHIV in the Western Cape province (WC), South Africa.

Design/Methods: The cohort included all pWLHIV with a first antenatal visit during 2018–2023 and a recorded birth outcome.

Results: The cohort included 513,556 women and 583,815 pregnancies, with an HIV prevalence of 17.5%. Of all pWLHIV, 95.7% had evidence of antiretroviral therapy (ART), of whom 22.8%% initiated or restarted ART during pregnancy. In total, 17,621 (17.6%) pWLHIV had evidence of previous TB. TB was diagnosed in 1.1%–1.9% of pregnancies per year. GXP testing during pregnancy increased annually from 6.3% in 2018 to 37.0% in 2023 with the largest changes occurring in 2019 (+7.5%) and 2020 (+12.4%) after the introduction of the 2019 guidelines. A corresponding annual decrease occurred in the proportion of positive GXP results, from 9.1% in 2018 to 2.5% 2023. In a subset of pWLHIV for whom data were available (8,732), TB symptom screening and GXP testing were performed among 84.6% and 10.8% of women, respectively, over the period.

Conclusions: TB is common before and during pregnancy in WLHIV in the WC. GXP testing among pWLHIV in the WC increased annually with implementation of the screening guidelines in 2019. The corresponding decline in the rate of GXP positivity supports the conclusion that these are screening, rather than diagnostic, tests. However, guideline implementation remains poor. Given the adverse maternal, pregnancy and neonatal outcomes of maternal TB, effort is required to improve screening uptake.

OA10-193-19 Pregnant women experience delay in initiating anti-TB treatment

S.-A. Meehan,[1] A.C. Hesseling,[1] M. Smith,[2,3] F. Phelanyane,[2,3] A. von Delft,[2,3] R. Dunbar,[1] J.A. Seddon,[1,4] M. Osman,[1,5]
[1]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child health, Cape Town, South Africa, [2]Health Intelligence Directorate, Western Cape Government, Department of Health, South Africa, Cape Town, South Africa, [3]University of Cape Town, Centre for Integrated Data and Epidemiology and Research, School of Public Health and Family Medicine, Faculty of Health Sciences, Cape Town, South Africa, Cape Town, South Africa, [4]Imperial College London, Department of Infectious Diseases, London, United Kingdom of Great Britain and Northern Ireland, [5]University of Greenwich, School of Human Sciences, Faculty of Education, Health and Human Sciences, London, United Kingdom of Great Britain and Northern Ireland
e-mail: sueannm@sun.ac.za

Background: Tuberculosis (TB) incidence peaks in women during their reproductive years and is a leading cause of maternal mortality. Pregnant women with TB have poor TB treatment outcomes, including failure to initiate TB treatment. Poor TB treatment outcomes are a predictor of adverse pregnancy outcomes. We determined the time to TB treatment initiation in pregnant women diagnosed in a routine programmatic setting.

Design/Methods: Using a Provincial Health Data Center, we identified women, 15-45 years, with laboratory-confirmed and clinically diagnosed TB, October 2018-December 2020, in 2 health sub-districts in Cape Town, South Africa. We compared women with TB by pregnancy status, used Kaplan-Meier curves to determine the time from TB diagnosis to initiation of antituberculosis treatment and Cox regression for determinates of treatment initiation.

Results: Of 5459 women, 292 (5.3%) were documented as being pregnant. Pregnant women were younger (median age 28.6 years; IQR:23.7–33.7) than non-pregnant women, (31 years; IQR:25.2–36.5). HIV prevalence was similar by pregnancy status (249/292; 60.6% in pregnant vs 4439/5167; 62% in non-pregnant women). The proportion initiated on TB treatment was similar (249/292; 85.3% in pregnant and 4439/5167; 85.9% in non-pregnant women), but the time to linkage was longer in pregnant women (Figure 1; Log-Rank test p=0.0046). In univariate Cox regression, being pregnant was associated with a lower likelihood of initiating treatment (HR=0.83; 95%CI: 0.73-0.95). In the multivariable model, being HIV-negative (aHR1.08 95%CI:1.02-1.16), being diagnosed at a primary healthcare facility compared to a hospital (aHR 3.83 95%CI:3.52-4.17), and having a clinical TB vs. laboratory-confirmed diagnosis (aHR 4.97 95%CI:4.57-5.39) were associated with greater likelihood of initiating TB treatment.

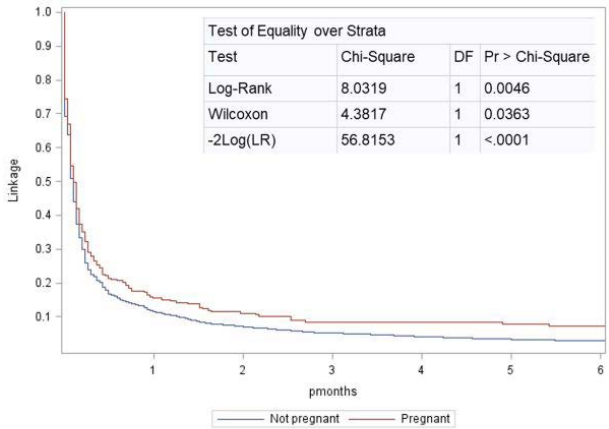


Figure 1: Time to linkage to care stratified by pregnancy status over 6 months

Conclusions: Pregnant South African women experienced more delay in initiating TB treatment and had high HIV prevalence. Linkages to TB treatment initiation should be strengthened to ensure timely treatment initiation in pregnant women, especially for women diagnosed in hospital.

OA10-194-19 Improving access to BDLLC regimens for pregnant women with rifampicin-resistant TB in South Africa

J. Hughes,[1] M. Loveday,[2] A. Hesseling,[1] I. Derks,[1] J. Ferguson,[3] N. Ndjeka,[4] [1]Stellenbosch University, Paediatrics and Child Health, Cape Town, South Africa, [2]South African Medical Research Council, HIV and Other Infectious Diseases Research Unit (HIDRU), Durban, South Africa, [3]WAMTech Systems, Public Health, Johannesburg, South Africa, [4]South African National Department of Health, TB Directorate, Johannesburg, South Africa
e-mail: jhughes@sun.ac.za

Background: People initiating rifampicin-resistant tuberculosis (RR-TB) treatment through the national treatment programme in South Africa are registered on the national Electronic Drug-Resistant Tuberculosis Register (EDR.web) database; historically, pregnancy test results were rarely recorded.
Here, we present an analysis of routine data from women treated for RR-TB since 2023, when pregnancy status was first introduced as a required data variable in EDR.web and when national treatment guidelines were updated to recommend a 6-month regimen containing bedaquiline, delamanid, linezolid, and levofloxacin and/or clofazimine (BDLLC) for pregnant women with RR-TB.
Design/Methods: Patient characteristics, RR-TB regimen composition and treatment outcomes obtained from patient records were routinely entered on EDR.web. Individual level patient data were filtered by pregnancy status and assimilated in Excel for descriptive analyses of characteristics and treatment outcomes of pregnant women through 2023 and 2024.
Results: Between 04 Jan 2023 and 11 March 2025, 6052 women were registered on EDR.web and 182 (3%) were pregnant (74% with HIV). Maternal characteristics and treatment regimens are presented in Table 1.

Characteristic	With HIV (n = 135)	Without HIV (n = 47, including 1 with unknown HIV status	Total (n = 182)
Age in years, median (IQR)	32 (28 – 34.5)	29 (23 - 32)	31 (27 – 34)
Previous TB treatment, number (%)	17 (12.6)	4 (8.5)	21 (11.6)
Baseline weight in kg, median (IQR)	62.3 (50.3 – 74.2)	58.8 (51.4 – 70)	62 (50.8 – 73)
RR/MDR-TB (including rifampicin-mono-resistant), number (%)	126 (93.3)	44 (93.6)	170 (93.4)
Pre-XDR or XDR-TB, number (%)	7 (5.2)	3 (6.4)	10 (5.5)
Initiated 6-month BDLL regimen, number (%)	62 (45.9)	18 (38.3)	80 (44)
Initiated other shorter regimen (9-11 months), number (%)	46 (34.1)	20 (42.6)	66 (36.3)
Individualised regimen, number (%)	27 (20)	9 (19.1)	36 (19.8)
On ART at start of RR-TB treatment (of those with HIV), number (%)	133 (98.5)	-	-

Table 1.

Since the updated treatment guidelines were implemented in September 2023, 80 (72%) of 111 pregnant women initiating RR-TB treatment started a 6-month BDLLC regimen. Of 149 pregnant women who initiated any RR-TB treatment before June 2024, 129 (87%) women had outcome data available at the time of analysis (March 2025). Of these, 100 (78%) were successfully treated, 4 (3%) died, 23 (18%) were transferred or lost-to-follow-up and 2 (1%) experienced treatment failure.
Conclusions: Inclusion of pregnancy status in the national RR-TB treatment register facilitated analysis of routine data from pregnant women and demonstrated improved access to BDLLC regimens following updated guideline implementation. Initiation of BDLLC regimens for pregnant women is expected to increase and treatment outcomes can now be routinely monitored as updated guidelines are implemented and when new regimens are recommended in future.

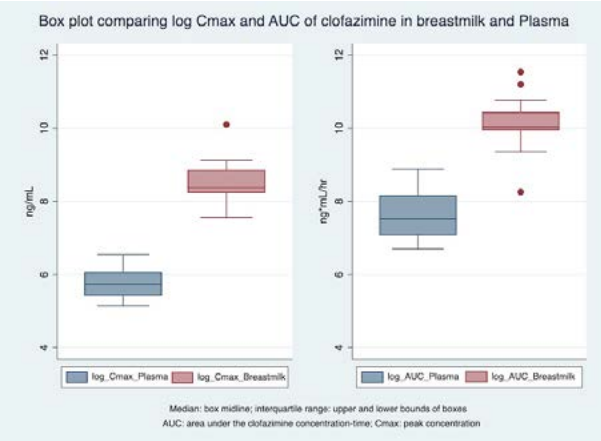
OA10-195-19 Clofazimine exposure in the breastmilk of women treated for rifampicin-resistant TB

R. Court,[1] B. Mkhize,[1] S. Castel,[1] S. Sawe,[1] G. Maartens,[1] P. Denti,[1] F. Conradie,[2] M. Loveday,[3] C. Waitt,[4] L. Wiesner,[1] [1]University of Cape Town, Division of Clinical Pharmacology, Department of Medicine, Cape Town, South Africa, [2]University of the Witwatersrand, Department of Clinical Medicine, Johannesburg, South Africa, [3]South African Medical Research Council, HIV and other Infectious Diseases Research Unit (HIDRU), Durban, South Africa, [4]University of Liverpool, Department of Women's and Children's Health, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: richard.court@uct.ac.za

Background: There are limited data describing the exposure of clofazimine in the breastmilk of lactating women treated for rifampicin-resistant tuberculosis (RR-TB). Quantifying clofazimine pharmacokinetics in breastmilk is important to understand drug exposure in breastfeeding infants. We explored the relationship between maternal plasma clofazimine and breastmilk concentrations.
Design/Methods: We performed plasma and breastmilk sampling approximately six weeks post-partum in pregnant women treated with regimens including clofazimine 100 mg daily, in two studies in South Africa: BEAT-tuberculosis was a randomised control trial comparing a novel RR-TB treatment regimen with standard of care; and the King Dinuzulu Hospital study, an observational study exploring maternal and fetal outcomes in pregnant women treated for RR-TB.
We sampled blood and breastmilk prior to and at 2, 4, 6, 8 and 24 hours when available, after observed dosing. We used validated liquid chromatography-tandem mass spectrometry assays, and compared clofazimine peak concentrations (C_{max}) and area under the concentra-

tion time curve (AUC) in plasma and breastmilk. Using breastmilk clofazimine AUC, we calculated the external infant dose (EID) assuming an average infant breastmilk intake of 0.15 L/kg/day; the relative external infant dose (REID) was calculated using the recommended infant clofazimine dose of 2-5 mg/kg/day.

Results: Fourteen women (12 living with HIV, median age 30.5 yrs, median weight 61.5 kg) completed blood and breastmilk sampling. The median AUC of clofazimine in breastmilk compared with plasma was 22.74 versus 1.85 mg·h/L; the median C_{max} in breastmilk and plasma was 4.31 and 0.31 mg/L, respectively. The mean AUC and C_{max} (breastmilk/plasma) ratio of clofazimine was 12.5 and 18.8, respectively. The estimated EID of clofazimine is 0.20 mg/kg/day; the REID is 0.04 - 0.1.



Conclusions: We observed a substantially higher concentration of clofazimine in breastmilk than in maternal plasma, possibly due to the drug's lipophilicity. Implications for infant safety require further investigation.

OA10-196-19 Risk of TB infection in young children exposed to multidrug-resistant TB in the TB-CHAMP multi-site randomised controlled trial

S. Purchase,[1] T. Duong,[2] J. Brigden,[2] J. Seddon,[1,3] H.S. Schaaf,[1] A. Hesseling,[1] S. Staples,[4] N. Martinson,[5,6] T. Wilkinson,[7] L. Fairlee,[8] [1]Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Cape Town, South Africa, [2]University College London, Institute of Clinical Trials and Methodology, MRC Clinical Trial Unit, London, United Kingdom of Great Britain and Northern Ireland, [3]Imperial College London, Department of Infectious Disease, London, South Africa, [4]THINK (SA), NGO, Durban, South Africa, [5]University of Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa, [6]Johns Hopkins University, Center for TB Research, BaltimoreSout, South Africa, [7]University of Cape Town, Health Economics Unit, Cape Town, New Zealand, [8]University of Witwatersrand, Wits RHI, Faculty of Health Sciences, Johannesburg, South Africa
e-mail: susanpurchase@gmail.com

Background: Young children have a high risk of developing tuberculosis (TB) disease following infection with *Mycobacterium tuberculosis* in the absence of preventive treatment. Infection prevalence and risk factors for infection impact delivery of prevention strategies. We aimed to determine the risk of infection in child household contacts aged < 5 years exposed to adults with confirmed pulmonary multidrug-resistant (MDR)-TB and to determine risk factors for infection.

Design/Methods: TB-CHAMP was a trial of MDR-TB prevention that recruited children under 5, regardless of M.tb infection status. All children enrolled had an interferon-gamma release assay (IGRA) at baseline. We described *M.tb* infection prevalence, developed directed acyclic graphs to clarify causal relationships and used modified Poisson regression models to assess the relationship between risk factors and IGRA positivity.

Results: Of 785 included children, 160 (20.4%) had a positive IGRA. Duration of cough and illicit drug use in the index patient, age of the child, relationship between the child and the index patient and study site were significantly associated with risk of infection.

Conclusions: The prevalence of infection was lower than observed in previous studies. This may be related to improved diagnosis and treatment of MDR-TB in the study setting and/or test limitations and has implications for TB preventive treatment (TPT).

When considering TPT for child contacts, healthcare providers should be especially concerned about any young child exposed to an adult index patient who is his/her parent/primary caregiver, has a chronic cough and/or a history of illicit drug use.

OA10-197-19 Preventing TB and deaths among children living with HIV: The efficacy of TPT among children in a programmatic setting

N. Ruswa,[1,2] G. Gunther,[3,2] R. Shililifa,[1] D. Vambe,[4] M. Claassens,[2] [1]Ministry of Health and Social Services Namibia, National TB and Leprosy Programme, Windhoek, Namibia, [2]University of Namibia, School of Medicine, Windhoek, Namibia, [3]University of Bern, Department of Pulmonology and Allergology, Inselspital Bern, Bern, Switzerland, [4]Baylor College of Medicine, Baylor Foundation, Mbabane, Eswatini
e-mail: ncruswa@gmail.com

Background: Tuberculosis is a leading infectious cause of death globally, and is the top cause of death among those with HIV. The uptake of TB preventive therapy (TPT) among children has been inconsistent. Studies on TPT efficacy in young children across different settings have shown mixed results. This study aimed to assess the efficacy of TPT in reducing TB incidence and mortality within a programmatic setting.
Design/Methods: We performed a secondary analysis of the nationwide electronic patient management system (EPMS) documenting children being followed up for long-term HIV care and the electronic TB registers in Namibia. Probabilistic linkage was conducted using Registryplus Linkplus software to identify children who had registered episodes of TB. Only children under the age of 15 years at the time of enrolment were included. Survival analysis was performed using Stata 18.0.
Results: Of 24,379 children enrolled between 2002 and 2022 (53% female; median age 4; IQR 1-8), 128,879.5 person years were followed up with 92,762.2PY for those who received TPT (total 14,800 children; 60.7% of total enrolled). There were at least 1338 incidents of TB and 1118 deaths.
Incidence of TB was 0.68/100PY in the TPT group and 2.20/100PY in the no TPT group (IRR 0.34). The mortality rate was 0.34/100PY in the TPT group and 2.23/100PY in the no-TPT group (IRR 0.15). In a Cox regression model, the adjusted hazard ratio for getting TB was 0.53 (95%CI 0.47-0.61) for TPT; and 0.38 for antiretroviral therapy. For preventing deaths, the aHR was 0.27(95%CI 0.30-0.50) for TPT and 0.39 for ART.
Conclusions: In tthis national cohort of children with HIV, TPT proved to be highly effective across all age-groups in protecting against TB (47% reduction) and death (73% reduction). These results are consistent with those observed in adults and reinforce the continued recommendations and implementation of TPT for all CL-HIV

OA11 Life after TB: Priorities and opportunities in post-TB health and wellbeing

OA11-198-19 Previous pulmonary TB as a risk factor for lung functional impairment: A cross-sectional study in a rural area of Senegal

L. Allavena,[1,2] I. Sini,[1,2] S. Sarr,[3] L. Ndong,[3] M. Ngom,[3] M. Ndiaye,[3] G. Besozzi,[2] N. Riccardi,[2,4] M. Mantero,[1] M. Tadolini,[2,5] F. Blasi,[1] L.R. Codecasa,[4,2] [1]Università degli studi di Milano, Department of Pathophysiology and Transplantation, Milano, Italy, [2]StopTB Italia ODV, Milano, Italy, [3]Centre de Santé de Diofior, Medicine, Diofior, Senegal, [4]Regional TB Reference Centre and Laboratory, ASST Niguarda Grane Ospedale Metropolitano Niguarda – Villa Marelli, Tuberculosis and Mycobacterial diseases, Milano, Italy, [5]Alma Mater Studiorum University of Bologna, Dept of Medical and Surgical Sciences, Bologna, Italy
e-mail: lucia.allavena@gmail.com

Background: Post-tuberculosis (TB) lung disease (PTLD) is a growing concern in low-resource settings, yet its burden remains unknown.
Design/Methods: We conducted a cross-sectional study in Fimela district, Senegal, to assess respiratory function in adults who had completed pulmonary tuberculosis treatment (post-TB), compared to adults from the same area with no prior TB diagnosis but similar environmental exposure (controls).
The aim of this study was to quantify the prevalence and types of ventilatory patterns in both groups and to investigate whether prior pulmonary TB increases the risk of lung function impairment.
All participants completed standardized questionnaires on respiratory symptoms, exposure history to indoor and outdoor air pollutants, and smoking habits; they underwent clinical evaluation and spirometry with bronchodilator testing in case of obstruction. Chest X-ray was performed only in the post-TB group. Ventilatory patterns were classified using current guidelines.
Results: Among 242 participants (77 post-TB subjects and 165 controls) ventilatory impairment was observed in 59.7% of the post-TB group and 22.0% of controls ($p<0.001$). Restrictive patterns were most common (41.7% post-TB vs. 15.3% controls), while obstructive and mixed defects occurred in 13.9% and 4.2% of post-TB individuals, and in 6.7% and 1.3% of controls, respectively. Radiological abnormalities were found in 48.6% of the post-TB group, with fibrotic sequelae as the most frequent abnormality (40.3%) (Table 1). Multivariate analysis identified previous TB as an independent risk factor for lung function impairment [OR 4.44; 95% CI: 2.36–8.34], after adjustment for potential confounders, including exposure to air pollutants and smoking, none of which were significantly associated with the outcome.

	Total subjects n=142	Post-TB subjects n=77	Controls n=165	P-value
Median age, years (25-75IQR)	41.5 (29-57)	39.0 (29.0-52.0)	43.0 (29.0-58.5)	0.14
Sex (M), n° (%)	122 (50.4%)	51 (66.2%)	71 (43%)	<0.001
BMI, mean (+SD)	22.5 (+4.4)	19,9 (+3.2)	23.7 (+4.3)	0.02
HIV infection, n° (%)	4 (1.7%)	2 (2.6%)	2 (1.2%)	0.43
Actual or former smokers, n° (%)	46 (19.0%)	25 (32.5%)	21 (12.7%)	<0.001
Spirometric Alterations, n° (%)	76 (34.2%)	43 (59.7%)	33 (22.0%)	<0.001
Restrictive pattern, n° (%)	53 (23.9%)	30 (41.7%)	23 (15.3%)	<0.001
Obstuctive pattern, n° (%)	20 (9.0%)	10 (13.9%)	10 (6.7%)	0.08
Mixed disorder, n° (%)	5 (2.3%)	3 (4.2%)	2 (1.3%)	0.18

Conclusions: PTLD is associated with a high burden of ventilatory impairment in rural Senegal. Prior TB is a strong predictor of functional decline. Routine functional and radiological follow-up after TB treatment completion is feasible and valuable in rural low-income settings to detect lung functional impairment.

OA11-199-19 An assessment of abnormal 6 Minute Walk Distance (6MWD) and associated factors in people with post-TB lung disease at a tertiary hospital (Zambia): Cross-sectional study

C. Sinyangwe,[1] W. Chewe,[2] L. Siame,[3] C. Mulenga,[1] A. Mubanga,[4] N. Mbewe,[5] B. Malambo Hamooya,[6] C. Chanda,[4] [1]University Teaching Hospital, Infectious Disease, Lusaka, Zambia, [2]AIDS Health Care Foundation, Medical, Ndola, Zambia, [3]Mulungushi University School of Medicine and Health Sciences, Livingstone, Zambia, Public Health, Livingstone, Zambia, [4]Ministry of Health, National TB and Leprosy Program, Public Health, Lusaka, Zambia, [5]Ministry of Health, Public Health, Lusaka, Zambia, [6]Mulungushi University, Public Health, Livingstone, Zambia
e-mail: chishasinyangwe.md@gmail.com

Background: Post TB lung disease (PTLD) can result in functional disability and remains a public health concern. Therefore, this study aimed to investigate the 6MWD outcomes and associated factors among adult PTLD patients presenting to the Adult University Teaching Hospitals (UTH), a tertiary health institution in Lusaka, Zambia.
Design/Methods: A cross-sectional study was conducted at the Adult University Teaching Hospital (UTH) between March 2023 and November 2024. Adults aged 18 and older with a history of treated TB, proven clinically or microbiologically, were included. Demographic and Clinical data were collected using a data abstraction form. Descriptive analysis and logistic regression were performed using STATA 15.
Results: The study included 105 participants, with a median age of 45 years (IQR 18-71). The median 6MWD was 345meters (IQR 279- 405). Individuals with abnormal 6MWD had a generally lower median BMI (19.8 vs. 22.2, p = 0.049). A higher proportion of individuals with abnormal 6 MWD had monthly incomes below $35 compared to those earning $180 and above (50% vs. 33.3%, 16.7%).
Additionally, breathlessness was more common among those with abnormal 6MWD than those presenting without this symptom (52.0% vs. 48.0%).
Females had higher odds of having abnormal 6 MWD compared to males (adjusted (aOR) = 6.99, 95% CI: 1.75–27.83, p = 0.006). Participants with fibrotic change were more likely to have abnormal 6 MWD compared to those without fibrotic changes (cOR: 0.36, 95% CI: 0.13–1.00, p = 0.050). Individuals experiencing breathlessness had higher odds of having abnormal 6 MWD compared to those without (aOR = 4.46, 95% CI: 1.22–17.51, p = 0.024).
Conclusions: The abnormal 6MWD among people with PTLD is common among those with low weight and significantly associated with breathlessness, low socioeconomical status and lung fibrosis. Disability related to TB remains a critical challenge and requires further research.

OA11-200-19 Patterns of pulmonary impairment before and after TB treatment

M. Marll,[1] S. El Sammak,[2] F. Willis,[3] A. Queiroz,[4] A. Rajaratnam,[3] N. Mofokeng,[5] L. Mngomezulu,[5] P. Maenetje,[5] G. Bisson,[6] S. Auld,[1] [1]Emory University, Department of Medicine, Atlanta, United States of America, [2]Emory University, School of Medicine, Atlanta, United States of America, [3]Emory University, School of Public Health, Atlanta, United States of America, [4]FIOTEC, Bioinformatics, Rio de Janeiro, Brazil, [5]The Aurum Institute, Tembisa CRS, Tembisa, South Africa, [6]University of Pennsylvania, Department of Medicine, Philadelphia, United States of America
e-mail: mmarll@emory.edu

Background: Despite growing awareness of the burden of post-TB lung disease (PTLD), our understanding of the natural history of TB-associated lung injury remains limited. In this study, we assess the prevalence and trajectories of pulmonary function patterns during and after TB treatment with comprehensive PFTs, including spirometry, lung volumes, and diffusion capacity of carbon monoxide (DLCO).
Design/Methods: In this ongoing prospective observational cohort study in Johannesburg, South Africa, adults with and without HIV were enrolled within two weeks of initiating treatment for a first episode of rifampin-suscep-

tible pulmonary TB. Participants completed chest x-ray (CXR) imaging and comprehensive PFTs including lung volumes and DLCO upon enrollment, with repeat PFTs at 6 months (TB treatment completion) and 12 months. PFT patterns were assigned according to ATS/ERS definitions. Agreement between PFT patterns across all timepoints was assessed using Cohen's kappa coefficient.

Results: Among 215 participants with baseline PFTs, most were male (70%), had a history of smoking (58%), and presented with moderate-to-severe disease on CXR (91%). At enrollment, 95 (44%) had normal PFTs, 62 (29%) had restriction, 27 (13%) had obstruction, and the remainder (31, 14%) had either a mixed or vascular pattern with an isolated reduction DLCO reduction. There were 85 participants with PFTs available at 12 months, of whom 47 (55%) had normal PFTs, 15 (18%) had restriction, and 14 (17%) had obstruction (Figure 1). There was moderate concordance across timepoints ($\kappa = 0.47$, $p < 0.001$ for baseline vs. 12 months, $\kappa = 0.60$, $p < 0.001$ for 6 vs. 12 months).

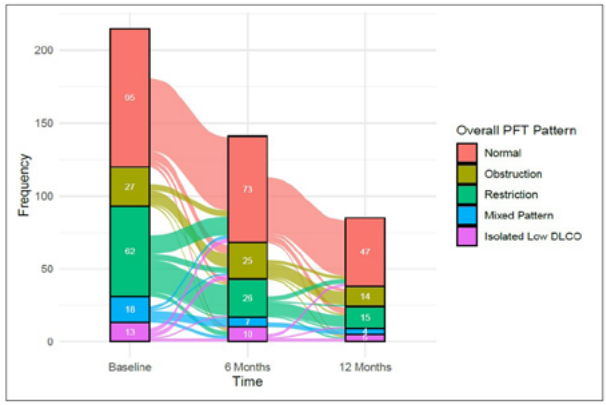


Figure 1. Sankey diagram of patterns of lung function at baseline (within 2 weeks of TB treatment initiation), 6 months (end of TB treatment), and 12 months after diagnosis. The flow of bands represents individual participant transitions between categories. Agreement between all timepoints was assessed using Cohen's kappa coefficient ($\kappa = 0.47$ for baseline vs. 6 months, $p<0.001$; $\kappa = 0.60$ for 6 vs. 12 months, $p<0.001$), indicating moderate concordance.

Conclusions: In individuals with newly diagnosed, moderate-to-severe pulmonary TB, a restrictive pattern of pulmonary function was the most common type of impairment. There was only moderate concordance between PFT patterns at TB diagnosis, treatment completion, and 6 months after treatment completion, suggesting significant heterogeneity in the natural history of TB-associated lung injury.

OA11-201-19 Trajectories of lung function in people with and without HIV during and after pulmonary TB treatment

M. Marll,[1] A. Rajaratnam,[2] F. Willis,[2] A. Queiroz,[3] T. Ngwanto,[4] P. Maenetje,[4] L. Jane Choene,[4] R. Ramaite Malemela,[4] R. Nkanyane,[4] G. Bisson,[5] S. Auld,[1] [1]Emory University, Department of Medicine, Atlanta, United States of America, [2]Emory University, School of Public Health, Atlanta, United States of America, [3]FIOTEC, Bioinformatics, Rio de Janeiro, Brazil, [4]The Aurum Institute, Tembisa CRS, Tembisa, South Africa, [5]University of Pennsylvania, Department of Medicine, Philadelphia, United States of America
e-mail: mmarll@emory.edu

Background: While up to half of tuberculosis (TB) survivors have impaired lung function after TB treatment, the impact of HIV coinfection on lung function recovery remains unclear. This study aims to determine whether trajectories of lung function during and after TB treatment differ according to HIV and antiretroviral therapy (ART) status.

Design/Methods: For this observational cohort study in Johannesburg, South Africa, adults with and without HIV were enrolled within two weeks of initiating TB treatment for rifampin-susceptible pulmonary TB. Participants newly diagnosed with HIV were initiated on ART within two months of starting TB treatment, as per national guidelines. All participants completed comprehensive pulmonary function testing (spirometry, lung volumes (data not shown), diffusion capacity for carbon monoxide [(DLCO])) at enrollment, 1-, 6-, and 12-months. Lung function over time was compared using a Kruskal-Wallis test.

Results: Among 231 participants, median age was 36 years (IQR 30-44), 70 (30%) were female, and 104 (45%) had HIV coinfection, of whom 60 (58%) were not on ART at enrollment. Participants without HIV had a lower forced expiratory volume in one second (FEV1) and forced vital capacity (FVC) at enrollment than those with HIV, and had steady improvements in FEV1 and FVC during and after TB treatment (Figure).

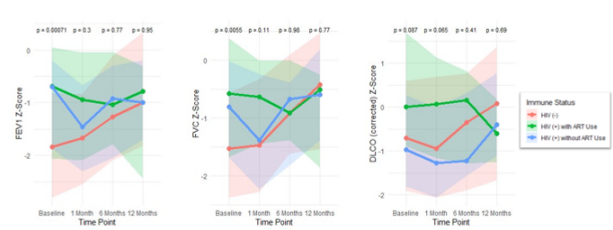

Figure 1. Line plots of median trajectories with shaded regions representing interquartile ranges for spirometry and diffusion capacity of the lung for carbon monoxide (DLCO) in participants with rifampin-susceptible pulmonary TB, with and without HIV and antiretroviral use at enrollment. Pulmonary function was assessed at the time of TB diagnosis and TB treatment initiation with repeat testing at 1-, 6-, and 12-month intervals. Between group comparisons were performed at each time point using Kruskal-Wallis testing. FEV1 = forced expiratory volume in one second, FVC = forced vital capacity, ART = antiretroviral therapy.

Participants with HIV had more variable trajectories, including early declines in FEV1 and FVC for those not on ART initially. DLCO at enrollment was lowest for those

with HIV not on ART and highest for those with HIV on ART. By 12 months, FEV1, FVC, and DLCO were similar irrespective of HIV and initial ART status.
Conclusions: We found differences in lung function at diagnosis and in trajectories of recovery during and after TB treatment by HIV and ART status. Future studies should explore whether this variability reflects differences in the pathophysiology of TB-associated lung damage with HIV coinfection.

OA11-202-19 Silent aftermath: Cardiovascular risks in post-TB survivors

M. Chopra,[1] A. Singh,[1] D. Walia,[1] [1]Post Graduate Institute of Medical Education and Research, Department of Community Medicine and School of Public Health, Chandigarh, India
e-mail: mrinalimachopra@gmail.com

Background: Tuberculosis (TB) continues to be a leading infectious killer worldwide, with 10.6 million cases and 1.3 million deaths reported in 2022, primarily impacting low- and middle-income countries. Emerging evidence suggests that individuals who have completed TB treatment are at heightened risk of cardiovascular diseases, including ischemic heart disease, myocardial infarction, and atherosclerotic conditions. This increased risk is driven by persistent systemic inflammation, coexisting comorbidities, and inadequate management of latent TB infection, underscoring the need for integrated long-term care for TB survivors.
Design/Methods: A systematic review was conducted following PRISMA guidelines to evaluate the association between TB and subsequent cardiovascular disease (CVD) risk. Comprehensive searches were performed in Web of Science (n=44), Scopus (n=104), and PubMed (n=10), yielding a total of 158 records.
After removing duplicates and screening titles, abstracts, and full texts, ten studies met the inclusion criteria and were included in the final synthesis. The review focused on adults (≥18 years) with a history of completed TB treatment as the population.
Results: The included studies found a consistent association between TB survivors and increased risk of cardiovascular diseases. Large cohort studies showed TB survivors had higher risks of acute myocardial infarction (up to aHR 1.96), stroke (aHR 1.22–1.47), and cardiovascular mortality (aHR 1.63). The risk was highest during the acute post-TB phase. Pulmonary hypertension (PH) was observed in 4–9% of post-TB individuals, with risk increasing with recurrent TB. TB-HIV co-infection may further exacerbate cardiovascular risk, underscoring the need for long-term cardiovascular monitoring in TB survivors.
Conclusions: TB survivors face significantly higher risk for long-term cardiovascular diseases, including myocardial infarction, stroke, and pulmonary hypertension. Routine cardiovascular screening and follow-up should be integrated into post-TB care, especially for individuals with recurrent TB or coexisting conditions such as HIV infection.

OA11-203-19 Breaking the silence: The power of TB survivor stories in reducing stigma and fear

U. Ekwugha,[1] E. Okoro,[1] Q. Ogbuji,[1] B. Nwaogu,[1] T. Adetiba,[2] O. Olupitan,[2] E. Ubochioma,[3] M. Zamzu,[4] J. Kimeu,[4] [1]Association For Reproductive and Family Health, TB/HIV, FCT, Nigeria, [2]Institute of Human Virology, Nigeria (IHVN), Global Fund N-THRIP, FCT, Nigeria, [3]National TB and Leprosy and Buruli Ulcer Control Programme Nigeria, Global Fund N-THRIP, FCT, Nigeria, [4]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Geneva, Switzerland, Grant Management Division, Geneva, Switzerland
e-mail: ekwugha.u@arfh-ng.org

Background: Tuberculosis (TB) remains a significant global health challenge, with stigma and fear creating substantial barriers to diagnosis, treatment, and social acceptance. Studies conducted in various settings have revealed that between 42% and 82% of TB patients experience stigma, making it one of the biggest obstacles to TB prevention and control. Misconceptions that TB is a death sentence or highly contagious have led to discrimination and social isolation of survivors, exacerbating their psychological burden. This study investigates how TB survivor stories can directly reduce stigma and fear, while promoting a more accurate understanding of TB and timely healthcare-seeking behavior.
Design/Methods: This qualitative study involved in-depth interviews with 12 TB survivors, selected through snowballing sampling method. Participants shared their experiences, challenges, and recovery journeys. Interviews were transcribed and thematically analyzed using NVivo version 15 to identify key themes such as resilience, community support, and the role of personal narratives in reshaping public perceptions of TB.
Results: The analysis identified several key themes:
1. Overcoming Isolation — Survivor stories highlighted the importance of social support in recovery, helping to break the social isolation that often comes with TB stigma;
2. Dispelling Myths — Firsthand accounts provided credible information that countered common misconceptions about TB, significantly reducing fear and stigma;
3. Empowerment and Advocacy — Sharing their personal stories enabled survivors to reclaim their dignity and advocate for TB awareness, thus promoting behavior change and supporting stigma reduction efforts.
These findings divulge how Survivor-led storytelling effectively reduces stigma, promotes early healthcare seeking, and serves as a community advocacy tool for TB control.

Conclusions: The findings demonstrate the transformative role of survivor storytelling in reducing stigma and changing public perceptions of TB. To maximize impact, TB programs should integrate survivor storytelling into public health campaigns, media advocacy, and community-based education efforts aimed at stigma reduction.

OA11-204-19 What's special about quality of life in TB: A qualitative appraisal of generic frameworks

N. Bedingfied,[1,2] K. Fiphaza,[3] M. Girma,[2] L. Majiza,[3,4] L. De Vos,[3] D. Oliver,[3] A. Kipp,[5] A. Medina-Marino,[3] A. Daftary,[2,6] [1]Research Institute of the McGill University Health Centre, Medicine, McGill, Canada, [2]York University, School of Global Health, Toronto, Canada, [3]University of Cape Town, The Desmond Tutu Health Foundation, East London, South Africa, [4]University of Pretoria, Health Sciences, Pretoria, South Africa, [5]East Carolina University, Department of Public Health, Brody School of Medicine, Greenville, United States of America, [6]University of KwaZulu-Natal, Centre for the AIDS Programme of Research in South Africa, Durban, South Africa
e-mail: nancy.bedingfield@ucalgary.ca

Background: Quality of life (QoL) is a complex construct focused on perceived wellbeing relative to culture, personal values and expectations and can be devastatingly low in tuberculosis (TB). Generic QoL framings may miss dimensions of wellbeing relevant to people with TB. We qualitatively appraised the applicability of two QoL frameworks to TB narratives collected in an endemic, peri-urban region of Eastern Cape, South Africa.
Design/Methods: From November 2023 to April 2024, private interviews were completed with thirty-three men and women (≥18 yrs) with pulmonary TB in diverse stages of treatment. Questions explored illness and treatment experiences, personal goals, and perspectives on various QoL domains. For the primary analysis, a coding framework based on the World Health Organization (WHO) QoL facets and Bury's process of biographical disruption in chronic illness was applied, adding novel codes as needed. For the secondary analysis, fit between theoretical frameworks and data was assessed by contrasting the original and the final coding framework, identifying gaps. An audit trail documenting coding framework changes, and analytical notes supported rigor.
Results:
Codes reflecting WHO facets in the physical, social, and independence domains were used frequently and highly relevant. However, codes related to social and emotional domains required adjustment to capture internalized, anticipated, and experienced stigma. Codes for nutrition and personal motivation were added. Participants strongly valued physical energy which was needed for work/employment, critical for advancing towards personal motivation.
The biographical disruption phases of increasing symptoms, seeking and disclosing diagnosis, mobilizing resources, and managing uncertainty were highly relevant. However, the individualized process did not adequately capture participants' interdependence with, and level of concern for family. (Figure 1)

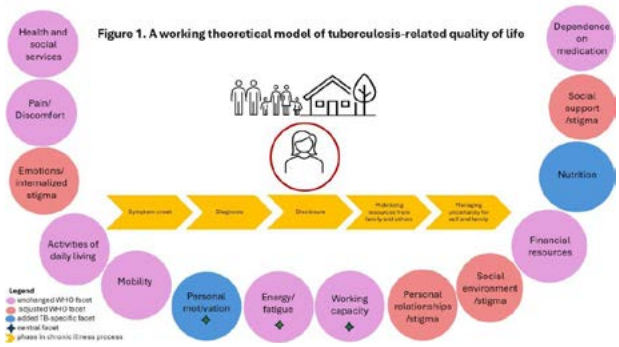

Figure 1.

Conclusions: WHO facets and biographical disruption are an appropriate but insufficient basis for a TB-QoL framework. Stigma, motivation, and family implications must be addressed to ensure QoL-enhancing interventions are meaningful for people experiencing TB.

OA11-205-19 Medium- and long-term post-TB sequelae burden and health-related quality of life in sub-Saharan Africa

G. Agbota,[1] B. Cuer,[1] S. Ouédraogo,[1] A. Fiogbé,[2] G. Agodokpèssi,[3] B.D. Diallo,[4] B. Bah,[4] E. Nuwagira,[5] D. Atwine,[6] B. Degano,[7] M. Bonnet,[1] [1]Université de Montpellier, TransVIHMI/IRD, Montpellier, France, [2]Programme national contre de la tuberculose Bénin, Département de recherche opérationnelle, Cotonou, Benin, [3]Centre National hospitalier et universitaire de pneumo-phtysiologie de Cotonou, Pneumologie, Cotonou, Benin, [4]Centre Hospitalier Ignace Deen de Conakry, Service of pulmonology, Conakry, Guinea, [5]Mbarara University of Science and Technology, Departement of internal medicine, Mbarara, Uganda, [6]Mbarara University of Science and Technology, Epicentre / MSF, Mbarara, Uganda, [7]Centre Hospitalier Université de Grenoble, Service of pulmonology, Grenoble, France
e-mail: gino.agbota@ird.fr

Background: There is still limited information on the mid-long-term burden of post-tuberculosis lung disease (PTLD) and its effect on health-related quality of life (HRQoL). The Post-TB SIQ study (ANRS405s), assessed the medium-long-term burden and HRQoL in sub-Saharan Africa.
Design/Methods: Former clinical trial adults (≥18years) in Benin, Guinea, Uganda were contacted 2-20 years after TB cure and invited for a comprehensive evaluation for PTLD. We conducted clinical assessment, spirometry,

six-minute walking test, chest X-ray, and administered the St George Respiratory Questionnaire (SGRQ) and the 36-item Short Form Health Survey (SF-36) for HRQoL assessment.

Characteristics	Categories	Total, n=600	Non-PTLD n = 339 (57%)	PTLD N = 261 (44%)	p-value
Age (years)#		43 (35, 52)	43 (35, 53)	43 (35, 52)	0.36
Male^		442 (75%)	187 (73%)	255 (76%)	0.36
Delay between end of TB treatment and assessment (years)	Median (IQR) (n=596)	11.1 (2.5, 11.6)	11.1 (2.5, 11.5)	11.1 (2.5, 11.6)	0.97
	> 10 years	309 (52%)	136 (53%)	173 (51%)

	>10 (poor HRQoL)	271 (45%)	99 (38%)	172 (51%)	0.02
	SF-36 score (n-597) Score from 0-100, the lower score indicates worse quality of life				
	Median (IQR)	70 (55, 77)	72 (57, 77)	67 (52, 77)	0.33
	< 62 (poor HRQoL)	352 (59%)	157 (61%)	195 (58%)	0.41

Table.

*#:Median(Interquartile range); ^:effective(proportion); *:in the last 2years; £:in the last 12months*

A chest high resolution computed tomography (CT) scan was done for participants with clinical suspicion of bronchiectasis. We used the consensus definition of PTLD (according to GLI 2022 standards): presence of pulmonary functional impairment on spirometry and/or the presence of symptomatic bronchiectasis. Characteristics between PTLD and non-PTLD were compared using Chi-squared, Wilcoxon rank sum or Fisher's exact tests depending of the variable.

Results: A total of 600 participants were included. The median delay between TB cure to evaluation were 11.1years, 204 (35%) participants were living with HIV and 72 (12%) presented a dyspnea scale ≥2. Of the 551 participants that underwent spirometry, the patterns were: 45% (250/551) normal, 21% (118/551) obstruction, 25% (138/551) restriction and 8% (45/551) mixed. Symptomatic bronchiectasis was diagnosed in 14% (84/598) participants.

The proportion of PTLD was 57% (339/600). PTLD patients were more likely to have lower BMI, recent history of hemoptysis, poorer exercise tolerance, higher proportion of cough and abnormal chest X-ray, and poor HRQol (Table). About 34% (116/339) with PTLD had FEV1< -2.5 zscore.

Conclusions: PTLD, 2-20 years after TB treatment is highly common in sub-Saharan Africa. A poor HRQoL in people with past-TB treatment history is more prominent among those with PTLD.

OA11-206-19 Post-treatment outcomes three years after a 9-month regimen for rifampicin-resistant TB in Vietnam

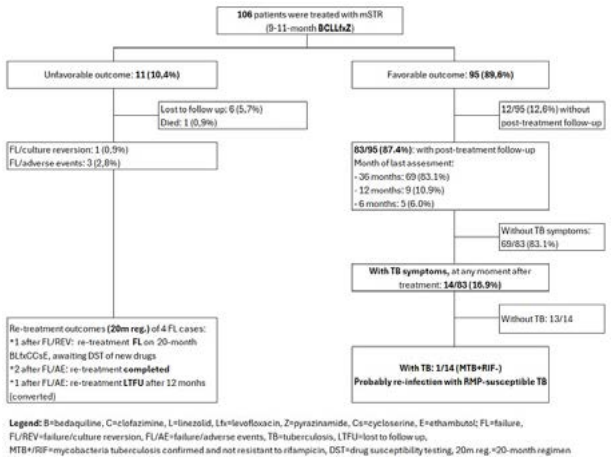
T.M.P. Nguyen,[1,2,3] T. Decroo,[2] B.H. Nguyen,[4] T.T.T. Hoang,[1] V.L. Dinh,[1] [1]National Lung Hospital, Network Steering Department, Hanoi, Viet Nam, [2]Institute of Tropical Medicine, Department of Clinical Sciences - Unit of HIV and Tuberculosis, Antwerp, Belgium, [3]Ghent University, Faculty of Medicine and Health Sciences, Ghent, Belgium, [4]National Lung Hospital, Research Center, Hanoi, Viet Nam
e-mail: phuongnguyen1186@gmail.com

Background: WHO recently recommended a 5-drug 9-11-month rifampicin-resistant tuberculosis (RR-TB) treatment regimen including bedaquiline, levofloxacin, linezolid, clofazimine and pyrazinamide (BCLLfxZ) based on results of endTB clinical trial. In Vietnam, between 2020-2021, 106 patients were enrolled on BCLLLfxZ. We aim to show outcomes 36 months after treatment completion.

Design/Methods: Prospective cohort study until 36 months post-treatment after BCLLfxZ regimen for RR-TB without confirmed fluoroquinolone resistance.

Results: Of 106 patients, 95 (89.6%) had treatment success. Of 95, 83 (87.4%) had post treatment follow-up information; of which 69 (83.1%), 9 (10.9%) and 5 (6%) were assessed until month 36, 12 and 6, respectively. Of 14 (17%) with TB symptoms during post-treatment, one had a reinfection with rifampicin-susceptible TB. None had recurrent RR-TB 36 months after BCLLfxZ. Of 11 with an unsuccessful outcome, four had stopped due to adverse

events and converted on longer regimens (2 completed, 1 lost to follow up). One with bacteriological failure on BCLLfxZ also experienced failure during retreatment.



Conclusions: The study result showed high and sustained treatment success rate of 9-11-month BCLLfxZ regimen from endTB trial. Given that 6-month regimen including new drug pretomanid is not yet available in many settings, BCLLfxZ is a robust alternative for fluoroquinolone-susceptible RR-TB treatment.

OA11-207-19 Pulmonary rehabilitation for post-TB lung disease in Kenya: A mixed-methods study of implementation context

N. Navuluri,[1,2] I. Amiri,[1] M. Omollo,[3] S. Bakari,[3] J. Omondi,[3] L. Diero,[3,4] H.E. Parnell,[2,5] L. Enane,[6,7] K. Wools-Kaloustian,[8] L.G. Que,[1] [1]Duke University School of Medicine, Division of Pulmonary and Critical Care, Department of Medicine, Durham, United States of America, [2]Duke University, Duke Global Health Institute, Durham, United States of America, [3]Academic Model Providing Access to Healthcare, N/A, Eldoret, Kenya, [4]Moi University School of Medicine, Medicine, Eldoret, Kenya, [5]Duke Cancer Institute, Behavioral Health and Survey Research Core, Durham, United States of America, [6]Indiana University, Thee Ryan White Center for Pediatric Infectious Disease and Global Health, Department of Pediatrics, Indianapolis, United States of America, [7]Indiana University Center for Global Health Equity, Indiana University Center for Global Health Equity, Indianapolis, United States of America, [8]Indiana University School of Medicine, Division of Infectious Disease, Department of Medicine, Indianapolis, United States of America
e-mail: nn12@duke.edu

Background: Pulmonary rehabilitation (PR) improves respiratory and functional symptoms in individuals with post-tuberculosis lung disease (PTLD) but is not widely available in high-tuberculosis (TB) burden countries, including Kenya. To understand contextual factors for implementing PR in Kenya, we assessed PR knowledge, attitudes, and practices among individuals treated for TB, healthcare workers (HCWs), and TB and healthcare leaders.

	Healthcare Worker (HCW) Survey (n= 200)	Individuals Treated for TB Interviews (n = 22)	Key Informant Interviews (n = 23)
Need:	• 90.5% of participants agree or strongly agree that enrolling patients with lung disease into a PR program is/would be beneficial. • 62.5% of HCWs felt that 50% or more of their patients with lung disease could benefit from a PR program.	• There is a strong need for establishing PR programs which involve specialists, doctors, and educators. • Greatest needs include breathing exercises, reducing stressful thoughts, exercise to promote a healthier lifestyle, advice to stop using cigarettes and alcohol, aerobic and stretching exercises, and strength training. • Flexibility in the cost, location (home vs hospital), and timing of the program was also considered very important, given that participation during work hours/days may act as a barrier.	• There is an urgent need for PR implementation for both children and adults, as many patients return to clinics without improvement and there is little to offer them. • Education directed to healthcare workers is needed about what PR is, why it is important, why multidisciplinary teams are needed, and which exercises improve lung function, symptoms, and mobility.
Capability	• 14% of respondents correctly identified the components of PR programs (aerobic exercise, strength and resistance training, tobacco cessation, dietary or nutritional counseling, inhaler technique counseling). • 27.5% selected an incorrect population for PR referral (i.e., chronic kidney disease or hypertension). • 30% disagreed or strongly disagreed with the statement that individuals with severe lung disease should participate in moderate-intensity activities.	• Most participants had never heard of PR. • Among those who had heard of PR, some confused it with spirometry or connected it with advice they had received about stopping tobacco use or alcohol. • A minority of participants were aware of PR, having heard about it from their physicians. They described blowing a balloon to help expand their lungs and going for walks.	• Most were aware of PR or at least the general concept of rehabilitation programs and could extrapolate that knowledge to PR. • There was a limited understanding of the details of what PR involves in terms of specific activities, location of service delivery, and patient populations, especially among clinical officers. • Consultant physicians were more knowledgeable about indications for PR and its components, but most of that knowledge came from reading about PR instead of seeing it first-hand.
Opportunity	• 36% of HCWs agreed or strongly agreed that PR is available and accessible for their patients. • The top 4 entities selected to take the initiative to start and/or expand PR programs were: 1. Kenyan Ministry of Health (77%) 2. National Referral Hospitals (74.5%) 3. County hospitals (71.5%) 4. County/sub-county clinics (61.5%)	• Once PR was explained, participants expressed a high level of trust in providers and were open to participating. • Believe PR could improve lung function, regain strength, enable them to return to work and improve their quality of life, and consider it an important and beneficial program. • Emphasize that education and exercise are key components that will significantly enhance their quality of life. • Barriers that would prevent participation include cost, transportation, limiting timing, and distance from their home to the hospital. Suggestions include offering sessions early in the morning, on specific days, or through online platforms to increase accessibility.	• There are currently no opportunities for enrolling individuals in a structured PR program, but if available they would be willing to do so. • Strategies that could facilitate implementation include providing local data to show PR can work in Kenya, establishing the infrastructure needed for PR, and collaborating with other sites where PR has already been implemented. • Determining how financing of the program and the cost to participants are key areas which could impact the opportunity to implement PR. • Resources are currently directed towards curative care, and sometimes prevention, and so participants felt they would need the Ministry of Health to help engage in PR implementation.
Motivation	• 88% of HCWs would refer patients with lung disease or respiratory symptoms to pulmonary rehabilitation.	• Personal motivation to regain health and return to normal daily activities drives desire to participate in PR. • Lack of knowledge about PR is discouraging. However, if available, clearly explained, and run and recommended by their doctors, participants would be motivated to join. They view medical advice as a strong motivator. • An assurance that their lungs would improve would be a motivating factor.	• Participants generally felt that PR was important to implement, would be beneficial to individuals with PTLD, and would be welcome. • Strong motivation to participate in education efforts to raise awareness of PR. • Physiotherapists and clinicians were motivated to start programs and receive training in PR.

Table 1: Joint Display of Survey and Interview Findings on CFIR Individuals Characteristics of Pulmonary Rehabilitation (PR) Implementation in Kenya

Design/Methods: We conducted a convergent parallel mixed-methods study in western Kenya between May and December 2024. This included a survey administered to HCWs via REDCap, semi-structured interviews with individuals treated for TB, and interviews with key informants (e.g. pulmonary physicians, TB care providers, hospital administrators, and national TB and health program leaders). Survey questions and interview guides

assessed PR implementation according to the Consolidated Framework for Implementation Research (CFIR). Descriptive summary statistics were calculated using SPSS. Interview transcripts were analyzed using rapid qualitative analysis, with a focus on the individual characteristics CFIR domain (e.g. need, capability, opportunity, and motivation).

Results: Of 340 HCWs contacted for the survey, 200 (55.5% female) responded, and we completed 45 interviews (22 individuals treated for TB; 23 key informants). Need and motivation for implementing PR was high across groups and in both survey and interview data (Table 1). However, the capability to implement PR is limited by poor awareness and knowledge about PR indications, components, and patient eligibility. For example, only 14% of HCWs correctly identified core components of PR and 27.5% selected an incorrect population for PR referral. Finally, several opportunities for PR implementation were identified, including high motivation among participants, trust in TB providers, close collaboration with the Ministry of Health, and piloting implementation.

Conclusions: To meet the high demand and motivation for implementing PR in Kenya, focused education and training for HCWs and raising awareness among individuals with TB will be essential.

OA11-208-19 Sustained effects of community-based pulmonary rehabilitation (PR) for adults with post-TB lung disease in Malawi

B. Matewere,[1] V. Alvarez-Manon,[2] M. Drage,[2] B. Stenberg,[2] D. Zenengeya,[1] [1]Paradiso Patient Trust, N/A, Lilongwe, Malawi, [2]LHL International Tuberculosis Foundation, N/A, Oslo, Norway
e-mail: brucematewere@paradisomw.org

Background and challenges to implementation: Follow-up and management of TB survivors has been ignored despite estimations of up to 2/3 of survivors presenting respiratory impairments after treatment. In Malawi, no protocols or guidelines existed for follow-up of TB survivors, and no PR program. The project thus implemented pioneer work aimed at demonstrating by proof of concept the feasibility and effectiveness of a low-cost PR by supporting TB survivors struggling with poor lung health, implementing a culturally appropriate, low-cost, community-based PR, measuring its sustained effect on health and wellbeing.

Intervention or response: We designed and implemented a community-based PR in nine districts in Malawi for 467 TB survivors with pulmonary complaints. Directly observed exercise sessions were done in groups of 16-25 people twice a week for 12 weeks. Data on 13 health variables was collected before and after the PR. A subset of 110 participants were followed up one year post PR and assessed again using the same data collection tools, enabling us to compare data on 13 variables at three stages: Baseline, endline and one year later. In-depth interviews were conducted with 7 of the 110.

Results/Impact: 110 TB survivors aged 20-80 were assessed. Preliminary data analysis shows that health gains from the PR were sustained one year after endline. Interestingly, the 6 Minute Walk test showed that endurance and functional capacity actually had increased, from a baseline mean of 397,6 meters, to 475,7 at endline and 480 one year after.

Also, symptoms such as cough continued to reduce with 56,4% experiencing cough at baseline, 9,1% at endline (12 weeks) and only 6,4% one year after.

Conclusions: The program had a significant positive effect on health and well-being, also one year after the PR, and it is now integrated in Malawi's National TB strategy. The benefits of such programs are immense, and we encourage other NTPs to follow.

OA12 Navigating TB therapy: Side effects, adverse events and tolerability

OA12-209-19 QT interval prolongation in children taking moxifloxacin and clofazimine for rifampicin-resistant TB treatment in South Africa, India and the Philippines

Y. Zou,[1] M. Palmer,[2] H.R. Draper,[2] J. Nielsen,[3] M.V.G. Frias,[4] A.A. Kinikar,[5] I. Courtney,[2] A.J. Garcia-Prats,[2,6] A.C. Hesseling,[2] M.O. Karlsson,[1] E.M. Svensson,[1,7] [1]Uppsala University, Department of Pharmacy, Uppsala, Sweden, [2]Stellenbosch University, Department of Paediatrics and Child Health, Desmond Tutu TB Centre, Cape Town, South Africa, [3]Hassenfeld Children's Hospital at NYU Langone, Department of Pediatrics, Pediatric Cardiology, New York, United States of America, [4]De La Salle Medical and Health Sciences Institute, De La Salle Medical and Health Sciences Institute, Dasmarinas, Philippines, [5]B.J. Government Medical College, B.J. Government Medical College, Pune, India, [6]University of Wisconsin-Madison, Department of Pediatrics, Madison, United States of America, [7]Radboud University Medical Center, Department of Pharmacy, Pharmacology and Toxicology, Nijmegen, Netherlands
e-mail: yuanxi.zou@uu.se

Background: Clofazimine (CFZ) and moxifloxacin (MFX) are commonly used for the treatment of rifampicin-resistant tuberculosis (RR-TB). Both drugs prolong QT interval. We aimed to characterise the associations between their pharmacokinetics (PK) and the Fridericia-corrected QT interval (QTcF) in children treated for RR-TB.
Design/Methods: CATALYST was a multisite open-label trial evaluating the PK, safety and acceptability of MFX and CFZ in children <15 years treated for RR-TB. At study entry, participants had received MFX and CFZ for <16 weeks as part of routine optimized RR-TB regimens, with no restriction on concurrent bedaquiline (BDQ) or delamanid (DLM). Electrocardiograms with time-matched PK samples were collected at enrolment, and 16, 20, and 24 weeks on study. QTcF were analysed using nonlinear-mixed-effect modelling.
Results: Thirty-six children were enrolled [median 4.8 years old (range 0.4-15), 15.6 kg (range 6.9-42)]. Of these, 15 also received BDQ and 9 received DLM. Based on the final PK-QTcF model, the QTcF baseline, referring to 15-year-olds at RR-TB treatment start, was estimated at 416ms. QTcF in 5-month-old (0.4-year-old) children were typically 42ms lower than in 15-year-olds, reaching 50% difference by 4.9 years old. QTcF increased up to 7.1ms from baseline over time on treatment, reaching half-maximal effect at 7.5 weeks.
Drug effect for QTcF prolongation was modelled jointly for CFZ, MFX, and metabolites of BDQ and DLM, using a competitive antagonist model with effects of metabolites of extrapolated from adult studies. As shown in Figure 1, based on simulations using the final model, MFX primarily contributed to QT prolongation 2h post-dose at its peak concentration. CFZ and metabolites of BDQ/DLM drove prolonged QTcF effects over time, given their accumulative PK exposures (terminal half-lives range 1-5 months).

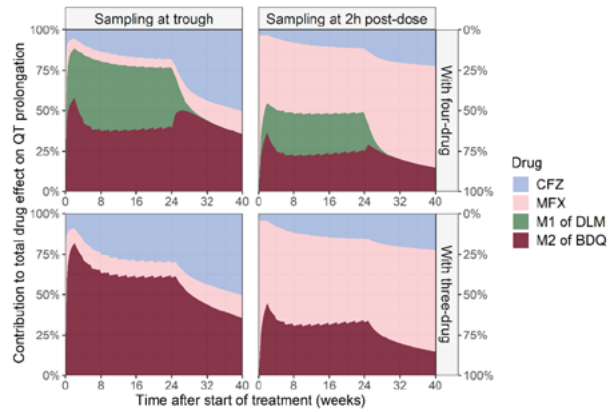


Figure 1: Model-predicted percentage contribution of TB drugs to total drug effect on QT prolongation with time after start of treatment. Four-drug and three-drug combinations of prioritised options for individualisation are visualised, including CFZ for clofazimine, MFX for moxifloxacin, M2 of BDQ for metabolite M2 of bedaquiline, and M1 of DLM for metabolite M1 of delamanid. The percentage contribution was illustrated for trough samples or 2h post-dose. The reference child is 16 kg in weight, 101 cm in height, 4.8 years old, female, non-black, albumin level of 4.45 g/dL, receiving CFZ 50 mg and MFX 300 mg daily for 40 weeks, BDQ 200 mg for 14-day loading phase and 100 mg Mon/Wed/Fri for 22-week maintenance phase, or additionally DLM 50 mg morning and 25 mg evening daily for 24 weeks.

Conclusions: Younger children had lower QTcF before and during RR-TB treatment. CFZ and metabolites of BDQ/DLM drove long-term QTcF prolongation, while MFX was the primary contributor at 2h post-dose.

OA12-210-19 Linezolid interruption and rechallenge, and their effect on clinical outcomes, in people with rifampicin-resistant TB: Appraisal of South African programmatic data from 2018 to 2022

S. Oelofse,[1,2] A. Esmail,[1,2] T. Perumal,[1,2] J. Swanepoel,[1,2] S. Meier,[1,2] L. Mbuthini,[1,2] S. Jaumdally,[1,2] A.J. Scott,[1,2] L. Kühn,[1,2] A. Pooran,[1,2] N. Ndjeka,[3] K. Dheda,[1,2,4] [1]University of Cape Town Lung institute, Centre for Lung Infection and Immunity, Cape Town, South Africa, [2]South African Medical Research Council, Centre for the Study of Antimicrobial Resistance, Cape Town, South Africa, [3]South African Department of Health, National TB Control & Management, Pretoria, South Africa, [4]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, Department of Infection Biology, London, South Africa
e-mail: suzette.oelofse@uct.ac.za

Background: Linezolid is a key component of treatment regimens for rifampicin-resistant/ multidrug-resistant tuberculosis (RR-/MDR-TB). Toxicity-related linezolid interruption is not uncommon, but little is known about its impact on treatment-related outcomes.
Furthermore, there are no data about the frequency of successful rechallenge and its associated predictors.

Design/Methods: We evaluated South African RR-/MDR-TB programmatic data from 2018-2022 using a national drug-resistant TB database. The frequency of linezolid interruption and rechallenge was evaluated. Odds ratios (ORs) for unfavourable outcome and rechallenge success were estimated using logistic regression.

Results: 83·7% of patients who received linezolid (10102/12064) met the study inclusion criteria and were included in the final analysis. 19·5% (1974/10102) interrupted LZD; the median time to interruption was 4·6 weeks.

After adjusting for age, HIV status, previous TB and smear status, linezolid-interrupters had 4·24 times greater odds of an unfavourable outcome compared to non-interrupters (95%CI 3·79–4·75; *p<0.001*). Only 3·3% (65/1974) of linezolid-interrupters were rechallenged with linezolid. Of those rechallenged, 72·3% (47/65) successfully completed their linezolid course.

Those successfully rechallenged had 4·03 times greater adjusted odds of favourable outcome compared to rechallenge failures (95%CI 1·03-11·70; *p=0·04*). A shorter time to initial linezolid interruption was associated with greater unsuccessful rechallenge and higher likelihood of unfavourable outcome (*p<0·001*).

Conclusions: Linezolid interruption was common and associated with unfavourable clinical outcomes. Linezolid rechallenge was frequently successful and associated with better clinical outcomes.

These findings inform clinical practice and have implications for management of patients receiving oral short course regimens for MDR-TB.

OA12-211-19 QTcF prolongation associated with bedaquiline-delamanid-linezolid regimens containing levofloxacin or moxifloxacin: A multicentre retrospective cohort study in rifampicin-resistant TB

L. Fu,[1] R. Liu,[2] J. Sun,[3] M. Zhao,[4] G. Deng,[5] [1]Southern University of Science and Technology/Shenzhen Third People's Hospital, Pulmonary Disease Department, Shenzhen, China, [2]Capital Medical University Beijing Tuberculosis & Thoracic Tumor Research Institute/Beijing Chest Hospital, Research Ward/Department of Tuberculosis, Beijing, China, [3]Changchun Fourth Hospital / Changchun Infectious Disease Hospital, Drug-Resistant Tuberculosis Department, Changchun, China, [4]Shenzhen University/Medical School, Medical School, Shenzhen, China, [5]Southern University of Science and Technology/Shenzhen Third People's Hospital, Pulmonary Diseases Department, Shenzhen, China
e-mail: flk1981@qq.com

Background: The 6-month all-oral regimen combining bedaquiline, delamanid, and linezolid (BDL) with levofloxacin (Lfx) or moxifloxacin (Mfx) is increasingly used for rifampicin-resistant tuberculosis (RR-TB) in China. Given the QT-prolonging potential of fluoroquinolones, the comparative cardiac safety of Lfx versus Mfx in BDL regimens warrants evaluation.

Design/Methods: We conducted a multicenter retrospective cohort study involving RR-TB patients treated at three designated tuberculosis hospitals in Shenzhen, Beijing, and Changchun between December 2022 and December 2024. Patients were grouped into BDL, BDLL (containing Lfx), and BDLM (containing Mfx) regimens. Clinical data and electrocardiograms were collected. QT intervals were corrected using Fridericia's formula (QTcF). QTcF ≥500 ms or an increase ≥50 ms from baseline was defined as clinically significant prolongation.

Results: A total of 150 patients were included: 66 in the BDL group, 10 in BDLL, and 74 in BDLM. No baseline differences in QTcF were observed (P=0.509). Clinically significant QTcF prolongation occurred in 16.1%, 0%, and 4.1% of patients, respectively, within the first 4 weeks, with similar proportions during the entire treatment course. No statistically significant difference was found among groups. Regimen adjustments due to QTcF prolongation or drug intolerance occurred in 14 patients (9.3%), mostly requiring discontinuation of Mfx/Lfx while retaining the BDL core. No torsades de pointes (TdP) was observed. Multivariate analysis indicated that QTcF prolongation was associated with metabolic disease, electrolyte imbalance, cardiac disorders, and autonomic dysfunction; Lfx and Mfx were not independent risk factors.

Characteristics	ALL (N=150)	BDL (N=66)	BDLL (N=10)	BDLM (N=74)	P-value
Baseline QTc (ms)	445.87±43.36	446.98±44.62	430.40±53.67	446.99±40.93	0.509
QTc prolongation after baseline					0.085
Regular range	13(9.6%)	3(5.1%)	1(14.3%)	9(13%)	
Non-severe prolongation	80(59.3%)	39(66.1%)	6(85.7%)	35(50.7%)	
Severe prolongation	42(31.1%)	17(28.8%)	0	25(36.2%)	

Conclusions: Addition of Lfx or Mfx to the BDL regimen did not significantly increase the risk of QTcF prolongation or severe arrhythmias. A slightly better profile was observed for Lfx, though the sample size was small. QTcF prolongation was mainly associated with underlying comorbidities, underscoring the importance of risk stratification and ECG monitoring in vulnerable populations. Further studies are warranted to clarify cardiac safety differences among regimens.

OA12-212-19 Optimising tigecycline administration based on blood concentration monitoring in people with TB and NTM infections

R. Zheng,[1] K. Xu,[2] F. Pan,[3] G. Zhang,[1] X. Cai,[4]
[1]Zhejiang Integrated Hospital of Traditional Chinese and Western Medicine, Department of Pharmacy, Hangzhou, China, [2]Zhejiang Integrated Hospital of Traditional Chinese and Western Medicine, Thoracic surgery, Hangzhou, China, [3]Zhejiang Integrated Hospital of Traditional Chinese and Western Medicine, Gastroenterology, Hangzhou, China, [4]Zhejiang Integrated Hospital of Traditional Chinese and Western Medicine,, Department of Pharmacy, Hangzhou, China
e-mail: zjtcmcxj@zcmu.edu.cn

Background: Tigecycline (TGC), a glycylcycline antibiotic, shows promise in treating non-tuberculous mycobacterial (NTM) infections. However, its pharmacokinetics (PK) in patients with concurrent tuberculosis (TB) and NTM infections, particularly alongside P-glycoprotein (P-gp) inducers like rifampicin, remains unclear.
Design/Methods: A prospective cohort study enrolled 32 critically ill TB/NTM patients receiving TGC. Plasma concentrations were quantified via validated LC-MS/MS. A population PK (PPK) model was developed using nonlinear mixed-effects modeling, with evaluations including bootstrap analysis and visual predictive checks.
Results: Method validation demonstrated acceptable accuracy (85.0–115.0%) and precision (intra-day and inter-day relative standard deviation <15.0%) for TGC quantification. The cohort comprised 32 critically ill patients, yielding 224 analyzable blood samples.
PPK analysis identified a two-compartment model as optimal for characterizing TGC pharmacokinetics. Population estimates for key parameters were as follows: apparent clearance (CL/F) = 3.15 L/h; central compartment apparent volume of distribution (Vc/F) = 51.5 L.
Covariate analysis revealed body weight as the sole significant predictor of TGC PK variability ($p<0.05$), whereas age, hepatic function, and renal biomarkers showed no statistically significant influence.
Notably, concomitant administration with the P-gp inducer rifampicin exhibited no clinically relevant impact on TGC exposure parameters (AUC0–24 and Cmax; $p>0.05$).
Conclusions: This investigation successfully developed a PPK model for TGC in critically ill patients with TB/NTM co-infections. The findings underscore body weight as the primary covariate influencing TGC disposition, while concomitant P-gp inducer therapy did not significantly alter its PK profile. These insights support the rationale for weight-adjusted dosing regimens to optimize therapeutic efficacy in complex infections.
Nevertheless, external validation through multicenter studies with expanded sample sizes is warranted to enhance the generalizability of these conclusions.

OA12-213-19 Hepatotoxicity rates and risk factors within the endTB regimens approved for multidrug-resistant TB

C. Sepulcri,[1,2] A. Abubakirov,[3] S. Ausim,[4] D. Dulani,[5] M. Gouillou,[6] L. Guglielmetti,[7,8] M. Kunda,[9] N. Lachenal,[10] C.D. Mitnick,[11,12] I. Motta,[13] S. Mucching Toscano,[14] A. Stambekova,[3] endTB Clinical Trial Team, Hepatotoxicity working group [1]University of Genova, Division of Infectious Diseases, Department of Health Sciences (DISSAL), Genova, Italy, [2]San Raffaele Scientific Institute, Emerging Bacterial Pathogens Unit WHO collaborating Centre and TB Supranational Reference Laboratory, Milan, Italy, [3]Partners in Health, Partners in Health Kazakhstan, Almaty, Kazakhstan, [4]Research and Develpoment, Research and Develpoment Pakistan, Islamabad, Pakistan, [5]Médecins Sans Frontières, Médecins Sans Frontières India, Mumbai, India, [6]Epicentre, Epicentre research department, Paris, France, [7]Médecins Sans Frontières, Médecins Sans Frontières Paris, Paris, France, [8]Sorbonne Université, INSERM Unité 1135, Centre d'Immunologie et des Maladies Infectieuses, Paris, France, [9]Partners in Health, Partners in Health Lesotho, Maseru, Lesotho, [10]Médecins Sans Frontières, Médecins Sans Frontières Genève, Genève, Switzerland, [11]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States of America, [12]Partners In Health, Partners In Health Boston, Boston, United States of America, [13]University College London, MRC Clinical Trials Unit at, London, United Kingdom of Great Britain and Northern Ireland, [14]Socios En Salud, Sucursal Peru, Lima, Peru
e-mail: chiara.sepulcri@gmail.com

Background: Hepatotoxicity is a frequent adverse event of tuberculosis treatment and often leads to treatment interruptions and poor outcomes. We describe hepatotoxicity rates and associated risk factors within the three 9-month regimens recently endorsed as treatment options for rifampicin-resistant/multidrug-resistant tuberculosis (RR-TB/MDR-TB), consisting of combinations of bedaquiline (B), delamanid (D), linezolid (L), levofloxacin (Lfx) or moxifloxacin (M), clofazimine (C), pyrazinamide (Z) (endTB trial,ClinicalTrials.gov NCT02754765).
Design/Methods: We included participants of the safety population receiving 9BLMZ, 9BCLLfxZ, 9BDLLfxZ, and control standard-of-care. Hepatotoxicity was graded using the MSF Severity Scale. Investigators were encouraged to modify/withhold study drugs potentially related to ≥grade 3 adverse events. Cox regression was used to identify variables associated with ≥grade 3 drug-related hepatotoxicity and time to hepatotoxicity development was assessed.
Results: The rate of participants with drug-related hepatotoxicity ranged from 44.1% to 68.2%. Grade 3 or higher hepatotoxicity was reported in 5.5% to 16.7% participants in the experimental arms and in 6.3% in the control arm. Median time (weeks) from treatment initiation to the first ≥grade 3 event was 8 to 9.57 in the experimental arms and

11.5 in the control arm. Among participants experiencing a ≥grade 3 event who could not tolerate their full regimen, pyrazinamide was the study drug more frequently permanently discontinued (0.8%-5.6%), followed by bedaquiline and linezolid (0.8%-1.6%). Most participants recovered without complications; no deaths were related to hepatotoxicity (table).

After adjusting for age, region, baseline hepatitis status and baseline liver enzymes levels, being treated with 9BLMZ was the only variable associated with ≥grade 3 hepatotoxicity [adjusted Hazard Ratio 2.66 (95% CI 1.18; 6.04) p=0.019].

	Control n=126	9BLMZ n=126	9BCLLfxZ n=122	9BDLLfxZ n=127
	Hepatotoxicity events (all grades)			
Participants with ≥1 related event (n,%)	59 (46.8)	86 (68.2)	64 (62.5)	56 (44.1)
	Hepatotoxicity events (≥ grade 3)			
Participants with ≥1 related event (n,%)	8 (6.3)	21 (16.7)	12 (9.8)	7 (5.5)
Incidence/100 person-weeks (95% Confidence Interval)	0.08 (0.04-0.16)	0.22 (0.14-0.34)	0.12 (0.07-0.21)	0.06 (0.03-0.14)
Median time to 1st event weeks [Interquartile Range]	11.57 [4.93-44.93]	8.00 [4.00-19.86]	9.57 [4.79-18.71]	8.00 [3.86-8.14]
Death due to hepatotoxicity (n,%)	0	0	0	0
Participants with resolved ≥grade 3 events (n,%)	7 (5.6)	19 (15.1)	10 (8.2)	6 (4.7)
Permanent drug discontinuation due to hepatotoxicity (n,%)				
Bedaquiline	2 (1.6)	1 (0.8)	2 (1.6)	1 (0.8)
Clofazimine	1 (0.8)	0	2 (1.6)	0
Delamanid	0	0	0	1 (0.8)
Levofloxacin/Moxifloxacin	1 (0.8)	0	2 (1.6)	1 (0.8)
Linezolid	1 (0.8)	1 (0.8)	2 (1.6)	1 (0.8)
Pyrazinamide	1 (0.8)	7 (5.6%)	3 (2.5%)	2 (1.6)

Conclusions: Hepatotoxicity was common within the endTB trial, with significant differences among experimental regimens. Being treated with 9BLMZ was significantly associated with the development of ≥grade 3 drug-related hepatotoxicity. These findings should be considered to tailor the choice of the optimal regimen for MDR/RR-TB.

OA12-214-19 Incidence and risk factors of anti-TB drug induced liver injury: A multicentre retrospective study involving 482 Chinese paediatric TB patients

F. Wang,[1] Y. Zhou,[2] H. Xu,[3] Q. Cai,[4] H. Li,[5] M. Tian,[6] X. Zeng,[7] P. Liu,[8] T. Yang,[9] J. Jiang,[1] B. Chen,[1] L. Huang,[10] [1]Zhejiang Provincial Center for Disease Control and Prevention, Department of Tuberculosis Control and Prevention, Hangzhou, China, [2]Hangzhou Medical College, School of Public Health, Hangzhou, China, [3]Chongqing Medical University Affiliated Children's Hospital, Division of Infectious Diseases, Chongqing, China, [4]Hangzhou Red Cross Hospital, Department of Tuberculosis, Hangzhou, China, [5]The Second Affiliated Hospital and Yuying Children's Hospital of Wenzhou Medical University, Department of Pediatric Pulmonology, Wenzhou, China, [6]Children's Hospital of Nanjing Medical University, Department of Respiratory Medicine, Nanjing, China, [7]Hainan Women and Children's Medical Center, Department of Infectious Diseases, Haikou, China, [8]Shanghai Public Health Clinical Center, Department of Tuberculosis, Shanghai, China, [9]Zhejiang Sukean Pharmaceutical CO.LTD, Department of Tuberculosis, Hangzhou, China, [10]The Children's Hospital, Zhejiang University School of Medicine, National Clinical Research Center for Child Health, Department of Infectious Diseases, Hangzhou, China
e-mail: 2909406946@qq.com

Background: Anti-tuberculosis drug induced liver injury (ATDILI) is one of the most common and severe adverse reactions during the tuberculosis (TB) treatment. This study aims to investigate the incidence of ATDILI among children with TB and its related risk factors.

Design/Methods: A national multi-center retrospective study was employed to collect data from 11 representative children's specialist or general hospital for TB treatment. Outcomes of interest was the occurrence of ATDILI, and multivariable logistic regression analysis was performed to assess the impact factors associated with the occurrence of ATDILI based on different definitions in children with TB.

Results: Among 482 patients included in the study, based on different definitions, 18 patients (3.73%) and 51 (10.58%) experienced ATDILI, respectively. Among these patients, 11 out of 18 (61.11%) and 38 out of 51 (74.51%) were classified as having mild ATDIL. And the occurrence time was 0.70 (IQR: 0.23-1.23) months and 1.00 (IQR: 0.30-3.10) months after anti-TB treatment, respectively. The multivariate analysis results showed that based on definition 1, patients who using second line drug (s) in the intensive phase were more likely to experience ATDILI (OR =3.88, 95% CI: 1.40 ~ 10.76, P = 0.009). And for definition 2, patients with severe TB and using second line drug (s) regimen were more likely to develop ATDILI (OR = 2.18, 95%CI: 1.05 ~ 4.54, P = 0.037 for severity of TB; OR =2.76, 95% CI: 1.37 ~ 5.56, P = 0.005 for treatment).

Conclusions: In our study, there were differences in the incidence of ATDILI based on different definitions, but in general, mild ATDILI was dominant. Comprehensive

consideration of laboratory indicators and clinical practice, early identification and detection of ATDILI in children during anti-TB treatment, and timely intervention measures can effectively prevent and control the harm caused by ATDILI.

OA12-215-19 Hepatoprotective role of N-acetylcysteine in anti-TB drug-induced hepatotoxicity: A meta-analysis of controlled clinical studies

G. Aliska,[1,2,3] J.E. Marzuki,[4,5] R. Russilawati,[6,7]
[1]Universitas Andalas, Pharmacology and Therapeutics, Padang, Indonesia, [2]Dr M Djamil General Hospital, Clinical Pharmacology, Padang, Indonesia, [3]Universitas Andalas, Centre for Diagnostic and Research on Infectious Disease (PDRPI), Padang, Indonesia, [4]Universitas Surabaya, Pharmacology, Surabaya, Indonesia, [5]Ubaya Hospital, Clinical Pharmacology, Surabaya, Indonesia, [6]Universitas Andalas, Departement of Pulmonology and Respiratory Medicine, Padang, Indonesia, [7]Dr M Djamil General Hospital, Departement of Pulmonology and Respiratory Medicine, Padang, Indonesia
e-mail: aliska@med.unand.ac.id

Background: Anti-tuberculosis drug-induced hepatotoxicity (ATDH) is a significant complication that may compromise the efficacy of tuberculosis (TB) therapy. N-acetylcysteine (NAC), a glutathione precursor, has shown potential hepatoprotective effects in various clinical settings. This meta-analysis aimed to evaluate the efficacy and safety of NAC in preventing or reducing ATDH.
Design/Methods: A systematic search was conducted across five databases—PubMed, ScienceDirect, Cochrane Library, Web of Science, and Google Scholar—from inception to March 2025. Eligible studies included randomized or controlled trials comparing NAC with placebo or standard care in TB patients, reporting incidence of hepatotoxicity as a clinical outcome. Of the six included studies (n = 834), three were peer-reviewed full articles, and three were published conference abstracts. Data were pooled using a random-effects model, and risk of bias was assessed using Cochrane's Risk of Bias tool.
Results: The pooled analysis demonstrated a significant reduction in hepatotoxicity risk in the NAC group, with a pooled risk ratio (RR) of 0.32 (95% CI: 0.14–0.73). This indicates a 68% relative reduction in ATDH risk. Among the included studies, four reported significant improvements in liver biochemistry, including reductions in alanine aminotransferase (ALT), aspartate aminotransferase (AST), and bilirubin levels. NAC was generally well-tolerated, with no serious adverse events attributed to its use. Risk of bias across studies was moderate, with most concerns related to blinding and allocation concealment.
Conclusions: NAC significantly lowered the risk of ATDH and improved liver biochemical profiles in patients undergoing anti-TB therapy. Given its safety, affordability, and ease of administration, NAC may be considered an adjunctive protective agent, particularly in high-risk populations.
Further well-designed, large-scale, randomized controlled trials are warranted to confirm these findings and optimize clinical implementation.

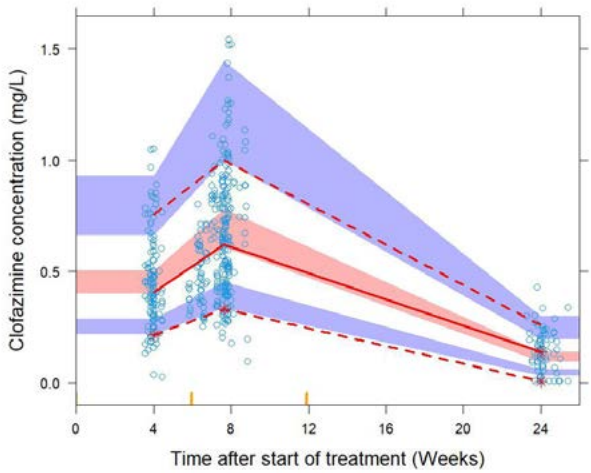
OA12-216-19 Clofazimine pharmacokinetics in shorter treatment regimens for drug-sensitive TB

A. Kengo,[1] C. Cousins,[2] E. Challenger,[3] R. Ruslami,[4] M.M. Golla,[5] A. Avihingsanon,[6] N. Kai Ng,[7] R. Aarnoutse,[8] S. Khoo,[9] C. Sekaggya-Wiltshire,[1] N. I. Paton,[10] E. M. Svensson,[11] [1]Infectious Diseases Institute, Makerere University, Research, Kampala, Uganda, [2]City St George's, University of London, Infection and Immunity, London, United Kingdom of Great Britain and Northern Ireland, [3]University of Liverpool, Clinical Pharmacology and Therapeutics, Liverpool, United Kingdom of Great Britain and Northern Ireland, [4]Universitas Padjadjaran, Clinical Pharmacology, Bandung, Indonesia, [5]De La Salle Medical and Health Sciences Institute, Research Services, Tuberculosis Research Laboratory (TRL), City of Dasmarina, Philippines, [6]Chulalongkorn University, Medicine, Bangkok, Thailand, [7]Infectious Diseases Translational Research Programme and Yong Loo Lin School of Medicine, National University of Singapore, Medicine, Singapore, Singapore, [8]Radboud University Medical Center, Department of Pharmacy, Nijmegen, Netherlands, [9]University of Liverpool, Department of Pharmacology and Therapeutics, Liverpool, United Kingdom of Great Britain and Northern Ireland, [10]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, United Kingdom of Great Britain and Northern Ireland, [11]Uppsala University, Department of Pharmacy, Uppsala, Sweden
e-mail: akengo@idi.co.ug

Background: Clofazimine (CFZ), recommended for treatment of drug-resistant tuberculosis, has extensive tissue distribution and long elimination half-life, with potential for post-treatment efficacy. Pharmacokinetics (PK) of CFZ used in ultra-short treatment regimens has not been described.
Design/Methods: We evaluated PK of CFZ (200mg, higher than conventional dose) administered with high-dose rifampicin (35mg/kg) and standard-dose isoniazid, pyrazinamide, ethambutol as a daily 8-week regimen in the TRUNCATE-TB (NCT03474198) trial. Blood sampling for sparse PK was done in all participants at weeks 4 (pre-dose and 2h post-dose), 8 (pre-dose and 4h), and 24 (anytime); and for intensive PK in a subset of participants at weeks 4 and 8 (pre-dose, 1, 2, 3, 4, 5, 6, 8 and 12h). Drug assay used liquid chromatography-mass spectrometry.
A previously-published, 3-compartment PK model (Abdelwahab et al, JAC, 2020), was used for analysis and to evaluate attainment of a putative efficacy threshold of 0.25mg/L (Swasnson et al, AAC, 2016).

Results: 490 (67% sparse) samples were available from 77 participants (18 with intensive PK) from Indonesia (48%), Philippines (42%) and Thailand (10%); 61% were male; median (IQR) weight 50 kg (44-58) and age 29 yr (24-41). With all other parameters fixed and allometric scaling by weight, we estimated CFZ clearance and terminal half-life of 7.46 L/h and ~50 days, respectively. The day 56 (Week 8) area under the curve (AUC_{0-24}, IQR) was 16.0 mg·h/L (11.1-20.6). CFZ levels were above the efficacy target in 84% at week 4, 100% at week 8 and 8% at week 24 (Figure 1).

Among participants who received greater than 42 doses, CFZ concentrations remained above the target for a median of 8.40 weeks (IQR: 3.80-11.6) following the last dose.



Conclusions: CFZ clearance was lower and elimination half-life longer than previously-published estimates. Concentrations likely persist at potentially-efficacious levels for a prolonged period after completion of an 8-week treatment regimen.

OA12-217-19 Adequacy of recommendations for adverse event management in national and international treatment guidelines for rifampicin-susceptible TB: A systematic review

W. Burman,[1] J. Ellis,[2] G. Hale,[3] K. Hill,[4]
[1]Denver Health, University of Colorado, Public Health Institute, Denver, United States of America, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, Clinical Research Department,, London, United Kingdom of Great Britain and Northern Ireland, [3]Makerere University, Infectious Diseases Institute, College of Health Sciences, Kampala, Uganda, [4]University of St. Andrews, Department of Medicine, St. Andrews, United Kingdom of Great Britain and Northern Ireland
e-mail: Bill.burman@dhha.org

Background: Treatment-related adverse events (AEs) are common and have strong negative impacts on quality of life, adherence, and standard outcomes of treatment (treatment non-completion, treatment failure, recurrence, death during treatment). We performed a systematic review of treatment guidelines for rifampicin-susceptible TB to evaluate the adequacy of recommendations for AE management.

Design/Methods: We searched national TB program websites, guideline registries, PubMed, and mobile health Apps for TB to identify treatment guidelines. We also obtained national guidelines from the WHO-defined 30 high-burden countries for TB.

Results: We included 47 guidelines: 25 from high-burden countries, 12 international and prominent national guidelines, and 10 non-governmental guidelines. 37 guidelines (79%) included recommendations for managing adverse events: 24 (96%) of guidelines from high-burden countries, eight (80%) of those from non-governmental organizations, and four (33%) of international and prominent national guidelines (none of the 21 mobile health Apps had such recommendations).

Only four recommendations had formal ratings of supporting evidence. 27 guidelines (59%) included recommendations for managing nausea/vomiting, though only 8 recommended specific pharmacologic interventions, and only one recommended specific medication doses. Most guidelines (76%) included recommendations for managing hepatoxicity, and there was greater specificity than for nausea/vomiting.

Concerns identified in a qualitative evaluation of international guidelines included weblinks that did not function, difficulty in finding sections on AE management, and lack of specificity in the recommendations (see Table).

Conclusions: Despite their frequency and impact on treatment outcomes, international guidelines frequently lack recommendations for AE management. Treatment guideline should provide recommendations on management of adverse events, even if the evidence for doing so is of low quality.

Research on prevention and management of adverse events should be a priority for improving the patient's experience and the outcomes of tuberculosis treatment. Greater attention to ease of use of recommendations for adverse event management would help clinical staff.

OA12-218-19 Examining the differences and similarities of three adverse event grading systems used in TB clinical trials

S. Nachman,[1] J. Maceren,[2] M. Maurelli,[3]
[1]SUNY Stony Brook, Pediatrics, Stony Brook, United States of America, [2]SUNY Stony Brook, Chemistry, Stony Brook, United States of America, [3]SUNY Stony Brook, Pharmacology, Stony Brook, United States of America
e-mail: sharon.nachman@stonybrookmedicine.edu

Background: Division of AIDS (DAIDS), Common Terminology Criteria for Adverse Events (CTCAE), and Médecins Sans Frontières (MSF) are prominent adverse event grading systems used in tuberculosis (TB) clinical trials. Differences and inconsistencies in the grading of drug-related toxicities may impact clinical trial and licensure outcomes.
Design/Methods: We compared adverse event grading criteria for 353 conditions across DAIDS, CTCAE, and MSF. We report on the nine most notable similarities and differences across cardiovascular, hematologic, psychiatric, hepatobiliary, and enzymatic/chemical disorder categories. DAIDS tables were obtained from the 2017 DAIDS Table for Grading the Severity of Adult and Pediatric Adverse Events, Corrected version 2.1. CTCAE adverse events tables were obtained from 2016 PV-TB-D12 TB Severity Grading Scale Version 5.0. MSF tables were obtained from the 2016 PV-TB-D21 TB Severity Grading Scale version 5.0.
Results: We found notable discrepancies in grade 3 and grade 4 severities for absolute lymphocyte count, neutrophil count, depression, anxiety, AST/ALT, hyperbilirubinemia, alkaline phosphatase, and creatinine levels. In general, many grade 3 AEs in CTCAE and MSF are grade 4 in DAIDS. Specific examples of concern include AST/ALT, alkaline phosphatase, and absolute lymphocyte count (Table 1).

	Source	Grade 3	Grade 4
Neutrophil Count (decreased)	CTCAE	500/mm^3 to <1000/mm^3	<500/m^3
	DAIDS	400/mm^3 to 599/mm^3	< 400/m^3
	MSF	N/A	N/A
AST/ALT and Alkaline Phosphatase	CTCAE	>5.0 to 20.0 x ULN	>20.0 x ULN
	DAIDS	5.0 to < 10.0 x ULN	≥ 10.0 x ULN
	MSF	>5.0 to 20.0 x ULN	>20.0 x ULN
Creatinine (increased)	CTCAE	>3.0 to 6.0 x ULN	>6.0 x ULN
	DAIDS	> 1.8 to < 3.5 x ULN	≥ 3.5 x ULN
	MSF	N/A	N/A

Psychiatric disorders are the most discrepant, with variable approaches to AE groupings and no specification of the screening criteria used for anxiety or depression. Grading criteria for QTc intervals are consistent across all grading systems. No group provided grading criteria specific to premature infants or pregnant women.
Conclusions: AE grading for TB therapeutics in clinical trials vary considerably across DAIDS, CTCAE, and MSF, particularly within hematologic, psychiatric, and hepatobiliary disorders. These inconsistencies may impact clinical decision-making, prematurely terminate active trials, and lead to improperly assigned warnings for new TB therapeutics.

OA13 Optimising community-based TB screening and finding people with TB

OA13-219-19 Who benefits from community-based active TB screening programs? Diagnostic yields, early detection, and demographics

L. Linde,[1] B. Roman Sinche,[2] A.K. Millones,[2] J. Jimenez,[2] E. Osso,[3] L. Lecca,[2] M. Brooks,[4] [1]Boston University School of Public Health, Epidemiology, Boston, United States of America, [2]Socios En Salud, Tuberculosis, Lima, Peru, [3]Harvard Medical School, Global Health, Boston, United States of America, [4]Boston University School of Public Health, Global Health, Boston, United States of America
e-mail: llinde@bu.edu

Background: A community-based mobile tuberculosis screening program, TB Móvil, has operated in Lima, Peru since 2019. From 2022-2023, TB Móvil conducted screening three days per week, targeting areas with previously observed high TB-screening yields. We evaluated the population reached by this screening and the TB diagnostic yield among key demographic groups.
Design/Methods: We compared the distributions of individuals screened and diagnosed with TB. We calculated the percentage of individuals that completed each stage of the screening process, including a chest radiograph, symptom screen, GeneXpert testing, and treatment initiation. We did this in aggregate, by age group and sex. We compare diagnostic test results, including smear positivity, to those from individuals diagnosed with TB at local health facilities from the same time period.
Results: TB Móvil registered 8,218 individuals for screening. Individuals aged 15-29, aged 80+, and men were disproportionately likely to be diagnosed with TB. Individuals aged 15-29 comprised 19% of those screened but 38% of those diagnosed (Figure).

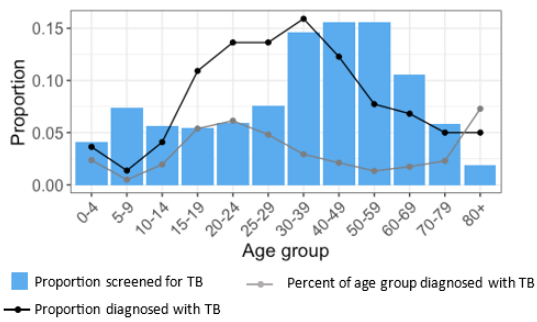


Figure. Distribution of population screened for TB and population diagnosed with TB by age group, and percent of each age group diagnosed with TB, resulting from one year of a mobile TB screening operation in Lima, Peru.

Of males screened, 4% were diagnosed with TB, compared to 2% of females. Among those with abnormal x-ray results, children aged 5-14 were less likely to complete symptom screening and further diagnostic testing than other age groups (52% versus 74%, c^2=6.3 p=.012). 17% of individuals diagnosed with TB by TB Móvil were smear positive, versus 54% of those diagnosed at local health facilities in the same area.
Conclusions: In this active screening program, TB Móvil effectively identified individuals earlier in their course of TB disease compared to individuals presenting at local health facilities. Youths and young adults (aged 15-29) were disproportionately diagnosed with TB via TB Móvil, indicating them as an important subgroup among which to focus future engagement strategies. To end the TB epidemic, global efforts must prioritize active screening to reach the undiagnosed earlier and target high-risk groups more effectively.

OA13-220-19 Enhancing tuberculosis screening integration in Malawi: Revolutionizing and enhancing uptake of community case-finding programs

M. Mmanga,[1] [1]National TB and Leprosy Elimination Program, Community and Preventive Health, Lilongwe, Malawi
e-mail: mmangamadalitso@gmail.com

Background and challenges to implementation: Tuberculosis (TB) is still a major public health concern, especially in low- and middle-income countries. Community-based active case-finding (C-ACF) interventions have shown to increase TB detection rates, but their uptake has been declining in previous years of implementation. Informal community audits revealed that providing only screening services for a longer period communities loose interest, and in order to preserve access and increase uptake of ACF interventions, the program piloted integration of TB screening with other essential health services.
Intervention or response: The program used a mixed-methods approach, whereby program quantitative data (2018-2024) on key performance indicators, such as the number of people screened for tuberculosis, diagnosed, and treatment initiation, were reviewed and analyzed from 12 active TB screening intervention sites that use mobile digital X-rays for CXR and symptomatic screening.
In particular, for the years 2023 to 2024, performance review meetings with community members and health workers were intensified to have a wider understanding of some factors upon observing a decline in the number of people screened.
The community-based ACF integration approach was piloted in 2024 and integrated HIV services, malaria screening and testing, leprosy screening, syphilis testing, and hypertension screening and monitoring.
Results/Impact: TB screening findings (Table 1) for years 2023 and 2024, where integration was introduced, have shown an increase in the number of people screened for

TB from 128,535 to 217,129, with a marginal increase of 26%. In terms of screening by gender, 48% were males. In terms of TB case notification, there was also an increase from 1,164 to 1,408 with 100% treatment initiation.

Table 1: Integrated screening outcomes for community-based active TB case finding

Services	Year	People screened	Males screened	People screened/Tested positive	Males screened/Tested positive	People with TB	Males with TB	Clients referred for further management
Only TB Screening (CXR & Symptom)	2023	128,535	62,960	7,267	5,232	1,164	838	1,164
Integrated TB screening	2024	217,129	104,222	11,910	8,575	1,408	1,014	1,408
Hypertension screening	2024	13,206	5,316	2,122	961	1	1	2,122
HIV screening & Testing	2024	13,559	6,532	83	32	0	0	83
Leprosy screening	2024	116,290	50,979	1,559	96	0	0	1,559
Malaria screening & Testing	2024	4,187	1,661	1,322	559	0	0	1,322
Syphilis screening	2024	111	72	15	9	0	0	15
Diabetes Screening	2024	3,789	1,721	244	125	82	82	244

Conclusions: Community-based ACF is significantly more likely to be sustained when TB screening is integrated with necessary health services. This underscores the importance of holistic integration models in enhancing TB detection, and scaling up is one of the future recommendations to optimize TB control efforts.

OA13-221-19 Creative and comprehensive community engagement in community-based screening and treatment of TB infection and disease

M. Namaibai,[1] H. Philemon,[1] C. Dawai,[1] J. Aide,[2] S. Hohoa,[2] T. Keam,[3] G. Hamilton,[3] A. Aung,[1] N. Pank,[1] T. Marukutira,[1] G. Kama,[4] SWEEP-TB Study Group
[1]Burnet Institute, International Development, Daru, Papua New Guinea, [2]World Vision, STOP TB Project, Daru, Papua New Guinea, [3]Burnet Institute, International Development, Melbourne, Australia, [4]Western Provincial Health Authority, Public Health, Daru, Papua New Guinea
e-mail: mavis.namaibai@burnet.edu.au

Background and challenges to implementation: Community engagement processes have been foundational in implementing a population wide screening (SWEEP-TB) in Daru, Papua New Guinea. The experience of COVID-19 vaccination awareness and provision in Daru provided valuable lessons in the need for multi-layered education and engagement of the community. Hence, multiple avenues have been used to inform and enable community members to take up SWEEP-TB services offered.
Intervention or response: A Community Advisory Group was developed in 2019 with 25 members and has provided ongoing essential cultural and contextual guidance on implementation of screening (e.g. messaging, security processes).
118 representatives from schools, churches, youth and women's groups and an organisation for people with disabilities have been trained and supported to provide education to their own group members. From June 2023 to March 2025, awareness was provided directly to 29,194 community members through the trained community representatives and structured awareness campaigns by the SWEEP-TB team. Other engagement avenues included a mural competition to decorate the screening truck, SWEEP-TB sponsored rugby teams, and activities at World TB Day and Independence Day celebrations.
Results/Impact: Interaction with the community prior to this project showed a lack of understanding of TB transmission and infection. However, the uptake of screening services has been high with 12,204 (54%) screened of the island population of 22,548 as of the end of February 2025. 171 of those screened have been diagnosed with active disease (150 initiated treatment), and 1,750 (75%) of 2,327 eligible people initiated on TB preventive therapy. This strong uptake reflects the impact of the community engagement approach in increasing understanding of TB and encouraging participation.
Conclusions: The multi-faceted community engagement approach has been effective in increasing knowledge of TB disease and infection and understanding of the importance of screening and treatment. The findings provide a roadmap for future interventions including in other settings in PNG.

OA13-222-19 Engagement of local market actors to expand the reach of active case finding: Impact of TB screening at daily markets in Bauchi State, Nigeria

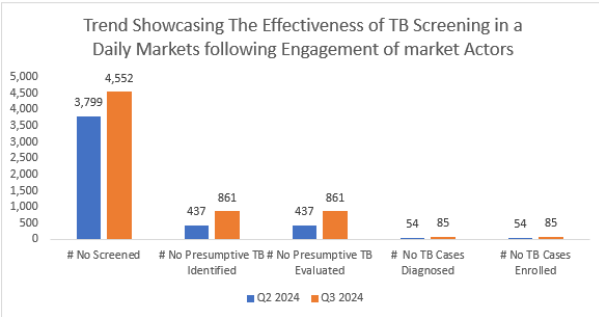
B. Nuhu,[1] M. Bajeson,[2] H. Baffa,[2] M. Tukur,[2] B. Odume,[3]
[1]KNCV Nigeria, M&E, Kano, Nigeria, [2]KNCV Nigeria, Progarmm, Kano, Nigeria, [3]KNCV Nigeria, Programm, Abuja, Nigeria
e-mail: bnuhu@kncvnigeria.org

Background and challenges to implementation: Tuberculosis remains a significant public health concern in Nigeria still ranked first in Africa and 6th globally, with Bauchi State having one of the highest TB burdens in the country. Active Case Finding through community outreaches remains a critical strategy in detecting missing TB Cases in underserved communities with daily markets providing congregate settings where transmission occurs.
This paper presents the experience of reducing transmission and improving health outcomes as a strategy for community outreach using Wellness on Keke (WoK) focusing on the integration of daily Markets in Bauchi state.
Intervention or response: KNCV Nigeria deployed a mobile diagnostic unit called the WOK for active case finding in daily markets across 5 LGA's in Bauchi. In the initial phase, passive advocacy efforts were led by the Local Government Tuberculosis and Leprosy Supervisors (LGTBLS) to the market committees.
During the activity engagement phase, local committee leaders and mobilizers were engaged to enhance awareness creation and facilitate market screening participation. Data collected from participants included demo-

graphic information such as age & sex. Screening was conducted using the WHO 4-symptom screening tool. Sputum samples were collected from adults, while stool samples were collected from children. TB cascade data comparing results before and after the engagement of local market actors was collated and analyzed.

Results/Impact: Comparing Q2 and Q3 2024 we observed a 20% increase in the number of clients screened, with a 97% increase in number of TB presumptives identified and evaluated, the number of TB cases diagnosed also increased significantly by 57%.

Quarter	# No Screened	# No Presumptive TB Identified	# No Presumptive TB Evaluated	# No TB Cases Diagnosed	# No TB Cases Enrolled
Q2 2024	3,799	437	437	54	54
Q3 2024	4,552	861	861	85	85



Conclusions: TB screening at daily markets is an effective strategy for expanding the reach of ACF activities in Bauchi State. The intervention resulted in the detection of new TB cases that would have otherwise been missing and by leveraging existing social networks and cultural capital, we recommend a similar approach across the country.

OA13-223-19 Assessing the detection efficiency of community-based active case finding interventions across 7 waves of TB REACH

C. Mergenthaler,[1] L. van Eck,[1] M.I. Bakker,[1] T. Garg,[2] J. Creswell,[2] [1]KIT Royal Tropical Institute, Global Health, Amsterdam, Netherlands, [2]Stop TB Partnership, Innovations and Grants, Geneva, Switzerland
e-mail: m.bakker@kit.nl

Background: Tuberculosis (TB) is a preventable and treatable respiratory disease, yet remains the leading cause of death from an infectious disease globally. Active case finding (ACF) supports routine passive case finding by identifying people with TB earlier. However, ACF is costly, and the detection efficiency varies considerably between target populations and case-finding approaches. Since 2010, TB REACH supports interventions to increase TB notifications, many using community-based ACF interventions. Comparing the number needed to screen to detect one person with TB (NNS) as a measure of detection efficiency is useful for advising future ACF planning.

Design/Methods: 113 projects, comprising 198 interventions, were selected from TB REACH Waves 1- 7. Health-facility based projects and projects targeting specific risk groups (including contacts) were excluded. ACF TB care cascade indicators were abstracted from project reports: number screened, presumptive, tested, bacteriologically positive, and treated; as well as target population details, the screening and diagnostic tools applied, and where available, the pre-screening efforts. Crude NNS was calculated by dividing total number screened by total number of bacteriologically confirmed TB, combining data from all projects. Random effects meta-analysis of proportions (Stata's *metaprop_one)* provided a pooled overall NNS as well by intervention characteristics.

Results: Preliminary results showed a crude NNS of 293. The pooled NNS was much lower at 146 (95% CI 141-151) due to large, low-yield interventions inflating the crude NNS. We present an overview of the NNSs of TB REACH ACF interventions disaggregated by geographic region, case-finding strategy (Figure 1; excluding NNS>1000), target population, and screening and diagnostic tests applied.

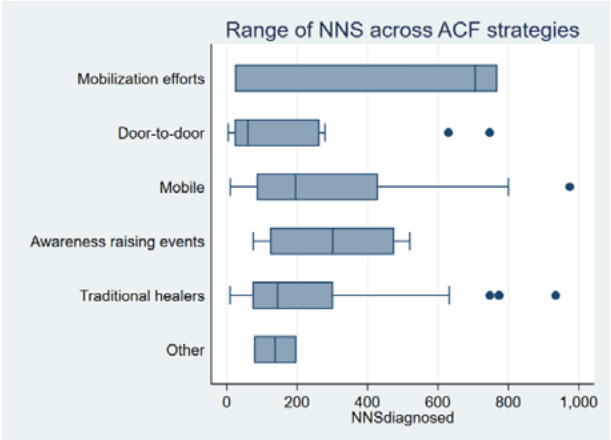


Figure 1.

Conclusions: We found substantial heterogeneity in NNS across ACF characteristics, limiting firm conclusions; however, our findings contribute to the knowledge base required to assess ACF efficiency. Standardized reporting on pre-screening awareness creation activities and size of the catchment population will be important to better evaluate future ACF efficiency.

OA13-224-19 Point-of-care molecular diagnostics for community-based active case-finding: A multicentre randomised controlled trial on TB detection and treatment initiation

T. Perumal,[1] S. Jaumdally,[1] A. Esmail,[1] A. Chizema,[2] C. Phiri,[3] I. Massango,[4] A.J. Scott,[1] S. Oelofse,[1] B. Meggi,[4] J. Mutsvangwa,[2] H. Ayles,[3,5] K. Dheda,[1,6] [1]University of Cape Town Lung Institute, Medicine, Cape Town, South Africa, [2]Biomedical Research and Training Institute, Research, Harare, Zimbabwe, [3]Zambart, Medicine, Lusaka, Zambia, [4]Instituto Nacional de Saúde, Centro de Investigação e Treino em Saúde da Polana Caniço, Maputo, Mozambique, [5]London School of Hygiene and Tropical Medicine, Clinical Research, London, Zambia, [6]London School of Hygiene and Tropical Medicine, Infection biology, London, South Africa
e-mail: tahlia.perumal@uct.ac.za

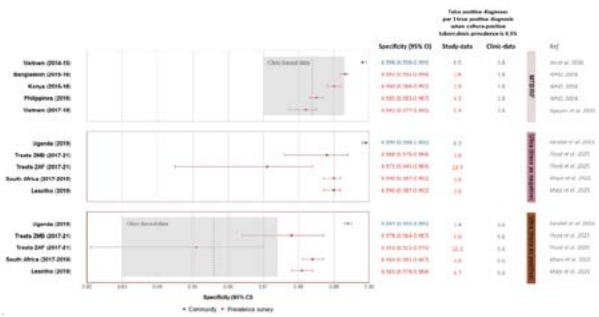
Background: Identifying the ideal active case-finding (ACF) strategy is critical to improving TB detection. We investigated the feasibility and impact of a point-of-care (POC) Xpert-driven ACF strategy in an open-label, multi-country randomised controlled trial to ascertain whether POC diagnosis is a critical component of an ACF strategy.
Design/Methods: We performed ACF using a mobile clinic fitted with a portable Xpert system and staffed by minimally-trained healthcare workers to screen passers-by in peri-urban areas of major cities in four African countries (South Africa, Zambia, Zimbabwe, and Mozambique). We compared treatment initiation failure in those randomised to diagnostic testing performed at (1) POC (battery-powered Xpert Ultra in the mobile van) or (2) in a centralised laboratory. Sputum culture was the reference standard.
Definite TB was defined as culture or Xpert Ultra positive. The primary endpoint was the arm-specific proportion of TB-positive individuals failing to initiate treatment over 60 days.
Results: Of 7506 individuals screened, 3288 (46·9%) participants at risk for TB were randomised (POC arm, n=1643; central arm, n=1645). 122/3288 (3·71%) had definite TB. Xpert detected 73·0% (65/89) of culture-positive TB overall. POC Xpert detected significantly more culture-positive TB than the centralised Xpert (35/37 [94·6%] versus 30/52 [57·7%], p<0·0001).
The probability of treatment initiation failure over 60-days (using Xpert + culture) was significantly higher in the central versus POC arm [RTML ratio 1·390 (1·088-1·775); p= 0.008]; and over 28 days: 1·633 (1·633–2·220, p=0·002).
Participants in the POC Xpert arm initiated treatment significantly faster (median time-to-treatment-initiation, [IQR]; 3 [1-8] versus 8 [3-24] days; p<0·001).
Conclusions: Community-based active case-finding using a point-of-care (POC) molecular tool is feasible in resource-limited settings. This strategy improves treatment initiation compared to centralised laboratory-based testing. These findings show that POC diagnosis is critical for an effective ACF strategy.

OA13-225-19 Mind the clinic-community gap: How concerned should we be about false positive tests in community screening?

L. Veeken,[1,2,3] A. Schwalb,[2,3,4] K. Horton,[2,3] R. Koesoemadinata,[5] B. Alisjahbana,[5,6] R. Van Crevel,[1,7] R. Houben,[2,3] [1]Radboud University Medical Center, Internal Medicine and Radboud Community for Infectious Diseases, Nijmegen, Netherlands, [2]London School of Hygiene and Tropical Medicine, TB Modelling Group, TB Centre, London, United Kingdom of Great Britain and Northern Ireland, [3]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [4]Universidad Peruana Cayetano Heredia, Instituto de Medicina Tropical Alexander von Humboldt, Lima, Peru, [5]Universitas Padjadjaran, Research Center for Care and Control of Infectious Disease, Bandung, Indonesia, [6]Dr. Hasan Sadikin General Hospital, Department of Internal Medicine, Bandung, Indonesia, [7]University of Oxford, Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, Oxford, United Kingdom of Great Britain and Northern Ireland
e-mail: lara.veeken@radboudumc.nl

Background: Community-wide screening for bacteriologically confirmed pulmonary tuberculosis will likely reduce tuberculosis burden. However, concerns of false positive diagnoses and overtreatment remain due to subpar specificity of current bacteriological tests for screening. Current estimates of test specificity are widely used in planning of but are seldom based on performance in community studies.
Design/Methods: We reviewed and extracted test performance data of GeneXpert (MTB/RIF or Ultra) against culture in community-based studies, prevalence surveys and clinic-based studies. Community-based studies used Xpert as initial screening test, whereas in prevalence surveys Xpert was used for individuals who screened positive on symptoms and/or radiological abnormalities by chest X-ray. Using these data, we estimated Xpert specificity and determined the number of false positive diagnoses per one true positive diagnosis assuming a sputum culture-positive tuberculosis prevalence of 500 per 100,000. Our key comparator was Xpert performance against culture among individuals with presumed pulmonary tuberculosis in primary care facilities and local hospitals (per Zifodya 2021). Additionally, we calculated the required sample size to confirm specificity estimates in the community with a 95% confidence interval width of ±0.2.
Results: Xpert specificity in communities is underestimated when compared to clinic-based testing, both for Xpert MTB/RIF (community=99.8% [95%CI: 99.8-99.9]

vs clinic=98.4% [95%CrI: 97.0-99.3]) and Xpert Ultra (community=99.4% [95%CI: 99.3-99.5] vs clinic=95.6% [95%CrI: 93.0-97.4]). The number of false positive diagnoses was reduced by 86.8% and 85.4% for sputum Xpert MTB/RIF and Ultra, respectively (Figure). Sample sizes required to confirm these estimations in a community with a sputum culture-positive tuberculosis prevalence of 0.5% were 5,757 for an Xpert test specificity of 99.4% and 1,927 for a specificity of 99.8%



Conclusions: Clinic-based Xpert specificity likely overestimates the number of false positive Xpert diagnoses in community-wide tuberculosis screening. These findings further support its use in evaluation of community-wide screening for tuberculosis.

OA13-226-19 Game Changer – The role of mobile active case finding initiative in Cambodia under the USAID funded COMMIT project

M. Chry,[1] K. Mom,[2] S.C. Choub,[3] B. Heng,[4] H. Som,[5] S.T. Kheang,[6] N. Song,[7] S. Nop,[8] C.Y. Huot,[9] M.T.E. Mao Tan Eang,[10] S. Soung,[11] S. Tuot,[12] [1]Cambodia Anti-Tuberculosis Association, Programme, Phnom Penh, Cambodia, [2]Cambodia Anti-Tuberculosis Association, Management, Phnom Penh, Cambodia, [3]KHANA, Management, Phnom Penh, Cambodia, [4]Cambodian Health Committee, Management, Phnom Penh, Cambodia, [5]Health and Social Development, TB Program, Phnom Penh, Cambodia, [6]Health and Social Development, Management, Phnom Penh, Cambodia, [7]USAID Cambodia, Public Health, Phnom Penh, Cambodia, [8]USAID Cambodia, USAID Cambodia, OPHE, Phnom Penh, Cambodia, [9]National Center for Tuberculosis and Leprosy Control, Management, Phnom Penh, Cambodia, [10]Ministry of Health - Cambodia, Public Health, Phnom Penh, Cambodia, [11]Cambodia Anti-Tuberculosis Association, TB Program, Phnom Penh, Cambodia, [12]KHANA-Cambodia, Research, Phnom Penh, Cambodia
e-mail: csokchamreun@khana.org.kh

Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge in Cambodia, with an estimate of 35% of TB cases areundiagnosed. Limited access to quality diagnostic tools, inadequate healthcare management of resources, and ineffective interventions among service providers continue to hinder TB control efforts. As the population ages, TB prevalence may rise, further complicating containment and treatment strategies.
Intervention or response: The Community Mobilization Initiatives to End Tuberculosis (COMMIT) is a USAID-funded project aimed at improving TB case detection, prevention, and treatment support in Cambodia. This initiative employs a multi-pronged approach, combining community engagement and innovative screening methods. The intervention targets high-risk populations, including individuals aged 55 and older, the close contacts of pulmonary TB patients, diabetic patients, and symptomatic individuals. Screening is conducted using chest X-rays and Xpert MTB/RIF testing, ensuring early detection and accurate diagnosis.
Results/Impact: A comparative analysis of TB interventions in 2023 (previous initiatives) and 2024 (USAID-funded COMMIT program) revealed significant improvements in case detection across 13 operational districts. In 2023, other TB control initiatives identified a total of 3,093 TB cases, with 1,520 bacteriologically confirmed cases. In contrast, from January to September 2024, the COMMIT intervention detected 4,994 TB cases, including 2,677 bacteriologically confirmed cases. This represents a 161% increase in total TB cases and a 176% rise in bacteriologically confirmed cases. A key contributor to this success was Active Case Finding (ACF), which accounted for approximately 40% of newly identified cases, demonstrating the effectiveness of proactive detection methods.
Conclusions: Delivering quality TB services closer to high-risk populations has proven to be a transformative strategy. The USAID-funded COMMIT project demonstrated that targeted interventions, advanced diagnostic tools, and community-driven engagement significantly enhance TB detection and treatment outcomes.

OA13-227-19 Tuberculosis prevention and care in Madagascar: A mixed-method study investigating the determinants of community health workers involvement

E.H. Andriamasy,[1] H. Razafimanantsoa,[1] O.G. Ravololohanitra,[1] N. Muller,[2] [1]Doctors for Madagascar, Research Department, Antananarivo, Madagascar, [2]Charité – Universitätsmedizin Berlin, Global Digital Last Mile Health Lab at Charité Center for Global Health, Berlin, Germany
e-mail: nadine.muller@charite.de

Background: With an estimated incidence of 233 cases per 100,000, Tuberculosis (TB) remains a major public health challenge in Madagascar. WHO estimates 45% of TB cases remain undetected. Although the country has 40,000 community health workers (CHWs) tasked with basic TB prevention and care, fewer than 5% are trained

specifically for TB tasks. This study investigates CHW involvement in TB prevention and care and identifies factors influencing their participation to inform strategies to strengthen community-based TB control.

Design/Methods: We conducted a mixed-methods study with a sequential explanatory design across four regions (Analamanga, Atsimo-Andrefana, Androy, Anosy). Between March and June 2024, a cross-sectional survey of 408 CHWs was conducted using two-stage cluster sampling to assess involvement in TB, support received, and work environment.

Additionally, 24 stakeholder interviews and five focus group discussions with CHWs explored contextual factors. Quantitative data were analyzed in R, including logistic regression; qualitative data were transcribed and analyzed thematically in NVivo.

Results: Of 408 CHWs, 96 (23.5%) reported any involvement in TB prevention and care. Among them, 91/96 (95%) engaged in sensitization, 47/96 (49%) in identifying and referring presumptive cases, and 23/96 (25%) in contact referral. CHWs with written work guidance (OR=2.41, 95% CI [1.44 - 4.08]) or with any prior training (OR=2.68, 95% CI [1.36 - 5.66]) were more likely to be involved. NGO collaboration was negatively associated with engagement (OR=0.45, 95% CI [0.45 - 0.80]).

Qualitative findings revealed several barriers to engagement, including limited overall and NGO support (e.g., lack of TB-specific training or protective equipment), disease-related stigma, the vulnerability of people with TB, and perceived infection risk for CHWs, contributing to a deprioritization of TB in comparison to other health topics.

Conclusions: CHW engagement in TB remains limited due to insufficient training, guidance, and support. Strengthening CHW capacity and addressing contextual barriers are essential for community-based TB control.

OA13-228-19 Strengthening TB policy through community-led monitoring: Multi-country evidence

O. Klymenko,[1] [1]CO TBPeople Ukraine, Department of development, Kyiv, Ukraine
e-mail: olyaklymenko2910@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a global health challenge, with barriers such as stigma, access to care, and weak accountability hindering effective responses. Community-led monitoring (CLM) offers a promising approach to empower communities and drive systemic change, but its impact on national TB policies has been underexplored. The "One Voice, Many Lives" project aimed to analyze how CLM data, particularly through the OneImpact platform, influences TB policy and service delivery across diverse health systems.

Intervention or response: From July to December 2025, a mixed-methods study was conducted in seven countries (Ukraine, Kyrgyzstan, Moldova, Nepal, Philippines, DR Cameroon, Uganda). Using OneImpact data, we analyzed community-reported barriers to TB care, conducted 70 key informant interviews with policymakers and health providers, and held 35 focus group discussions with TB-affected communities.

Quantitative analysis compared TB service indicators (e.g., treatment success rates, diagnostic uptake) before and after CLM interventions, while qualitative case studies documented policy changes. Findings were mapped against WHO IHR Benchmarks to assess CLM's role in health system strengthening.

Results/Impact: The study gathered substantial community feedback via OneImpact, highlighting critical issues such as stigma and barriers to treatment access. In countries like Ukraine and Nepal, CLM data informed revisions to national TB guidelines, emphasizing patient-centered care. In Uganda, community advocacy contributed to reducing financial barriers to treatment. Across several countries, improvements were observed in treatment outcomes and service utilization, linked to CLM engagement.

Qualitative findings underscored enhanced accountability, with policymakers using CLM data to guide resource allocation. A set of proposed CLM benchmarks was developed, with initial adoption by national TB programs as a pilot framework.

Conclusions: CLM, supported by platforms like OneImpact, is a transformative tool for aligning TB services with community needs and strengthening health systems. Institutionalizing CLM as a standard practice can accelerate progress toward TB elimination and pandemic preparedness.

OA14 Predicting TB: New disease, reinfection and relapse

OA14-229-19 Integrated machine learning and proteomic profiling reveal host-specific response proteins as predictive biomarkers for tuberculosis diagnosis

P. Lu,[1] H. Ding,[2] J. Wang,[1] [1]Nanjing Medical University, School of Public Health, Nanjing, China, [2]Jiangsu Provincial Center for Disease Control and Prevention, Department of Chronic Communicable Disease, Nanjing, China
e-mail: lpjscdc@163.com

Background: Current immunodiagnostic tools for tuberculosis (TB) latent infection, including tuberculin skin tests and interferon-γ release assays, demonstrate suboptimal positive predictive values, leading to excessive prophylactic treatments.
This study aimed to identify high-accuracy protein biomarkers predictive of progression from latent TB infection (LTBI) to active TB (ATB).
Design/Methods: We analyzed QuantiFERON supernatants from a school TB outbreak cohort, longitudinally tracking 40 LTBI students over two years (21 progressing to ATB). Proteomic profiling quantified 1,248 serum proteins. Differential expression analysis identified ATB-associated proteins, with functional annotation through Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment. A Random Forest model incorporating 3-fold cross-validation and oversampling techniques was developed to select predictive biomarkers and assess diagnostic performance using AUC, sensitivity, and specificity.

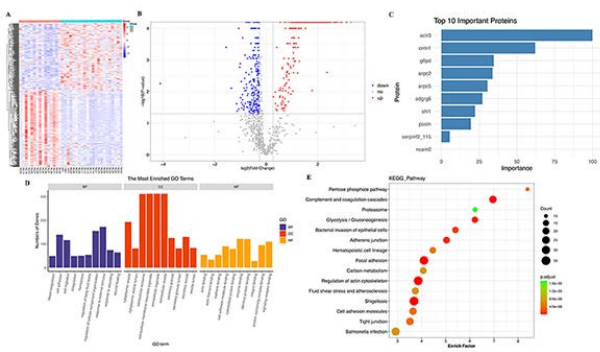


Figure 1. A ; Heatmap of protein expression profiles; B: Volcano plot; C: Gene Ontology (GO) enrichment analysis; D:KEGG pathway enrichment analysis; E:Feature importance ranking of the top 10 biomarker candidates from Random Forest classification model

Results: Comparative proteomics revealed 514 differentially expressed proteins between LTBI and ATB groups (276 upregulated, 238 downregulated). Cluster analysis demonstrated distinct expression patterns distinguishing disease states.
Key enriched pathways included phagocytosis (FDR = 2.1×10^{-7}), complement activation (FDR = 1.8×10^{-5}), and cell-matrix adhesion (FDR = 4.5×10^{-3}).
The optimized Random Forest model identified 10 predictive biomarkers (ACTR3, CNTN1, G6PD, ARPC2, ARPC5, ADGRG6, CHL1, POSTN, SERPINF2_115, NCAM2). Model performance peaked at mtry=2 with AUC=0.989 (sensitivity=90.1%, specificity=83.3%), significantly outperforming mtry=6 (AUC=0.985) and mtry=10 (AUC=0.985).
Conclusions: This study establishes a novel 10-protein biomarker panel that accurately predicts TB progression risk through machine learning-enhanced proteomic profiling. The high diagnostic performance suggests clinical utility for risk-stratifying LTBI populations, potentially reducing unnecessary chemoprophylaxis by 83% based on specificity estimates. Future multi-center validation and mechanistic studies on the ACTR3-mediated immune-stromal crosstalk could enable targeted interception of TB progression.

OA14-231-19 Exploring nuclear magnetic resonance metabolomics in serum samples for TB diagnosis in pediatric population: A pilot study

A. López-Suárez,[1,2] P. Alonso-Moreno,[3] P. Comella del Barrio,[1,2] N. Apaolaza,[3] P. Rodriguez-Molino,[1,4] D. Blázquez-Gamero,[1,5] S. Rodriguez-Martín,[6] J. Hurtado-Gallego,[1,4] T. Sainz-Costa,[1,4] J.L. Izquierdo-García,[3,7] B. Santiago-García,[1,2] [1]Carlos III Health Institute, Centre for Networked Biomedical Research in Infectious Diseases (CIBERINFEC), Madrid, Spain, [2]Hospital General Universitario Gregorio Marañón, Pediatric Infectious Diseases Section, Paediatrics Department, Gregorio Marañón Research Institute, Madrid, Spain, [3]Complutense University of Madrid, NMR and Imaging in Biomedicine Group, Pluridisciplinary Institute. Department of Chemistry in Pharmaceutical Sciences, Madrid, Spain, [4]Hospital La Paz, General Paediatrics, Department of Infectious and Tropical Diseases, Hospital La Paz, Madrid, Spain, Madrid, Spain, [5]Hospital Universitario 12 de octubre. Research institute Hospital 12 octubre (imas12). Universidad Complutense de Madrid, Paediatric Infectious Diseases Unit, Department of Pediatrics, Madrid, Spain, [6]Hospital Universitario Príncipe de Asturias, Service of Pediatric, Alcalá de Henares, Spain, [7]Carlos III Health Institute, Centre for Networked Biomedical Research inRespiratory Diseases (CIBERES), Madrid, Spain
e-mail: aalopezsuarez@gmail.com

Background: Recent research underscores Nuclear Magnetic Resonance (NMR)-based metabolomics as a promising diagnostic tool for early pediatric tuberculosis (TB) detection, capable of revealing a unique metabolic signature of disease.
In this study, we applied NMR spectroscopy to identify metabolomic fingerprints associated with TB in serum samples, offering a non-sputum-based method enhancing diagnostic accuracy.

Design/Methods: This pilot study included 30 subjects under 18 years of age from the Spanish Pediatric TB Network: 10 microbiologically confirmed TB (cTB), 10 with *Mycobacterium tuberculosis* infection (TBI), and 10 healthy controls (HC). Serum samples were collected at diagnosis, frozen for storage, thawed prior to analysis, and filtered by ultracentrifugation to remove lipid and protein constituents. High-Field NMR (500 MHz) and benchtop NMR (80 MHz) spectroscopy were used. Spectra analysis and metabolomic classification models via Partial Least Squares Discriminant Analysis (PLS-DA), cross-validation, and diagnostic performance metrics were conducted using Mnova software and Metaboanalyst 6.0, respectively.
Results: Participants had a median age of 8.45 years [1.9–18.2], with no differences between groups (cTB 8.05 [3.4–18.2], TBI 9.9 [4.7–15.4], HC 6.75 [1.9–14.4]). Two scenarios were evaluated using both HF-NMR and b-NMR spectroscopies: scenario 1 (cTB vs. HC) and scenario 2 (cTB vs. TBI). Accuracies exceeding 0.60 were achieved with both spectrometers. Sensitivity, specificity, and AUC-ROC values using HF-NMR were 90%, 100%, 1 (95% CI 1–1) for scenario 1 and 100%, 70%, and 0.95 (95% CI 0.77–1) for scenario 2, respectively. b-NMR yielded sensitivity, specificity, and AUC-ROC values of 100%, 90%, and 0.95 (95% CI 0.77–1) for scenario 1 and 80%, 70%, and 0.95 (95% CI 0.77–1) for scenario 2.

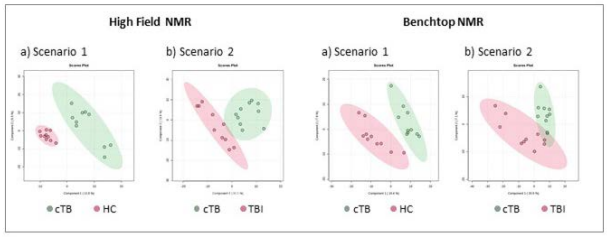

Figure 1. Two-dimensional view showing the distribution of the groups according to the first two components of the Partial least squares discriminant analysis (PLS-DA) model of serum spectra measured using both High Field NMR (H-F-NMR) and Benchtop NMR (b-NMR) spectroscopy. a) Scenario 1. Comparison between confirmed TB (cTB) and healthy controls (HC); b) Scenario 2. Comparison between confirmed TB (cTB) and MTB infection (TBI).

Conclusions: These findings underline the potential of NMR metabolomics potential for distinguishing pediatric TB from HC and TBI. Further validation with a larger sample size is needed to confirm these promising results.

OA14-232-19 Development of a four-gene host signature for paucibacillary TB diagnosis among individuals with Xpert MTB/RIF Ultra very low and trace results

K. Lopez,[1] R. Reiss,[1] V. Kaipilyawar,[1] N. Modi,[2] C. Eichberg,[3] L. Nakiyingi,[4] C. Centner,[5] K. McCarthy,[6] D. Alland,[1] W.E. Johnson,[1] Y. Xie,[1] P. Salgame,[1] [1]Rutgers University - New Jersey Medical School, Medicine, Newark, United States of America, [2]Baylor College of Medicine, Medicine, Houston, United States of America, [3]Medical University of South Carolina, Medicine, Charlestone, United States of America, [4]Makerere University College of Health sciences, Medicine, Makerere, Uganda, [5]University of Cape Town, Medicine, Cape Town, South Africa, [6]CDC, KEMRI, Kisumu, Kenya
e-mail: kl916@gsbs.rutgers.edu

Background: The Xpert MTB/RIF Ultra (Ultra) assay is widely used for pulmonary TB diagnosis. However, how frequently a 'very low' or 'trace' semiquantitative Ultra result reflects paucibacillary TB versus a false positive is unknown, complicating diagnosis in the absence of confirmatory culture results.
New tools are needed to detect TB in individuals with low bacterial load, where standard diagnostics fail. This study assessed whether host transcriptomic signatures can predict paucibacillary TB when Ultra readouts are very low/trace and culture is unavailable.
Design/Methods: We performed transcriptional profiling from whole blood of symptomatic adults in Uganda, Kenya, and South Africa whose sputum underwent Ultra, MGIT and LJ culture testing. Using a customized NanoString Codeset covering 81 genes across 14 published TB signatures, we derived a novel four-gene host signature using machine learning algorithms (H2O.ai) ("Lopez_Trace_4"). Two independent validation cohorts were used to assess specificity. Sensitivity and specificity were calculated based on the minimum WHO targets for triage and diagnostic tests.
Results: Of 321 Ultra-positive participants, 90 had 'very low' or 'trace' results; 17 (18.8%) of these were culture-confirmed TB cases. In this group, our signature achieved an AUC of 0.88 (95% CI: 0.71-0.99) with 100% sensitivity at 70% specificity. It outperformed prior TB history as well as previously published transcriptomic signatures and showed high specificity in participants with other respiratory diseases and in TB-unexposed North American controls.
Conclusions: Our four-gene host signature showed high performance in identifying TB among culture-positive individuals with Ultra very low/trace results. The four-gene host signature outperformed the use of prior TB history or other published TB and met WHO TPP (designed for all, not just paucibacillary TB) for a triage test. With further validation, this blood-based test could be an effective triage tool for paucibacillary TB and exploratory biomarker for culture-negative TB.

	Diagnostic Sensitivity [95% CI][1]	Diagnostic Specificity [95% CI][1]	Triage Sensitivity [95% CI][2]	Triage Specificity [95% CI][2]	AUC [95% CI]
Comparator					
Prior TB history as a diagnostic[3]	0.33 [0.00-0.64]	0.53 [0.29-0.76]	-	-	N/A
Signature					
Lopez_Trace_4	0.33 [0.00, 0.83]	0.82 [0.65, 1.00]	1.00 [0.33, 1.00]	0.76 [0.59, 0.94]	0.88 [0.71, 0.99]
Darboe_RISK_11	0.33 [0.00, 0.83]	0.71 [0.24, 1.00]	0.67 [0.17, 1.00]	0.29 [0.12, 0.88]	0.76 [0.51, 0.96]
Zak_RISK_16	0.17 [0.00, 0.67]	0.71 [0.24, 1.00]	0.67 [0.17, 1.00]	0.29 [0.12, 0.82]	0.74 [0.49, 0.93]
Maertzdorf_4	0.00 [0.00, 0.50]	0.76 [0.29, 0.94]	0.67 [0.00, 1.00]	0.47 [0.24, 0.82]	0.70 [0.47, 0.90]

[1]Sensitivity and specificity are calculated at 0.98 specificity and 0.65 sensitivity, respectively, the WHO TPP required minimum for a biomarker-based non-sputum-based diagnostic assay for detecting TB.
[2]Sensitivity and specificity are calculated at 0.70 specificity and 0.90 sensitivity, the WHO TPP required minimum for a biomarker-based non-sputum-based TB screening assay.
[3]Prior TB history: consideration of a trace Ultra result as false positive in the presence of TB treatment. Diagnostic performance was assessed based on its association with culture positivity among very low- and trace-positive participants.

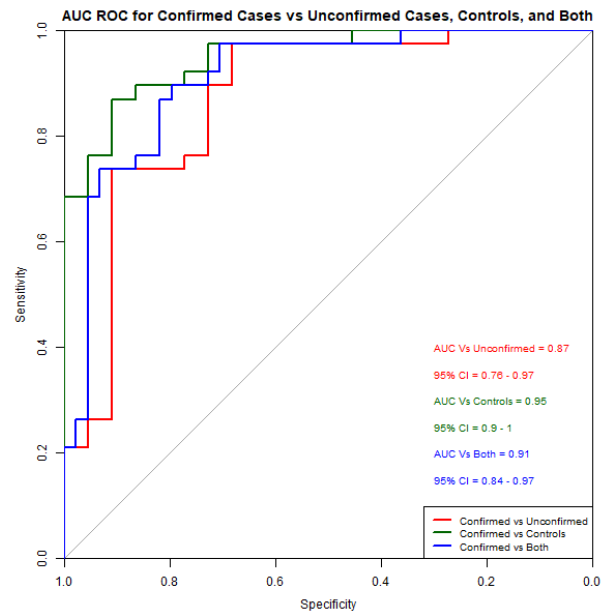

Figure.

OA14-233-19 Advancing extrapulmonary tuberculosis diagnosis and treatment monitoring with RISK6 transcriptomic biomarker

A. Islam,[1] S. Pouzol,[2] M.K.M. Uddin,[1] T. Alam,[3] M.S. Jabin,[1] S. Banu,[1] J. Hoffmann,[2] [1]icddr,b, Infectious Diseases Division, Dhaka, Bangladesh, [2]Fondation Mérieux, Public Health Department, Lyon, France, [3]icddr,b, Nutrition Research Division, Dhaka, Bangladesh
e-mail: ashabul.islam@icddrb.org

Background: Diagnosing extrapulmonary tuberculosis (EPTB) is challenging due to diverse clinical manifestations of the disease, need for invasive sampling, and specialized processing. Furthermore, existing methods cannot monitor treatment efficacy, despite the frequent need to extend standard EPTB treatment regimens.
Therefore, we aimed to assess the RISK6 transcriptomic signature's performance for EPTB diagnosis and treatment monitoring in alignment with the WHO target product profile (TPP) for biomarker tests.
Design/Methods: We enrolled 382 individuals presumed to have EPTB and 35 healthy controls, all older than 11 years, from TB screening and treatment centers of icddr,b in Dhaka, Bangladesh, between March 2022 and March 2023. Different clinical samples were obtained depending on the clinical presentation of symptoms.
These samples underwent GeneXpert MTB/ RIF, culture, and microscopy testing to confirm EPTB. Blood samples were obtained from all participants at enrolment and post-treatment (for confirmed cases) to measure the RISK6 score via RT-qPCR. RISK6 signature performance was evaluated using the Area Under the receiver-operating characteristic curve (ROC AUC) and Student's t-test.
Results: Among 382 presumptive cases, 75 were microbiologically confirmed for EPTB and 307 were unconfirmed (not diagnosed with EPTB). Ongoing RISK6 testing is available for 38 confirmed cases at baseline (with post-treatment scores for 36), 22 unconfirmed cases, and 22 controls. RISK6 discriminated confirmed cases from controls (AUC 95%), unconfirmed cases (AUC 87%) and both groups combined (AUC 91%) (Figure). Furthermore, RISK6 scores for confirmed cases decreased significantly ($p<0.001$) post-treatment.
Conclusions: Our initial findings indicate that the RISK6 signature performance for EPTB effectively meets the WHO's biomarker test criteria in the TPP. RISK6 testing offers a promising development in EPTB diagnosis through a minimally invasive and accessible approach, particularly for challenging cases with insufficient evidence for biopsy. Furthermore, its post-treatment performance highlights a potential role in aiding clinicians to better elucidate treatment outcomes.

OA14-234-19 Prediction of tuberculosis by the QuantiFERON-TB Gold Plus assay in immunocompromised individuals: A prospective TBnet study

O. Skouvig Pedersen,[1,2] M. Sester,[3,4] L. Martinez,[5] C. Lange,[6,7,8,9] for the Tuberculosis Network European Trialsgroup (TBnet) [1]Aarhus University Hospital, Department of Respiratory Diseases and Allergy, Aarhus, Denmark, [2]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark, [3]Saarland University, Department of Transplant and Infection Immunology, Homburg, Germany, [4]Saarland University, Center for Gender-specific Biology and Medicine (CGBM), Homburg, Germany, [5]Boston University, Department of Epidemiology, School of Public Health, Boston, United States of America, [6]Clinical Infectious Diseases. Leibniz Lung Center, Department of Clinical Infectious Diseases, Research Center Borstel, Borstel, Germany, [7]German Center for Infection Research (DZIF), Tuberculosis Unit, Borstel, Germany, [8]Respiratory Medicine & International Health, University of Lübeck, Lübeck, Germany, [9]Baylor College of Medicine and Texas Children's Hospital, Global TB Program, Houston, United States of America
e-mail: oleskouvigpedersen@gmail.com

Background: In low tuberculosis (TB)-endemic countries, preventive therapy (TPT) is recommended for immunocompromised individuals with positive immunodiagnostic tests. This study assessed the performance of the QuantiFERON-TB Gold Plus (QFT+) assay and its predictive value for TB progression in immunocompromised individuals.
Design/Methods: Immunocompromised adults – including people living with HIV (PLHIV), chronic renal failure, rheumatoid arthritis, solid-organ or stem-cell transplantation – and immunocompetent adults with and without TB were recruited from 11/2015 to 03/2019 at 21 sites in 11 European countries. QFT+ testing was performed at baseline; participants without TB were followed for incident disease.
Results: Among 1758 immunocompromised individuals without TB, 13.6% had positive QFT+ results. Sensitivity and specificity for TB were 70.0% (52.1-83.3%) and 91.4% (89.6-92.9%) in immunocompromised, and 81.4% (76.6-85.3%) and 96.0% (92.5-97.9%) in immunocompetent individuals. Addition of the TB2-tube conferred no added diagnostic benefit over TB1. Over 2457 person-years of follow-up (PYFU) among 932 non-HIV immunocompromised participants, no-one developed TB – even among 83 with positive QFT+ without TPT. In contrast, among 642 PLHIV without TPT, 3/30 PLHIV with positive and one with indeterminate QFT+ developed tuberculosis; all had detectable HIV-replication and low CD4 T-cell counts (incidence 4.1 [95% CI 1.3-12.4] per 100 PYFU).
No TB occurred among TPT recipients (269 PYFU). In comparison to immunocompetent controls without TPT and with negative QFT+ results, incidence rate ratios (IRRs) were markedly elevated in PLHIV with positive (IRR 44.3 [95% CI 4.6-426.0]) or indeterminate (IRR 216.0 [95% CI 13.5-3446.0]) QFT+ results. Aalen-Johansen curves confirmed increased cumulative TB risk in PLHIV with detectable HIV-load and low CD4 counts.
Conclusions: In low-endemic settings, TB risk among immunocompromised individuals is low, except among PLHIV with unsuppressed HIV and low CD4 counts. The QFT+ assay remains a poor predictor of TB progression. Moreover, the assay does not meet WHO performance targets as a non-sputum test for diagnosis of active tuberculosis.

OA14-235-19 Reinfection as a cause of recurrence involving drug-resistant bacilli arising from initially susceptible isolates in tuberculosis

T. Yoshiyama,[1,2] A. Takaki,[3] A. Aono,[3] S. Mitarai,[3] Y. Murase,[3] K. Mizuno,[4] [1]Research institute of tuberculosis, epidemiology, Kiyose, Japan, [2]Fukujuji hospital, Department of respiratory diseases, Kiyose, Japan, [3]Research institute of tuberculosis, micobacteriology reference and research, Kiyose, Japan, [4]Fukujuji hospital, microbiology laboratory, Kiyose, Japan
e-mail: yoshiyama@jata.or.jp

Background: The role of re-infection in the recurrence of tuberculosis cases involving a shift from drug-susceptible to drug-resistant bacilli remains unclear.
Design/Methods: Whole genome sequencing was performed on two or more Mycobacterium tuberculosis isolates from patients whose drug susceptibility profiles to isoniazid and rifampicin changed over time.
Results: Out of 6,228 culture-positive tuberculosis cases treated at Fukujuji Hospital between January 2005 and July 2022, 485 cases had multiple drug susceptibility tests conducted at intervals of at least 1.5 months due to persistent culture positivity. Among these, 10 cases exhibited changes in drug susceptibility patterns confirmed by both MGIT and broth MIC testing.
Six cases showed a shift from susceptibility to resistance to either isoniazid or rifampicin: In two cases, phenotypic resistance was observed early, with consistent genotypic resistance from the start.
In another two cases, phenotypic resistance developed alongside newly acquired resistance-conferring mutations. The remaining two cases involved genotypically distinct strains, indicating reinfection.
Four cases showed a reversal from resistance to susceptibility: One case was attributed to re-infection. Another demonstrated a genotypic shift from mutant to wild-type.
Conclusions: Re-infection or hetero infection explained two of the six cases that developed resistance during the study period.
Additionally, two cases appeared to acquire resistance during treatment. The frequency of drug resistance acquisition (to isoniazid or rifampicin) during treatment was 2 out of 6,228 culture-positive cases. Phenotypic drug

susceptibility tests occasionally demonstrated unstable results in the absence of corresponding genotypic mutations.

OA14-236-19 Whole-genome sequencing provides insights into recurrent tuberculosis in Madagascar over two decades

F. Randria-Andrianomanana,[1] M.T. Radimison,[1] M.S. Raherison,[1,2] P. Ranaivomanana,[1] N. Rakotosamimanana,[1] [1]Institut Pasteur de Madagascar, Mycobacteriology, Antananarivo, Madagascar, [2]National Tuberculosis Control Program (PNLT), National laboratory, Antananarivo, Madagascar
e-mail: niaina@pasteur.mg

Background: Identifying relapse versus reinfection in patients with recurrent tuberculosis (reTB) could help in developing effective public health and control strategies, as limited information is available on reTB worldwide. To address this knowledge gap, this study aimed to provide valuable molecular insights into reinfection versus relapse.
Design/Methods: We conducted a retrospective investigation on reTB episodes from 2002 to 2022 at the National reference laboratory for Mycobacteriology of Madagascar. *M. tuberculosis* (MTB) isolate strains from reTB episodes distanced for a period of 12 months from the same patients were selected. Strains were grown on liquid media and the DNA was whole-genome sequenced using Illumina Novaseq. A threshold of 12 Single Nucleotide Polymorphism (SNP) was employed to differentiate between relapse and reinfection among recurrent tuberculosis genomes and clustering analysis among datasets was performed.
Results: In total, 125 MTB isolates from 65 reTB patients were included in the study. Following whole-genome sequencing, the MTB Lineage 4 is accounting for 65.85% (n=28/41) of reTB-isolates, while Lineages 3, 2 and 1 represents 21.95% (n=9/41), 7.32% (n=3/41) and 4.88% (n=2/41) respectively.
A proportion of 57 % of the reTB was reinfection and 43% as relapse rates. Three cases of TB-drug resistance were observed from the second episodes of the reinfection case but none for the relapses. The clustering proportion among datasets were 66.67% (n=28/42).
Conclusions: These findings highlight the nature of reTB in Madagascar suggesting ongoing active community transmission, whereas the emergence of drug-resistant strains in reinfection cases raise concerns about the spread of drug-resistant strains.

OA14-237-19 The impact of prior tuberculosis on risk of subsequent TB in people living in households affected by tuberculosis – Results from the *ERASE-TB* study

A.-L. Behnke,[1] L. Larsson,[1] E. Marambire,[2,1] D. Banze,[3,1] C. Nhamuave,[3] A. Mfinanga,[4,1] C. Calderwood,[5,2] C. Khosa,[3] L.T. Minja,[4] K. Held,[1,6] N. Heinrich,[1,6] K. Kranzer,[5,2,1,6] ERASE-TB consortium
[1]LMU Hospital, Institute of Infectious Diseases and Tropical Medicine, Munich, Germany, [2]Biomedical Research and Training Institute, The Health Research Unit Zimbabwe, Harare, Zimbabwe, [3]Instituto Nacional de Saúde, INS, Marracuene, Mozambique, [4]National Institute for Medical Research, Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, [5]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom of Great Britain and Northern Ireland, [6]German Centre for Infection Research (DZIF), Partner site Munich, Munich, Germany
e-mail: anna-lisa.behnke@med.uni-muenchen.de

Background: Patients previously treated for tuberculosis (TB) are at risk of recurrent TB either through reinfection or relapse. Whether prior TB is an independent risk factor for subsequent TB, particularly in high-incidence settings, is currently unknown.
Design/Methods: We analysed the association between prior TB and TB identified as part of household contacts (HHC) screening among 2,109 HHCs aged 10 years and older. HHCs were enrolled across Mozambique, Tanzania, and Zimbabwe and followed every 6 months for a maximum of 24 months.
We estimated odds ratios (OR) with 95% confidence intervals (CI) using univariate and multivariable logistic regression, adjusting for age, sex, HIV status, and site, with household clustering as a random effect. Variable selection for multivariable analysis was guided by a directed acyclic graph (DAG).
Results: Median age of participants was 27 years (IQR 17–42), 38% were men. At baseline, 123 (5.9%) participants reported having been treated for TB in the past, median time since the last TB episode was 8 years (IQR 3–15). Participants with prior TB were older (median age 45 vs 25 years) and more likely to be living with HIV (46% vs 14%). Among 59 participants who were diagnosed with TB either at baseline or during follow-up, 9 (15%) had previous TB.
In the unadjusted analysis, the odds of being diagnosed with TB were higher in participants with prior TB (OR: 2.8, 95% CI: 0.73–11, p=0.13) compared to those without. In the multivariable analysis, prior TB was associated with an increased odds of TB (adjusted OR: 2.4, 95% CI: 0.61–9.7, p=0.21).
Conclusions: Prior TB was a risk factor for subsequent TB independent of age, sex and HIV status. Possible reasons are genetic susceptibility, persisting lung damage,

and other vulnerabilities on an individual or household level, which we did not measure or adjust for (residual confounding).

OA14-238-19 Timing of asymptomatic and symptomatic tuberculosis recurrence diagnoses after successful tuberculosis treatment completion in India

S. Gaikwad,[1] M. Paradkar,[2,3] C. Padmapriyadarsini,[4] M. Barthwal,[5] N. Gupte,[2,3] J. Golub,[6] A. Gupta,[6] V. Mave,[2,3] E. Kendall,[6] TBDM-CTRIUMPh-RePORT India Study Team

[1]BJ Government Medical College and Sassoon General Hospitals, Pulmonary Medicine, Pune, India, [2]BJ Government Medical College - Johns Hopkins University Clinical Research Site, Clinical Research, Pune, India, [3]Johns Hopkins India, Center for Infectious Diseases in India, Pune, India, [4]Indian Council of Medical Research, National Institute of Research in Tuberculosis, Chennai, India, [5]Dr DY Patil Medical College, Hospital and Research Center, Pulmonary Medicine, Pune, India, [6]Johns Hopkins University, School of Medicine, Division of Infectious Diseases, Baltimore, United States of America

e-mail: sangaiabdc@gmail.com

Background: Patients completing tuberculosis (TB) treatment are at high risk of TB-recurrence in the subsequent year, and recurrent-TB might be present and potentially infectious (as indicated by *Mycobacterium tuberculosis* (*Mtb*) in respiratory secretions) before any symptoms develop.

Within cohort studies that performed universal microbiological testing at fixed intervals after treatment, we evaluated the timing of diagnosis of asymptomatic and symptomatic TB-recurrence.

Design/Methods: Participants >14 years of age in two prospective Indian cohorts (CTRIUMPh and TBDM), were followed up to 18 months after successful drug-susceptible pulmonary TB treatment (clinical response with or without microbiological evidence of cure). Sputum smear microscopy and cultures were performed six (TBDM) and/or twelve (TBDM and CTRIUMPh) months post-treatment, and at symptom-triggered visits.

Recurrent-TB diagnoses were classified as asymptomatic (no symptoms but positive smear or culture) or symptomatic (with or without positive mycobacteriology).

Results: A total of 752 patients with culture-confirmed TB and successful treatment completion were followed for median 10.9 (IQR:9.8-16.5) months post-treatment. Sixty-five (9%) developed TB-recurrence (incidence rate: 9.0% (95%CI:7.0-11.5%)/year). Of these, 22 (34%) were asymptomatic at the time of diagnosis (*Figure 1*).

Of the recurrent-TB diagnosed at study visits with scheduled microbiological testing, 11 of the 19 diagnoses at 6-month post-treatment visit, and 11 of 12 diagnoses at the 12-month post-treatment visit, were asymptomatic. Of the 43 recurrences that were symptomatic, 14 (33%) were diagnosed at scheduled study visits (with median reported symptom-duration 21 days [IQR:10-45 days]) and the rest through symptom-driven evaluations, but only 12 (38%) had completed negative microbiological testing between their end-of-treatment visit and TB-recurrence diagnosis.

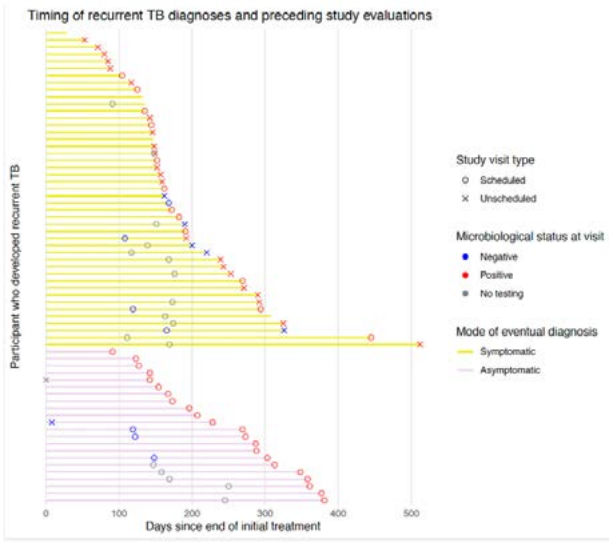

Figure 1: Time to recurrent TB diagnosis, and preceding study visits, for participants with recurrent TB. Each horizontal line represents the duration of post-treatment follow-up for one patient who was eventually diagnosed with recurrent symptomatic (lavender lines) or asymptomatic (yellow lines) TB. Study visits that occurred after the end of treatment are represented as shapes and are color-coded by microbiological status (smear and/or culture; positive if either had a positive result) at that visit.

Conclusions: Recurrent-TB occurred in 9% of TB patients and was often asymptomatic at the time of diagnosis, despite microbiological testing being performed infrequently. Some participants may have had prolonged asymptomatic TB prior to testing, and earlier, more frequent testing would likely diagnose a higher proportion at an asymptomatic stage.

OA15 Differentiated service delivery in precarious conditions

OA15-239-19 From silence to strength: How tuberculosis affected communities in Kenya are accessing justice through paralegal TB Champions

I. Maina,[1] S. Sarune,[1] G. Mutinda,[1] J. Nyanga,[1] M. Ngure,[2] S. Anguva,[3] [1]Kenya Red Cross Society, Global Fund Programme, Nairobi, Kenya, [2]Kenya Red Cross Society, Global Fund, Nairobi, Kenya, [3]Network of TB Champions Kenya, Network of TB Champions Kenya, Nairobi, Kenya
e-mail: ish.irungu@gmail.com

Background and challenges to implementation: Tuberculosis (TB) is not only a global public health concern but also a human rights issue. TB-affected communities frequently experience stigma, discrimination, harassment, and systemic barriers that limit access to timely diagnosis, treatment, and justice. Kenya, listed among the top 30 high TB burden countries, faces critically low levels of legal literacy and access to redress mechanisms.
Studies indicate that over 60% of TB-affected individuals are unaware of their legal rights, and fewer than 10% know how to pursue formal redress. These barriers disproportionately impact individuals affected by TB and TB/HIV, perpetuating cycles of marginalization and poor health outcomes.
Intervention or response: In 2024, Kenya Red Cross Society in collaboration with its Sub-Recipients, the National Network of TB Champions and the National TB Programme, with support from the Global Fund, piloted a training of 60 TB champions as Community Paralegals in high TB -burden counties in Kenya. These champions, primarily TB survivors, were trained on legal frameworks, rights-based advocacy, documentation of violations, and referral pathways to strengthen legal literacy and address human rights violations among TB-affected communities. They conducted community legal literacy sessions, offered basic legal aid services, documented rights-abuses, and supported affected persons to access justice and healthcare services.
Results/Impact: From September 2024 to February 2025, paralegals documented 205 cases of human rights violations (144 female, 62 male), including 52 physical abuse, 36 verbal abuse, 34 stigma, 29 harassment, 18 land/inheritance disputes, 13 sexual abuse, 10 employment discrimination, 8 tenancy breaches, and 5 illegal arrests. 70% of cases were resolved through Alternate Dispute Resolution mechanism, legal aid, while the rest are in trial stages.
Conclusions: Empowering TB champions as Community Paralegals is a powerful community-led model that integrates legal empowerment into TB programming. Their dual role as both advocates and peers uniquely positions them to address barriers in access to care and justice.

OA15-240-19 Temporal trends and spatial clusters in tuberculosis treatment interruption among homeless people in Brazil

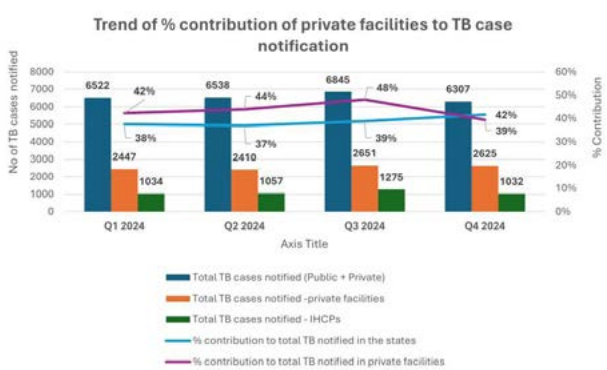
G. Pavinati,[1] L.V. Lima,[2] R. Meggiato Nabas,[1] M. Fairuzy Stolarz,[1] M. Ferrari Gomes,[2] P. Augusto Bossonario,[1] F. Beraldi de Magalhães,[3] G. Tavares Magnabosco,[1] [1]State University of Maringá, Nursing Department, Maringá, Brazil, [2]State University of Maringá, Graduate Program in Nursing, Maringá, Brazil, [3]Pequeno Príncipe Colleges, Medical Department, Curitiba, Brazil
e-mail: gtmagnabosco@uem.br

Background: Homeless individuals are disproportionately affected by tuberculosis (TB), experiencing high treatment interruption rates due to structural vulnerabilities and healthcare access barriers. This study aims to analyze temporal trends and spatial clusters of TB treatment interruption among homeless people in Brazil, identifying associated sociodemographic, epidemiological, and programmatic factors.
Design/Methods: This ecological study evaluated TB treatment interruption indicators from 2015 to 2023 using national surveillance data. Temporal trends were analyzed using joinpoint regression, stratified by sociodemographic and clinical-epidemiological variables. A k-means clustering approach identified geographic patterns of treatment interruption based on correlations with contextual indicators, including social vulnerability, healthcare access, and programmatic factors. Statistical significance was assessed through confidence intervals for trend estimates.
Results: Treatment interruption increased among men (average quarterly percent change [AQPC]: 0.15%; 95% confidence interval [CI]: 0.04% to 0.29%), individuals aged 40–59 years (AQPC: 0.38%; CI: 0.25% to 0.53%), tobacco users (AQPC: 0.72%; CI: 0.61% to 0.82%), and those not receiving directly observed treatment (DOT) (AQPC: 0.49%; CI: 0.39% to 0.63%). The North (AQPC: 1.51%; CI: 0.96% to 2.21%) and Central-West (AQPC: 0.83%; CI: 0.17% to 1.59%) regions exhibited the highest increases in treatment interruption rates. Cluster analysis revealed four distinct spatial patterns: states with lower treatment interruption rates and better healthcare access; states with high social vulnerability, low educational levels, and primary healthcare deficiencies, showing significant treatment discontinuation; states with better socioeconomic indicators and moderate treatment interruption; and states with extreme social and healthcare inequalities, where TB treatment interruption rates were the highest in the country.
Conclusions: Socioeconomic and programmatic inequalities significantly impact TB treatment adherence among homeless individuals. Strengthening DOT programs, integrating TB care into social assistance networks, and expanding social protection policies are critical to improving treatment retention.

OA15-241-19 The role of informal health care providers in TB epidemic control in Nigeria

C. Eze,[1] C. Nwafor,[1] A. Meka,[1] F. Iyama,[1] D. Egbule,[1] A. Agbaje,[2] A. Adekunle,[3] O. Chijioke-Akaniro,[4] C. Adesigbin,[5] M. Zamzu,[6] J. Ssekitooleko,[6] O. Ezeakile,[1]
[1]RedAid Nigeria, Programs Department, Enugu, Nigeria, [2]Global Fund N-THRIP, Institute of Human Virology, Nigeria (IHVN), Office of the CEO, Abuja, Nigeria, [3]Global Fund N-THRIP, Institute of Human Virology, Nigeria (IHVN), Program Coordinating Unit, Abuja, Nigeria, [4]National TB and Leprosy and Buruli Ulcer Control Programme Nigeria, GF Program Coordinating Unit, Abuja, Nigeria, [5]National TB and Leprocy and Buruli Ulcer Control Programme Nigeria, GF Program Coordinating Unit, Abuja, Nigeria, [6]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Program Coordinating Unit, Geneva, Switzerland
e-mail: chinwendu5000@gmail.com

Background: Public and private sectors play significant roles in healthcare service delivery globally. In Nigeria, private health facilities (PHF) constitute a major part of the healthcare system, serving as the first point of contact for over 60% of Nigerians seeking care. This justified their engagement by the National Tuberculosis (TB) Program in TB control efforts in 2019. Since then, their contribution to total TB case notification has increased from 11% in 2017 to 33% in 2024, significantly increasing the TB treatment coverage from 25% in 2018 to 75% in 2024. The PHFs comprise of formal (private-for-profit and Faith-based organization health facilities) and informal healthcare providers-IHCPs (patent medicine vendors, community pharmacists, traditional birth attendants and standalone laboratories).
The study aims to highlight the contributions of IHCPs to the total TB case notifications in 2024 in four supported states of RedAid Nigeria under the Global fund-GC7 grant.
Design/Methods: A retrospective desk analysis of routine data collected from Benue, Delta, Edo and Taraba states in 2024 was conducted using MS Excel. Quarterly contributions of TB cases from the IHCPs were expressed as both absolute counts and proportions of total TB cases notified in the private facilities in these states.



Results: In 2024, a total of 26,212 TB cases were notified across the four quarters in the states. PHFs contributed 38–42% of the total cases. The proportion of TB notifications from IHCPs as a share of PHF contribution ranged from 42% in Q1 to a peak of 48% in Q3 before dropping to 39% in Q4.
Conclusions: The findings highlight the significant contribution of IHCPs in TB case notification, underscoring the importance of continued engagement and support for IHCPs in TB control strategies. Strengthening collaboration, capacity building, and resource allocation to IHCPs will further enhance TB case finding towards achieving the END TB targets.

OA15-242-19 Strategies employed to improve treatment outcomes amongst alcoholic TB patients in Korogocho informal settlements, Nairobi Kenya

M. Ombuya,[1] E. Mueni,[2] [1]Nairobi City County Government, Public Health, Nairobi, Kenya, [2]Elizabeth Mueni, Public Health, Nairobi, Kenya
e-mail: milcahya@gmail.com

Background and challenges to implementation: Kenyan urban slums have the highest burden of TB due to overcrowding. Nairobi county contributes 15% of the TB cases reported in the Country. In 2022 cohort, 5% of clients in Kenya were lost to follow-up(LTFU), with Nairobi recording a slightly higher rate of 6% attributed to highly mobile impoverished populations and alcoholics. Korogocho, an informal settlement in Ruaraka Sub-county, Nairobi, which faces a significant tuberculosis (TB) burden, has been experiencing poor treatment outcomes,largely linked to alcoholism. Comboni Sisters, a faith based organization in Korogocho slums has been managing TB patients whom > 50% are alcoholics. In 2021, the facility reported a Treatment success rate among alcoholics of 61% (11/18).
Intervention or response: In 2022, the facility introduced an innovative approach to support alcoholic patients in adhering to their daily medication. This included providing daily porridge as they give DOTs and establishing support groups specifically for alcoholic patients. With the help of the TB champions, TB nurse, Specialized counselors (Mental health and gender-based violence counselors), nutritionist and the TB Coordinator were able to offer support on adherence, drug and substance abuse, stigma and discrimination, gender-based issues, nutrition and drugs side effects.
Results/Impact: Across the years the Treatment success rate among the alcoholics has been achieved as follows; In 2022, 21/22 (95%TSR), in 2023, 38/38 (100%TSR) and in 2024 January to September 50/50 (100%TSR) with an increase in case detection and good case retention across the years.

Conclusions: This study demonstrates that it is possible to achieve good treatment outcomes among st alcoholics with TB**.** Use of DOT plus strategy for patients who are alcoholics, psychological support and food incentive significantly improves drug adherence and reduces lost to follow ups.

OA15-243-19 From stigma to support: Rethinking TB care in factories and communities, a learning from India

R. Dasari,[1] P. Vikas,[1] R. A,[2] S. Jitendra,[2] M. Balakrishna,[3] A. Versfeld,[4] J. Malar,[4] [1]TB Alert India, Programs, Hyderabad, India, [2]National TB Elimination Program, Programs, Hyderabad, India, [3]TB Alert India, M&E, Hyderabad, India, [4]Stop TB Partnership, Programs, Geneva, Switzerland
e-mail: rameshdasari@tbalertindia.org

Background and challenges to implementation: Tuberculosis (TB)-related stigma continues to be a major barrier to diagnosis, treatment adherence, and patient well-being. Industrial settings where fear of job loss and social exclusion are prevalent hold additional challenges. TB Alert India implemented a project: IMA4TB (Industry Action & Management for TB) in Telangana State, India, under Stop TB Partnership (STP) CFCS Round 12.
Taking suggestion from UNHLM on TB political declaration from 2023 to include a target to end TB stigma, STP is rolling this out in a coordinated fashion across 15 countries.
Intervention or response: IAM4TB project fostered a TB-enabling environment in 160 high-risk industries across Telangana by training 320 TB Ambassadors, forming 122 Action Groups, and reaching nearly 21,000 workers through awareness sessions. Conducted X-ray screening camps and community-led monitoring, identifying and initiating treatment for 136 PwTB . A cross-sectional study with 152 PwTB (102 in intervention areas and 50 in control areas) was conducted with an aim to assess differences in stigma level, between intervention areas (project activities taken up) and control areas (project activities not taken up). Ethical approvals and informed consent were obtained from all participants.
Results/Impact: PwTB in intervention areas reported significantly lower stigma. Social exclusion was experienced by only 14% in intervention areas compared to 36% in control areas. Internalized stigma (feelings of guilt/shame) affected 18% of PwTB in intervention areas vs. 33% in control areas. Disclosure concerns were reported by 16% in intervention areas compared to 28% in control settings. PwTB in control areas expressed greater fear of discrimination and job loss, contributing to nondisclosure.
Conclusions: The IAM4TB project demonstrated that targeted, workplace-based stigma-reduction strategies such as employer engagement, peer education, and awareness activities can foster supportive environments. These approaches encourage early disclosure, timely treatment, and adherence. Scaling similar interventions across high-risk industries can strengthen community TB responses and improve outcomes for working populations.

OA15-244-19 Lessons learnt in the TB projects for the unhoused people of Delhi, India between 2017-2025 - Experiences of Humana People to People India

S. Mukhopadhyay,[1] R. Kumar,[2] M. Sharma,[2] M. Gurjar,[2] J. Alam,[3] L. Aarup,[3] B. Malik,[4] N. Singh,[5] M. Mayank,[1] S. Narang,[1] [1]Humana People to People India, Partnership and TB projects, New Delhi, India, [2]Humana People to People India, Project Management, Delhi, India, [3]Humana People to People India, Partnership and TB projects, Delhi, India, [4]Humana People to People India, Data Section, Delhi, India, [5]Humana People to People India, National HQ, New Delhi, India
e-mail: sugamukho17@gmail.com

Background and challenges to implementation: The urban, unhoused and underprivileged people have high TB-prevalence, and mortality due to chronic malnutrition, overcrowded living conditions, frequent migration, and poor accesses to health-services. Providing optimal services to those people was a long-standing challenge of the National TB Elimination Program (NTEP) of India. Humana People to People India (HPPI), a national-level NGO of India, had demonstrated the feasible ways to reach and serve the urban unhoused people of Delhi through various projects implemented between 2017 to 2025. HPPI chose Delhi as the implementation site because it houses more than 250,000 unhoused people, maximum among the metropolitan cities of India.
Intervention or response: HPPI implemented the projects within different time-frames and durations, in partnership with external funding agencies, local foundation, and the NTEP, and with the help of dedicated outreach workers and project-teams.
The overall chief activities of the projects were TB screening with different modalities (symptomatic, Chest x-ray, AI-based cough-sound), linkage-development to the local NTEP services, treatment education and adherence support, addressing stigma, gender and human right issues, community engagement by empowering and mobilizing TASA (TB Affected Street Activists), and SAHELI (local women groups), and facilitating multi-sectoral collaboration to optimize socio-economic support for the unhoused PwTB.
Results/Impact: The projects were chiefly responsible for detection of missing PwTB in the urban unhoused communities. Additionally, the intensified follow-up and tracking systems established by the projects for the PwTB decreased high mortality and LTFU rates. Strategic community engagement enhanced community voices, repre-

sentation, de-stigmatization and gender responsiveness. They also mobilized different partners to further support the unhoused PwTB with supplementary nutrition, and civic amenities.

Project name	Period	Target groups	# screened	# pre-sumptive	# tested	# PwTB	#PwTB detected per 100 people screened
Homeless TB Project (Azim Premji Philanthropic Initiative)	Dec'17 to Aug'19	Unhoused population	24538	864	585	233	1
Homeless TB Project supported by HPPI internally	Nov'19 to Oct'21	Unhoused population	8283	421	261	90	1
LEAD 1 (Leveraging Engaging Advocating to disrupt TB transmission), supported by USAID	May'23 to Jul'24	Unhoused population, migratory population, people living in unauthorized slums	154601	6225	5158	1547	1
Interim Project between LEAD 1 and LEAD 2	Aug'24 to Oct'24	Unhoused population, migratory population, people living in unauthorized slums	780	177	172	24	3
LEAD 2 (Leveraging Engaging Advocating to disrupt TB transmission), supported by USAID	Oct'24 to Jan'25	Unhoused population, migratory population, people living in unauthorized slums	26334	2784	2394	241	1
TASA (TB Affected Street Activist) supported by Round 11 of CFCS grant, Stop TB Partnership	May'23 to May'24	Unhoused population	7994	228	201	93	1
SWEET (Street Women Engaged and Empowered to stop TB) supported by Round 12 of CFCS, Stop TB Partnership	Dec'23 to Jan'25	Unhoused population	1946	158	85	51	1
Total			224575	10857	8856	2279	

Conclusions: The HPPI-led projects had displayed that we can optimize TB services for urban unhoused people with community-friendly and convenient outreach programs, high-quality screening, dynamic facilitation of service-utilization at the NTEP, need-based patient and family-centred care, and active engagement of community-members and multiple stakeholders.

OA15-245-19 Urban gardens: A sustainable food supplementation model for persons with TB and their families in Lusaka, Zambia

E. Machisa,[1] C. Chanda,[2] N.E. Maswabi,[3] M. Bwalya,[3] A. Hoejrup,[4] K. Tyrrell,[5] [1]Federation for Associations connected to the International Humana People to People, Projects and Program Development, Shamva, Zimbabwe, [2]National Ministry of Health, National TB and Leprosy program, Lusaka, Zambia, [3]Development Aid from People to People in Zambia, Programs, Lusaka, Zambia, [4]Development Aid from People to People, Partnerhip team, Lusaka, Zambia, [5]Humana People to People Spain, Partnerships, Madrid, Spain
e-mail: Emelly.machisa@humana.org

Background and challenges to implementation: Persons with TB (PWTB) require 20–30% more calories and protein than healthy individuals to support recovery and immune function (WHO 2022). Malnutrition in PWTB is associated with treatment failure, adverse drug reactions, prolonged recovery, and increased mortality risk. Furthermore, PWTB face food insecurity, exacerbated by loss of income due to stigma, disability and discrimination. An estimated 5.8 million Zambians (33%) experience high level food insecurity exacerbated by climate change, with a TB incidence rate of 283/100.000 (20250116_ACAPS).
Intervention or response: This study examined the effect of Urban gardens/ bachelor beds to support food supplementation among PWTB and their urban households. A DAPP (local NGO) project was implemented in three high-TB burden urban shanty compounds (kombonis) of Lusaka, Zambia. Over one year (2024-2025) DAPP provided basic lessons in urban gardens techniques to each volunteering households (HH) of PWTB in the project. 46 households established gardens and were regularly monitored to assess garden growth, collect participant feedback, and track changes in household nutrition and food security.
Results/Impact: 46 urban gardens for 46 HH (from only very few at baseline) were established during the project. Families produced tomatoes, onions and green vegetables which in long periods fed 4 to 6 members of the HH 2 days a week. Within six months, 80% (n=37/46) households reported improved dietary diversity. Weight gain were reported in 70% (n=32/46) of HH. Twenty percent (n=9) at times generated surplus produce for sale, improving households' livelihood. Participants also reported improved mental well-being, as gardening fostered community involvement.
Conclusions: Findings highlight the potential of urban gardens as a scalable, low-cost intervention to enhance TB recovery, mental well-being and economic resilience. Strengthening health promotion within TB programs can increase food production and improve outcomes. A multidisciplinary approach with integrated support systems to enhance food production should be considered in high TB burden settings.

OA15-246-19 Leave no one behind TB care: New vulnerable population group has appeared following the start of full-scale war in Ukraine

E. Geliukh,[1] V. Shalashny,[1] Z. Islam,[1] S. Morhun,[2]
[1]ICF "Alliance for Public Health", Treatment, Procurement and Supply Management, Kyiv, Ukraine, [2]Medical Forces Command of the Armed Forces of Ukraine, Central Sanitary and Epidemiological Directorate, Kyiv, Ukraine
e-mail: geliukh@aph.org.ua

Background and challenges to implementation: Immediately after the russian invasion to Ukraine in February 2022 mass mobilization began in Ukraine. The need to significantly increase the size of the active army to confront the invader made it impossible to adhere to the medical protocols for examining conscripts at military commissariats.
As a result, large number of people with TB (known or undiagnosed) joined acting army in 2022. Poor living conditions and huge stress of militaries have enabled TB infection spread among the military contingent.
There is a limited access to TB diagnostics services in militaries, since all military hospitals/clinics/units prioritize aiding for injuries and traumas, not focused on TB. In late summer 2022, Alliance responded to a request from Medical Forces of the Armed Forces of Ukraine (MFAFU) to provide support with TB diagnostics among military contingent close to the frontline.
Intervention or response: For this purpose, Alliance allocated the mobile ambulance (MA) equipped with X-ray, Gene-Xpert, refrigerator, generator, modem, solar panel etc. and leased it to MFAFU for operation. MA is capable to work remotely for a long time.
Mobile team consists exclusively of the personnel of MoD, while Alliance provides technical assistance to MA team (trainings, monitoring visits) as well as support to the MA work (petrol, technical service, insurance). MA team reports to Alliance and together they plan MA work and assess the project results.
Results/Impact: MA started working in February 2023 and partnership has enhanced the TB case finding within the militaries.

	# of MA visits	# of persons screened	TB cases diagnosed	NNI	Enrolled in treatment	Other pulmonary pathology diagnosed
2023 (11 months)	74	16,884	91	186	91	-
2024	61	8.556	73	117	73	249

Conclusions: Collaboration between Alliance and MFAFU continues and there is a plan to expand this collaboration in 2025 in the Ministry of Internal Affairs specially targeting reserve soldiers. Collaboration includes training for MA staff, TA and join planning of the MA work. There is a greater need expand these services and equip MA with the Starlink and electronic warfare device to prevent its damage.

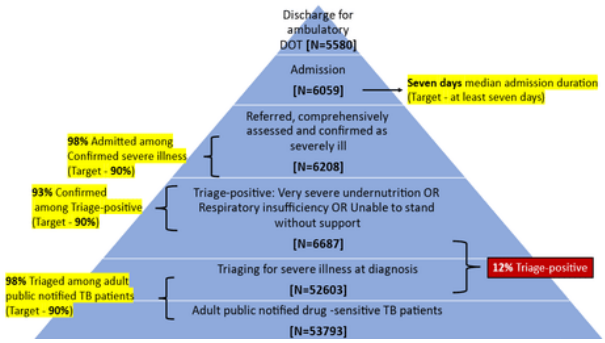
OA15-247-19 First statewide differentiated TB care: Care cascade and death rate reduction in 2024

R Vijayaprabha,[1] H.D. Shewade,[1] A. Frederick,[2] KV. Suma,[3] R Sabarinathan,[4] K Rambha,[2] K Gayathri,[5] A Jeyakumar,[5] D. Kabir,[1] M Jeen Melfha,[1] R Srinivasan,[6] S. Shanmugasundaram,[1] [1]ICMR National Institute of Epidemiology, Division of Health Systems Research, Chennai, India, [2]Directorate of Medical and Rural Health Services, State TB Office, Government of Tamil Nadu, Chennai, India, [3]Office of the World Health Organization (WHO) Representative to India, WHO Country Office, New Delhi, Chennai, India, [4]ICMR National Institute of Epidemiology, Computing and Information Sciences, Chennai, India, [5]ICMR National Institute of Epidemiology, ICMR School of Public Health, Chennai, India, [6]ICMR National Institute of Epidemiology, Infectious Disease Epidemiology, Chennai, India
e-mail: stotn@rntcp.org

Background: To address high TB mortality, Tamil Nadu (a southern Indian state) implemented differentiated TB care from April 2022, based on successful pilots of a triage tool in Karnataka (2020) and Gujarat (2021). The Tamil Nadu *Kasanoi Erappila Thittam* (TN-KET), meaning „TB death-free project," aimed to triage adults with TB at diagnosis for high risk of death. Triage-positive (very severe undernutrition or respiratory insufficiency or poor performance status) were prioritized for referral, comprehensive assessment, and inpatient care in all TB districts except Chennai (n=30 districts), the capital city (*Figure*).
After adjusting for potential confounders, TN-KET was associated with 20% and 11% reduction in early and overall TB death rate in July-September 2022 diagnosis cohort when compared to January-March 2022. Sustained assessment of care cascades and effect on TB death rate needs to be documented.
Design/Methods: Cohort study involving secondary data extracted for Severe TB Web Application (TB *SeWA*) – the case-based severe TB information management system of TN-KET and *Ni-kshay* – the case-based TB information management system of TB program.
Results: In 2024, of 53 793 adults with TB diagnosed from public facilities, 52 603 (98%) were triaged and 6687 (12%) were triage-positive (eligible for referral). Of 6687 eligible, 6208 (93%) were referred, comprehensively assessed and confirmed as severely ill at nodal inpatient facilities.
Of 6208 confirmed, 6059 (98%) were admitted for inpatient care and 5580 (92%) were successfully discharged for ambulatory care. The median admission duration was

seven days (*Figure*). When compared to baseline, among the July-September 2024 cohort, 25 districts have documented at least 20-30% reduction in reported TB death rate.

Figure. TN-KET care cascade, 2024



Conclusions: In the third year of TN-KET, the losses in the TB care cascade have significantly reduced and many districts have documented reduction in TB death rates. This effect needs to be confirmed through confounders adjusted individual level data analysis and is ongoing.

OA15-248-19 Inuit experiences and expertise on the 21st century tuberculosis epidemic in Nunavik, Quebec, Canada: A qualitative community-based participatory study

B. Geboe,[1] G. Sandy,[2] D. Tooktoo,[3] S. Tukalak,[4] S. Law,[1] S. White-Dupuis,[5] Q. Nappaaluk,[6] N. Aliqu,[7] M. Emudluk Sr.,[8] L. Watt,[9] N.I. MacDonald,[10] F. Ahmad Khan,[1,4,11]
[1]McGill University, Respiratory Division, Department of Medicine, Montreal, Canada, [2]Nunavik Regional Board of Health & Social Services, Kanniq Program, Department of Public Health, Kuujjuaq, Nunavik, Canada, [3]Research Institute of the McGill University Health Centre, Respiratory Epidemiology & Clinical Research Unit, Kuujjuaraapik, Nunavik, Canada, [4]Research Institute of the McGill University Health Centre, Respiratory Epidemiology & Clinical Research Unit, Montreal, Canada, [5]Puvaqatsianirmut, Nunavik Lung Health Steering Committee, Kuujjuaq, Nunavik, Canada, [6]Community Leadership, Mayoress, Kangiqsujuaq, Nunavik, Canada, [7]Puvaqatsianirmut, Nunavik Lung Health Steering Committee, Akulivik, Nunavik, Canada, [8]Puvaqatsianirmut, Nunavik Lung Health Steering Committee, Kangiqsualujjuaq, Nunavik, Canada, [9]Ungava Tulattavik Health Centre, Executive Director, Kuujjuaq, Nunavik, Canada, [10]Silattusarniq Community Solutions Consulting, Inuit-led research, Nunavik, Canada, [11]Institut nordique du Québec & McGill University, Northern Research Chair in Respiratory Health & Health Services, Montreal, Canada
e-mail: ben.geboe@mail.mcgill.ca

Background: In the mid-20th century, Canadian federal and provincial governments addressed high tuberculosis rates amongst Inuit through colonial policies centered on forced removal to distant sanatoria causing significant individual and societal trauma. In Nunavik, the Inuit homeland in Quebec (Canada), tuberculosis incidence has risen again in the 21st century, and in 2024 reached 150-times the Quebec average. We undertook the first-ever investigation to understand Nunavik Inuit („Nunavimmiut“) experiences with tuberculosis care in the 21st century.
Design/Methods: A community-based participatory action research project working with Nunavik's health authorities, leaders, and an Inuit steering committee. Indigenous researchers (First Nations & Nunavimmiut) conducted interviews and focus groups with Nunavimmiut about tuberculosis and healthcare experiences. Iterative data analyses used constructivist grounded theory and Indigenous Research Methodology within a reconciliation framework, and considered service delivery challenges observed in outbreaks occurring during the research. We report policy recommendations that emerged from data analysis.
Results: From 2022-2023, we interviewed 156 Nunavimmiut in 5 Nunavik communities and Montreal. Nunavimmiut shared a strong desire to protect individual and community health, which contrasted with under-resourced health services. Contemporary tuberculosis care pathways and interventions were themselves identified as sources of hardship from cultural and linguistic dissonance of health services, displacement for investigation and treatment, isolation requirements, lack of support, and stigma. The paucity of Inuktitut language in health services contrasted with its supremacy in day-to-day life. A paradigm emerged of program-centered tuberculosis services, arising in part from under-resourcing. Healthcare workers largely echoed these perceptions. Nunavimmiut recommendations for improving their tuberculosis experiences included increasing Inuit agency over services and data, Inuit healthcare workers, greater support for affected individuals, and increasing local services to minimize displacement.
Conclusions: Nunavimmiut called for shifting from program-centered to person-centered and community-driven tuberculosis care, which will necessitate increasing resources and entrenching Inuit agency over services through reconciliation- and decolonization-aligned policy changes.

SHORT ORAL ABSTRACT SESSION (SOA)

SOA03 Refining the performance of computer-assisted TB diagnostics

SOA03-523-19 Man vs machine: A comparative analysis of AI-assisted screening and community referrals for TB detection under the C-PAT project

V. Panibatla,[1] R. Dasari,[2] E. Babu,[3] M Balakrishna,[4]
[1]TB Alert India, Program Implementation and Research, Hyderabad, India, [2]TB Alert India, Program, Hydeabad, India, [3]TB Alert India, Program Implementation, Hyderabad, India, [4]TB Alert India, M&E, Hyderabad, India

Background and challenges to implementation: The Community-led Patient Active TB Case Finding (C-PAT) project, implemented across Telangana, Uttar Pradesh, and Bihar, aimed to enhance early TB detection among underserved populations.
Two complementary strategies were adopted:
1. AI-enabled handheld X-ray screening through organized camps, and;
2. Community-led referrals of people with TB-like symptoms (PTS) by trained local stakeholders.
These approaches were introduced to address persistent challenges of delayed diagnosis, and limited access, settings.
Intervention or response: A total of 241 screening camps were conducted in collaboration with local health centres, using portable AI-powered X-ray devices used for screening and followed by diagnostic test TB identification.
In parallel, 314 community stakeholders—including women self-help group members, key opinion leaders, and members of village-level local self-governance bodies—were trained and supported to identify and refer individuals with TB-like symptoms.
All those identified were linked to appropriate testing for TB, with logistics facilitated for sample collection and transport.
Results/Impact: Over the course of one year, 8,754 individuals were screened using AI-enabled handheld X-ray tools, resulting in 51 people diagnosed with TB (0.5%). In contrast, in just three months, 1,172 individuals were referred by 314 community stakeholders, with 37 people diagnosed with TB (3%).
While artificial intelligence enabled large-scale, standardized screening, the human intelligence of community stakeholders—rooted in local knowledge and trust—proved six times more effective. This demonstrates the strength of combining technological scale with social precision.
Conclusions: The C-PAT experience shows that blending innovation with grassroots engagement creates a powerful hybrid model for TB detection. Integrating AI tools with community networks can significantly enhance case finding in resource-constrained, high-burden settings.

SOA03-524-19 Optimizing TB screening using chest X-ray with computer-aided detection: Diagnostic efficiency across threshold scores to assist human reading

N. Marquez,[1] M.R. Santiago,[2] R. Orillaza-Chi,[3] J. Calderon,[4] [1]Ateneo School of Medicine and Public Health, Research Methods and Translation, Pasig City, Philippines, [2]Philippine Tuberculosis Society, Research and Training Department, Quezon City, Philippines, [3]The Ruth Foundation, Clinical Department, Muntinlupa City, Philippines, [4]FHI 360, EpiC-HIV, Makati City, Philippines
e-mail: nichelmarquez@gmail.com

Background and challenges to implementation: Chest X-ray (CXR) remains a crucial screening tool for identifying tuberculosis (TB) through standard human interpretation. However, reading variability and resource constraints can limit its effectiveness. The emergence of computer-aided detection (CAD) systems provides a scalable alternative for automated screening, as they quickly analyze CXRs using artificial intelligence algorithms. Comparing CAD performance across different thresholds to human readings is essential for optimizing diagnostic efficiency.
Intervention or response: In selected cities in the Philippines, systematic TB screening utilized CXR with CAD to identify presumptive TB alongside radiologist readings. Retrospective data were analyzed using molecular World Health Organization-recommended rapid diagnostic test (mWRD) as the reference standard, covering the period July 2022-March 2024.
The assessment addressed diagnostic performance, threshold scores at 95% and 90% sensitivity, and TB diagnostic efficiency indicators, including number needed to test (NNT), missed cases, and saved mWRD.
Results/Impact: Using a 0.50 threshold, 2,087 individuals were screened with 229 diagnosed TB cases. The CAD demonstrated a 96% sensitivity and 42% specificity, while human readers achieved 83% sensitivity and 59% specificity. Increasing the CAD threshold to 0.56 optimized sensitivity to 95% and improved the rate of saved confirmatory testing from 38% to 42%. While enhancing specificity and resource efficiency, a 0.70 threshold significantly increased the number of missed cases from 9 to 22.
Compared to human readings, CAD detected more cases with a similar range of positive predictive values but fewer missed cases. Its adjustable thresholds allowed for programmatic trade-offs between sensitivity and resource use.

Variable	Total N=2,087[a]	mWRD (+) N=229 (11%)	mWRD (-) N=1,858 (89%)
Sex Male Female	937 (45%) 1,150 (55%)	141 (62%) 249 (38%)	796 (43%) 1,062 (57%)
Mean age (range)	52.7 (15-90)	47.4 (15-84)	53.4 (15-90)
Age Groups 15 to 39 40 to 59 60 and older	481 (23%) 743 (36%) 860 (41%)	74 (32%) 82 (36%) 72 (32%)	407 (22%) 661 (36%) 788 (42%)
CXR with CAD results TB Presumptive TB Negative	1,292 (62%) 795 (38%)	220 (96%) 9 (4%)	1,072 (58%) 786 (42%)
Human Reading Results TB Presumptive TB Negative	959 (46%) 1,128 (54%)	191 (83%) 38 (17%)	768 (41%) 1,090 (59%)

Table 1: Demographic and clinical description of participants tested by mWRD.

Parameters	No triage test[b]	Human Reading	Chest x-ray with CAD		
			0.50[c]	0.56	0.70
Performance metrics					
Sensitivity	-	83%	96%	95%	90%
Specificity	-	59%	42%	46%	57%

[c] AUROC = 0.86 (95% CI: 0.83, 0.88)
[d] Positive Predictive value

Table 2: Performance metrics and efficiency measures at different CAD threshold scores

Conclusions: Understanding the differences between CAD and human reading performance on CXR is essential for strengthening screening strategies, particularly when balancing case detection with resource constraints. CAD systems can enhance the efficiency of TB screening and offer flexible, threshold-based tuning to maximize sensitivity while effectively managing resources.
The findings highlight CAD potential to complement human interpretation and improve TB diagnostic workflows.

SOA03-525-19 CAD4TB's precision, threshold 45 optimizes tuberculosis screening in West Nile region, Uganda

L. Ocen,[1] S. Najjingo,[1] J. Muhangi,[1] H. Suubi,[1]
R. Tamale,[1] [1]Uganda Episcopal Conference, Uganda
Catholic Medical Bureau, Kampala, Uganda
e-mail: locen@ucmb.co.ug

Background: The Computerized Aided Detection for TB (CAD4TB), a component of TB screening using digital x-rays, uses a cut-off of 50 in Uganda to weigh between sensitivity and specificity for TB detection. The community awareness screening and testing (CAST+) for TB and other conditions' campaign 2024 experimented with lowering the CAD4TB threshold to 30 to maximize TB diagnosis. We evaluated CAD4TB version 7 (v7) in West Nile to identify an optimal cut off against the currently implemented values.
Design/Methods: Chest X-rays (CXRs) from 6,000 individuals (188 TB-positive, 4,690 TB-negative, confirmed by GeneXpert) were analyzed with CAD4TB v7. Receiver Operating Characteristic (ROC) analysis, including the area under the curve (AUC=0.97), assessed sensitivity, specificity, referral burden, number needed to test (NNT), and positivity yield at cut off 50 (national), 30 (CAST+), and other cut offs, including 45.
Results: The cut off 45 achieved a 96.81% sensitivity (95% CI: 93.1-98.9%) and a 94.22% specificity (95% CI: 93.5-94.9%), detecting 182 of 188 TB patients with 453 referrals. (NNT=2, yield=40%). Uganda's cut off 50 yielded 96.28% sensitivity (95% CI: 92.5-98.6%) and 98.02% specificity (95% CI: 97.6-98.4%), identifying 181 patients with 274 referrals (NNT=2, yield=66%). The sensitivity gains at 45 (+0.53%, p=0.045) detected one additional patient, with a specificity trade-off (-3.8%, p<0.001).
Compared to CAST's 30 (97.34% sensitivity, 70.3% specificity, 1,576 referrals, 12% yield), cut off 45 reduced referrals by 71% (1,123 fewer, p<0.001) while maintaining near-identical case finding (p=0.32).

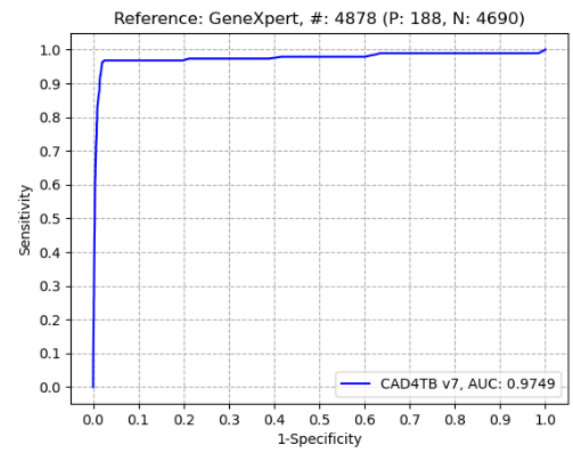

Figure. ROC curve and AUC computed from the obtained scores and provided reference.

Conclusions: In West Nile's region, cut off 45 optimizes CAD4TB screening, improving sensitivity over cut off 50. It reduces referrals and, improves case finding without compromising efficiency. We recommend use of context specific CAD4TB cut offs to optimize TB case finding and maximize efficiency.

SOA03-526-19 Impact of computer-aided X-ray diagnosis to optimise Xpert-orientated community-based active case-finding for tuberculosis: An open-label, randomised controlled trial

A.J. Scott,[1,2] T. Perumal,[1,2] S. Jaumdally,[1,2] A. Chizema,[3] D. Milimo,[4] S. Oelofse,[1,2] A. Esmail,[1,2] J. Mutsvangwa,[3] H. Ayles,[4,5] K. Dheda,[1,2,6] [1]University of Cape Town, Centre for Lung Infection and Immunity, Division of Pulmonology, Department of Medicine, Cape Town, South Africa, [2]University of Cape Town, South African MRC/UCT Centre for the Study of Antimicrobial Resistance, Cape Town, South Africa, [3]University of Zimbabwe, Biomedical Research and Training Institute, Harare, Zimbabwe, [4]University of Zambia, Zambart, Lusaka, Zambia, [5]London School of Hygiene and Tropical Medicine, Department of Clinical Research, Faculty of Infectious and Tropical Diseases, London, United Kingdom of Great Britain and Northern Ireland, [6]London School of Hygiene and Tropical Medicine, Department of Immunology and Infection, Faculty of Infectious and Tropical Diseases, London, United Kingdom of Great Britain and Northern Ireland
e-mail: alex.scott@uct.ac.za

Background: Almost one-third of individuals with new onset tuberculosis (TB) are unreported or undiagnosed. Thus, sensitive and user-friendly point-of-care (POC) screening tools are required to undertake community-based active case-finding (ACF) for TB.
Computer-aided detection (CAD) has been recommended by the WHO. However, the role of CAD and its impact, compared to alternative screening strategies, remains unclear.
Design/Methods: In this ongoing, open-labelled, randomised controlled trial (RCT), symptomatic and/or high-risk persons (HIV-positive, history of previous TB, diabetes, TB contact) were recruited from TB-endemic communities in South Africa, Zambia, and Zimbabwe.
Using a low-cost mobile vehicle staffed by three healthcare workers and equipped with an ultra-portable X-ray and GeneXpert® system, participants who questionnaire-screened positive (TB symptoms and/or risk factor present) were randomised (1:1) into either 'CAD+Xpert' (Arm 1: CAD followed by Xpert MTB/RIF Ultra in CAD-positive participants) or 'Xpert only' (Arm 2: POC Xpert MTB/RIF Ultra only).
CAD4TB version 7 was used with thresholds based on prior population-specific calibration. The primary outcome was the time-specific proportion of microbiologically confirmed TB by 60-days in each arm (Xpert Ultra and/or culture positivity). Here we present a preliminary interim analysis.
Results: From Feb 2022 to Sep 2024, 5,205 individuals were rapidly questionnaire-screened. 3,245 participants screened positive and were randomly assigned to CAD+Xpert (n=1,605) or Xpert only (n=1,640). 118/3,245 (3.6%) had microbiologically confirmed TB, of which 51/118 (43.2%) had asymptomatic TB. 105/118 (90.0) were included in the preliminary primary outcome analysis.
No difference was found in the proportion of TB detected by 60-days between arms (52/1,605 [3.2] vs 53/1,640 [3.2]).
Conclusions: Community-based ACF detected a high burden of TB. A CAD-directed Xpert strategy detected similar proportions of TB compared to universal Xpert testing. Feasibility and cost-effectiveness data are being analysed and will be presented along with the final results to demonstrate the full impact of a CAD-directed Xpert strategy.

SOA03-527-19 Large burden of asymptomatic tuberculosis detected with chest X-ray and computer-aided detection software

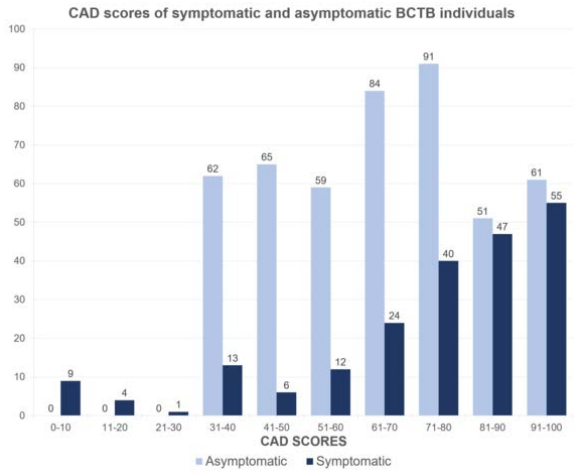
T.A. Thadhani,[1] C.A. Roma,[1] C.M. Villaruel,[1] M. Fernandez,[1] G. Babiker,[1] R. Castro,[2] F. Hossain,[3] C. Hewison,[4] [1]Médecins Sans Frontières, Medical Department, Manila, Philippines, [2]Manila Health Department, Health Department, Manila, Philippines, [3]Médecins Sans Frontières, Medical Department, Tokyo, Japan, [4]Médecins Sans Frontières, Medical Department, Paris, France
e-mail: cathy.hewison@paris.msf.org

Background and challenges to implementation: The World Health Organization recently highlighted the burden of asymptomatic tuberculosis (TB) (persons with TB disease who report no TB symptoms during screening), and its possible role in transmission. In prevalence surveys, half of people with confirmed TB do not report symptoms. Tondo — a densely populated area in Manila, Philippines — has high TB transmission rates.
We present results of an active case finding (ACF) activity using digital chest X-ray with computer-aided detection (CAD) software, and this technology's ability to detect asymptomatic TB.
Intervention or response: Analysis of programmatic screening data from July 2023 to February 2025 of the general population ≥ 15 years using symptoms and chest x-ray (CXR) with CAD (CAD4TB v7, Delft) was performed. TB symptoms were defined as: cough > 2 weeks, fever, weight loss or night sweats.
People with symptoms or CAD scores > 32 irrespective of symptoms were considered presumptive TB and underwent sputum GeneXpert MTB/RIF (Xpert) testing. In-

cluded in this analysis were TB treatment-naïve individuals with bacteriologically confirmed TB (BCTB) defined by positive sputum Xpert results.

Results/Impact: The CAD scores and symptom screening results are shown in Figure 1. Among all people with BCTB, majority (69%, 473/684) reported no symptoms. Only 7% (14/211) of symptomatic participants had CAD scores below threshold.

Median CAD scores for symptomatic and asymptomatic people were 66.5 and 79.6 respectively. The difference between CAD scores of symptoms negative (M = 65.52, SD = 19.09) and positive (M = 72.97, SD = 23.94) individuals was statistically significant, t (682) = 4.35, $p < 0.0001$, 95% CI [-10.8177, -4.0823].



Conclusions: During ACF, most treatment-naive people with BCTB report no TB symptoms. Symptom screening may not be cost-effective when systematically screening with CXR and CAD. In high-risk populations, symptom-agnostic screening strategies with CXR and CAD are important to detect people with asymptomatic TB, who possibly drive community transmission.

SOA03-528-19 Intensified TB case finding and GeneXpert optimisation using chest X-rays with computer-aided detection (CAD) in Kenyan hospitals

I. Kathure,[1] M. Githiomi,[1] J. Okari,[1] R. Choto,[2] G. Brigden,[3] B. Nzano,[4] S. Macharia,[1] A. Rono,[1] E. Muriithi,[1] J. Harwell,[5] D. Karambi,[6] [1]Ministry of Health, National TB Program, Nairobi, Kenya, [2]The Global Fund to fight AIDS, TB and Malaria, High Impact Africa 2 Department, Grant Management Division, Geneva, Switzerland, [3]The Global Fund to fight AIDS, TB and Malaria, Technical Advice and Partnerships, Geneva, France, [4]Clinton Health Access Initiative, Clinical Sciences, Nairobi, Uganda, [5]Clinton Health Access Initiative, Clinical Sciences, Nairobi, Australia, [6]Clinton Health Access Initiative, Infectious Diseases, Nairobi, Kenya

Background and challenges to implementation: Tuberculosis (TB) is a significant public health challenge in Kenya, with over 120,000 estimated TB cases in 2023; yet over 20% of TB cases were missed. Decreasing donor funding necessitates sustainable solutions for active case finding. By integrating Computer Aided Detection software (CAD) into existing x-ray equipment, the Kenya TB Program (NTP) aimed at finding the missed cases through screening of all chest x-rays for TB, allowing seamless expansion of TB screening within facility workflows, while mitigating against catastrophic patient costs.

Intervention or response: In May 2024, through Global Fund support, NTP deployed CAD software in X-ray units at 69 hospitals which was used to scan all chest X-rays taken irrespective of the initial purpose, and with no additional costs to patients. The TB diagnostic algorithm was revised to integrate CAD into the facilities' operational workflows and radiology professionals trained.

Patients with probable TB from CAD underwent molecular testing and those found to have TB were initiated on treatment while those with other diagnoses were referred for care. We analysed chest x-ray CAD data and GeneXpert data for the period May to December 2023 and 2024 from the 69 health facilities.

Results/Impact:

	May to December 2023	May to December 2024
Total X-rays read by CAD	No CAD available	35,592
X-rays with Probable TB from CAD	No CAD available	4,876
X-rays with Other Thoracic Abnormalities from CAD	No CAD available	14,842
Total GeneXpert Tests Done	81,521	131,639
MTB Positive Patients Diagnosed	10,060	15,155
% Increase in MTB Positive Patients Diagnosed	-	51%
GeneXpert Utilization (%)	52%	84%
GeneXpert Yield (%)	12%	12%

Table. Chest X-ray CAD and GeneXpert Data (May to December 2023, 2024) from 69 Health Facilities, Kenya.

Of the 35,592 X-rays read by CAD, 4,876 had probable TB while 14,842 were diagnosed with other thoracic abnormalities. Bacteriologically confirmed TB cases and GeneXpert utilization rates increased from 10,060 and 52% to 15,155 (51%) and 84% respectively between 2023 and 2024 for the same period. GeneXpert yield remained 12%.

Conclusions: Implementation of AI-enhanced surveillance of all chest X-rays CXRs within health facilities is a scalable and sustainable model for enhancing tuberculosis (TB) case detection in Kenya while simultaneously optimising limited TB laboratory investments. Optimizing use of this technology by reviewing the existing CAD thresholds has the potential to further improve GeneXpert testing prioritisation, and yields.

SOA03-529-19 Strengthening TB case detection in Uganda through mobile clinics and digital diagnostics: Lessons learned and future directions

A. Mulindwa,[1] D. Tugumisirize,[1] L. Mukisamuzaale,[1] B. Ayebazibwe,[1] N. Modi,[1] E. Quinto,[1] H. Luzze,[1] A. Burua,[1] S. Turyahabwe,[2] [1]Ministry of Health, National Tuberculosis & Leprosy Program (NTLP), Kampala, Uganda, [2]Ministry of Health, Communicable Disease Prevention & Control, Kampala, Uganda
e-mail: mulindwaalex@gmail.com

Background and challenges to implementation: The tuberculosis epidemic in Uganda is exacerbated by inaccessible diagnostic services in rural and remote regions with over 3,377 Diagnostic and treatment units (DTUs). Logistical barriers, limited resources, and underdeveloped healthcare infrastructure cause delays in TB diagnosis and treatment, increasing disease burden.

To address these challenges, Uganda implemented an innovative approach by integrating mobile clinics and digital diagnostics into its national TB response.

Intervention or response: Since July 2023 to December 2024, Uganda's National TB and Leprosy Program (NTLP), funded by the Global Fund, deployed five mobile clinics equipped with Xpert MTB/RIF and CAD4TB technologies.

These units were strategically located in underserved areas to improve access to TB services. The intervention featured community awareness campaigns, healthcare worker training, and collaboration with stakeholders to strengthen service delivery.

Monitoring and evaluation informed program improvements and scalability. Uganda plans to expand this initiative by procuring 11 additional clinics to cover all other 11 health regions.

Results/Impact: A total of 56,337 individuals were screened using Mobile TB Clinic equipped with Xpert MTB/RIF, digital X-ray and CAD4TB with 5,361 abnormal chest X-ray results documented. Additionally, 13,255 sputum samples were collected, and tested with GeneXpert, leading to the diagnosis of 1,072 TB patients, 58% (627) bacteriologically confirmed, including 11 RR-TB patients. 97% (1,038/ 1,072) of patients were initiated on same-day treatment. The decentralized mobile TB clinics at regional referral hospitals contributed 49% (525/1,072) of the total TB patients notified highlighting their effectiveness.

The use of Mobile digital technologies in TB Case Finding

Conclusions: Uganda's mobile clinics demonstrate the transformative power of integrating technology and community-centered approaches to overcome barriers in TB care. This scalable model supports Uganda's goal to end TB by 2030 and offers valuable insights for other low-resource countries aiming to enhance healthcare access and equity. Continued investment and collaboration are essential for sustainability.

SOA03-530-19 Reducing the tuberculosis case detection gap with AI: Advancing health equity in remote rural communities in Nigeria

C. Okoye,[1] J. Ilozumba,[2] A. Ohde,[3] J. Creswell,[4] [1]Catholic Caritas Foundation of Nigeria, TB/HIV, Abak, Nigeria, [2]Catholic Caritas Foundation of Nigeria, TB/HIV, Abuja, Nigeria, [3]Qure Ai, Clinical Team, New Delhi, India, [4]STOP TB Partnership Geneva, TB/HIV, Geneva, Switzerland
e-mail: cezeobi@ccfng.org

Background and challenges to implementation: Nigeria has one of the world's highest TB burdens, with a Case Detection Rate of 74% in 2023. Remote rural communities face major diagnostic barriers due to poverty, lack of chest X-ray and GeneXpert services at the primary care level, and limited transport to urban centers. These challenges delay diagnosis and widen health inequities. This study presents our experience implementing the INTEGRATE TB project, which deployed AI-enabled portable digital X-ray systems with WHO-endorsed CAD software (qXR) in three underserved LGAs of Ebonyi State.

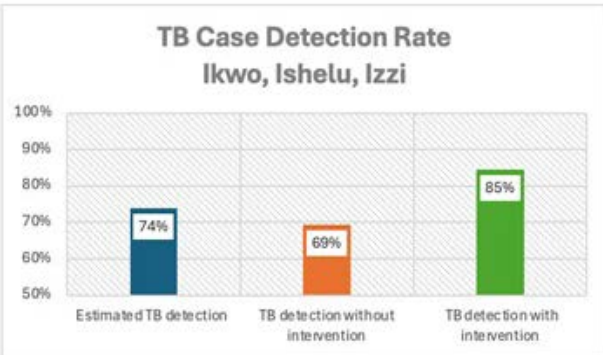
Intervention or response: Caritas Nigeria implemented the INTEGRATE TB project from July 2023 to December 2024, conducting community outreach in remote rural areas Ikwo,Izzi and Ishielu LGAs of Ebonyi state Nigeria. Screening followed a dual parallel approach: WHO symptom screening and AI-enabled chest X-ray (qXR). Individuals with symptoms or qXR AI scores ≥0.30 provided sputum for GeneXpert testing. Those with AI scores ≥0.30 but GeneXpert-negative were referred to radiologists for further clinical evaluation. Reported TB incidence from WHO (2023) served as the denominator to calculate the Case Detection Rate (CDR), with the CDR gap representing the additional cases identified through the intervention.

Results/Impact: The TB case detection rate computed without the intervention was 69%, five percentage points lower than the nationally reported in Nigeria, 74%.

With the intervention, the CDR reached 85%, a marked 11 percentage points increase with respect to the previous reported figure.

TB case detection rate in three Ebonyi LGAs: Ikwo, Ishelu and Izzi

	Case detection rate	TB cases
Estimated TB incidence	-	1,971
Estimated TB detection	74%	1,459
TB detection without intervention	69%	1,369
TB detection with intervention	85%	1,667



Comparator: Annual Incidence in Nigeria, 219 per 100,000 (WHO)

Conclusions: INTEGRATE TB project deployed the use of AI-enabled portable digital X-ray to provide a scalable, equity-driven solution to Nigeria's TB diagnostic challenges. Deploying AI tools at the community level offers a promising strategy to close the diagnostic gap, enhance early detection, and accelerate efforts toward TB elimination in high-burden, resource-limited settings.

SOA03-532-19 Accelerating TB screening and case finding through artificial intelligence retrofits into existing X-ray systems in Kenya

I. Kathure,[1] R. Choto,[2] G. Brigden,[3] M. Githiomi,[1] J. Okari,[1] [1]Ministry of Health, National TB Program, Nairobi, Kenya, [2]The Global Fund to fight AIDS, TB and Malaria, High Impact Africa 2 Department, Grant Management Division, Geneva, Switzerland, [3]The Global Fund to fight AIDS, TB and Malaria, Technical Advice and Partnerships, Geneva, France

Background and challenges to implementation: Artificial Intelligence (AI) has been deployed in active TB case finding through portable X-rays in remote settings, addressing the gap in trained radiology manpower. Hundreds of chest X-rays (CXRs) are taken for various clinical indications, yet facilities miss the opportunity to screen them for TB.

The Kenya TB program through Global Fund support retrofitted AI into facility-based X-ray systems, allowing for standardised, opportunistic TB screening without disrupting routine workflows. The integration experience and lessons will be useful for other countries considering this approach.

Intervention or response: A baseline facility assessment was conducted by a multidisciplinary team of engineers, TB program staff and radiologists on infrastructure readiness, internet availability, patient pathways, diagnostic services, and compatibility of AI software with existing X-ray modalities.

Thereafter, 69 sites (sub-county and County referral hospitals) were selected and a multimodal AI deployed between May and November 2024. An on-premise deployment model was used across all sites, requiring laptops with cloud synchronization capabilities.

AI-generated TB and lung health screening dashboards were availed for various stakeholders. All chest x-rays were reported using CAD.

Challenges	Mitigation
Lack of internet connectivity	• TB Program provided mobile Wi-Fi – MiFi • Additional data packs enabled to allow for non-TB screening
Limited lung health data available	• TB program set up a lung health program and developed health care worker resource tools to facilitate patient management and referral
Issues with data sync due to unstable internet	• Hospital ethernet was used
Lack of streamlined workflows at facilities	• Trained the health care workers on the AI solution using a standardised protocol. • Standard Operating Protocols and information posters put up in radiography rooms
Hardware challenges during set up	• AI provider ensured there were well trained and responsive in-country support partners to troubleshoot

Results/Impact: Seamless adoption of AI enabled screening of all 35,593 CXRs taken in these facilities for TB using existing infrastructure at no additional cost to patients and no increase in radiologist workload. Of these, 4,876 had probable TB. TB case finding in these sites increased by 51%.

Challenges identified during deployment included lack of or interrupted internet connectivity, weak patient referral for non-TB lung conditions, inefficient patient workflows and hardware challenges.

Conclusions: Kenya's experience demonstrates that a multimodal AI retrofit into existing X-ray infrastructure is feasible, has no cost implication to patients, enhances diagnostic accuracy and optimises radiologists' workload. Lessons learnt will enable other countries to rapidly adopt and scale up this facility-based approach to accelerate TB detection by ensuring no chest X-ray is missed for screening of TB.

SOA03-533-19 Enabling access to TB diagnosis and treatment through AI-enabled portable solution in Ukraine

O. Pavlenko,[1] Z. Karpenko,[2] M. Germanovych,[1] A. Bogdanov,[1] G. Dravniece,[1] [1]PATH, STBCEU, Kyiv, Ukraine, [2]Chernigiv Regional TB Dispensary, TB Department, Chernihiv, Ukraine

Background and challenges to implementation: The Chernihiv region of Ukraine had encountered significant medical service access disruptions due to its front-line proximity. The Regional Pulmonology Center (TB Center) sustained infrastructure damage, loss of medical equipment and vehicles, and faced healthcare personnel shortages, particularly radiologists. Number of visits to TB Center has declined due to difficulties in accessing healthcare facilities.

Confirmation of TB diagnosis, including X-ray interpretation, transportation and analysis of biological samples, was centralized and took up to 5 days, exceeding national TB care standards.

Intervention or response: Under the USAID-funded Support TB Control Efforts in Ukraine (STBCEU) project, PATH procured a mobile medical unit (MMU) equipped with Lunit INSIGHT CXR AI-enabled portable X-ray machine and telemedicine solution for the TB Center to provide decentralized case finding services.

In the fourth quarter of 2024, the project rolled out the MMU. STBCEU experts and local leadership collaboratively developed a tailored screening algorithm for remote settlements, enabling on-site X-ray analysis without the internet connection. This initiative included the immediate collection of biological samples from individuals with chest X-ray abnormalities indicative of TB and implementation of telemedicine solutions for TB treatment prescriptions.

Results/Impact: In the first quarter of 2025, the TB Center conducted seven visits to remote settlements based on prior risk groups identification, screened 951 individuals using Chest X-ray, revealed 39 abnormalities, with 9 individuals (23.1%) exhibiting TB-indicative findings on Lunit INSIGHT CXR. Sputum samples were collected from all 9 patients. TB was confirmed in 5 (12.8%) individuals: 3 began TB treatment within one day of confirmation, while 2 patients initiated treatment on day two after TB confirmation.

Results	Number of observations (n)	Distribution of abnormalities by type (%)
Total, screened by Lunit INSIGHT CXR	**951**	
Total, abnormalities	**39**	
Pulmonary, non-TB	**30**	**76.9%**
oncopathology	9	23.1%
pneumonia	21	53.8%
Findings suggestive of TB	**9**	**23.1%**
TB confirmed	5	12.8%
TB not confirmed	4	10.3%

Table 1. Abnormalities identified by Lunit INSIGHT CXR in Chernihiv Oblast, Ukraine.

Conclusions: The AI-enabled mobile approach reduced the average TB diagnosis time to approximately 1.5 days and facilitated prompt treatment initiation through teleconsultation in regions where healthcare access and public transportation was limited.

SOA04 Innovative programmatic approaches to eliminate TB

SOA04-534-19 Enhancement of village midwife contribution to increase coverage of TB preventive treatment (TPT) in 3 selected districts in Sumatera Utara Province, Indonesia

E.S. Siahaan,[1] R. Pasaribu,[1] [1]Yayasan Menara Agung Pengharapan Internasional, Program, Medan, Indonesia
e-mail: elvi.siahaan@gmail.com

Background and challenges to implementation: In three districts (Dairi, Tapanuli Utara, Toba Samosir), there have been no cases of individuals initiated on TB preventive treatment (TPT) or contact individuals tested for infection over a period of two consecutive years. To address this gap, village midwives, who are government health workers for maternal health stationed in local villages, have been involved in contact investigation and sputum collection procedures.
Intervention or response: With funding from the STOP TB Partnership, TB workers at puskesmas (community health center) were involved and trained to improve their skills in planning, organizing, recording, and reporting TB contact investigation and TPT. TB workers then train Midwives on TPT, methods to educate the community, screen and link to puskesmas for testing and treatment. Village midwives visited TB index patients, screened their contacts for TB, and collected sputum from those with symptoms. They also tested those without symptoms and over five years of age for TB Infection (TBI).

Indicators	Project targets	Project Achievement				% of target achieved
		Child 0-4	Child 5-14	Adult	Summary	
Number of people screened	4.725	602	3.055	9.362	13.019	275%
Number of people tested for infection	2.561	0	1.765	5.113	6.878	268%
Number of people who test positive for infection	512	0	233	913	1.146	224%
Number of people with TB disease (ineligible for TPT because of active TB or for other reasons)	19	6	15	66	87	456%
Number of people eligible for TPT	737	166	233	913	1.312	178%
Number of people started on TPT	516	34	162	649	845	164%
Number of people completing TPT	490	24	89	403	516	105%

Results/Impact: A total of 159 TB workers from 58 puskesmas (community health centers) were trained and they continuously trained 917 midwives. Over the course of a year, 13,019 contacts were screened. Of these contacts, 6,878 (53%) were tested for TBI and 1,146 (17%) were positive Tuberculin Skin Test (TST). The total number of eligible for TPT was 1,312 (19%) and 845 (64%) of these contacts initiated TPT. The primary factor contributing to the low initiation rate was the limited availability of treatment.
Conclusions: Involvement of midwives in the initiation of TPT has been demonstrated to yield a substantial increase in number of individuals who started TPT. It increased TBI screening and testing, recording and reporting in national system and subsequently assist those eligible to initiate TPT until completion. The potential for increasing the number of initiations is significant, contingent upon the timely distribution of logistics by government.

SOA04-535-19 The positive impact of using riders for health in TB specimen transportation compared to health workers in Ogun State

O. Edwin,[1] E. Salau,[1] L. Folorunso,[1] F. Muse,[1] A. Adeniyi,[1] T. Lawal,[1] P. Dakum,[2] O. Olupitan,[2] O. Chijioke-Akaniro,[3] U. Ochuko,[3] J. Kimeu,[4] A. Reilly,[4] [1]Damien Foundation Belgium (Nigeria Project), Programme, Ibadan, Nigeria, [2]Institute of Human Virology, Nigeria, Programme, Abuja, Nigeria, [3]National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Programme, Abuja, Nigeria, [4]Global Fund Country Team, Programme, Geneva, Switzerland
e-mail: fadeyi.muse@dfbnigeria.org.ng

Background and challenges to implementation: Timely and efficient transportation of sputum samples for tuberculosis (TB) diagnosis is essential for early detection and prompt treatment initiation. In high-burden settings, healthcare workers are often tasked with transporting TB specimens. This dual responsibility contributes to delays due to competing clinical duties, transportation limitations, and workforce shortages. Riders for Health (RFH)—a specialized logistics system using trained motorcycle riders—offers a promising solution to improve TB diagnostic efficiency. This study evaluates the impact of RFH compared to healthcare worker-led specimen transport on turnaround time, sample integrity, and treatment initiation.
Intervention or response: A comparative analysis was conducted across high TB-burden districts where RFH was implemented. Data sources included laboratory records, patient registers, and interviews with healthcare providers. Key indicators included sample transit time, percentage of samples delivered to laboratories within 24 hours, diagnostic turnaround time, and treatment initiation rates. Operational challenges and cost-effectiveness were also assessed.
Results/Impact: RFH reduced sample transit time by 47%, with 89% of specimens delivered within 24 hours, compared to 50% under the healthcare worker-led system. Diagnostic turnaround time improved by an average of 2 days, enabling earlier case detection. Treatment initiation increased by 35% as individuals received results more quickly. Better sample handling and reduced con-

tamination under RFH improved specimen integrity. Relieved of transport duties, healthcare workers dedicated more time to person-centred care. While RFH involved higher initial investment, long-term efficiencies and improved outcomes supported its sustainability.
Conclusions: Riders for Health enhances TB diagnostic services by ensuring timely specimen transport, preserving sample integrity, and allowing healthcare providers to focus on patient care. Scaling up this approach in high-burden and remote areas, alongside digital tracking and cost optimization, can further strengthen TB control efforts.

SOA04-536-19 Overview of cross-border TB management in West and Central Africa

C.K. Houessinon,[1] A.P. Wachinou,[1,2] C. Merle,[3] D. Affolabi,[1,2] [1]West and Central African Regional Network for Tubersulosis control (WARN/CARN-TB), Executive Secretariat, Cotonou, Benin, [2]National Tuberculosis Program in Benin, Programme Management, Cotonou, Benin, [3]World Health Organization, the Special Programme for Research and Training in Tropical Diseases (TDR), Geneva, Switzerland
e-mail: ckevinhouessinon@gmail.com

Background: Migrants and refugees are at greater risk of TB exposure due factors such as overcrowded living and working conditions and increased vulnerability to HIV. TB treatment remains a challenge among migrant populations due to frequent movement and lack of coordinated cross-border systems. We sought to understand systems for cross- border management of TB in West and Central Africa.
Design/Methods: A cross-sectional, multi-country study was conducted in February to December 2024 to understand the existing collaborative mechanisms for cross-border TB management and the impact of cross-border patient flows on programmatic TB management. A semi-structured survey was administered by the secretariat of the WARN/CARN TB, a regional network of 27 NTPs in West and Central Africa, among NTP heads.
Results: Responses were received from 23 countries (82%), with 18 (78%) reportingcross-border flows of TB patients. A total of 15 countries reported outgoing patient flow, and 17 reported incoming patient flow. No countries reporting formal mechanisms for recording cross-border management of TB patients; consequently, the migratory flows of TB could not be quantified. No country had cross-border referral-counter-referral system for TB patients and only 1 country had the contacts for TB clinics in border areas in neighboring countries. 13 (86%) of countries of origin reported not knowing whether their patients were continuing their treatment abroad. Only 4 countries (22%) reported collaborations with international partners on managing cross-border populations, and 5 (28%) reported collaboration between neighboring countries. The most affected components of TB programming were patient follow-up, followed by TB data collection, supply of drugs and diagnostic products, and TB diagnosis.
Conclusions: Cross-border TB management remains a major challenge for NTPs, with limited systems available to mitigate this impact and manage patients across different countries. There is an urgent need to put in place appropriate mechanisms for collaboration between countries and with partners.

SOA04-537-19 Evaluation of a low-cost digital courier monitoring system using Kobo Collect, R, and Shiny to strengthen specimen referral performance in Zambia

J. Chama,[1,2] M. Muvwimi,[3] A. Mubanga,[2] J. Mzyece,[3,2] [1]The Global Fund to Fight AIDS, Tuberculosis and Malaria,, Zambia Country Office, Lusaka, Zambia, [2]Ministry of Health, National TB and Leprosy program, Lusaka, Zambia, [3]Ministry of Health, Pathology and Laboratory Services Unit, Lusaka, Zambia
e-mail: mpunduj@gmail.com

Background and challenges to implementation: In Zambia, inefficiencies in specimen referral systems—such as delayed dispatches, missed transports, and lack of visibility—have hindered timely diagnosis and surveillance for TB and other priority conditions. Despite routine courier activities, key indicators were not systematically tracked due to the absence of a standardized reporting format, limiting accountability and data use. These gaps, particularly at the facility–hub interface, highlighted the need for a scalable, low-cost digital system.
This evaluation assessed the implementation and early performance of a courier monitoring system built on Kobo Collect, R, and Shiny.
Intervention or response: From December 2024 a digital tool has deployed using Kobo Collect for mobile data capture and R with Shiny for automated analytics and dashboard visualization. It collects structured weekly data from spokes, hubs, testing, and reference laboratories on dispatches, turnaround times, missed trips, transport availability, and supervision. Dashboards were generated in real time and accessed by district, provincial, and national program teams.
The system is implemented entirely on open-source platforms, allowing unlimited customization. District Sample Referral Focal Point Persons (DSR-FPPs) were trained to supervise reporting and use the dashboard for targeted follow-up.
Results/Impact: From December 2024 to March 2025, 235,828 samples were reported from spoke facilities, with submission rates increasing from 13.4% to 19.8%. Concurrently, hub-level data showed 1,025,479 samples recorded over the same period, with peak volumes in January 2025 (459,173).

The consistent rise in reporting reflects increased engagement by facility and hub staff. The dashboard now enables real-time tracking across courier tiers, improving supervision, resource allocation, and accountability.
Conclusions: This evaluation demonstrates the potential of low-cost, open-source tools to strengthen diagnostic logistics. The system's adaptability, rising usage, and integration into supervision workflows make it a scalable model for improving health system performance and public health responsiveness.

SOA04-538-19 QR code efficiency: Transforming specimen management in laboratories

V.A. Laxmalla,[1] S. Pandey,[1] S. Agarwal,[1] R. Mishra,[1] U. Singh,[2] S.K. Mattoo,[2] N. Kumar,[2] [1]Hindustan Latex Family Planning Promotion Trust, Public Health, Noida, India, [2]Ministry of Health and Family Welfare, Central TB Division, New Delhi, India
e-mail: lvishalabhishek@gmail.com

Background and challenges to implementation: Reliance on manual processes for monitoring quality of diagnosis led to errors, and delays in obtaining test results. To address the challenges in tracking the journey of specimen transport from collection to testing sites, a QR Code-based system was introduced into Ni-KSHAY.
This innovation encodes crucial information, including Patient & Sample ID, Sample Type (e.g., sputum, blood), Timestamp of Collection, Collection Location, and Laboratory Details.
Intervention or response: Under the PPSA project, HLFPPT has trained community health workers involved in the initiative on SCT mechanism utilizing QR codes. During sputum collection, the agent affixes a QR code to the falcon tube, linking it with the respective Ni-KSHAY ID of the individual, and transports it to the nearest laboratory. At the testing facility, the lab technician scans QR code, logs into the system, and updates the results upon completion of testing. This process ensures seamless transparency in the specimen's journey.
The study analyzed 5,331 QR-coded samples transported in Lucknow, selected from over 15,000 samples in Uttar Pradesh and extracted data from program records, laboratory reports, and Nikshay, the national TB database. The study facilitated an in-depth examination of logistical efficiency, diagnostic timelines, and outcomes, providing valuable insights into TB specimen tracking.
Results/Impact: The study findings reveal that the average time taken from sample collection to test result generation for QR-coded samples is 1 day. It marks a significant improvement compared to samples without QR codes, showcasing the streamlined processing and rapid diagnostics enabled by QR-coded systems.

TAT - Sample collection to Test result	Number of samples (N = 5331)	Percent
Within 2 days	3724	70%
3 to 4 days	1108	21%
> 4 days	499	9%

Table. Proportion of samples - TAT for NAAT grouping.

Conclusions: The integration of QR Codes into Ni-KSHAY represents a significant leap towards improving TB specimen transport tracking systems. The implementation of QR Codes has enhanced specimen transport pathways by:
1. Enabling accurate tracking and real-time monitoring of specimens.
2. Ensuring accurate linkage of test results to original specimens.
3. Facilitating Turnaround Time (TAT) analysis to enhance operational efficiency.

SOA04-539-19 Following tuberculosis testing: Safe disposal of molecular testing waste in Kenya

J. Gituma,[1] K. Yatich,[2] J. Marcomic,[2] J. Magiri,[3] S. Musau,[4] B. Ulo,[5] [1]Jomo Kenyatta University of Agriculture and Technology, School of Health Sciences, Nairobi, Kenya, [2]Moi University, School of Health Sciences, Nairobi, Kenya, [3]Kenya Methodist University, School of Health Sciences, Nairobi, Kenya, [4]Kenyatta University, School of Public Health, Nairobi, Kenya, [5]Moi University, School of Medicine and Health Sciences, Nairobi, Kenya
e-mail: gituma7@gmail.com

Background and challenges to implementation: Molecular rapid diagnostics like Xpert MTB/RIF, Truenat, TB-LAMP, LF-LAM, and Virology Xpert for HIV support timely detection of TB and HIV. However, some contain Guanidinium Isothiocyanate (GITC), that if improperly disposed produce hydrogen cyanide, posing serious risks to health and the environment.
To address this, 19 Counties in Kenya were supported to enhance hazardous waste management through infrastructure upgrades, incinerator servicing and waste referral systems.
Intervention or response: Between 2019–2020, Amref Health Africa, Ministry of Health and CDC-Kenya, assessed molecular laboratory waste management practices across the country. Sixty-eight incinerators were mapped, revealing functional limitations and infrastructural gaps. Between 2023–2024, the Global Fund supported improvement of 19 key incinerators (each per county), ensuring they reached over 1000°C for safe destruction of GITC as recommended by World Health Organization (WHO). A waste referral network was also established, with 79 riders trained and stationed in 79 facilities gener-

ating molecular waste. They were tasked to transport the waste to designated disposal sites. High-workload facilities received weekly transport, while others were served on need basis.

Results/Impact: Of the 68 incinerators assessed, 45 were sub optimally functional. Of the 45, nineteen (one per county) were upgraded at average cost of USD 9,302.33 each, achieving >1000°C with 2-second retention time. Seventy-nine high-volume facilities generating molecular waste were each assigned a trained rider for safe transportation, at a cost of USD 0.62 per kilometer.

During implementation period, 2,052 kg of hazardous molecular waste was safely transported to the incinerator site for incineration.

Conclusions: Upgrading incinerators to achieve high temperatures >1000°C with proper retention time and establishing a functional waste referral system enabled safe disposal of over 2,000 kg of hazardous molecular waste in 19 counties. This approach proves effective and scalable, with potential for broader adoption to strengthen diagnostic waste management across Kenya.

SOA04-540-19 Enhancing sample transportation under National TB Elimination Programme through a cost-effective multisectoral accountability model

K.K. Rajaram,[1] A. Mohan,[2] V. Ambareesh,[3] D.S. Krishna,[1] L.R. Chitra,[1] H. Vijayan,[1] T. Anupkumar,[4] A.V. Gayathri,[5] S. Achanta,[6] N. Kumar,[7] U. B Singh,[7] [1]State TB Office, Department of Health Services, Thiruvananthapuram, India, [2]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, Thiruvananthapuram, India, [3]Government of India, Department of Post, Thiruvananthapuram, India, [4]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, Kannur, India, [5]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, Kochi, India, [6]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [7]Government of India, Central TB Division, New Delhi, India
e-mail: mohana@rntcp.org

Background and challenges to implementation: In Kerala, India, strengthening the TB diagnostic network requires advanced lab infrastructure and a reliable sample transport system. Despite well-equipped labs, the lack of an end-to-end transport mechanism aligned with National TB Elimination Programme (NTEP) norms hindered service quality.

To address this, the State TB Office (STO) launched a collaborative initiative to establish a streamlined, cost-neutral network linking peripheral health centers with central labs for timely diagnosis.

Intervention or response: The STO held extensive consultations with potential agencies before partnering with India Post, the world's largest public sector postal network. In a show of commitment to TB elimination, India Post agreed to waive pickup fees, significantly reducing overall costs.

Subsequent stakeholder meetings culminated in the signing of a Memorandum of Understanding (MoU) with India Post to guarantee sample delivery from any location in the state to designated laboratories within 24 hours, as mandated by NTEP. Comprehensive mapping was undertaken to link all healthcare institutions and TB laboratories to their nearest post offices. Concurrently, extensive training was provided to the personnel of both the STO and India Post on MoU implementation and quality assurance protocols. A joint monitoring and feedback system was also established.

To ensure sustainability, partnerships with corporates, Non-Government Organizations, and private banks supported high-quality packaging, sample transportation cost, and expanded diagnostic capacity—enabling uninterrupted case-finding without placing additional financial burden on the health system.

Results/Impact: Post-implementation analysis of laboratory indicators shows substantial improvements which are summarized in Table 1.

Sl. No	Indicators	Before the implementation of new sample transportation system	After the implementation of new sample transportation system
1.	Proportion of samples offered molecular WHO-recommended rapid diagnostic tests (mWRD) as the first test	49%	76%
2.	Proportion of microbiologically confirmed pulmonary TB patients with valid test result for Rifampicin resistance	88%	94%
3.	Proportion of microbiologically confirmed extrapulmonary TB patients with valid test result for Rifampicin resistance	85%	86%
4.	Proportion of microbiologically confirmed pulmonary TB patients with valid test result for Isoniazid resistance	66%	73%
5.	Proportion of microbiologically confirmed extrapulmonary TB patients with valid test result for Isoniazid resistance	29%	31%
6.	Average number of days from date of diagnosis to date of valid test result for Rifampicin resistance	16	1
7.	Average number of days from date of diagnosis to date of valid test result for Isoniazid resistance	29	12

Table 1: Key indicators of TB laboratory services before and after the implementation of sample transportation system through India Post.

Conclusions: This innovative model—anchored by collaboration between two government entities—shows how public-sector synergy, accountability, and strategic resource mobilization can deliver scalable impact. It enhances access to universal Drug Susceptibility Testing, early treatment initiation, and interruption of TB transmission. Its success and user-friendliness position it as a strong candidate for adaptation as a multi-disease sample transport system across health programs.

SOA04-541-19 Leveraging digital technologies to reduce service downtime and improve turnaround time of results from GeneXpert testing facilities in Southwest Nigeria

O. Rayi,[1] J. Olabamiji,[2] B. Kadri,[3] M. Pedro,[4] A. Agbaje,[5] O. Daniel,[6] C. Mensah,[7] P. Dakum,[8] R. Eneogu,[9] D. Nongo,[9] O. Sokoya,[10] S. Labaran,[11] [1]Institute of Human Virology Nigeria, Clinical Labortory Services, Lagos, Nigeria, [2]Institute of Human Virology Nigeria, Clinical Laboratory services, Lagos state, Nigeria, [3]Institute of Human Virology Nigeria, Prevention Care and Treatment, Lagos state, Nigeria, [4]Institute of Human Virology Nigeria, Strategic Information, Lagos, Nigeria, [5]Institute of Human Virology Nigeria, Prevention care and Treatment, Lagos, Nigeria, [6]Institute of Human Virology Nigeria, Prevention Care and Treatment, Lagos, Nigeria, [7]Institute of Human Virology Nigeria, Office of the COO, Abuja, Nigeria, [8]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [9]United States Agency for International Development, Program Management, Abuja, Nigeria, [10]Lagos State TB and Leprosy Control Program, TB Unit, Lagos, Nigeria, [11]National TB and Leprosy Control Program, National Cordinator, Abuja, Nigeria

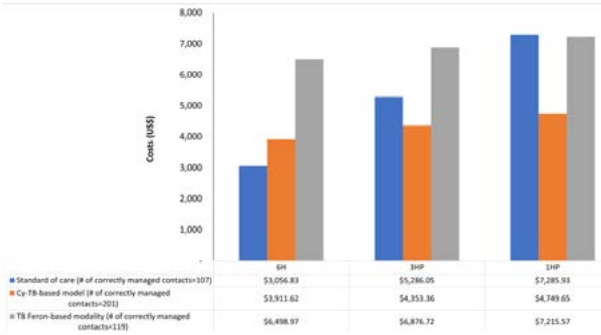
Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge in Nigeria, made worse by delays in diagnosis, equipment downtime, and inefficiencies in laboratory operations. These issues are linked to poor infrastructure, inconsistent power supply, limited technical capacity, and slow specimen transport and result delivery. These factors contribute to missed diagnoses, prolonged transmission, and poor treatment outcomes.
To address this, the TB LON-3 project introduced digital solutions to strengthen the performance of GeneXpert testing facilities in Southwest Nigeria.
Intervention or response: In 2022, the project deployed a digital dashboard for weekly monitoring of 150 rapid molecular diagnostic machines, including 85 GeneXpert, 55 TB LAMP, and 11 Truenat platforms. The dashboard tracked performance indicators such as sample volumes, error rates, equipment functionality, and turnaround time (TAT). Real-time insights allowed for quick identification of underperforming laboratories. Daily and weekly performance reviews enabled timely corrective actions to resolve issues related to power, equipment faults, reagent stockouts, and staffing gaps.
Results/Impact: This approach led to a reduction in GeneXpert equipment's downtime and improved modular functionality and service efficiency. Since its implementation in 2022, modular functionality has increased from 73% to 98%, while turnaround time for TB test results dropped from more than 120 hours to 24-48 hours. Using an approved benchmark of 20 samples per functional module per week, the average weekly equipment utilization rates across the four implementing states have increased, from 84% to 126% and overall weekly project evaluation rates improved from 69% to 96%, enhancing diagnostic efficiency and service delivery.
Conclusions: Integrating digital laboratory monitoring tools significantly reduced downtime, improved result turnaround time, and enhanced resource use across testing sites.
This experience highlights the power of digital innovation in improving TB diagnostics and enabling data-driven decisions. Scaling this strategy across more facilities could further strengthen Nigeria's TB diagnostic system and support national efforts to eliminate TB.

SOA04-542-19 A comparative analysis of novel latent tuberculosis infection screening tests to drive economic gains in TB Preventive Ttherapy (TPT) program in Zambia

L. Mwenge,[1] V. Moonga,[1] R. Mwape,[1] A. Schaap,[1] B. Tapisha,[1] M. Cheeba,[2] A. Mubanga,[3] N. Kasanda,[4] M. Simwinga,[1] K. Shanaube,[1] H. Ayles,[1] [1]Zambart, Research Directory, Lusaka, Zambia, [2]Zambart, Laboratory, Lusaka, Zambia, [3]Ministry Of Health, National Tuberculosis and Leprosy Programme, Lusaka, Zambia, [4]ministry of Health, Ndola District Health Office, Ndola, Zambia
e-mail: lawrencemwenge4@gmail.com

Background: Zambia is among the 30 high tuberculosis burden countries, with an incidence rate of 319 per 100,000. TPT uptake is currently low, except in PLHIV, and needs to be efficiently scaled up. We measured the cost and cost-effectiveness of adding Cy-Tb™ skin test and STANDARD™ F TB-Feron FIA (IFN-gamma) test, to the current standard of care, no TBI testing, for the TPT program in Zambia.
Design/Methods: A prospective economic evaluation was nested in a three-arm cluster-randomised trial comparing Cy-TB and TB-Feron to standard of care. Cost data were collected from the provider's perspective using the Time-Driven Activity-Based Costing method. We used the global drug facility cost for Cy-TB and TPT drugs and a plausible range of cost for TB Feron. We modeled costing using a cohort of 324 TB contacts to calculate the cost of TPT initiation for the different scenarios to assess the affordability and value-for-money of introducing TBI testing into the TPT program.
Results: TB screening and TPT initiation cost US$1.87 and US$0.78, respectively. Cy-TB testing costs US$3.70 and TB Feron testing cost was estimated as $5-$15.90. Figure 1 presents estimated total costs of TPT by regimen. The cost per person initiated on TPT were US$10.69, US$18.48 and US$25.48 for 6H, 3HP and 1HP in the SOC arm, US$44.37, US$53.57 and US$61.83in the Cy-TB arm, and US$83.86, US$91.57, and US$98.49 in the TB Feron arm. Programmatically adding Cy-TB testing

saved US$1,321.88 and US$2,710.81 for the 3HP and 1HP regimens, respectively. TB Feron was only cost-saving (US$1,376.39) for the 1HP regimen.



Conclusions: While TBI testing increases the cost per individual receiving TPT, introducing Cy-TB would be cost-saving if 3HP or 1HP regimens are used in Zambia, due to more efficient targeting of TPT offsetting the additional costs. TB Feron would only be cost-saving for the 1HP regimen.

SOA04-543-19 Assessing the acceptance and effectiveness of a digital adherence technology for TB preventive treatment in Bangladesh

M.R. Haidar,[1] T. Rahman,[1] T. Ibrahim,[1] M.S. Sarker,[1] K.I.A. Chowdhury,[1] S.S. Noor,[1] M. Ash-hab,[1] S. Ahmed,[1] M.K. Mafij Uddin,[1] S. Kabir,[1] S. Banu,[1] P. Samina,[2]
[1]icddr,b, Infectious Disease Division, Dhaka, Bangladesh, [2]McMaster University, Canada, Centre for Health Economics and Policy Analysis (CHEPA), Ontario, Canada
e-mail: saminap@mcmaster.ca

Background: Traditional directly observed therapy (DOT) has been criticized for compromising patient autonomy, privacy and dignity. Citro et al. (2022) advocate for rights-based, patient-centered approaches that move beyond coercive models of care. In response, iDOTS, a locally developed digital adherence tool was introduced to empower patients through remote, non-intrusive monitoring of tuberculosis preventive treatment (TPT) adherence. This study assessed acceptance and effectiveness of iDOTS among TPT eligible individuals.
Design/Methods: A mixed-methods observational study was conducted across two districts (intervention and control sites) in Bangladesh. Pre- and post-intervention assessments included 461 patients and 77 healthcare providers, guided by the "UTAUT" theory. TPT adherence was measured using self-reports, iDOTS dashboard and urine IsoScreen testing. Qualitative data were analyzed thematically to explain quantitative results. Statistical analyses involved descriptive statistics, inferential tests and regression modeling.
Results: Among iDOTS users, 95% completed TPT against 40% in control group. IsoScreen testing confirmed adherence in 79% of intervention group versus 17% of controls.
Over 97% of participants reported iDOTS helped build medication habits and served as effective reminders. High mobile phone ownership (96%) and network availability (95%) enabled its use, although 23% cited insufficient phone recharge as a barrier.
Male participants showed significantly higher acceptance than females across usability and belief measures: 84.3% of males had enough recharge (vs. 63.5% of females, $p<0.001$), 89.5% found it user-friendly (vs. 76.6%, $p=0.006$), and 89.5% found it easy to learn (vs. 80.0%, $p=0.013$).
Additionally, 82.2% of males vs. 58% of females ($p<0.001$) and 100% participants with advanced education ($p=0.028$) believed iDOTS would prevent future infections if they complete treatment.
Conclusions: iDOTS demonstrated strong effectiveness and acceptability, aligning with human rights-based TB care by enhancing patient autonomy, privacy and dignity. However, sex disparities and limited phone recharge remained barriers. Sex-sensitive engagement strategies and recharge support should be incorporated to promote equitable and sustained TPT adherence.

SOA04-544-19 Estimating healthcare worker time for tuberculosis preventive treatment activities in high TB-HIV burden countries in sub-Saharan Africa

S. Shrestha,[1] O. D'Silva,[1] R.M. Tazinya Asong,[2] N.O. Mzizi,[3] N. Kota,[4] P. Dlamini,[4] A. Vasiliu,[3] D. Vambe,[4] T. Steffy,[5,3] A. Kay,[3] A. Mandalakas,[3] A. Zwerling,[1] [1]University of Ottawa, School of Epidemiology and Public Health, Ottawa, Canada, [2]University of Ottawa, Interdisciplinary School of Health Sciences, Ottawa, Canada, [3]Baylor College of Medicine and Texas Children's Hospital, NA, Houston, United States of America, [4]Baylor College of Medicine and Texas Children's Hospital, NA, Mbabane, Eswatini, [5]Baylor College of Medicine and Texas Children's Hospital, NA, Maseru, Lesotho
e-mail: suvesh.shrestha@gmail.com

Background: Tuberculosis (TB) is major public health issue in sub-Saharan Africa, where TB-HIV co-infection rates are high. Tuberculosis Preventive Treatment (TPT) is vital for reducing TB, yet data essential for resource planning and evaluation such as healthcare worker (HCW) costs associated with TPT implementation are scarce in the African setting. This study aims to estimate HCW time for delivering TPT services using data from Lesotho and Eswatini.
Design/Methods: Three tools assessed HCW time spent on TPT provision with either 6 months of isoniazid and 3 months of isoniazid and rifapentine: the time and mo-

tion (TAM) tool (direct observation), the time estimation questionnaire (TEQ), and self-reported time sheets (TS). Salary data were converted to per-minute rates, with costs calculated based on the range of time spent, adjusted to 2023 USD.

Results: Data from nine HCW cadres in Eswatini and Lesotho, encompassing 218 activity records, showed that overall, HCW time for TPT delivery ranged from 27 to 58 minutes, resulting in HR costs between $5 and $10.

When this is broken down by activity, triage ranged from 2 to 7 minutes, with associated HR costs between $0.10 and $0.40, the time required for consultations to initiate TPT ranged from 9 to 11 minutes, resulting in HR costs between $1.90 and $2.90.

Monthly compliance monitoring for TPT ranged from 7 to 8 minutes, with HR costs from $1.40 to $1.90. Treatment literacy activities ranged from 8 to 10 minutes, with HR costs between $1.10 and $1.30. The time for dispensing TPT ranged from 1 to 3 minutes, with HR costs from $0.15 to $0.30.

Activity	Median Time (Minutes)	Cost ($)
Triage	2-7	0.12 – 0.4
Consultation to initiate TPT	9-11	1.97 – 2.9
TPT Dispensing	1-3	0.15 – 0.3
Monthly compliance/AE monitoring of TPT	7-8	1.4 - 1.9
Treatment Literacy for TPT	8-10	1.1 – 1.3
Consultation on TB Diagnosis	15-17	3.6 – 3.8
ATB Treatment Drug Dispensing	1-3	0.15 - 0.3
Monthly compliance/AE monitoring of ATB	8	1.4-2.0
Treatment Literacy for ATB	5 - 35	0.8 - 2.3

Table: HCW time and cost.

Conclusions: This study provides valuable data on required resources to scale up TPT services including HCW time and cost to inform and support planning and resource allocation, staff workload optimization, and efficient TPT program implementation in sub-Saharan African settings.

SOA04-545-19 Acceptability of home-based TB prevention services by community health workers in the CHIP-TB trial

A. Bergman,[1] C. Mulder,[2] F. Mulatu,[3] G. Conradie,[4] R. Chaisson,[5] J. Golub,[5] G. Churchyard,[6] A. Bedru,[3] D. Kerrigan,[7] N. Salazar-Austin,[5] [1]University of Virginia, School of Nursing, Charlottesville, United States of America, [2]KNCV, Epidemiology, The Hague, Netherlands, [3]KNCV, KNCV Ethiopia, Addis Ababa, Ethiopia, [4]Johns Hopkins University, School of Medicine, Cape Town, South Africa, [5]Johns Hopkins University, School of Medicine, Baltimore, United States of America, [6]The Aurum Institute, Professor and Group Chief Executive Officer Aurum Institute, Johannesburg, South Africa, [7]George Washington University, Milken Institute School of Public Health, Washington DC, United States of America
e-mail: dhm8ax@virginia.edu

Background: Ethiopia's health-care system is underpinned by community health workers (CHWs), who deliver community-based preventative services. The CHIP-TB trial assessed whether a home-based task-shared intervention could improve the uptake of tuberculosis preventive treatment (TPT) in exposed children < 15 years of age compared with facility-based standards. Post-trial, we qualitatively explored interest-holders' perceptions of the acceptability, feasibility and sustainability of home-based contact management and TPT delivery by CHWs.

Design/Methods: In-depth qualitative interviews were conducted with 47 key interest-holders including 15 adult caregivers of TB-exposed children, 15 CHWs, 9 TB providers, and 8 TB-program managers. Interviews were conducted in East Shewa Zone of Oromia, Ethiopia from October 2022 to March 2023. A semi-structured interview guide sought feedback on the intervention and suggestions for improvement and sustainability. Interviews were coded independently and analyzed by two researchers using thematic analysis.

Results: Four themes were extracted from the data; first, the impact of the intervention on TPT adherence. The home-based intervention delivered by CHWs bolstered the perceived value of TPT through individualized treatment schedules and accommodating family-preferences, thus increasing adherence. Second, although challenges to CHW-initiated TPT were identified including concerns around CHW safety while traveling, other concerns such as TPT stigma, CHW skill, and lack of community buy-in, were not reported to hinder implementation or acceptability of the intervention. Third, CHW commitment to community strengthened the intervention. CHWs were committed to TPT access; their dedication helped to overcome structural barriers such as lack of transportation to deliver home-based services. Finally, CHWs preferred individualized supervision and support for the intervention. Some CHWs requested hands-on field training and supervision for real-time feedback to support the intervention's impact during scale-up.

Conclusions: Overall, TPT delivered in a task-shared model was acceptable and CHWs overcame potential challenges to home-based care that supported TPT access and family-centered care.

SOA05 Surveillance in the digital age

SOA05-546-19 The impact of early warning outbreak recognition system (EWORS) on improving tuberculosis case finding in Katsina, Nigeria

I.T. Lawrence,[1] A.Y. Galadima,[2] P.S. Batur,[2] M. Sheshi,[3] A. Okoh,[3] B. Odume,[4] S. Dimang,[5] T. Adetiba,[6] A. Adekunle,[6] [1]KNCV Nigeria, Programmes, Katsina, Nigeria, [2]KNCV Nigeria, Technical, Katsina, Nigeria, [3]KNCV Nigeria, Programmes, Abuja, Nigeria, [4]KNCV Nigeria, Executive Management, Abuja, Nigeria, [5]NTBLCP, Programmes, Abuja, Nigeria, [6]IHVN, Programmes, Abuja, Nigeria
e-mail: ilawrence@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains a leading cause of morbidity and mortality in high-burden regions, where delayed case detection undermines control efforts. Traditional case-finding strategies often lack precision, missing emerging transmission clusters. In Nigeria's North West, the absence of real-time data systems has hindered early intervention in TB hotspots.
This study evaluates the impact of integrating the Early Warning Outbreak Recognition System (EWORS)—a digital surveillance platform—into TB control activities to enhance case detection in high-transmission zones.
Intervention or response: From January to June 2024, a phased intervention was implemented across selected Local Government Areas (LGAs). In Quarter 1 (Q1), TB case-finding relied on routine facility-based methods. In Quarter 2 (Q2), EWORS was deployed to analyze syndromic and geo-spatial data to identify potential TB outbreak hotspots. Outreach teams used EWORS-generated alerts to direct mobile screening, sputum collection, and diagnostic testing in flagged areas. All data were documented using harmonized digital tools linked to national TB surveillance platforms.
Results/Impact: Following EWORS implementation, TB case notifications increased from 1,548 in Q1 to 2,312 in Q2—a 49.3% rise. Of these, 1,404 cases (60.7%) were directly linked to EWORS-guided outreach. Importantly, bacteriologically confirmed TB rose by 55%, and detection of TB among children under 15 doubled. The intervention also reduced the average time from symptom onset to diagnosis by 40%. These findings underscore EWORS' effectiveness in enhancing precision screening, improving early diagnosis, and maximizing resource use.
Conclusions: The integration of EWORS into TB surveillance significantly improved case detection and reduced diagnostic delays in a high-burden setting. By enabling real-time identification of transmission hotspots and guiding targeted outreach, EWORS offers a scalable, data-driven solution for strengthening TB control. Its adoption should be prioritized in national TB strategies for high-incidence regions.

SOA05-547-19 Geospatial analysis and optimization of tuberculosis diagnostic network coverage in Zambia

J. Mzyece,[1,2] M. Muvwimi,[1] A. Mubanga,[2] J. Chama,[2,3]
[1]Ministry of Health, Pathology and Laboratory Services Unit, Lusaka, Zambia, [2]Ministry of Health, National TB and Leprosy program, Lusaka, Zambia, [3]The Global Fund to Fight AIDS, Tuberculosis and Malaria,, Zambia Country Office, Lusaka, Zambia
e-mail: judithmzyece@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a significant public health threat in Zambia, with limited access to quality diagnostic services hindering timely case detection and treatment. Zambia has made progress replacing microscopy with GeneXpert testing since 2017. However, case detection remains below 70% of estimated incidence, suggesting a substantial untested population.
The aim of this study was to evaluate the current GeneXpert instrument availability and efficiency of use in Zambia and determine gaps through geospatial mapping.
Intervention or response: The analysis employed ArcGIS for geospatial mapping and FICO Xpress Optimization to evaluate service accessibility. A master health facility database was integrated with GeneXpert inventory, testing statistics, smear microscopy data, and geographic coordinates of 1,607 health facilities. Population density maps and road network data were incorporated to assess spatial accessibility of services.
Facilities were classified as baseline (existing GeneXpert sites), candidate, or other. Spatial optimization models were developed to select candidate facilities that would maximize population coverage and demand.
Results/Impact: Geospatial mapping revealed that 66% of the 255 baseline GeneXpert facilities, were underutilized. That 75% of Zambia's population lives within 35 km of GeneXpert services (82% within 50 km), with high coverage in urban and low coverage in rural area.
Heat maps of accessibility demonstrated that population coverage could be increased to 86% by improving sample referral and to 90% by adding GeneXpert machines at spatially optimized candidate facilities. Five spatial optimization scenarios illustrated incremental coverage improvements based on service area distances from 5 km to 50 km.
Conclusions: Geospatial analysis showed there is good GeneXpert coverage in urban areas but gaps remain in rural areas. Improving specimen referral networks to existing GeneXpert facilities and placement of new machines in underserved areas could be impactful.
The results highlight the need for follow up geospatial analysis every two years to keep track of changes in diagnostic network.

SOA05-548-19 Leveraging AI for targeted TB/HIV control: Insights from the EPCON pilot in Katsina State, Nigeria

A. Galadima,[1] I. Lawrence,[2] M. Sheshi,[3] M. Bajehson,[4] A. Okoh,[5] B. Odume,[6] T. Adetiba,[7] O. Olupitan,[8] O. Chijioke- Akaniro,[9] E. Ubochioma,[9] J. Ssekitooleko,[10] M. Zamzu,[10] [1]KNCV Nigeria, Technical, Katsina, Nigeria, [2]KNCV Nigeria, Program, Katsina, Nigeria, [3]KNCV Nigeria, Private Sector, Abuja, Nigeria, [4]KNCV Nigeria, Program, Kano, Nigeria, [5]KNCV Nigeria, Technical, Abuja, Nigeria, [6]KNCV Nigeria, Executive, Abuja, Nigeria, [7]Institute of Human Virology, Nigeria (IHVN), Technical, Abuja, Nigeria, [8]Institute of Human Virology, Nigeria (IHVN), Program, Abuja, Nigeria, [9]National TB and Leprocy and Buruli Ulcer Control Programme Nigeria, Program, Abuja, Nigeria, [10]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Program, Switzerland, Switzerland
e-mail: agaladima@kncvnigeria.org

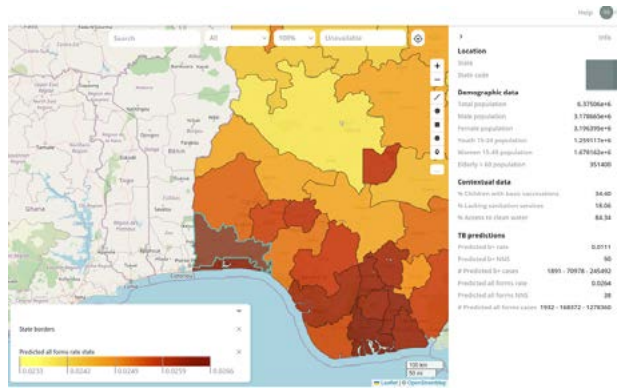
Background and challenges to implementation: In Katsina State, Nigeria, identifying TB and HIV among pregnant women, other high-risk individuals and treating them remain a major public health challenge. Many of this high-risk group are missed due to limited data visibility, poor access to health services, and the inability to accurately target interventions. Traditional screening approaches often fail to identify hotspots or underserved populations where the disease burden is highest and treatment access is lowest. Addressing these challenges, KNCV Nigeria funded by the Global Fund, implemented the EPCON pilot study, identifying high-risk communities and populations for TB and HIV using the AI-powered epidemiological tool.
Intervention or response: EPCON was adapted to target communities where pregnant women and other high-risk individuals that are likely not accessing TB/HIV services. Guided by AI predictions, screening and outreach activities were implemented in identified hotspots. Data from these activities were gathered and analyzed to evaluate the effectiveness of the intervention.
Results/Impact: Through Epcon 78 TB cases in pregnant women was diagnosed which was 3.6% of the total TB cases identified within the study period. Prior to the introduction of Epcon, TB cases among pregnant women were not systematically tracked, indicating a significant gap in surveillance.
Similarly, Epcon facilitated the screening of pregnant women for HIV, resulting in the detection of 87 HIV-positive pregnant women. Among these, 15 (17.2%) were found to be co-infected with TB, highlighting the burden of TB/HIV co-infection in this vulnerable population.
Conclusions: The EPCON pilot shows that AI can play a vital role in transforming complex health data into actionable insights. By supporting smarter, faster, and more targeted public health responses, AI-powered tools offer a promising future for TB/HIV control efforts and broader

disease surveillance. Scaling this approach can enhance efficient deployment of health resources, improving coordination between facility and community services.

SOA05-549-19 Next-gen TB analytics in Nigeria: AI-enhanced DHIS2 integration for smarter predictions and reporting (EPCON AI in Focus)

B. Shokunbi,[1] O. Daniel,[2] M. Pedro,[1] F. Muritala-Ibrahim,[3] A. Agbaje,[4] C. Mensah,[5] P. Dakum,[5] R. Eneogu,[6] S. Labaran,[7] B. Pillatar,[3] D. Olaniyan,[1] P. Alu,[1] [1]Institute of Human Virology, Nigeria, Strategic Information, Lagos, Nigeria, [2]Institute of Human Virology, Nigeria, Prevention and Care Treatment, Lagos, Nigeria, [3]Institute of Human Virology, Nigeria, Strategic Information, Abuja, Nigeria, [4]Institute of Human Virology, Nigeria, Office of CEO, Lagos, Nigeria, [5]Institute of Human Virology, Nigeria, Office of CEO, Abuja, Nigeria, [6]United State Agency for Internal Development, Nigeria, HIV/AIDS & TB Office, Abuja, Nigeria, [7]National TB, Buruli and Leprosy Control Program, Public Health, Abuja, Nigeria
e-mail: sstephen@ihvnigeria.org

Background and challenges to implementation: District Health Information System 2 (DHIS2) is widely used for health data management, it lacks predictive analytics and geospatial visualization capabilities. Integrating Artificial Intelligence (AI) with DHIS2 through the EPCON Geoportal and Dashboard platform enhance TB surveillance by enabling predictive geo-mapping and improving the reporting system for more effective decision-making.
Intervention or response: This study employs AI-driven machine learning models to analyse historical TB data from DHIS2 system used by TB-LON3 project in Nigeria, generating predictive insights and spatial distributions of TB cases. The EPCON Geoportal facilitates geospatial analysis, real-time mapping, and automated reporting, ensuring seamless integration with DHIS2. The effectiveness of AI-enhanced predictive geo-mapping was compared with traditional epidemiological models, while the impact on reporting efficiency was assessed.
Results/Impact: The AI-powered system significantly improved TB case prediction accuracy and enabled real-time identification of high-risk areas through geospatial analytics with hotspot mapping giving the exact location. The integration of EPCON with DHIS2 streamlined TB data reporting using its dashboard views to present analyses through different queries, reducing errors and improving response time.
Interactive dashboards and notification system make data accessibility for health officials, facilitating timely interventions and resource allocation. The integration of AI-driven predictive geo-mapping with DHIS2 via the EPCON Geoportal and Dashboard platform in TB-LON3 program has transformed TB surveillance in Nigeria. By providing real-time spatial analytics and improved reporting, which enhanced disease monitoring, supports targeted interventions, and strengthens TB control strategies for the program.



Conclusions: AI-powered predictive analytics and geospatial visualization have significantly improved TB surveillance and reporting in Nigeria. The successful integration of AI with DHIS2 through EPCON demonstrates the feasibility of leveraging advanced technology for disease control. Expanding this approach to other infectious diseases will further enhance Nigeria's healthcare data ecosystem.

SOA05-550-19 Impact of scaling-up an automated monitoring system, TB-Watch, on programmatic performance for TB elimination in Uttar Pradesh, India

S. Joshi,[1] S. Bhatnagar,[2] V. VG,[1] S. Chandra,[1] S. Mohan,[1] S. Lawaniya,[3] B. Bajaj,[4] A. Srivastav,[5] R. Rao,[6] U. Singh,[6] [1]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [2]Swasthya Bhawan, State Tuberculosis Cell, Uttar Pradesh, Lucknow, India, [3]State TB Training and Demonstration Centre, Supervision and Operational Research, Agra, India, [4]State TB Training and Demonstration Centre, Monitoring, Agra, India, [5]State TB Training and Demonstration Centre, Training, Agra, India, [6]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India
e-mail: joshis@rntcp.org

Background and challenges to implementation: India is committed to achieve the Tuberculosis (TB) related Sustainable Development Goals (SDGs) through its comprehensive efforts under the National TB Elimination Programme (NTEP). The World Health Organization, in its End TB strategy underscores the importance of robust monitoring in TB elimination efforts which is also integrated in the country's National Strategic Plan.

Hence, this research assessed the impact of scaling up an automated monitoring system called TB-Watch in all the 75 districts of Uttar Pradesh based on NTEP.

Intervention or response: TB-Watch processes data from Ni-kshay, India's case-based digital TB surveillance system, and provides weekly offline NTEP indicator updates for uniform performance monitoring at district and tuberculosis unit levels. Stratified randomized parallel arm study design was used to pilot TB-Watch after which the Government of the State of Uttar Pradesh decided to scale this up for all 75 districts of the state in August 2024. TB-Watch scale-up was operationalized through the dedicated systems identified by the Government of Uttar Pradesh. Comparative analysis was done using the Z-test for proportions.

Results/Impact: TB Score, which is a composite measure of TB program performance, increased by 40% from August 2024 to December 2024 following the TB-Watch scale-up. This increase was significantly higher compared previous year before the scale-up ($p<0.001$). Subcomponents of TB Score showed notable improvements: TB Prevention Treatment in household contacts rose by 19.94%, direct benefit transfers increased by 13.2%, and the state budget utilization against the approved record of proceedings for NTEP increased by 60%.

Additionally, Universal Drug Susceptibility Testing saw a delta of 2.25%, and treatment success improved by 1.38%.

Conclusions: TB-Watch is a no-cost, highly replicable model for automating the routine monitoring workflow. It provides a user-friendly solution for field-level targeted monitoring with offline action lists and leverages on existing TB surveillance system to enhance data-driven decision-making for improving programmatic performance.

SOA05-551-19 Digital transformation in TB surveillance: Enhancing health system responsiveness using Power BI in Telangana, India

A. Rajesham,[1] S. Shukla,[2] G. Mahesh,[2] V. Chandrasekhar,[2] P. Blessy esther,[2] G. Srigana,[2] A. Shanta,[3] S. Chandra,[4] U. B Singh,[5] [1]Government of Telangana, Ministry of Health and Family Welfare, National TB Elimination Program, Natioal Health Mission, Hyderabad, India, [2]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, Hyderabad, India, [3]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, Visakhaptnam, India, [4]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [5]Government of India, Ministry of Health and Family Welfare, National TB Elimination Program, New Delhi, India
e-mail: shuklas@rntcp.org

Background and challenges to implementation: Efficient data utilization is central to achieving National TB Elimination Program (NTEP) goals. However, decentralized health functionaries at the sub-district level often lack tools for real-time data visualization, delaying localized decision-making and response. Telangana adopted Microsoft Power BI to build an integrated dashboard that addresses this gap.

Intervention or response: Power BI-enabled visualization is used to improve TB program performance monitoring, responsiveness, and data-driven decision-making. Key performance indicators (KPIs) were extracted from Nikshay, the national TB surveillance system. These included presumptive examination rates, case notifications, treatment timelines, and diagnostic performance.

A dynamic dashboard was developed, offering facility-level drilldowns, conditional formatting for performance stratification, and real-time auto-updating charts. It was used routinely by program managers at state and district levels from April 2023 to March 2024.

Indicator	Pre-Dashboard (2023)	Post-Dashboard (2024)
Presumptive Examination Rate	1,050 / lakh	2146 / lakh
TB Notification Rate	175 / lakh	210 / lakh
Delay in Notification	5 days	2 days
Delay in Treatment initiation	7days	3 days
Manual Reporting Time (days/month)	7	2
Treatment Success Rate (DSTB)	85%	95%

Results/Impact: Power BI intervention led to a substantial improvement across critical KPIs (Table 1). Presumptive examination and notification rates increased by 28% and 20%, respectively. Microbiological confirmations rose from 62% to 78%, while treatment initiation within 7 days improved from 68% to 85%. Missed diagnostic opportu-

nities declined by more than half, and manual reporting time was reduced by over 60%. These improvements are visually summarized in Table 1.

Conclusions: Conclusion: Integration of Power BI into TB surveillance has strengthened health system responsiveness by decentralizing data access and enhancing analytical autonomy at the field level.

The intervention reduced reporting delays, improved oversight, and fostered a culture of real-time, evidence-based action.

This scalable digital approach can be replicated across vertical disease control programs to support India's broader digital health mission.

SOA05-552-19 Integrating socioeconomic determinants with tuberculosis surveillance: A data linkage approach to addressing TB burden and poverty in Indonesia

F. Yunita,[1] N. D Anggraeni,[2] N. Rohani,[2] [1]former USAID funded LEAP Global, Health Quality Improvement, Jakarta, Indonesia, [2]Coordinating Ministry of Human Development and Culture, Health Quality Improvement, Jakarta, Indonesia
e-mail: ferdiana.yunita@gmail.com

Background and challenges to implementation: Tuberculosis (TB) continues to be a significant public health concern in Indonesia, where socioeconomic factors such as poverty, unemployment, and limited access to social support amplify the burden of the disease. To address this challenge, understanding the interplay between these social determinants and TB prevalence is crucial.

This study integrates data from the Tuberculosis Information System (SITB) and the National Extreme Poverty Targeting System (P3KE) to explore the relationship between socioeconomic vulnerabilities and TB at the household level.

Intervention or response: We conducted a data integration analysis by linking information from 417,614 individuals affected by TB, representing 404,585 households in SITB, with P3KE's dataset, which includes 237 million individuals. The integration was done using unique identifiers (ID) to match individuals by name and address. The data were analyzed using Tableau Public, which enabled a detailed exploration of the socioeconomic factors contributing to TB prevalence.

Results/Impact: The findings revealed that a significant portion of TB cases were concentrated in families, with 41.9% of cases affecting fathers, 32.4% children, and 20.5% mothers, highlighting the familial nature of TB transmission. The majority of individuals with TB were of working age (73.9%), with 44.56% unemployed.

Additionally, 45.78% of TB-affected households fell within the lowest socioeconomic deciles. The highest TB burden was observed in provinces such as West Java (10.4%) and East Java (6%).

Despite the high vulnerability, only 7.4% of affected households received support from *Program Keluarga Harapan (PKH)*, and 12.5% received food assistance.

Conclusions: This integration of TB and socioeconomic data reveals significant overlaps between TB prevalence and vulnerability, emphasizing the need for systematic data integration across sectors. Expanding social support for TB-affected households, particularly the most vulnerable, is essential. Data-driven, cross-sectoral interventions can address both TB and its social determinants effectively.

SOA05-553-19 Integrating genomics and digital innovation for tuberculosis surveillance in Nigeria

S. Cadmus,[1,2,3] O. Alayande,[1] V. Akinseye,[2] T. Olagunju,[4] B. Johnson,[5] S. Akingbesote,[6] O. El tayeb,[1] C. Anyaike,[7] V. Dreyer,[8] S. Niemann,[8] A. Grinev,[9] A. Rosenthal,[9] [1]University of Ibadan, Damien Foundation Genomics and Mycobacteria Research and Training Centre, Ibadan, Nigeria, [2]Nigerian Institute of Medical Research, Yaba, Microbiology, Lagos, Nigeria, [3]University of Ibadan, Department of Veterinary Public Health and Preventive Medicine, Ibadan, Nigeria, [4]University of Ibadan, Department of Computer Science, Ibadan, Nigeria, [5]Oyo State Ministry of Health, Ministry of Health, Ibadan, Nigeria, [6]Institue of Human Virology, Department of Prevention, Care, and Treatment, Ondo, Nigeria, [7]Federal Ministry of Health, Nigeria, National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Abuja, Nigeria, [8]Research Center Borstel, Molecular and Experimental Mycobacteriology, Borstel, Germany, [9]National Institute of Allergy & Infectious Diseases, Office of Cyber Infrastructure & Computational Biology, Maryland, United States of America
e-mail: opealayandea@gmail.com

Background: Nigeria ranks prominent among the high-burden tuberculosis (TB) endemic countries globally. Efforts to prevent TB are undermined by inefficient diagnostics and treatment systems, increasing drug resistance, and poorly understood transmission dynamics. Whole-genome sequencing (WGS) offers unprecedented resolution for understanding TB spread and resistance evolution, and provides a reliable framework for infection management. However, in Nigeria, its utility has been constrained by fragmented data systems and a lack of integrated analytical infrastructure.

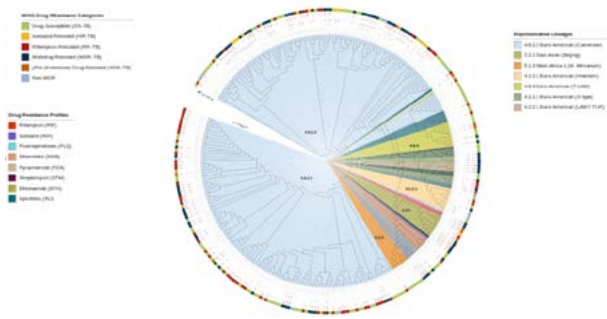
We aim to deploy a digital system that (1) streamlines and coordinates TB genomic surveillance and (2) advances the application of WGS data to inform TB research and support public health interventions.

Design/Methods: Leveraging the TB-Portals digital platform, we processed 105 newly-sequenced and 279 publicly available (NCBI) Nigerian *Mycobacterium tuberculosis* (*Mtb*) WGS datasets. We systematically screened and catalogued genomic markers associated with drug resis-

tance, virulence, diversity, and *Mtb* spread across different patient populations. Guided by these data, we are developing the Nigerian-TB-Genomic-Surveillance (NTBGS) platform to support real-time TB genomic surveillance and facilitate advanced interactive exploration of TB epidemiological trends across the country.

Results: The NTBGS platform currently hosts 384 *Mtb* genomic information across 15 Nigerian States and provides a geographically diverse genomic representation of TB infection dynamics in the country. Of these, 45.8% (176/384) are pan-susceptible, while 53.4% (205/384) show resistance to at least one drug.

Among the DR strains, 41% (84/205) and 7.3% (15/205) are rifampicin and isoniazid mono-resistant respectively, 34.6% (71/205) are multidrug-resistant, and 5.4% (11/205) are (pre-)extensively drug-resistant. Predominant lineages represented include isolates of Euro-American, *M. africanum,* and Beijing origin.



Conclusions: This initiative promotes sustainable integration of genomics for TB surveillance. We anticipate that the NTBGS platform will foster equitable WGS adoption, enhance TB management, bolster the National TB program, and position national datasets as globally relevant resources to accelerate diagnostic and therapeutic discoveries, vaccine design, and evidence-based interventions.

SOA05-554-19 Connectivity technology monitors and reduces high test error rates reported among drug resistance TB testing in Nigeria

K. Jimoh,[1] D. Meshak,[2] E. Ubochioma,[3] [1]Connected Diagnostics Nigeria, Management, Abuja, Nigeria, [2]Connected Diagnostics Nigeria, Implementation, Abuja, Nigeria, [3]National TB and Leprosy Control Program, Program Management Unit, Abuja, Nigeria
e-mail: kagbaiyero@connecteddiagnostic.com

Background and challenges to implementation: Nigeria is a high-burden country for drug-resistant tuberculosis (DR-TB). However, national diagnostic and surveillance capacities are compromised due to high error rates on GeneXpert MTB/RIF machines testing for DR-TB. The Nigerian Tuberculosis and Leprosy Control Program (NTBLCP) pursued the development of a cost-effective technology, GxAlert/Aspect, to improve DR-TB reporting speed and accuracy and to monitor individual GeneXpert machine error rates to strengthen both healthcare system responses to DR-TB and management of GeneXpert investments.

Intervention or response: GxAlert/Aspect is an innovative, cost-effective solution that networks GeneXpert machines, sending average error rates by individually identified machines in real-time to an online database, making reporting time from months to seconds and enabling more timely interventions such as recalibration of machines and staff supervision. GxAlert/Aspect also tracks the status of service warranty and module replacement for each device.

Results/Impact: The GeneXpert testing error rate in 350 facilities decreased to 5% and below in September 2024 from 9% and above in September 2023. Data on machines producing higher than normal error rates were uploaded automatically from GeneXpert systems to a secure online dashboard display to improve national-level program management. At the same time, SMS alerts were sent to Facility Managers, Local Government supervisors, and State program managers for immediate action. Faster, better quality data on the MDR-TB portion of total TB indicators are now reported with minimal error rates.

Conclusions: The use of GxAlert/Aspect to network GeneXpert test results and operational status is a cost-effective model for the national sustainability of rapid molecular diagnostic systems. Training and installation are done locally, and the technology uses local, readily available and affordable telecom modems. GxAlert enables quick remote technical support, troubleshooting, and maintenance of the GeneXpert machines and ongoing disease surveillance. Based on Nigerian experience, a scaleup of the GxAlert in high-burden DR-TB countries is recommended.

SOA05-555-19 Leveraging artificial intelligence predictive maintenance models for timely GeneXpert module replacement in tuberculosis diagnostics

T. Julius,[1] K. Joel,[2] [1]Uganda National TB Reference Laboratory, TB, Kampala, Uganda, [2]National TB Reference Laboratory, LAB, Kampala, Uganda

Background and challenges to implementation: The GeneXpert system has accelerated tuberculosis (TB) diagnosis since its endorsement by WHO in 2010 by providing rapid, accurate, and scalable molecular testing. The platform has enhanced diagnostic access but is prone to wear and failure over time. Delays in module replacement disrupt testing, hence compromising patient care. Traditional maintenance approaches, often reactive or based on fixed schedules, fail to account for the variable usage

patterns and environmental factors that influence module lifespan. To address this challenge, we introduced an innovative application of artificial intelligence (AI) predictive maintenance models to optimize the timing of GeneXpert module replacement, enhancing diagnostic efficiency and reducing downtime.

Intervention or response: This was a cross-sectional study carried out in Uganda, targeting TB testing sites with GeneXpert installed. An AI-driven predictive maintenance framework that integrates machine learning algorithms with real-time operational data from GeneXpert systems, including test volume, error logs, and environmental conditions was developed.

Data was collected from 300 GeneXpert machines at 280 GeneXpert sites from January 2022 to December 2024. A predictive model that employs xgboost algorithm to forecast module failure was then trained with high accuracy. Performance metrics, including precision, recall, and mean time to failure prediction, were assessed against conventional maintenance strategies.

Results/Impact: Findings demonstrated that the AI model accurately predicts 75-80% of all module failures 3 months before they happen. This prediction enables proactive scheduling of replacements, minimizing diagnostic interruptions and optimizing resource allocation. The model is able to adapt to diverse operational contexts with the potential for scalability across TB programs globally.

Conclusions: This AI model for monitoring GeneXpert module failure enhanced the reliability of GeneXpert systems and aligned with the broader goal of strengthening TB diagnostic infrastructure.

This study underscores the transformative potential of AI in TB diagnostics, paving the way for smarter, data-driven maintenance strategies in global health.

SOA05-556-19 Development of a novel digital lung auscultation annotation platform for improving artificial intelligence-powered lung sound classification algorithms: Auscultation Lab

S. Kapoor,[1] A. Gaudio,[2] N. Hoekstra,[3] L.-M. Laubscher,[4] H. Hahn,[2] A. Gie,[5] P. Goussard,[5] A. Redfern,[5] A. Hesseling,[4] M. van der Zalm,[4] M. Elhilali,[2] E. McCollum,[1,4]

[1]Johns Hopkins University School of Medicine, Global Program in Pediatric Respiratory Sciences, Baltimore, United States of America, [2]Johns Hopkins University Whiting School of Engineering, Department of Electrical and Computer Engineering, Baltimore, United States of America, [3]University of North Carolina School of Medicine, Department of Pediatrics, Chapel Hill, United States of America, [4]Stellenbosch University, Health Sciences and Medicine, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Tygerberg, South Africa, [5]Stellenbosch University Health Sciences and Medicine, Department of Paediatrics and Child Health, Tygerberg, South Africa

e-mail: skapoor@jhmi.edu

Background: Artificial intelligence (AI) lung sound classification algorithms may be useful diagnostic tools, especially in resource-limited settings lacking physicians. Training supervised AI algorithms requires labeled datasets annotated by human expert listeners. Beyond conventional auditory sound recognition, spectrograms can provide humans a powerful three-dimensional visual aid, displaying frequency ranges and sound intensity to enhance lung sound pattern recognition and differentiate lower from upper respiratory sounds or environmental noises.

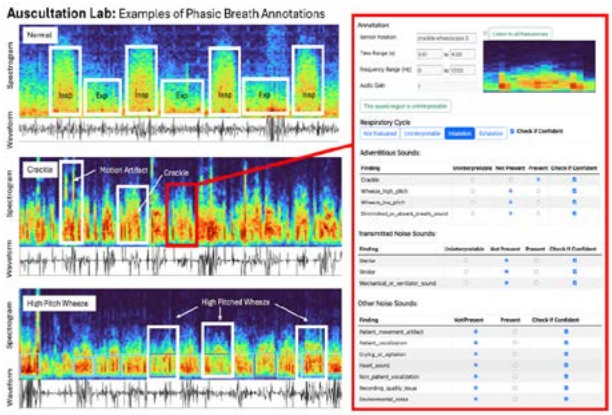
We aim to improve human listening panel training and thus AI lung sound classification by developing a novel annotation platform called Auscultation Lab that incorporates these features.

Design/Methods: A multi-modal platform was created for digital lung sound auscultation and listening panel training. Pediatric lung sound recordings were obtained from children ≤10 years old presenting to care at Tygerberg Hospital (South Africa) and Johns Hopkins Hospital (USA).

The platform allows for recording playback with spectrogram and waveform visualizations and the ability for detailed phasic or half breath-level annotations. Pediatric physicians created annotation boxes around each half breath to provide information on the respiratory cycle phase, adventitious lung sounds, transmitted upper airway sounds, and environmental noises with confidence levels for each annotation (Figure).

Results: To date, the platform has been used to train and certify nine pediatric physicians from the lung sound listening panel for the 'Xilonga' study. Members of the panel utilized the platform to annotate 63 pediatric chest position digital stethoscope recordings for a total of 781 half-

breath classifications of breath cycles, adventitious lung sounds (wheeze, crackle), transmitted sounds, environmental noises, and confidence levels.



Conclusions: Auscultation Lab utilizes spectrograms to provide a three-dimensional visual and auditory aid for detailed lung sound annotation and classification. This platform is an innovative tool for training lung sound listening panel physicians and thus advancing AI algorithm performance, and for teaching lung auscultation in medical education.

SOA05-557-19 Innovative use of mobile digital chest-Xray equipped with artificial intelligence (AI) to improve TB diagnosis among PLHIV at primary health centers (PHCs) in Lagos, Nigeria

O. Udunze,[1] B. Odume,[2] T. Osatuyi,[3] E. Chukwu,[4] S. Olusola,[5] M. Sheshi,[6] E. Ubochioma,[7] [1]KNCV Nigeria, Strategic Information, Lagos, Nigeria, [2]KNCV Nigeria, Executive Directorate, Abuja, Nigeria, [3]KNCV Nigeria, Project Coordination, Lagos, Nigeria, [4]KNCV Nigeria, Project Coordination, Abuja, Nigeria, [5]Lagos State Ministry of Health, State Tuberculosis and Leprosy Control Program, Lagos, Nigeria, [6]KNCV Nigeria, Programs, Abuja, Nigeria, [7]National Tuberculosis and Leprosy Control Program, Programs, Abuja, Nigeria
e-mail: udunzeobioha@gmail.com

Background and challenges to implementation: Deployment of Mobile digital Chest X-Ray (CXR) vans equipped with artificial intelligence (CAD4TB) is a joint investment of the State Government and Global Fund to complement other interventions in TB program, to find and treat the missing persons with TB. The CXR intervention will further increase access to free TB screening and treatment as part of the Global Strategy to end TB. Three mobile CXR Vans, equipped with A.I(CAD4TB) was used for this activity. This provided an opportunity for adequate TB/HIV integration and collaboration at PHCs.

The objective of this study is to highlight the effectiveness of TB/HIV service integration at the PHCs, characterized with client referrals to other diagnostics centers.

Intervention or response: The use of mobile digital CXR at the PHCs for active TB case finding was conceptualized and conducted from January – December 2024 to address the existing 32% TB notification gaps in Lagos Nigeria. This however, provided an opportunity to adequately screen PLHIV for TB at PHCs. DHIS2 was used to determine the PLHIV currently on Treatment across 8 flagship PHCs in the State, following facility assessment and advocacy visit. TB facility cascade management team meeting were conducted and CXR mobile Vans deployed. WHO 3B TB screening algorithm was adopted. Specimen were collected and sent for GeneXpert test.

Results/Impact: For the A.I supported TB screening among PLHIV, the average TB yield as calculated is 23%, NNS and NNT calculated were 24 and 4 respectively given a better yield compared to the conventional TB screening (symptom screening) at 8% TB yield, 123 NNS and 12 NNT calculated respectively.

Type of TB screening (Screening with A.I supported CXR versus Symptom screening)	No. of PLHIV screened for TB with A.I supported CXR mobile machine	No. of TB presumptive among PLHIV	No. of TB presumptive clinically evaluated	No. diagnosed with TB	No. linked to care.	% TB yield	No. needed to screen (NNS)	No. needed to test (NNT)
TB screening using A.I supported CXR at PHCs	1,128	203	203	47	47	23%	24	4
Symptom screening at other Secondary facilities	7,898	789	789	64	57	8%	123	12

Conclusions: Artificial Intelligence powered Mobile Digital CXR has demonstrated efficiency in TB diagnosis among PLHIV while fostering adequate integration of TB/HIV. Therefore, the expansion of Mobile digital CXR equipped with A.I, will further strengthen this collaboration and improve quality of care among PLHIV in Nigeria.

SOA06 Window of opportunity: Integrated service delivery for co-morbidities

SOA06-558-19 Impact on patient wait times at Yala Sub-County Hospital through the integration of comprehensive care centers and tuberculosis clinics into mainstream outpatient health services

F. Oloo,[1] G. Nyanaro,[2] N. Olunga,[3] [1]Siaya County, Department of Health, Siaya, Kenya, [2]Centre for Health Solutions, Health, Siaya, Kenya, [3]Siaya County, Health, Siaya, Kenya
e-mail: emikanto@gmail.com

Background and challenges to implementation: With the rapid expansion of HIV and TB treatment programs in sub-Saharan Africa, the enduring health policy discourse over the advantages and disadvantages of integrating comprehensive care centers and tuberculosis clinics with other outpatient health services has resurfaced.
Recent trials of integrating comprehensive care centers and tuberculosis clinics into conventional outpatient health services have demonstrated enhanced patient outcomes in certain areas, although have resulted in increased waiting times, potentially leading to adverse health effects over time.
Intervention or response: We examined a pilot intervention aimed at integrating comprehensive care centers and tuberculosis clinics into conventional outpatient health services at Yala Sub-County Hospital. We gathered data on patient waiting times during two five-day intervals preceding and three months following the integration, utilizing a time and motion study.
We conducted statistical analyses to determine any variations between the two observation periods regarding operational aspects such as personnel, appointment scheduling, and patient demographics. We developed a discrete event simulation model to enable an equitable comparison of waiting times prior to and following integration.
We additionally devised different integration configurations and assessed the resultant waiting times utilizing the simulation model.
Results/Impact: The integration of comprehensive care centers and tuberculosis clinics into standard outpatient health services led to a 20% and 24% rise in waiting times, respectively ($p<0.01$). Simulation modeling indicated that the substantial rise resulted from operational changes before to and following integration, including a reduction in personnel ($p<0.01$) and a varied patient demographic ($p<0.04$). Addressing these disparities via service integration would have led to a notable reduction in waiting times for conventional outpatient health treatments, alongside a small decline in service efficiency.
Conclusions: Integrating healthcare might potentially diminish wait times by optimizing the utilization of available resources.
Nonetheless, additional operational concerns, such personnel availability, must be taken into account to guarantee that integration does not adversely affect outcomes.

SOA06-559-19 Comorbidities, determinants and disability management in TB treatment: An observational cohort study under routine program conditions in YiChang, China

Z. Jin,[1] M. Lin,[1] C. Liao,[1] Q. Yang,[1] R. Li,[1] [1]The Third People's Hospital of YiChang, Pulmonology Department, YiChang, China
e-mail: 18654108@qq.com

Background: A significant proportion of successfully treated TB patients remain with TB-related functional disability, but most TB programs focus diagnosis and TB treatment only. It is suggested to manage comorbidities, risk determinants and disability at the start and the end of treatment.
Design/Methods: We conducted an observational cohort study in YiChang, China to assess burden of these problems at the start and end of anti-TB treatment; and whether referral mechanisms for further care were functional.
Results: Among 63 drug-susceptible TB patients treated under routine program conditions in China, 88% were symptomatic at treatment initiation (cough 60.3%, dyspnea 20.3%). Key comorbidities included diabetes (15.8%) and hypertension (7.9%), while risk determinants comprised smoking (17.4%) and excess alcohol use (12.6%). Functional disability (6MWT <400m) was observed in 25.3% of patients at baseline.·
At treatment completion (96.8% success rate), symptom prevalence decreased to 26.9% (cough 26.3%). Comorbidity rates declined to diabetes (14.2%) and hypertension (5%), with smoking (1.5%) and alcohol use (1.5%). Disability persisted in 15.8% of patients. All patients with these problems were referred to appropriate care. Referral systems functioned effectively for most comorbidities and risk factors (76.1-92% actually receipt the care) except for mental health disorder (18.0%) and pulmonary rehabilitation (9.45%).
Notably, patients with abnormal 6MWT at baseline showed significant improvement (25.3%→15.8%, $p<0.01$), particularly among older adults (54.5% abnormal in ≥60 age group). Smoking cessation interventions demonstrated success (10/11 smokers quit during treatment).
The combined questionnaire and 6MWT assessment required only 17.2 minutes per patient on average, demonstrating excellent feasibility for routine outpatient implementation.
These findings highlight both the progress and persistent gaps in managing TB-associated conditions through standard programmatic approaches.

Conclusions: Post-TB comorbidity and disability screening proves feasible in routine care, yet persistent gaps in mental health and pulmonary rehabilitation services require urgent programmatic strengthening for comprehensive patient management.

SOA06-561-19 Enhancing TB Detection in Ethiopia: Results from the Oromia TB Catch-Up Campaign

B.A. Fetenesa,[1] K.G. Banata,[1] D.A. Kumsa,[1] A.R. Tusho,[1] T.T. Lencha,[1] D.A. Kumsa,[1] [1]Oromia Health Bureau, Disease Prevention and Health Promotion, Addis Ababaet, Ethiopia
e-mail: wabizuneh@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a significant global health challenge, particularly in Ethiopia. The COVID-19 pandemic disrupted TB control efforts, likely contributing to increased undetected cases.
To address this, a one-month intensive TB Catch-Up Campaign was implemented in Oromia, Ethiopia, utilizing multiple strategies to enhance case detection among high-risk and vulnerable populations.
Intervention or response: The campaign covered 44 zones and 298 woredas in Oromia, targeting contacts of confirmed TB cases, diabetes (DM) patients, healthcare workers (HCWs), and Key Affected Populations (KAPs) such as prisoners, internally displaced persons (IDPs), and miners.
The campaign ran from April 1 to April 30, 2024, and employed three tailored interventions:
Intervention 1: Retrospective Contact Tracing
Health Extension Workers (HEWs) conducted house-to-house visits to map contacts of confirmed TB, drug-resistant TB (DRTB), and leprosy cases. Health professionals then performed community-based screenings, collecting sputum samples for lab testing. TB preventive treatment (TPT) was also provided to eligible contacts.
Intervention 2: Screening of High-Risk Groups
DM patients and HCWs were screened at health facilities, with sputum samples collected and sent to laboratories for testing.
Intervention 3: Screening of Key Affected Populations (KAPs)
Individuals in congregate settings (prisoners, IDPs, miners) were screened at designated sites, with sputum samples transported to labs for diagnosis.
Results/Impact: 1,187,951 individuals screened
57,064 presumptive TB cases identified
38,181 tested via GeneXpert and 18,883 via AFB microscopy
5,907 TB cases and 13 rifampicin-resistant (RR) TB cases detected
377 leprosy cases identified
8,388 individuals received TB preventive treatment (TPT)
Conclusions: The TB Catch-Up Campaign in Oromia, Ethiopia, demonstrated success in enhancing TB case detection through a multi-faceted approach, including contact tracing, high-risk group screening, and targeted interventions for vulnerable populations.
The campaign not only identified thousands of TB and leprosy cases but also provided preventive treatment to at-risk individuals.
These results highlight the importance of integrated, community-based screening strategies in high-burden settings

SOA06-562-19 Integrated service delivery for TB and non-communicable disease case detection using a primary health care approach in Cambodia

S. Chay,[1] J. Brophy,[2] A. Tan,[3] C.Y. Huot,[4] S.H. Muy,[5] B. Chhun,[6] K. Seak,[7] S. Scotney,[8] [1]Clinton Health Access Initiative, TB Program, Phnom Penh, Cambodia, [2]Clinton Health Access Initiative, Clinical Sciences Team, Ottawa, Canada, [3]Clinton Health Access Initiative, New Initiatives, Phnom Penh, Singapore, [4]Ministry of Health, National Center for Tuberculosis and Leprosy Control, Phnom Penh, Cambodia, [5]Ministry of Health, Preventive Medicine Department, Phnom Penh, Cambodia, [6]Clinton Health Access Initiative, Malaria, Phnom Penh, Cambodia, [7]Clinton Health Access Initiative, TB and ATscale, Phnom Penh, Cambodia, [8]Clinton Health Access Initiative, Cambodia Office, Phnom Penh, France
e-mail: schay@clintonhealthaccess.org

Background and challenges to implementation: The COVID-19 pandemic led to decreased TB case detection in Cambodia, with an estimated one-third of cases undiagnosed. Simultaneously, non-communicable diseases (NCDs) like diabetes mellitus (DM) and hypertension (HTN) contribute significantly to premature mortality, but screening is limited.
Project Boost implemented integrated service delivery (ISD) to enhance TB and NCD detection among individuals ≥45y in Kampong Chhnang province.
Intervention or response: With TB Reach funding, Clinton Health Access Initiative collaborated with Kampong Chhnang Provincial Health Department to increase TB and NCD screening at 45 health centers (HCs) from Q2/2023 to Q4/2024, using two approaches: algorithmic screening at HCs and active case finding (ACF) community events. HC activities included symptom screening for TB/DM/HTN for those ≥45y, sputum GeneXpert testing for TB-symptomatic individuals, and blood pressure (BP) and blood glucose (BG) measurements.
At ACF events, upfront digital chest x-ray with artificial intelligence analysis (CXR-AI) was added, with sputum GeneXpert for those with TB symptoms or abnormal X-rays.

Results/Impact: Project Boost screened 364,989 individuals for TB, identifying 16,606 presumptive cases, doing GeneXpert for 10,163, and diagnosing 982 bacteriologically-confirmed TB cases and 2,123 total TB cases – double the target of 1,010 diagnoses. For NCDs, 16,264 had BG measured, diagnosing 3,197 with DM (19.7%). 74,554 had BP measured, with 10,371 diagnosed with HTN (13.9%).
Across 37 ACF events, 7,603 individuals had TB screening, 7,457 received CXR-AI, 1,228 (589 asymptomatic) showed abnormalities, 1,336 had GeneXpert, leading to 82 bacteriologically-confirmed cases.
Ultimately, 402 (175 asymptomatic) were diagnosed with all forms of TB. For NCDs, 7,448 had BG measured, with 1,041 (14.0%) having hyperglycemia and 603 starting DM treatment; 7,448 had BP measured, with 3,810 (51.2%) having HTN and 2,310 commencing treatment.
Conclusions: Project Boost demonstrated a successful model for integrated TB and NCD screening at HC and community level. ACF events in particular demonstrated high diagnostic yield for asymptomatic TB and NCDs.

SOA06-563-19 Mental health interventions in TB care: A systematic scoping review in the SAARC region

N. Rana,[1] P. Samina,[1,2] G. Sidhu,[2] A. Daftary,[2]
[1]McMaster University, Faculty of Health Science, Mary Heersink School of Global Health and Social Medicine, Hamilton, Canada, [2]York University, Dahdaleh Institute for Global Health Research, Toronto, Canada
e-mail: namratagrana@gmail.com

Background: One in four people with TB face mental health challenges. Poor MH hinders TB health-seeking, treatment success, and post-treatment outcomes. We aimed to review approaches to provide MH care for people with TB in the South Asian Association for Regional Cooperation (SAARC) region, where 37% of people with TB live.
Design/Methods: Using Arksey and O'Malley's scoping review methods, we searched three databases (Medline, Embase, Global Health) for studies implementing an explicit mental health service or intervention to people undergoing TB screening, diagnosis and/or treatment in a SAARC country from 2000-2024. Extracted data were narratively synthesized.
Results: 2304 unique records were retrieved and yielded 17 eligible studies from India (n=10), Pakistan (n=6), and Nepal (n=1). Eight studies were among people with MDRTB.
Interventions included MH counselling (n=15, varied schedule, content, framework, and delivery approach), pharmacological intervention (n=9, anti-depressants, anxiolytics, withholding MDRTB drugs) and breathing exercises (n=1).
Interventions were implemented at clinics providing TB services (n=15) with off-site activities (n=5) and/or referrals to mental health centres (n=4); one was entirely via telehealth. MH professionals (psychiatrists, psychologists, n=9), nurses (n=1), social workers (n=3), pharmacists (n=1), and other cadres (peer supporters, patient navigators, lay counsellors, DOTS facilitators, n=9) were engaged in intervention delivery.
Mental health was assessed using standardized tools (n=14); five studies assessed substance use. All studies reporting post-intervention mental health outcomes (n=7) (anxiety, depression) and TB outcomes (n=10) (case notifications, treatment completion, adherence, failure, loss-to-follow-up, drug resistance, death) reported improved outcomes.
Improved patient satisfaction (n=2), quality of life (n=2), cardio-pulmonary measures (n=1), and reduced stigma (n=1) were also reported.
Seven studies implemented cointerventions: nutrition (n=5), economic support (n=7), and vocational rehabilitation (n=2).

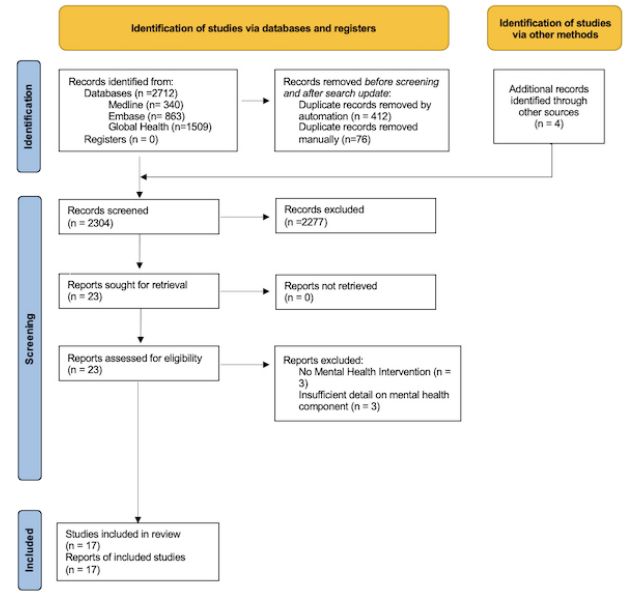


Figure 1. PRISMA CHART.

Conclusions: Effective people-centred TB care requires address to TB-comorbidities. We found MH interventions can be integrated in TB care settings to support achievement of improved TB and MH outcomes.

SOA06-564-19 Depression as a comorbid factor in patients with tuberculosis attending the rural Government TB Hospital in Tamil Nadu, India

D.L. Francis,[1] [1]Saveetha Dental College and Hospital, SIMATS, Saveetha University, Public health, Chennai, India
e-mail: delfin_lovelina@yahoo.co.in

Background: Tuberculosis (TB) is still the largest infectious cause of illness and mortality worldwide. Medication noncompliance has been identified as a disadvantage in the successful management of this disease. TB is related with psychological morbidity, notably depression, which has been identified as a cause of poor compliance as well as increased morbidity and mortality from the disease. Despite this acknowledgement, little emphasis is made to identifying depression in TB patients.
The purpose of this study was to investigate the prevalence of depression in TB patients attending the rural Government TB hospital in Tamil Nadu, India, as well as the factors that may be linked with it.
Design/Methods: A cross sectional descriptive study was carried out among 130 TB patients in both outpatient and inpatient settings. Sociodemographic questionnaire and a nine item HADS scale designed to test for sadness anxiety and depression.
Results: The study included 130 patients, 61% of whom were men and 39% of whom were women. The respondents' average age ranged from 25 to 70 years. 57% of the patients suffered from depression. Depression was substantially related with sociodemographic characteristics and a clinical component (persistent cough).
Conclusions: Depression is a common disorder among tuberculosis patients in rural Tamil Nadu. Almost half of these patients have concomitant depression, and up to 90% present low to moderate treatment adherence. This poor adherence puts them at risk of becoming treatment defaulters, which increases the risk of development of drug-resistant tuberculosis.
Comorbid depression is an important issue in this patient population, and its effective management may improve treatment outcomes and lessen the burden of drug-resistant tuberculosis in rural communities.
Effective symptom control, particularly of coughing, and actions to enhance the socioeconomic position of this group of patients should be included in initiatives to minimize depression among TB patients.

SOA06-565-19 Developing a pilot clinical and programmatic handbook on integrated service delivery of tuberculosis, community-acquired pneumonia, asthma and COPD in Nigeria

N. Murphy-Okpala,[1] C. Eze,[1] C. Nwafor,[1] M. Njoku,[1] O. Urhioke,[2] D. Egbule,[1] C. Adesigbin,[3] O. Chijioke-Akaniro,[3] A. Muhammad Ozi,[4] E. Sadoh,[5] O. Ezeakile,[1] I. Alobu,[6]
[1]RedAid Nigeria, Programs Department, Enugu, Nigeria, [2]National TB and Leprocy and Buruli Ulcer Control Programme Nigeria, GF Program Coordinating Unit, Abuja, Nigeria, [3]National Tuberculosis, Leprosy and Buruli Ulcer Program, GF Program Coordinating Unit, Abuja, Nigeria, [4]Federal Ministry of Health, Nigeria, Non Communicable Disease Program, Abuja, Nigeria, [5]University of Benin Teaching Hospital, Medicine, Benin, Nigeria, [6]Center for Disease and Reproductive Health, Programs Department, Abakaliki, Nigeria
e-mail: ngozi.murphyokpala@redaidnigeria.org

Background and challenges to implementation: In Tuberculosis high-burden countries like Nigeria, fragmented siloed health programmes result in poor coverage, high costs, inefficiencies and sub-optimal outcomes. WHO has long recommended the Practical Approach to Lung Health (PAL) for contextual application of integrated symptom-based management to detect TB and common lung conditions but requires bespoke country-level implementation and operational manuals/guides. Through TB REACH Wave 11 grant, RedAid Nigeria adapted PAL for multiple respiratory conditions (Tuberculosis, Community-Acquired Pneumonia, Asthma and COPD) and their major risk factors, cigarette smoking and indoor air-pollution. Project's active case-finding deploys digital tools as AI-enabled Chest X-rays, handheld peak expiratory flowmeters, and digital spirometers in 5 hard-to-reach districts of southern Nigeria.
Intervention or response: A 25-person Technical Working Group consisting of multidisciplinary interministerial stakeholders representing both programmatic, academia and clinical expertise was constituted to collaboratively develop clinical and programmatic guidance. Content development occurred within 3 sub-committees (Training and capacity building, SOPs and SBCC patient-facing materials, and Monitoring and Evaluation) through 4 hybrid meetings over a 6-weeks period.
Primary resources were international reference documents and national disease control guidelines, including the Nigerian-adapted integrated management of childhood illness chart booklet.
Results/Impact: Output generated was the first jointly produced Clinical and Programmatic Handbook on Integrated Service Delivery of multiple respiratory diseases (Tuberculosis, Community-Acquired Pneumonia, Asthma and COPD) in Nigeria. It formed the bedrock of the training manual and standard operating procedures for frontline health workers. It has been deployed in the 5 project districts for pilot implementation in Nigeria.

Critically, it also yielded a preliminary integrated monitoring and evaluation framework to be deployed by the national TB program.
Conclusions: The development of a unified ISD handbook using a robust stakeholder composition of a multidisciplinary team facilitated rollout of in-country adaptation of PAL strategy in Nigeria.
Lessons learnt from this pilot implementation will inform future strategies to improve efficiency and scale-up nationwide.

SOA06-566-19 Primary care visits: A window for timely tuberculosis screening in migrants to British Columbia, Canada?

K. Romanowski,[1,2] J.C. Johnston,[3] S.K. Brode,[4,5] J.R. Campbell,[6] [1]McGill University, Global and Public Health, Montreal, Canada, [2]BC Centre for Disease Control, Provincial TB Services, Vancouver, Canada, [3]University of British Columbia, Medicine, Vancouver, Canada, [4]University of Toronto, Medicine, Toronto, Canada, [5]West Park Healthcare Centre, Tuberculosis Program, Toronto, Canada, [6]McGill University, Medicine & Global and Public Health, Montreal, Canada

Background: In low tuberculosis (TB) incidence countries such as Canada, most TB diagnoses occur among people born outside the country, often due to the progression of infection acquired prior to migration. Ensuring timely TB prevention in primary care may accelerate elimination efforts.
We aimed to determine the timing of the first primary care visit among new permanent residents in British Columbia, Canada, and to estimate the potential impact of offering TB infection screening and preventive treatment at that first visit.
Design/Methods: We conducted a retrospective cohort study using linked health administrative data. We calculated the cumulative proportion of individuals accessing primary care and time from establishing permanent residency to their first visit. TB disease was considered potentially preventable if diagnosed ≥6 months after their first primary care visit, assuming rapid screening and preventive treatment could prevent progression. People with a high-risk medical indication for TB screening were censored. Descriptive statistics were used to summarize findings.
Results: Among 846,453 people in the cohort, 709,405 (83.8%) accessed primary care at least once during the follow-up period (median follow-up: 91.4 months, IQR: 48.9, 161.9).
Half of the cohort (n = 424,673; 50.2%) had their first visit within 15 months, and 75.3% (n = 637,625) within 35 months. In total, 1,327 individuals (0.16%) were diagnosed with TB disease. The median time to diagnosis was 53.4 months (IQR: 22.3, 104.8).
Of those diagnosed, 911 (68.7%) had no high-risk medical indication for screening. We estimate that 629 TB diagnoses, equivalent to 47.4% of all people diagnosed in the cohort, could have been potentially prevented by initiating the process of screening and preventive treatment at the first primary care visit (Table).

	N (%)
Total diagnosed with TB	1327
No high-risk medical indication for screening prior to TB disease diagnosis	911 (68.7)
Not preventable	
TB diagnosis before first primary care visit or <6 months after first primary care visit	251 (18.9)
No primary care visit before TB diagnosis	31 (2.3)
Potentially preventable*	
TB diagnosis ≥ 6 months after first primary care visit	629 (47.4)
Had a high-risk medical indication for screening prior to TB disease diagnosis**	416 (31.3)

**Under the assumption that TB infection screening and preventive treatment at the first primary care visit could prevent progression to TB disease ** Censored at time of high-risk medical indication*

Conclusions: Our findings suggest incorporating TB infection screening and preventive treatment into initial primary care encounters could support efforts toward TB elimination in low-incidence settings.

SOA06-567-19 Innovative models for TB/HIV integrated service delivery in Osun State

O. Peter,[1] O. Kolade,[1] K. Okewumi,[1] O. Adedokun,[1] M. Agbonyin,[1] J. Bamigbade,[1] P. Dakum,[2] C. Mensah,[2] O. Chijioke-Akaniro,[3] S. Dimang,[3] M. Zamzu,[4] A. Reilly,[4] [1]Damien Foundation Belgium (Nigeria Project), Programme, Ibadan, Nigeria, [2]Institute of Human Virology, Nigeria, Programme, Abuja, Nigeria, [3]National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Programme, Abuja, Nigeria, [4]Global Fund Country Team, Programme, Geneva, Switzerland
e-mail: dayo.loremikan@dfbnigeria.org.ng

Background and challenges to implementation: Tuberculosis (TB) and HIV co-infection remain a significant public health challenge, especially in high-burden settings. Integrated service delivery models improve outcomes by ensuring early diagnosis, timely treatment initiation, and better adherence. However, traditional TB/HIV service models often experience fragmented care, high loss to follow-up, and overburdened health facilities. This study explores innovative integration models and their impact on service efficiency and outcomes.
Intervention or response: Three TB/HIV integrated service delivery models were reviewed across multiple high-burden settings:
1. One-Stop Shop Model – TB and HIV screening, diagnosis, treatment, and counseling are provided at a single facility by a multidisciplinary team.

2. Community-Based Integrated Care – Decentralized care through trained community health workers (CHWs), mobile clinics, and home-based directly observed treatment (DOT).
3. Digital Health Integration – Use of shared digital platforms to track both TB and HIV services.
Key performance indicators, such as case detection rates, were analyzed. Qualitative data were collected from healthcare workers and individuals receiving care to assess feasibility and acceptability.
Results/Impact: Through the One-Stop Shop Model, 14,500 women accessed TB screening and HIV testing at engaged unconventional birth homes in Osun State. Community-Based Integrated Care led to a 45% increase in case detection among key populations and improved retention in care.
The Sample Logistics Dashboard improved accountability for TB and early infant diagnosis (EID) samples by tracking logistics and result retrieval. Both healthcare workers and individuals receiving services reported higher satisfaction with streamlined, person-centered care.
Identified challenges included training gaps, data harmonization issues, and funding sustainability.
Conclusions: Innovative TB/HIV integration models enhance patient outcomes, improve efficiency, and reduce loss to follow-up. Scaling up these models requires addressing operational barriers and strengthening policy, digital tools, and community engagement for sustainability.

SOA06-568-19 Localizing public-private mix: Advancing TB service integration through district government engagement in Indonesia

N. Nurliyanti,[1] H. Diatmo,[2] [1]Stop TB Partnership Indonesia, Program, Jakarta Selatan, Indonesia, [2]Stop TB Partnership Indonesia, Director, Jakarta Selatan, Indonesia
e-mail: nurliyanti@stoptbindonesia.org

Background and challenges to implementation: In Indonesia, 74.6% of individuals with TB symptoms initially seek care at private health facilities. However, it takes an average of six visits or 62 days before receiving a diagnosis, reflecting limited diagnostic and treatment capacity in private primary care (FKTP). An estimated 463,000 people with TB visit private clinics but remain undiagnosed, as most clinics refer presumptive cases without follow-up. Critical barriers include lack of personal protective equipment, diagnostics, basic supplies, infrastructure, and incentives—highlighting the need for stronger integration of private providers into national TB efforts.
Given Indonesia's decentralized health system, subnational governments are crucial for ensuring private sector engagement through local planning, budgeting, and regulation.
Intervention or response: To address these challenges, Stop TB Partnership Indonesia implemented targeted Public-Private Mix (PPM) advocacy in seven districts from March 2023 to June 2024. The intervention focused on three strategies:
1. Strengthening TB financing through local budgets and provider incentives;
2. Expanding the District PPM (DPPM) network to include diverse health facilities; and
3. Supporting enabling regulations and systems at the subnational level.
Advocacy workshops involving around 30 local stakeholders were conducted in each district, resulting in advocacy plans monitored by local civil society organizations.
Results/Impact: The initiative yielded significant outcomes. DPPM teams were revitalized through official decrees, and TB Elimination Task Forces (TP2TB) were established with actionable plans. Several districts issued policies recognizing private provider roles.
Collaboration between Puskesmas and private clinics was formalized, and 22 private facilities gained access to the national TB reporting system (SITB). Local governments began multisectoral budget mapping and integrated TB into district development planning. Some districts also initiated collaborations with private providers using local funds.
Conclusions: This initiative demonstrates how district leadership and public-private collaboration can institutionalize PPM and close service delivery gaps—paving the way for a more integrated and equitable TB response.

SOA06-569-19 Pharmacy engagement through hub and spoke model for tuberculosis case finding: An experience from four major cities of Nepal

B. Maharjan,[1] R.S. Gopali,[1] S. Poudel,[1] A. Acharya,[1] G. Joshi,[1] S. Rawal,[1] R. Mulmi Shrestha,[1] C. Valdesolo,[2] S. Stojanovik,[2] A. Shrestha,[3] [1]Japan-Nepal Health and Tuberculosis Research Association, Public Health, Kathmandu, Nepal, [2]The Global Fund to Fight AIDS, Tuberculosis and Malaria, South and East Asia, Geneva, Switzerland, [3]Save the Children, Global Fund-TB, Kathmandu, Nepal
e-mail: bjmaharjan28@gmail.com

Background and challenges to implementation: Private pharmacies are often the first point of care for people because of convenient operating hours and personalized services. Engaging them is therefore critical to close gaps in access to tuberculosis (TB) care and services.
Intervention or response: The Public-Private Mix (PPM) approach has been implemented in four main cities following the hub and spoke model from March 2021 to January 2025. Pharmacies were linked based on the number of patients flows per day, the quantity of cough syrup, ex-

pectorant, antibiotic and anti-TB drug sales per month. A total of 250 pharmacies were oriented on the model of the National TB program. The pharmacies were linked with 70 private doctors/clinics which had chest X-ray facilities. The linkage was facilitated by PPM mobilizers. Pharmacies were responsible for TB symptomatic screening among patients seeking medical help, referring presumptive TB cases, collecting sputum samples and recording and reporting.

Results/Impact: Of the participating pharmacies, 70% were community-based while 30% had clinic/X-ray facilities. The proportion of active pharmacies (referring at least one presumptive TB case per month) increased from 44% in 2021 to 54% in 2025. The number of referrals and diagnosed TB cases rose, whereas the positivity rate dropped from 13% in 2021 to 4% in 2025.

A total of 79,312 presumptive TB cases were identified and evaluated for TB (15% GeneXpert, 12% Microscopy, 73% other diagnostic tools for TB), of which 3969 (5.2%) were diagnosed: 61.6% were pulmonary, 38.2% were extrapulmonary, and 0.2% were drug-resistant TB. This intervention strengthened TB service coverage and enhanced referral pathways between pharmacies, doctors and diagnostic facilities.

Year	Presumptive TB	GeneXpert	Microscopy	Other diagnostic tools	TB cases	Yield Rate
Mar 21 to Dec 2021	2698	378 (14%)	324 (12%)	1997 (74%)	353	13%
Jan 2022 to Dec 2022	15476	2262 (15%)	2769 (18%)	10445 (67%)	1108	7%
Jan 2023 to Dec 2023	25913	3513 (14%)	3447 (13%)	18953 (73%)	1136	4%
Jan 2024 to Jan 2025	35225	5721 (16%)	3328 (9%)	26176 (74%)	1372	4%
Total	79312	11874 (15%)	9868 (12%)	57571 (73%)	3969	5%

Table 1: Year wise presumptive TB evaluated using different test and diagnosed TB cases.

Conclusions: Expanding private pharmacy engagement in TB program is essential. Future efforts should ensure accessibility of molecular WHO-recommended rapid diagnostic test, availability of sufficient advocacy materials, and establish a system to track patient visits to pharmacies for improved monitoring and case detection.

SOA07 Managing drug-resistant TB in the 21st century: Data, diagnostics and delivery

SOA07-570-19 Prevalence and risk factors of drug-resistant TB in Nepal: Findings from the sixth national drug-resistance TB survey

R. Basnet,[1,2] S.R. Tiwari,[3] N.P. Shah,[3] P. Shrestha,[4] M. Khanal,[5] S. Neupane,[6] R.B. Bhattarai,[7] L. Joshi,[8] A. Shrestha,[8] [1]National TB Program, Global Fund, Kathmandu, Nepal, [2]Maastricht University, Department of Health Services Research, Maastricht, Netherlands, [3]National TB Control Centre, Program, Kathmandu, Nepal, [4]National Academy of Medical Science, Bir Hospital, Pulmonary Medicine, Kathmandu, Nepal, [5]National TB Control Centre, Planning, Monitoring, Evaluation, Research, and Surveillance Section, Kathmandu, Nepal, [6]National TB Program, USAID Technical Assistance, Kathmandu, Nepal, [7]Sydani Group, Nepal, Kathmandu, Nepal, [8]Save The Children, Global Fund TB Program, Kathmandu, Nepal

Background: Tuberculosis continues to be a major public health concern in Nepal, with an estimated incidence rate of 229 cases per 100,000 people in 2023. Treatment coverage reached only 54%, leaving 46% of TB cases undetected. The estimated number of drug resistant tuberculosis (DR-TB) was 3,000, but only 693 were diagnosed, with 21% (147 cases) lost to follow-up at the initial stage. Nepal's National TB Program conducted its sixth drug-resistance TB survey in 2023 to update resistance patterns, confirm trends in rifampicin-resistant TB (RR-TB) and multidrug-resistant TB (MDR-TB).

Design/Methods: A cross-sectional survey administered based on World Health Organization protocols. Fifty clusters were selected from three strata, focusing on newly registered, bacteriologically confirmed pulmonary TB cases diagnosed via sputum smear microscopy or Xpert/MTB RIF at diagnostic centers. We utilized a paper-based clinical information form and conducted face-to-face interviews.

Data collection spanned 14 months, involving 1,768 patients (1,592 newly diagnosed and 176 previously treated) whose samples exhibited mycobacterium tuberculosis complex growth in culture. These samples underwent additional drug susceptibility testing (DST) using the mycobacteria growth indicator tube (MGIT) method for phenotypic DST and the line probe assay (LPA) for genotypic DST. Data analysis was conducted using R-studio.

Results: The prevalence of MDR TB was 2.1% (95% CI: 1.3-3.5) among newly diagnosed patients and 10.1% (95% CI: 5.1-19) among previously treated. The overall prevalence of pre-extensively drug-resistant TB was 1.3% (95% CI: 0.6-2.7) in new patients and 3.4% (95% CI: 1.2-8.8) in previously treated cases. Among rifampicin-resistant patients, 48.3% (95% CI: 35.2-61.7) had pre-XDR TB.

Conclusions: History of previous TB treatment was the only statistically significant risk factor ($p < 0.05$) for rifampicin-resistant TB (OR: 4.1; 95% CI: 2.6-6.4). Other factors such as HIV status, diabetes, and age group were not found to be statistically significant.

SOA07-571-19 Dominance of Lineage 2 and clonal endemic transmission of TB in Bhutan

K. Tshering,[1] R. Spies,[2,3] D. Moore,[4] S.T. Lhamu,[1] S. Zangmo,[1] T. Dolkar,[1] D. Dang Anh Thu,[3] N. Le Quang,[3] P. Bhujel,[1] T.M. Walker,[2,3] [1]Royal Centers for Disease Control, Ministry of Health, National TB Reference Laboratory, Thimphu, Bhutan, [2]University of Oxford, Nuffield Department of Medicine, London, United Kingdom of Great Britain and Northern Ireland, [3]Oxford University Clinical Research Unit (OUCRU), Tuberculosis Group, Ho Chi Minh City, Viet Nam, [4]London School of Hygiene and Tropical Medicine, Clinical Research Department, London, United Kingdom of Great Britain and Northern Ireland
e-mail: ruan.spies@ndm.ox.ac.uk

Background: In Bhutan, tuberculosis (TB) incidence has gradually decreased over the past decade; however, multidrug resistant tuberculosis (MDR-TB) case detection has risen sharply with a wide detection gap compared to WHO estimates.
This study investigates sources and transmission dynamics of TB to inform effective ending TB strategies.
Design/Methods: We retrospectively performed whole genome sequencing (WGS) on all pre-treatment, culture-positive *Mycobacterium tuberculosis* (MTB) isolates processed at Bhutan's National TB Reference Laboratory between 2016 and 2018. Local transmission was assessed by clustering sequences at 5 and 12 single nucleotide polymorphism (SNP) thresholds.
To evaluate cross-border transmission, we analysed publicly available MTB sequences from Bangladesh, China, England, India, Nepal, and Tibet, alongside sequences from Bhutan. Lineage-specific, time-scaled phylogenetic trees were constructed and geographic origins of ancestral strains were estimated using stochastic mapping.
Results: Among 899 sequences, 890 were single-lineage MTB and included in this analysis. Lineage 2 was predominant (496/890, 67%) and contained most drug-resistant TB (DR-TB) isolates (160/178, 90%).
A single Lineage 2 outbreak clade was responsible for 85% of all MDR-TB cases (99/117). A high proportion of isolates clustered at both 5 SNP (548/890, 62%) and 12 SNP thresholds (665/890, 75%), with Lineage 2 exhibiting the highest clustering (496/596, 83%).
Recent cross-border transmission occurred exclusively within Lineage 2, with four clusters sharing recent ancestors dated within 30 years. Historical introductions varied by lineage: Lineages 1 and 3 originated earlier from South Asian neighbours, primarily India; Lineage 2 emerged most recently from China via Tibet; and Lineage 4 was introduced through England and India during the British colonial period.

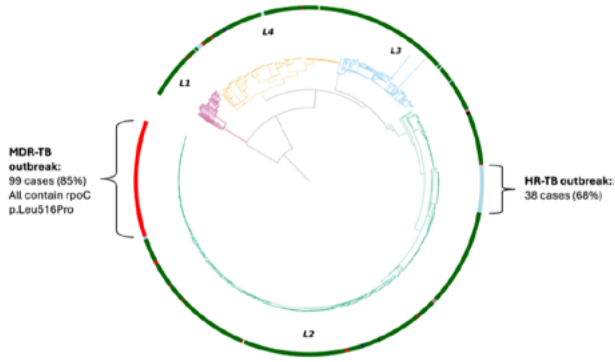

Figure: Phylogenetic reconstruction identifies dominant Lineage 2 clades driving MDR-TB transmission in Bhutan.

Conclusions: Despite its more recent introduction, Lineage 2 dominates TB in Bhutan, with most MDR-TB cases clustered and primarily driven by local transmission rather than migration/reactivation. Targeted interventions to disrupt transmission in high-burden areas, will be crucial for effective TB prevention and care.

SOA07-572-19 Application of targeted next-generation sequencing (tNGS) in diagnosis and drug resistance prediction of extrapulmonary TB

Y. Chen,[1] L. Fan,[2] C. Liu,[3] M. Wang,[4] X. Qin,[5] H. Zhu,[6] H. Liang,[7] B. Xu,[8] [1]Shenyang Tenth People's Hospital/Shenyang Chest Hospital;China Medical University, Department of Tuberculosis/Department of Epidemiology, School of Public Health, Shenyang, China, [2]Shenyang Tenth People's Hospital/Shenyang Chest Hospital, Department of Tuberculosis, Shenyang, China, [3]Shenyang Tenth People's Hospital/Shenyang Chest Hospital, Department of Thoracic Surgery, Shenyang, China, [4]The First Affiliated Hospital of China Medical University, Department of Plastic Surgery, Shenyang, China, [5]Shenyang Tenth People's Hospital/Shenyang Chest Hospital, Department of Neurology, Shenyang, China, [6]Shenyang Tenth People's Hospital/Shenyang Chest Hospital, Department of Health Management, Shenyang, China, [7]Shenyang Health Commission, Liaoning Province, Shenyang Health Commission, Shenyang, China, [8]Shenyang Tenth People's Hospital/Shenyang Chest Hospital, Hospital Office, Shenyang, China
e-mail: liuchang9011@aliyun.com

Background: Extrapulmonary tuberculosis (EPTB) is a complex health issue with increasing challenges due to drug-resistant strains. Targeted next-generation sequencing (tNGS) offers a promising approach for rapid and accurate diagnosis and resistance prediction directly from clinical samples.

Design/Methods: A prospective study was conducted from July 31, 2021, to December 31, 2024, at Shenyang Tenth People's Hospital, assessing diagnostic accuracy and resistance prediction using tNGS, Xpert, and culture drug sensitivity testing on extrapulmonary specimens from adults suspected of EPTB.

Results: Finally, 211 adults suspected of EPTB were included in the study, including 130 males and 81 females, aged 49±16.97. The sensitivity and specificity of tNGS to microbiologically and clinically confirmed TB were 73.3% (95% CI, 64.9%-81.8%) and 98.1% (95% CI, 95.5%-100.0%).

The manifestations of tNGS in different specimen types, among the cases confirmed by microbiological diagnosis and clinical diagnosis, tNGS showed the highest sensitivity (86.4%) in lymph node and soft tissue, moderate sensitivity (80.5%) in bone tissue, and relatively low sensitivity (61.8%) in pleural effusion. tNGS showed variable sensitivity to the prediction of drug resistance. The sensitivity of rifampicin resistance was 58.3%(95% CI, 31.4%-80.9%) and the specificity was 97.9%(95% CI, 94.4%-99.3%) based on Xpert.

According to pDST, the sensitivity of tNGS to isoniazid resistance was 40.0%(95% CI, 9.1%-73.7%), the specificity was 97.0%(95% CI, 92.2%-99.1%), and the sensitivity to rifampicin resistance was 80.0% (95%). 98.1%), the sensitivity to streptomycin was 75.0%(95% CI, 29.7%, 95.6%), the specificity was 95.1%(95% CI, 89.5%-98.2%).

Conclusions: tNGS is an effective diagnostic tool, which can be used for rapid diagnosis of EPTB. Its high sensitivity and specificity in the diagnosis of EPTB make it an important supplement to traditional diagnostic methods. The variability of drug resistance diagnosis needs to be further verified and solved in clinical application, and the best application mode of drug resistance diagnosis in EPTB management should be explored.

SOA07-573-19 Can targeted mentorship enhance multi-drug-resistant TB detection in resource-limited settings like Malawi? A quasi-experimental evaluation

S. Mtalika,[1] Y. Saidi,[1] D. Chimatiro,[1] D. Omotayo,[1] K. Mbendera,[1] T. Mwenyenkulu,[1] H. Kanyerere,[1] B. Belaineh,[1] B. Shigut,[1] P. Gomani,[1] [1]Ministry of Health, National TB and Leprosy Elimination Program, Lilongwe, Malawi
e-mail: sostenmtalika@gmail.com

Background and challenges to implementation: The 2018-2019 drug resistance survey in Malawi reported multidrug-resistant or rifampicin-resistant TB (MDR/RR-TB) in 2.3% of new and 6.1% of previously treated TB cases. However, the proportion of MDR/RR-TB detection among notified TB cases remains low, primarily due to gaps in healthcare workers' knowledge and skills. This evaluation assessed whether the mentorship program aimed at strengthening competence in drug-resistant TB (DR-TB) management enhanced case detection.

Intervention or response: The program, supported by the USAID-TB Implementation Framework Agreement (TIFA) mechanism, implemented targeted mentorship interventions to improve DR-TB case detection. A mentorship tool was developed with thematic areas designed to address challenges in DR-TB case detection.

Targeted healthcare workers at the intervention sites received monthly mentoring on these topics for nine months. Mentors were trained to assess the performance of both facilities and mentees using the tool. Mentorship support was offered in 15 of the 29 districts in Malawi from March 2023 to February 2024. Regular performance monitoring was carried out to track progress.

Results/Impact: A pre-and post-intervention assessment evaluated the impact of mentorship on MDR/RR-TB case detection. Between 2022 and 2024, in intervention sites, cases increased by 76%, rising from 74 to 130 cases. Non-mentorship sites experienced a slight increase of 2%, from 43 to 44 cases.

The increased case detection in intervention sites demonstrates the positive impact of mentorship support on improving MDR/RR-TB case detection. This also contributed to a 49% increase in national MDR/RR-TB case detection, rising from 117 to 174 cases.

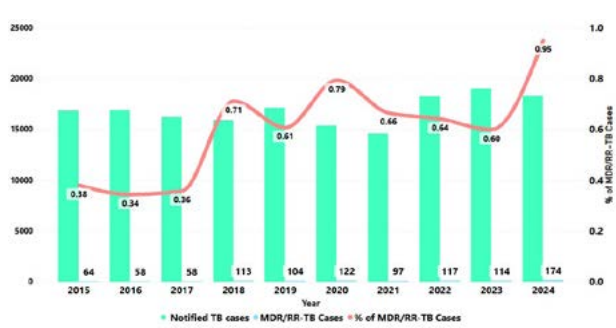

Figure 1. The proportion of MDR/RR-TB among notified TB cases

Conclusions: This targeted mentorship enhanced MDR/RR-TB case detection in intervention sites, supporting the necessity for scaling up and routine implementation. This approach provides lessons for implementing similar interventions in resource-limited settings to strengthen competence and improve MDR/RR-TB case detection. Further studies should explore the cost-effectiveness of mentorship to inform policy adoption.

SOA07-574-19 Tackling drug-resistant TB in Punjab, Pakistan: Treatment regimens and outcomes from a cohort study

M. Lightowler,[1] M. Gouillou,[2] K.K. Zaw,[3] A.G. Muhammad,[3] L. Sannino,[4] S. Khan,[5] A. Mohamed,[5] H. Huerga,[1] C. Hewison,[4]
[1]Epicentre, Field Epidemiology, Brussels, Belgium, [2]Epicentre, Research, Paris, France, [3]Medecins Sans Frontieres, Operational Centre Paris, Gujranwala, Pakistan, [4]Medecins Sans Frontieres, Operational Centre Paris, Paris, France, [5]Medecins Sans Frontieres, Operational Centre Paris, Islamabad, Pakistan
e-mail: Laura.SANNINO@paris.msf.org

Background: Multi-drug and rifampicin resistant tuberculosis (MDR/RR-TB) represent a major challenge in Pakistan. Since 2021, Médecins Sans Frontières, with National and Provincial TB programs, provides MDR/RR-TB care in Gujranwala, Punjab. While bedaquiline-based regimens have improved treatment care, emerging resistance threatens progress. We assess MDR/RR-TB treatment regimens used in this context, resistance patterns, and treatment outcomes.
Design/Methods: A retrospective analysis on MDR/RR-TB patients enrolled between December 2021 and March 2025. Regimens received were individualized long treatment (LTR, 18–24 months), a 6-month bedaquiline-pretomanid-linezolid with or without moxifloxacin (BPaL/M), or bedaquiline 9-11-month all-oral shorter treatment (STR). Baseline bedaquiline phenotypic drug susceptibility testing (DST) was performed. Enrolment periods varied by regimen to describe treatment outcomes (before September 2023 for LTR and before September 2024 BPaL/M and STR).

	Longer individualised regimen (LTR)	BPaL/M	Bedaquiline short regimen (STR)	Total
N (%)	205 (43.1%)	196 (41.2%)	75 (15.8%)	476 (100.0%)
Age Median [IQR]	39.0 [24.0; 55.0]	33.0 [21.5; 53.5]	23.0 [9.0; 37.0]	33.0 [21.0; 53.5]
HIV Positive status	3 (1.5%)	3 (1.5%)	0 (0.0%)	6 (1.3%)
Diabetes	61 (29.8%)	53 (27.0%)	10 (13.3%)	124 (26.1%)
Hepatitis C	33 (16.1%)	22 (11.2%)	5 (6.7%)	60 (12.6%)
Bilateral disease	88 (42.9%)	89 (45.4%)	20 (26.7%)	197 (41.4%)
Smear positive	65 (31.7%)	32 (16.3%)	12 (16.0%)	109 (22.9%)
Confirmed pre-extensively drug-resistant-TB (pre-XDR TB; MDR/RR-TB with fluoroquinolone-resistance)	71 (34.6%)	47 (24.0%)	0 (0.0%)	118 (24.8%)
Confirmed extensively drug-resistant-TB (XDR TB; pre-XDR with additional resistance to bedaquiline or linezolid)	4 (2.0%)	0 (0.0%)	0 (0.0%)	4 (0.8%)

Results: Main baseline characteristics of 476 patients (53% male) are in the table. Patients receiving LTR had more risk factors and baseline drug resistance. Amongst patients with baseline bedaquiline DST, 5% (10/201) had bedaquiline resistance. Of those with bedaquiline resistance, 3 had previous bedaquiline exposure (seven had prior TB treatment: four with second-line drugs), nine received LTR and one BPaL/M.
Treatment outcomes were for 137 patients on LTR, 74% (101/137) success, 6% (8/137) lost-to-follow-up (LTFU), 6% (8/137) failure, and 15% (20/137) death. For 101 patients on BPaL/M, 95% (96/101) success, 2% (2/101) LTFU, 2% (2/101) failure and 1% (1/101) death. For 50 patients on STR, 78% (39/50) success, 10% (5/50) LTFU, 10% (4/50) failure, and 4% (2/50) death.
Conclusions: BPaL/M showed high success rates in eligible patients. Despite having less risk factors and baseline resistance than patients on BPaL/M, patients on the STR had poorer outcomes. Moderate levels of baseline bedaquiline resistance is concerning considering bedaquiline is a key drug in all treatment regimens. New drugs are needed to provide treatment options for these patients.

SOA07-575-19 Characteristics, risk factors, and treatment outcomes of isoniazid mono-resistant TB in Cambodia: A retrospective study using Xpert XDR technology

S. Sam,[1] B. Heng,[2] N. Long,[3] C. Huot,[4] R. M. Hurtado,[5] A. E. Goldfeld,[6] [1]Cambodian Health Committee (CHC), MDR-TB Programme, Phnom Penh, Cambodia, [2]Cambodian Health Committee (CHC), TB and HIV, Phnom Penh, Cambodia, [3]CENAT, MDR-TB, Phnom Penh, Cambodia, [4]CENAT, NTP, Phnom Penh, Cambodia, [5]Massachusetts General Hospital, Infectious Diseases, Boston, United States of America, [6]Harvard Medical School and Children's Hospital Boston, Immunology and Infectious Diseases, Boston, United States of America
e-mail: samsophan@gmail.com

Background: Isoniazid (INH) mono-resistant tuberculosis (Hr-TB) is a prevalent form of drug-resistant tuberculosis (TB), but its detection has historically been very low, primarily due to limitations in phenotypic drug susceptibility testing (DST). By late 2022, Xpert XDR 10-color technology became available in Cambodia at MDR-TB treatment sites, offering a more efficient diagnostic tool for detecting Hr-TB.
Design/Methods: We retrospectively reviewed the medical records of Hr-TB patients treated in Cambodia between January 2023 and September 2024. Samples that tested positive for Mycobacterium tuberculosis (MTB) and negative for Rifampin were further tested using the Xpert MTB/XDR assay to identify Hr-TB.
Results: A total of 203 Hr-TB patients were included in the study. Of these, 123 (60.6%) were male, and the median age was 48 years [interquartile range: 37-62 years]. Among the patients, 32% had a history of prior TB treatment, while 171 (80%) had newly diagnosed TB, 197 (97%), had pulmonary TB, 9 (4.4%) patients had HIV co-

infection, and 43 (21.2%) had diabetes. Mutations in the katG gene were identified in 95 (46.8%) patients, including 4 with gyrA mutations.
Mutations in the inhA gene were found in 90 (45.3%), including 2 with gyrA mutations, and 16 (7.9%) had mutations in both katG and inhA. Regarding treatment outcomes, 184 (90.6%) had favorable outcomes, 17 (8.4%) died, and 2 (1.0%) were lost to follow-up.
In terms of mortality, prior TB treatment (OR=2.4, 95% CI: 0.79-7.42, p=0.156), HIV co-infection (OR=1.3, 95% CI: 1.16-11.69, p=0.556), diabetes (OR=0.8, 95% CI: 0.22-3.01, p=0.769), and mutations in both katG and inhA (OR=2.8, 95% CI: 0.71-11.07, p=0.140) were not significantly associated with mortality.
Conclusions: This study demonstrates that Hr-TB is prevalent in Cambodia, with the Xpert XDR assay serving as an important tool for detecting drug resistance. No significant associations were found between risk factors and mortality outcomes.

SOA07-576-19 Effects of pyrazinamide and/or ethambutol resistance on TB treatment outcomes determined by whole genome sequencing, South Africa, 2020 - 2025

S. Dlamini,[1] [1]National Institute for Communicable Diseases, Centre for Tuberculosis, Gauteng, South Africa
e-mail: sinodlamini99@gmail.com

Background and challenges to implementation: In South Africa, both pyrazinamide (PZA) and/or ethambutol (EMB) were included in the all-oral short-course regimen despite the high resistance rates to pyrazinamide (PZA) and/or ethambutol (EMB) reported among people with MDR-TB. The effect of resistance to these drugs on treatment outcomes are poorly understood.
This study evaluated the effects of PZA and/or EMB resistance on treatment outcomes among MDR-TB cases treated with the all oral short course regimen in South Africa from 2020 to 2022.
Intervention or response: We conducted a retrospective cohort study of people with MDR-TB detected through whole genome sequencing. Drug susceptibility patterns for PZA and EMB were classified into four categories: susceptibility to both drugs (EMB-S & PZA-S), resistance to PZA only (EMB-S & PZA-R), resistance to EMB only (EMB-R & PZA-S), and resistance to both drugs (EMB-R & PZA-R). Treatment outcomes were categorized as either successful patient outcomes (SPO) or unsuccessful patient outcomes (USPO). A directed acyclic graph (DAG) guided the selection of variables for the generalized linear model.
Adjusted incident rate ratio (aIRR) were calculated with 95% confidence intervals using modified Poisson regression with robust error variances.
Results/Impact: Among the 598 people with MDR-TB included in the analysis, 60% (356/598) were resistant to one or both TB drugs drugs.
There was little evidence that resistance to PZA and/or EMB increased USPO: resistance to PZA (aIRR = 1.18, 95% CI: 0.86–1.63), resistance to EMB alone (aIRR = 0.94, 95% CI: 0.67–1.32), and resistance to both drugs (aIRR = 0.97, 95% CI: 0.73–1.27).
Conclusions: This study emphasizes the complexity of understanding the effects of PZA and EMB resistance on MDR-TB outcomes. Investigations into circulating MDR strains across provinces would be beneficial to this understanding.
There is no evidence that PZA and/or EMB resistance influences the TB treatment outcomes and should not be included in this regimen.

SOA07-577-19 Early treatment outcomes for the six-month BPaLM regimen under programmatic conditions in Ethiopia

E. Tesema,[1] D. G Datiko,[2] Y. M Alemayehu,[2] T. Bogale,[1] M. Million,[1] G. Gizatie,[1] M. Tsehaye,[1] A. Gebreyohannes,[1] D. Jerene,[3] K. Johnson,[4] W. Chirs,[4] S. Konopka ,[4]
[1]USAID Eliminate TB Project, KNCV Tuberculosis Foundation, Addis Ababa, Ethiopia, [2]USAID Eliminate TB Project, Management Sciences for Health, Addis Ababa, Ethiopia, [3]USAID Eliminate TB Project, KNCV Tuberculosis Foundation, The Hague, Netherlands, [4]USAID Eliminate TB Project, Management Sciences for Health, Arlington, VA, USA, United States of America
e-mail: emawayish.tesema@kncvtbc.org

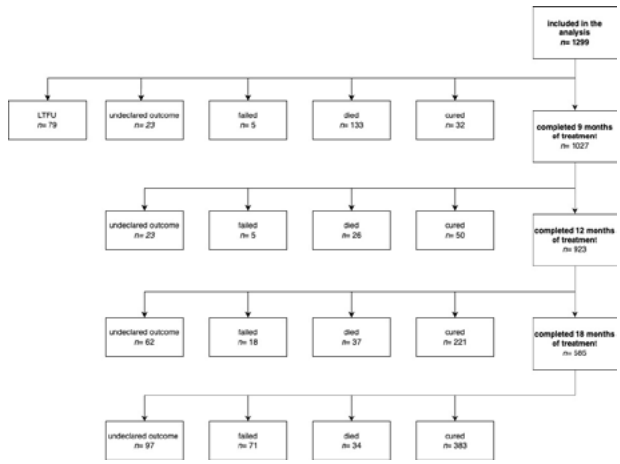
Background and challenges to implementation: Drug resistant tuberculosis (DR TB) remains a major public health concern. To improve the adherence and treatment outcomes of DR TB patients, the World Health Organization recommends the implementation of the six-month BPaLM regimen. This regimen is composed of Bedaquiline, Pretomanid, Linezolid, (600mg) and Moxifloxacin and has been implemented in Ethiopia since September 2023.
Regular follow up to monitor the effectiveness during programmatic implementation is essential to ensure the quality of care provided to patients.
Intervention or response: We described the routine national DR TB data of the district health information system (DHIS2) from 55 DR TB treatment initiating centers during September 2023-March 2024.
We compared the outcome of MDR-TB patients on six-month BPaLM regimen (in seven regions of Ethiopia with a population of 93 million people, 85.3% of the national) with the outcome of other DR TB regimen and all TB cases of similar period of national report using two sample proportion tests in STATA.

Results/Impact: A total of 189 patients were enrolled in the six-month BPaLM regimen. About 41% (77) were females. The mean age of DR TB patients was 31.8 years with a standard deviation of 15.1 years. Treatment was successful in 94.1% of patients including cure (73.5%) and treatment completion (20.6%).
The success rate is significantly greater than the 78% for DR TB cases (Z-test=4.96, p-value=<0.0001)) and 86% for all forms of TB (Z-test=3.21, p-value=0.0013) in Ethiopia. Five (2.6%) patients were lost to follow-up, two (1.1%) patients failed, and four (2.1%) died. The death rate is significantly lower than the 12% patients on the other regimens (Z-test=3.99, p-value=0.0001).
Conclusions: The six-month BPaLM regimen could contribute to better treatment outcome by improving treatment completion, decreasing lost to follow up, and reducing mortality. Routine patients follow up is required after treatment completion to prevent relapse.

SOA07-578-19 Long-term treatment outcomes of multi-drug-resistant TB/ rifampicin-resistant TB in Latvia

S.C. Meier,[1] C. Lange,[1] T.T. Brehm,[1] S. Ķauķe,[2] L. Kukša,[2]
[1]Research Centre Borstel, Leibniz Lung Centre, Department of Clinical Infectious Diseases, Borstel, Germany, [2]Riga East Clinical University Hospital, Department of Pneumology, Riga, Latvia
e-mail: sophiechmeier@gmail.com

Background: In Latvia, a high-priority country for tuberculosis (TB) in the WHO European Region, 11% of newly registered TB cases are multidrug-resistant and rifampicin-resistant (MDR/RR-TB). MDR/RR-TB is associated with significantly worse individual treatment outcomes, based on standard definitions that typically censor outcomes at the end of treatment. However, data on long-term treatment outcomes remain limited.
Design/Methods: A retrospective cohort study included all adult MDR-TB patients with genotypic rifampicin resistance in Latvia from 2005–2021. Data were collected from the national MDR/RR-TB database, patient records, the Centre for Disease Prevention and Control, outpatient providers, and regional TB offices. Treatment outcomes were classified using TBNET definitions.
Results: The study included 1,299 MDR/RR-TB patients (median age: 44 years; IQR 34–53), of whom 973 (74.9%) were male. Among them, 230 (17.7%) were classified as pre-extensive drug-resistant (pre-XDR). Median treatment duration was 17.4 months (IQR 10.5–19.9). At least 9 months of anti-TB treatment was received by 1,027 (79.1%) patients, ≥ 12 months by 923 (71.1%) patients, and ≥ 18 months by 585 (45%) patients.
Outcomes included: 686 (52.8%) cured, 99 (7.6%) treatment failure, 230 (17.7%) deaths, 79 (6.1%) lost to follow-up, and 205 (15.8%) undeclared outcomes. Follow-up data were available for ≥1 year in 848 (65.3%), ≥2 years in 749 (57.7%), and ≥5 years in 515 (39.6%). Of those, relapse-free rates were 98.6% (n=836) at 1 year, 98.3% (n=736) at 2 years, and 98.1% (n=515) at 5 years. Survival rates were available for 1246 patients: 81.6% (n=1,017) were alive after 1 year, 77.6% (n=968) after 2 years, and 67.7% (n=843) after 5 years.

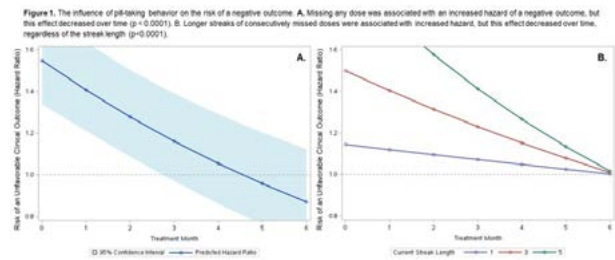


Conclusions: Many patients classified as "treatment failure" due to treatment durations <18 months remained TB-free post-therapy. Long-term follow-up should be incorporated into MDR/RR-TB outcome definitions to reflect patient prognosis better.

SOA07-579-19 Predicting drug-resistant TB outcomes: Examining pill-taking behaviours for bedaquiline

A. Wolf,[1] M. Zhao,[2] X. Lu,[3] K. Reis,[4] J. Zelnick,[5] R. Perumal,[6] M. Zulu,[7] KR. Amico,[8] K. Guzman,[1] B. Seepamore,[7,9] K. Naidoo,[7] M. O'Donnell,[1,6,10]
[1]Columbia University, Medicine, New York City, United States of America, [2]Lehigh University, Department of Industrial and Systems Engineering, Bethlehem, United States of America, [3]Columbia University, Medicine, New York, United States of America, [4]University of Washington, Medicine, Seattle, United States of America, [5]Touro University Graduate School of Social Work, School of Social Work, New York, United States of America, [6]Centre for the AIDS Programme of Research in South Africa, CAPRISA MRC-HIV-TB Pathogenesis and Treatment Research Unit, Durban, South Africa, [7]Centre for the AIDS Programme of Research, CAPRISA MRC-HIV-TB Pathogenesis and Treatment Research Unit, Durban, South Africa, [8]University of Michigan, Department of Health Behavior Health Equity, Ann Arbor, United States of America, [9]University of KwaZulu-Natal, School of Applied Sciences, Durban, South Africa, [10]Columbia University, Epidemiology, New York City, United States of America
e-mail: mo2130@cumc.columbia.edu

Background: Tuberculosis (TB) is a leading cause of mortality among people living with HIV, particularly in South Africa, driven by high rates of drug-resistant TB (DR-TB) and HIV co-infection. Research by our team has shown that cumulative six-month bedaquiline adherence, measured using an electronic dose monitoring (EDM) device, is a key predictor of clinical DR-TB outcomes in people living with HIV. However, the measure of cumulative adherence alone may identify individuals at risk for a negative clinical outcome too late for effective intervention.
This analysis aimed to determine whether specific patterns early in the course of DR-TB treatment can identify individuals at risk for negative outcomes sooner than cumulative adherence alone.
Design/Methods: Participants with DR-TB and HIV co-infection initiating a bedaquiline-containing regimen were recruited at a TB-referral hospital in Durban, KwaZulu-Natal, South Africa, 2016-2020 (the PRAXIS study, NCT03162107, NCT04032730) in Durban. We collected pill-to-pill bedaquiline adherence data over a six-month period using EDM device Wisepill RT2000. Time-varying Cox proportional hazards modeling was performed to examine the association between pill-taking behaviors and DR-TB treatment outcomes.
Results: Of 283 enrolled participants, 282 provided EDM bedaquiline adherence data. Timing of missed doses and number of consecutively missed doses ("streaks") were both independently and statistically significantly associated with an increased hazard of a negative outcome ($p<0.0001$, $p<0.0001$ respectively) (Figure 1, panels A and B).
Regardless of whether doses were missed consecutively or sporadically, the hazard for a negative outcome decreased by month of treatment (Figure 1, panels A and B).



Conclusions: Varying patterns of medication adherence were significantly associated with clinical DR-TB outcome. The indication that early missed doses were most strongly associated with negative treatment outcomes highlights the importance of treatment adherence support strategies, particularly at the beginning of treatment or when the patients begin in missing consecutive doses.

SOA07-580-19 The association between adherence and treatment outcomes among people with rifampicin-resistant TB who used the electronic pillbox in South Africa

T. Dube,[1,2] N. Maraba,[1] N. Ndlovu,[1] F. Mboniswa,[1] L. Masia,[1] N. Mokone,[1] F. Mkwanazi,[3] S. Abrahams,[4] H. Hausler,[5] S. Charalambous,[1,2] K. Fielding,[6,2] [1]The Aurum Institute, Implementation Research, Johannesburg, South Africa, [2]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [3]Isibani Development Partners, Global Fund TB/HIV Program, Johannesburg, South Africa, [4]City of Capetown Municipality Department of Health, TB Programme, Capetown, South Africa, [5]TB HIV Care, Executive, Capetown, South Africa, [6]London School of Hygiene & Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland
e-mail: tndube@auruminstitute.org

Background: Poor rifampicin resistant tuberculosis (RR-TB) treatment outcomes are a global concern. The World Health Organisation reported 68% treatment success rate globally among people who started RR-TB treatment in 2021. Digital Adherence Technologies (DATs) such as electronic pillboxes are being evaluated as approaches to improve outcomes. There is lack of data on understanding the relationship between digitally recorded adherence and TB treatment outcomes.
Our objective was to explore the association between adherence and poor treatment outcomes among people with RR-TB in South Africa.
Design/Methods: Data were obtained from a cohort of adults with RR-TB who participated in a pillbox observational study and started treatment between 04/2021-

03/2022 in two South African provinces. Adherence was measured by daily data on electronic pillbox openings as a proxy for doses taken, using pillbox data for the first two months of treatment. Treatment outcomes were ascertained from the TB registers. We used logistic regression to examine the association between adherence percentage categories (<90% and ≥90%) with poor treatment outcome (composite of death, treatment failure, loss to follow up) controlling for confounders.

Results: Preliminary analysis included 184 participants. Sixty-two percent were male, median age was 37 years, 54% were on short regimen, and 60% were living with HIV. Forty-eight percent (89/184) had <90% adherence and 28% (51/184) had a poor end of treatment outcome. In an adjusted analysis: controlling for gender, age, HIV status and short/long regimen, those with <90% adherence had a two-fold higher odds of the poor outcome compared to the group with the highest adherence (≥90%), (OR 2.05, 95% CI 1.03-4.08; p=0.041).

	Poor outcomes / N	Unadjusted OR(95% CI)	p-value	Adjusted OR* (95% CI)	p-value
Adherence					
0-89%	32/89 (62.7%)	2.24	0.0017 (1.15-4.35)	2.05 (1.03-4.08)	0.041
90-100%	19/95 (37.3%)				

**Adjusted for HIV status, gender, age and long/short regimen.*

Conclusions: Lower adherence levels, as measured by DATs, are associated with increased risk poor RR-TB treatment outcomes. Interventions targeting adherence are needed to improve TB treatment outcomes.

SOA07-581-19 Leveraging digital adherence technology and tele-counselling to improve monitoring of drug-resistant TB in Nigeria

K. Uche,[1] E. Okafor,[2] B. Osinubi,[1] B. Aiyenigba,[3] O. Ojelade,[3] I. Gordons,[4] O. Chijioke-AKaniro,[5] C. Adesigbin,[6] [1]Interra Networks Limited, Operations Department, Central Business District, Nigeria, [2]Interra Networks Limited, Corporate Services, Central Business District, Nigeria, [3]John Hopkins University, Center for Communication Programs, CBD, Nigeria, [4]KNCV Nigeria, KNCV Nigeria, CBD, Nigeria, [5]National TB Program, National Coordinator, National Office, Nigeria, [6]National TB Program, National Coordinator, National TB Office CBD, Nigeria
e-mail: kuche@interranetworks.com

Background and challenges to implementation: Nigeria ranks 6th globally and 1st in Africa among high-burden TB countries. While diagnostic and treatment services have expanded, challenges remain with drug-resistant TB (DR-TB), notably low adherence to prolonged, complex regimens. Psychosocial factors—including fear, isolation, and stigma—often lead to treatment fatigue, disengagement, and loss to follow-up.

In response, a pilot project assessed the impact of combining digital adherence technology (DAT) with tele-counseling to improve DR-TB treatment adherence. Interra Networks Limited, providers of the National TB Call Centre (3340), implemented the pilot with the National TB Program and USAID implementing partners.

Intervention or response: The pilot ran from June 2024 to March 2025 in Lagos, Osun, and Kano state, integrating two activities:

1. MedAdher, a digital adherence tool which tracks daily medication intake, and;
2. Structured tele-counseling sessions by trained health counselors to provide emotional support, education, and address patient-reported challenges.

DR-TB patients were enrolled at treatment initiation and received counseling scheduled to align with treatment stages (regimen: BPALM). Real-time adherence data triggered follow-up calls and, when necessary, escalations to health facilities.

Results/Impact: By September 2024, 268 DR-TB patients consented to counseling. Preliminary analysis showed a significant improvement in adherence. Of those, 262 completed treatments, achieving ≥98% adherence compared to 93% from baseline data. Compared to a previous study using digital adherence monitoring alone, this dual intervention recorded an 11.5% increase.

Amongst the benefits, patients reported a better understanding of side effects, and increased motivation, contributing to higher completion rates.

Conclusions: This pilot demonstrates the potential of combining digital tools and psychosocial support to close adherence gaps. Scaling such innovations nationally could reduce TB treatment failure and loss to follow-up. Further study is needed to control for external variables and confirm the intervention's specific impact.

E-POSTER SESSION (EP)

EP10 Enhanced TB detection: Integrating digital radiography with other tools

EP10-790-19 A decade of impact: How the South African TB Think Tank transforms evidence to policy and programming

M. Dube,[1] N. Ndjeka,[2,3] F. Abdullah,[4,5] J. Boffa,[6,1] P. Subrayen,[1]
[1]Aurum Institute; TB Think Tank Secretariat, Implementation Research Division, Johannesburg, South Africa, [2]National Department of Health South Africa, TB Control & Management, Pretoria, South Africa, [3]University of Cape Town, Medicine, Cape Town, South Africa, [4]South African Medical Research Council, Office of AIDS and TB Research, Pretoria, South Africa, [5]University of Pretoria, Department of Public Health Medicine, Pretoria, South Africa, [6]University of KwaZulu-Natal (UKZN), Centre for Rural Health, Durban, South Africa
e-mail: Mrdube.m.d@gmail.com

Background and challenges to implementation: South Africa remains among the highest TB-burden countries, with 270,000 TB cases reported in 2023, yet only a 72% treatment coverage and a TB mortality rate of 56/100,000. Despite the country's robust research landscape, translating evidence into policy remained a challenge. To address this, the National Department of Health required a sustainable solution to bridge the gap, leading to the establishment of the South African National TB Think Tank (TBTT) in 2014.
Intervention or response: TBTT is a multidisciplinary, evidence-driven advisory body designed to strengthen the National TB Programme (NTP). It fosters collaboration between government, researchers, civil society, funders, and technical partners through national oversight by the NTP Chief Director and the South African Medical Research Council Director in the Office of AIDS and TB Research. TBTT is supported by a dedicated secretariat and thematic technical task teams aligned with NTP priorities, which ensure sustainability through regular stakeholder engagements, policy dialogues and evidence dissemination. A rotating leadership model and multiple funding partners further enhance its viability.
Results/Impact: Over the past decade, TBTT has played a pivotal role in shaping national TB policy. Key contributions include the development of two national 5-year TB strategic plans, six clinical guidelines (including the 2024 update to the national child and adolescent TB guidelines), a post-COVID TB recovery plan, and guidance on the integration of new tools (e.g., urine LAM and digital chest X-ray).
TBTT has also expanded to over 300 members and established additional task teams to reflect emerging priorities, such as TB vaccine development.
Conclusions: The TBTT model demonstrates that structured collaboration can drive agile, evidence-based policy and programming in high-burden settings. Its success provides a scalable blueprint for other health programmes and countries, underscoring the importance of government buy-in, sustainable funding, and strong stakeholder engagement.

EP10-792-19 Comparative study of computer aided detection CXR AI threshold scores across TB diagnostic platforms in North Central Nigeria

D. Atuwo,[1] J. Bimba,[1] M. Iwakun,[1] P. Adogo,[1] J. Isaac,[1] E. Afe,[1] L. Shehu,[2] O. Chijoke-Akaniro,[2] N. Ebisike,[3] B. Onuoha,[4] T. Wingfield,[5] O. Akinwade,[5] [1]Bingham University, Nasarawa State, Zankli Research Centre, Auta Balefi, Nigeria, [2]National Tuberculosis Leprosy and Buruli Ulcer Conrol Programme (NTBCLP), Public Health, Abuja, Nigeria, [3]FCT Tuberculosis Leprosy and Buruli Ulcer Control Programme (FCT TBLCP), Public Health, Abuja, Nigeria, [4]Federal Capital Teritory Abuja, Health and Human Services, Disease Control, Asokoro, Nigeria, [5]Liverpool School of Tropical Medicine (LSTM), Clinical Sciences, Bembroke Place, United Kingdom of Great Britain and Northern Ireland
e-mail: atuwodavid@outlook.com

Background: Nigeria with the highest impact of TB in Africa reported its highest-ever people affected by TB in 2024 with over 400,000 cases, strategies like the gradual roll-out of four hundred (400) portable digital X-ray machines and integration of CXR (Chest X-ray) into the national TB screening algorithm helped achieve that.
This study compares CAD (Computer Aided Detection) CXR threshold scores with other TB diagnostic platforms.
Design/Methods: The Start Taking Action for TB Diagnostics (START4ALL) project conducted a cross-sectional survey in selected primary and secondary health facilities in Abuja and Nasarawa.
Blood, sputum, and urine samples, plus CXR scans, were collected from random consenting participants for various diagnostic tests for TB and HIV, including GeneXpert, culture, and Fujilam.
Results were analyzed using grouped AI threshold scores and chi-squared tests.
Results: A total of 1703 participants were recruited, with 1661 (97.5%) having a CXR scan done. Significant association was found between the grouped AI threshold scores and all diagnostic platforms used in the study (p-value <0.001). HIV status recorded a p-value of 0.007 against the grouped AI scores.
Interestingly, positive results in the lower score range (0.00 – 0.40) totalled 9.6% against GeneXpert, 31% against Fujilam, and 40.9% against Culture.

X-ray AI Scores		Overall	0.00 - 0.20	0.21 - 0.40	0.41 - 0.60	0.61 - 0.80	0.81 - 1.00	P- Value
Number of Participants		1661	1157 (69.7)	97 (5.8)	57 (3.4)	66 (4.0)	284 (17.1)	
HIV Status, n(%)	Negative	1414	1005 (71.1)	79 (5.6)	41 (2.9)	54 (3.8)	235 (16.6)	0.007*
	Positive	238	146 (61.4)	17 (7.1)	16 (6.7)	11 (4.6)	48 (20.2)	
MTB Status, n (%)	Mtb Not Detected	1463	1123 (76.7)	93 (6.4)	54 (3.7)	61 (4.2)	132 (9.0)	<0.001*
	Mtb Detected	156	12 (7.7)	3 (1.9)	2 (1.3)	3 (1.9)	136 (87.2)	
Fuji Lam, n (%)	Negative	1513	1114 (73.6)	92 (6.1)	53 (3.5)	63 (4.2)	191 (12.6)	<0.001*
	Positive	145	41 (28.2)	4 (2.8)	4 (2.8)	3 (2.1)	93 (64.1)	
Culture, n(%)	Negative	1358	997 (73.4)	76 (5.6)	48 (3.5)	63 (4.7)	174 (12.8)	<0.001*
	Positive	171	64 (37.4)	6 (3.5)	4 (2.3)	3 (1.8)	94 (55.0)	

N/B: Only 1568 culture results were available at the time of abstract submission.

Conclusions: High levels of association were observed amongst the threshold scores and diagnostic platforms with a substantial number of positive cases found across each score group. This study serves as further evidence in the push to recognize lower threshold scores when screening patients to avoid missing out on possible asymptomatic cases.

EP10-793-19 Chest X-ray AI scores guide pooled testing to increase access to rapid molecular testing for TB in communities in Cameroon

C. Mbuli,[1] N. Ndze Mbuh,[1] J. Konso,[1] Z. Adamou Mana,[1] A. Ngouno,[1] F. Souk,[1] G. Paul Koliyé,[1] M. Njang,[1] T. Fotso,[1] O. Bello,[2] M. Ganava,[2] M. Sander,[1]
[1]Center for Health Promotion and Research, Research, Bamenda, Cameroon, [2]National Tuberculosis Program, Regional Technical Group, ., Cameroon

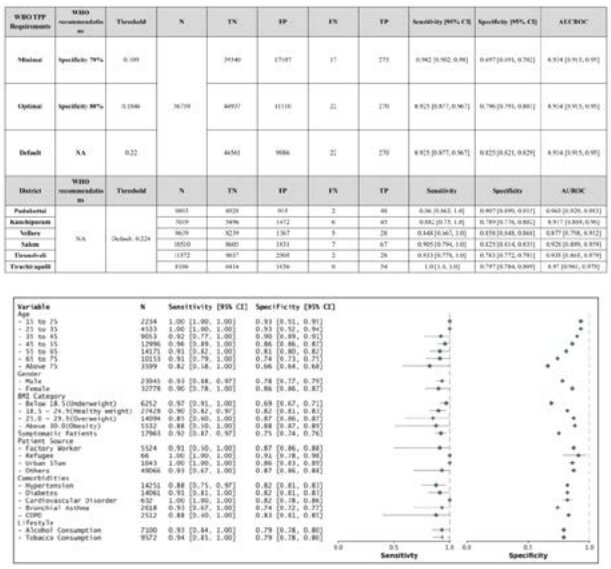
Background: Despite WHO's recommendation for universal rapid molecular testing, only 48% of people newly diagnosed with TB in 2023 were tested with a rapid test. A major obstacle is the high cost of the tests. A high AI score on chest X-ray screening correlates with higher likelihood of TB, and pooled testing of specimens improves testing efficiency. Using AI score results to inform whether to use pooled testing has the potential to greatly increase access to TB testing,
Design/Methods: People attending health camps in northern Cameroon were screened for TB using chest X-rays and symptoms. People with an AI score suggestive of TB and/or two or more symptoms of TB were referred for a TB test and coached on sputum collection. Depending primarily on the AI score, sputum specimens were tested either individually (typically for AI score >0.9) or in pools of 2-8 on the TrueNat MTB Plus assay (Molbio, India). We evaluated the efficiency and accuracy of this approach.
Results: From July 2024 to March 2025, following chest X-ray screening, 2,183 sputum specimens were tested for TB using Truenat MTB Plus following AI-informed individual or pooled testing. Among 683 specimens tested individually, 105 (15.4%) had TB detected. Among 1,510 specimens tested in pools, 24 (1.6%) had TB detected. Testing was performed using a total of 1,204 molecular tests, for a testing efficiency of 0.55 tests used per person with a test result, saving 45% of cartridges. Additional analyses are ongoing.
Conclusions: By using chest X-ray AI scores to inform pooled testing, almost twice as many people benefited from a rapid molecular test result as compared if everyone had been tested individually.

EP10-794-19 AI-assisted chest radiograph analysis for TB screening in mobile diagnostic units: Experience from a High TB-burden country, India

A. Kharat,[1] R. Pant,[2] A. Ojha,[2] S. Pardeshi,[2] A. Frederick,[3] R. Kubendiran,[3] T. Neelagandan,[3] K.K. Shankar,[3]
[1]DeepTek Medical Imaging Pvt. Ltd., Radiology, Pune, India, [2]DeepTek Medical Imaging Pvt. Ltd., Data Science, Pune, India, [3]Department of Health and Family Welfare, Department of Health and Family Welfare, Chennai, India
e-mail: stotn@rntcp.org

Background: Tuberculosis (TB) remains a global public health challenge, with detection often delayed by conventional screening methods. In Tamil Nadu, India, DeepTek's AI solution (GENKI) was integrated into the National TB Elimination Program (NTEP) via mobile X-ray vans to enhance detection rates through chest radiograph assessment.
This study aimed to assess GENKI's performance in community-based TB screening programs.
Design/Methods: GENKI analyzed chest X-rays to identify individuals who may have TB. Those flagged by the software or experiencing TB symptoms underwent sputum testing (smear microscopy/CBNAAT/TrueNat), which served as the reference standard. We evaluated GENKI's performance across different districts and demographic subgroups, including age, gender, co-morbidities, BMI category, lifestyle, and occupation.
Results: GENKI demonstrated an overall AUROC of 0.934, a sensitivity of 0.925, and a specificity of 0.828 at the deployed threshold. The model performs well across all age groups, with performance exceeding the WHO recommended optimal TPP in the 15-25 years (sensi-

tivity: 1.00, specificity: 0.93), 25-35 years (sensitivity: 1.00, specificity: 0.93), and 45-55 years (sensitivity: 0.96, specificity: 0.86) categories. For the 35-45 years (sensitivity: 0.92, specificity: 0.90), 55-65 years (sensitivity: 0.91, specificity: 0.81), and 65-75 years (sensitivity: 0.91, specificity: 0.74) age groups, the model meets the WHO-recommended minimal TPP threshold. The NPV values were exceptionally high (99.9%), ensuring reliable negative interpretations.



Conclusions: The AI model meets and, in some cohorts, exceeds the WHO's minimal TPP requirements, demonstrating its potential for effective integration into screening workflows for TB detection. The high AUROC across different demographic variables indicated the model's robust discriminative ability, reinforcing the potential of AI-assisted tools in large-scale TB screening programs.

EP10-795-19 Impact of mobile TB clinics with digital X-ray, CAD4TB, and Xpert MTB/RIF/Ultra on same-day TB diagnosis and treatment initiation: Insights from Uganda

A. Mulindwa,[1] A. Burua,[1] D. Tugumisirize,[1] N. Modi,[1] L. Mukisamuzaale,[1] B. Ayebazibwe,[1] E. Quinto,[1] V. Veronese,[2] S. Turyahabwe,[3] H. Luzze,[1] [1]Ministry of Health, National Tuberculosis & Leprosy Program (NTLP), Kampala, Uganda, [2]World Health Organization, The Special Programme for Research & Training In Tropical Diseases (TDR), Geneva, Switzerland, [3]Ministry of Health, Communicable Disease Prevention & Control, Kampala, Uganda
e-mail: mulindwaalex@gmail.com

Background: Tuberculosis (TB) is a persistent public health challenge in Uganda, with a high TB incidence rate of 198 per 100,000 population, an annual estimated notification of 96,000, and significant case detection and treatment gaps. Limited access to diagnostic services in underserved communities exacerbates TB transmission and mortality.

As part of Uganda's National TB and Leprosy Strategic Plan (2020/21–2024/25) and the global End TB initiative, mobile TB clinics equipped with digital X-ray, CAD4TB, and Xpert MTB/RIF/Ultra technologies were deployed. This study evaluated the clinics' impact on same-day TB diagnosis and treatment initiation.

Design/Methods: A mixed-methods cross-sectional study was conducted from February to June 2024 across 70 high-risk communities identified based on notification data and healthcare access limitations. Individuals aged 15 years and above were targeted, excluding pregnant women and those unable to undergo chest X-rays. Using purposive and consecutive sampling, 288 TB patients were targeted for same-day diagnosis and treatment initiation, requiring 5,760 clients to be screened given a 5% prevalence rate (5,000/100,000). Data collection utilized Open Data Kit (ODK) based structured questionnaires, and X-ray quality was validated. CAD4TB's diagnostic accuracy was compared to Xpert MTB/RIF/Ultra as the reference standard. Feasibility and cost-effectiveness were also evaluated.

Results: The intervention achieved 100% screening uptake, with 5,760 clients screened, predominately aged 24 – 44 years, with females constituting 55.4%. 1,690 presumptive TB cases were identified, with 1,172 sputum samples collected and tested, diagnosing 109 TB patients (73% bacteriologically confirmed and 29% clinically diagnosed). CAD scores ≥ 50 demonstrated a diagnostic yield of 19.7%. Same-day treatment initiation reached 98%.

Parameter	Diagnostic Performance Metrics					Socio-demographic	
	Screened (CXR)	Tested (Xpert)	MTB Detected	Yield (%)	Same-Day Tx Initiation (%)	Highest Age Group Screened	
CAD Score ≥ 50	397	380	75	19.7	97	35–44 years	Male (44.6%), Female (55.4%)
CAD Score < 50	5,363	792	5	0.6	100	35–44 years	Male (44.6%), Female (55.4%)
Total	5,760	1,172	80	6.8	98	35–44 years	Male (44.6%), Female (55.4%)

Table: Diagnostic Performance Metrics of Mobile TB Clinics Equipped with CAD4TB and Xpert MTB/RIF/Ultra in Uganda.

Conclusions: Mobile TB clinics with advanced diagnostic technologies effectively bridged critical care gaps in Uganda. These clinics align with national and global TB strategies, providing a scalable and replicable model for resource-limited settings. Sustained investment and partnerships are vital for expanding equitable TB care.

EP10-796-19 Pairing artificial intelligence (AI) with WHO-recommended rapid molecular diagnostics (mWRDs) in community settings: Targeted screening and early diagnosis for improved tuberculosis (TB) notification

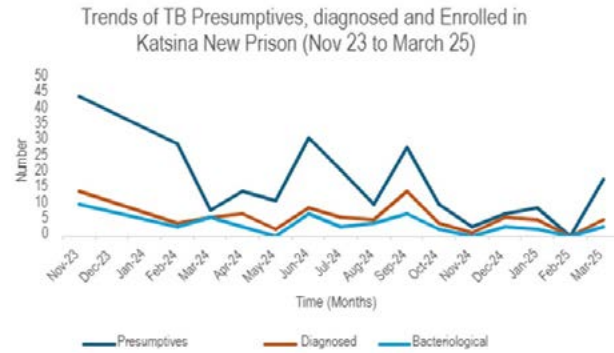
S. Balogun,[1] V.-I. Ovoh,[1] T. Theodore,[1] N. Nwokoye,[1] B. Odume,[1] [1]KNCV Nigeria, Technical Programs, Abuja, Nigeria
e-mail: sbalogun@kncvnigeria.org

Background and challenges to implementation: Ranking 6th amongst the Global High TB burden countries and 1st in Africa, Nigeria has taken measures towards the eradication of TB. However, due to the poor seeking health behaviour, it became imperative to decentralise TB screening and testing from facility-based to community-based screening and testing. KNCV Nigeria in collaboration with other partners introduced The Portable Digital Xray (PDX) with Computer Aided Detection (CAD), an AI equipment, a World Health Organisation (WHO) recommended tools for improved screening in both symptomatic and asymptomatic persons for increased TB case finding.
This was coupled with WHO rapid diagnostics (mWRDs) for sample analysis for onsite TB Diagnosis as a One-Stop-Shop approach. The study aims to evaluate the impact of this intervention on TB case finding.
Intervention or response: Implementation kicked-off with the coupling of 4 PDX (with CAD) and 4 mWRDs on Wellness on Keke (WOK), a KNCV mobile Innovative platform for Community ACF.
Screening was conducted using the WHO-4-symptoms-screening (W4SS) alongside PDX (with CAD). Samples were collected from clients whose radiographs had a screening score ≥50 and could produce sputum.
On-the-spot sample analysis was conducted using the coupled mWRDs in the communities and all positive TB Patients were immediately initiated on treatment.
Results/Impact: From Jan 2023 - December 2024, a total of 137,049 clients were screened for TB with 11,803 presumptive (9% presumptive TB yield) identified. 11,769 (99.7%) presumptive TB clients were evaluated, and 2359 TB cases were diagnosed (20% TB yield). 1754(74%) were bacteriologically diagnosed while 605(26%) were clinically diagnosed. All clients diagnosed were placed on treatment.
Conclusions: Coupling PDX (with CAD) and m-WRDs for C-ACF ensured no case was missed as clients were either diagnosed bacteriologically or clinically on the spot and initiated on treatment. Scale-up of PDX coupled with m-WRDs is key for targeted screening, diagnosis and treatment enrollment, ultimately increasing TB notification in Nigeria.

EP10-797-19 Monthly portable digital X-ray screening to combat tuberculosis burden in New Katsina Prison: A scalable model for prisons

S. Bello,[1,2] T. Mustapha,[3] M. Bajehson,[4] I. Lawrence,[1] S. Usman,[1] Y. Suleiman,[1] M. Sheshi,[5] O. Chukwuogo,[5] B. Odume,[5] [1]KNCV Nigeria, Katsina Office, Katsina, Nigeria, [2]Federal Teaching Hospital Katsina, Family Medicine, Katsina, Nigeria, [3]KNCV Nigeria, Kano Office, Kano, Nigeria, [4]KNCV Nigeria, Kano Cluster Office, Kano, Nigeria, [5]KNCV Nigeria, Abuja Office, Abuja, Nigeria
e-mail: sbello@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) control in correctional facilities remains a significant public health challenge due to overcrowding, poor ventilation, and delayed diagnosis. The Katsina New Prison in Nigeria, housing a dynamic population of inmates and staff, had persistent TB transmission concerns. A novel monthly screening approach using portable digital X-ray (PDX) machines was implemented to curb ongoing and new infections.
We present a result showcasing screening efforts to combat the TB burden in the Katsina correctional facility.
Intervention or response: Beginning in 2023, a dedicated TB screening team visited Katsina New Prison monthly. Each visit followed the intake of new inmates. A PDX machine with an artificial intelligence software was deployed to screen both the inmates and staff using a parallel algorithm, with presumptives identified via symptom screening and or abnormal CXR findings undergoing GeneXpert testing for confirmation. Active case finding and immediate linkage to TB treatment were ensured.



Results/Impact: From November 2023 to March 2025, 2,307 individuals were screened across 17 monthly visits. A total of 259 presumptive TB cases were identified via PDX, of which 90 were confirmed TB-positive through GeneXpert. This represents a TB detection rate of 35%. Notably, the presumptive and case detection continue to decline month by month, with some spikes noted in March when activity was skipped in February due to a stop work order. There was no significant outbreak or cluster of new infections recorded during the period, sug-

gesting an interruption of active transmission. Clients' compliance with screening remained above 90%, and repeat screenings helped identify late converters and monitor treatment response.
Conclusions: Monthly PDX-driven TB screening in Katsina New Prison significantly enhanced early detection and likely halted intra-facility transmission. This approach proved feasible, acceptable, and effective, presenting a scalable model for TB control in correctional settings globally.

EP10-798-19 Evaluating diagnostic yield of a numeric CAD score to triage mWRD negative patients for repeat mWRD testing in a rural Indian ACF programme

B. Datta,[1] A. Story,[2] P. Goyal,[1] A. Hayward,[2] E. Rogers,[2]
[1]Medanta The Medicity, Respiratory, New Delhi, India,
[2]University College London, Epidemiology, London, United Kingdom of Great Britain and Northern Ireland
e-mail: bornalidatta@gmail.com

Background: Tuberculosis Active case finding (ACF) is a key programmatic component in India's TB eliminations strategy. Targeted mobile digital radiology to triage candidates for confirmatory testing using mWRD assay is a well-established ACF strategy. CAD (computer aided detection) software has been demonstrated to outperform human readers and reduce mWRD cartridge use by 50% with cost savings. CAD is now recommended by WHO as an alternative to human readers. Nested in a ACF cluster RCT in district Karnal (India), we undertook a novel evaluation using numeric CAD cut-offs to triage mWRD negative TB suspects for a second assay.
Design/Methods: Symptomatic individuals identified through door-to-door screening were referred to local health subcenters for digital X-ray on a mobile van. X-rays scored at >0.6 using QURE.AI CAD underwent mWRD testing. A second assay was performed on WRD negative suspect cases able to provide sputum within 4 weeks.

CXR-AI scoring	First mWRD assay Positive	First mWRD assay negative	Second mWRD assay positive	Second mWRD assay negative
0.6-0.69	4	123		58
0.7-0.79	7	128		66
0.8-0.89	17	196		99
0.9-1.00	181	600	13	283
Total	209	1047	13	506

Table 1: Diagnostic yield of 1st and 2nd WRD assay by QureAI CAD cut-offs

Results: Of 6,408 suspected cases were X-rayed,1,369 had a CAD score of >0.6. 1,256 underwent mWRD testing of who 209 (17%) were positive. Of the 1,047 mWRD negative suspected cases, 519 could be located within 4 weeks and provide a voluntary specimen for repeat mWRD assay, of who 13 (2.5%) were positive and 506 negative. All 13 mWRD positive cases had a CAD score of >0.9.
Conclusions: Our novel findings demonstrate that increasing CAD cut-offs is potentially an effective approach to triage suspected cases who are negative on a first mWRD assay. Limiting repeat mWRD assay to only suspected cases with a CAD score of >0.9 could potentially reduce the use of cartridges by 43% without any significant loss in diagnostic yield. Optimising the efficiency and cost effectiveness of ACF strategies is a key research priority to accelerate TB elimination.

EP11 From mines to clinics, securing lung health in high-risk occupations

EP11-799-19 From awareness to action: Workplace initiative for TB screening and care

H. Auma,[1] M. Nakiryowa,[1] E. Atuheire,[1] M. Mwesige,[2] H. Luzze,[2] [1]Internal Security Organisation (ISO), Gender and Welfare, Kampala, Uganda, [2]Ministry of Health, National Tuberculosis and Leprosy Programme (NTLP), Kampala, Uganda
e-mail: aumahellen534@gmail.com

Background and challenges to implementation: Uganda faces a significant tuberculosis burden, with high incidence rates reported by the World Health Organisation. In 2024, the country reported 88,869 TB patients, an increase from 87,876 in 2023. To control the spread of the disease and mitigate its impact, the Office of the Prime Minister launched the Multi-Sectoral Accountability Framework for TB in 2020, directing Ministries, Departments, and Agencies to integrate TB prevention and control interventions into their Programme Implementation Action Plans to disrupt TB transmission and enhance early detection of the disease.
Intervention or response: In response to OPM's call to integrate tuberculosis interventions into PIAPs, in November 2023, Internal Security Organisation (ISO) launched a comprehensive initiative focused on tuberculosis awareness, screening, and testing, aimed at combating and disrupting the transmission chain of tuberculosis among its workforce.
The initiative aimed to improve employees' understanding of TB, reduce stigma, correct misconceptions about transmission, and enhance access to tuberculosis care services. 12 capacity-building sessions were conducted across 12 regions. 362 ISO employees in Kampala Metropolitan area participated in a week-long health camp organised at the ISO headquarters. The camp was facilitated by the Ministry of Health, which provided a TB mobile clinic van to deliver TB care services and linked identified patients to healthcare services.
Results/Impact: Increased awareness of tuberculosis prevention and control measures among 367 employees. 4 TB patients were identified and referred for care from 267 presumptive out of 367 employees screened. A positivity rate of 1.49%, which is considerably higher than the national average of 0.198%. All patients received timely medical interventions and social support as outlined by the ISO TB-HIV workplace policy.
Conclusions: ISO's workplace tuberculosis awareness initiative has enhanced employee health outcomes by tackling stigma and misinformation barriers, promoting early detection and treatment, and serves as a model for other organisations to replicate.

EP11-800-19 Epidemiology and statistical analysis of occupational health risks: Implications for workplace safety and worker well-being

I. Sarkodie,[1] [1]University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia
e-mail: isaac27newton@yahoo.com

Background: Occupational health refers to the prevention, diagnosis, and management of health conditions that arise from or are aggravated by workplace environments. With the global workforce increasingly exposed to diverse physical, chemical, and psychological risks, understanding the epidemiology of workplace health is crucial for effective interventions.
Given the significance of occupational health in preventing long-term health conditions and ensuring the well-being of employees, a systematic review of workplace risks is necessary to inform policy, improve safety.
Design/Methods: This study employed a systematic review and meta-analysis of epidemiological data to evaluate workplace health risks across various industries. Studies published between 2000 and 2024 were included, focusing on both physical and psychosocial hazards.
A statistical approach was used to calculate the prevalence of occupational diseases, identify risk factors, and examine the correlation between exposure and health outcomes using relative risks, odds ratios, and confidence interval.
Results: The results highlighted that approximately 35% of workers in high-risk industries experienced work-related health conditions, with musculoskeletal disorders accounting for the largest percentage (42%).
Additionally, mental health issues, particularly stress, were found to be disproportionately high in service-oriented sectors. The meta-analysis indicated a strong correlation between exposure to hazardous environments and increased incidence of chronic diseases. Statistical modeling suggested that improving ergonomic practices and reducing exposure to environmental toxins could reduce the prevalence of these diseases by up to 20%.
Conclusions: This study underscores the need for comprehensive occupational health policies that focus on both physical and mental health risks. The findings emphasize the importance of regular workplace health assessments and the implementation of preventive measures.
Addressing ergonomic issues, enhancing air quality, and promoting mental well-being programs are essential steps to mitigate the health impacts of work-related exposures. Ultimately, a proactive approach to occupational health can not only improve worker health but also reduce the economic costs of workplace illnesses.

EP11-801-19 TB among healthcare workers in Zambia: A trend analysis 2018-2022

J. M CHAMA,[1] P. Lungu,[2] A. Mubanga,[3] [1]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Zambia Country Office, Lusaka, Zambia, TB unit, Lusaka, Zambia, [2]East, Central, and Southern Africa Health Community (ECSA-HC), TB unit, Arusha, United Republic of Tanzania, [3]Zambia National TB Program, TB unit, Lusaka, Zambia
e-mail: mpunduj@gmail.com

Background: Tuberculosis (TB) remains a significant occupational hazard for healthcare workers globally. In Zambia, the burden of TB among healthcare workers (HCWs) has not been well characterized. This study aimed to analyze trends in TB among health workers and associated risk factors.
Design/Methods: We analyzed TB surveillance data from 597 healthcare workers diagnosed with TB between 2018-2022. Using negative binomial regression, we first conducted bivariate analyses for each potential predictor variable. Variables with $p<0.2$ in bivariate analyses (year, sex, TB type, patient category, and province) were included in the final multivariate model, while HIV status was excluded as it did not meet the threshold significance level. We assessed trends in TB cases and identified associated risk factors.
Results: The were a total of 597 cases of TB notified between 2018 and 2022 among HCWs. Most affected were in the 30-49 age group. The were more females 316(53%) than males 281(47%).
The annual number of TB cases among healthcare workers increased by 23.95% per year (95% CI: 15.22% to 33.35%) after adjusting for patient category and province. Most cases were pulmonary TB (71.2% clinically diagnosed; 21.3% bacteriologically confirmed), and 40% of HCWs were HIV-positive.
New TB cases predominated (88.5%) compared to relapse cases (11.3%), with relapse cases showing significantly lower incidence (IRR=0.49, $p<0.001$).
Healthcare workers in Lusaka (IRR=2.22, $p<0.001$) and Copperbelt (IRR=1.55, $p=0.027$) provinces had significantly higher TB rates compared to Central province. (59.2%).
Conclusions: The yearly increase in TB among healthcare workers in Zambia indicates a growing occupational health crisis requiring urgent intervention. With the increasing TB incidence among HCWs, healthcare facilities should prioritize implementation of TB infection prevention and control strategies, regular screening of healthcare workers, and prompt initiation of preventive therapy.
These findings underscore the critical need for enhanced occupational protection policies to safeguard the health workforce.

EP11-803-19 Impactful collaborations: Multi-sector engagement and accountability for TB free workplace in a mining predominant district of Karnataka, India

H. G,[1] S. Mattoo,[2] I Vokda,[3] S Ghatage,[1] S.S. Aithal,[1] S. Anjum,[1] J.J. Thomas,[1] S. Achanta,[1] N. Neeta,[4] U. Singh,[2] [1]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [2]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [3]District Tuberculosis Centre, National TB Elimination Programme, Ballari, India, [4]VIMS, Department of Community Medicine, Ballari, India
e-mail: gangaiahh@rntcp.org

Background and challenges to implementation: NTEP India is exploring and engaging for collaboration and partnership with potential non-health sectors for elimination of TB. The India TB Report 2024 underscores that 85% of notified TB occurs within the age group of 20 to 60 years. As per Periodic Labour Force Survey 2023, Karnataka's working population ratio is 34 million (46%), with 15% organized and 85% unorganized workers. They are supported by 42-line departments within the state. In response, this study aimed to improve TB service accessibility and affordability through targeted screening at mining workplaces, bolstered by enhanced resources and multi-department collaboration.
Intervention or response: Interventional study, focusing on engaging two key departments—the Department of Factories, Industrial Safety and Health, and the Department of Mines and Geology to address TB among those associated with iron mining in Bellary district, Karnataka. This involved high-level advocacy meetings, development of SoPs, sensitizing workplace establishments, screening at workplaces, and resource mobilization to augment laboratory testing through upfront NAAT (Nucleic Acid Amplification Test).
Results/Impact: Of the 207 workplace establishments, 66 (32%) were sensitized. Among them, six major industries initiated regular TB screening for their workers. All Occupational Health Centres were registered in Ni-kshay (national case-based, web-based surveillance system). This facilitated in enrolling 788 TB presumptive and, 27 PwTB received ongoing follow-up within these establishments. Notably, funding amounting to INR 30 million was secured from the District Mineral Fund to install three GeneXpert machines and fourteen Truenat machine, increasing capacity for upfront NAAT from 18000 to 52500 tests per million population.
Conclusions: This model demonstrates collaboration among departments, resource mobilization, leading to successful TB screening and care cascade at workplace addressing the gaps in routine systems may be one of the game-changers in TB elimination.

EP11-804-19 Artisanal and small-scale miners' perceptions on targeted TB and occupational health screening programme in Zimbabwe

A.M. Malhotra,[1,2] E. Marambire,[2,3] G. Madziva,[4] F. Moyo,[4] F. Kavenga,[5] C. Timire,[6,5] C. Calderwood,[7,2] B. Chigaraza,[4] R.T. Ncube,[8] A. Nyambo,[9] K. Ndlovu,[5] D. Moyo,[4,10,11] [1]Liverpool School of Tropical Medicine, Clinical Sciences, Liverpool, Zimbabwe, [2]Biomedical Research and Training Institute, Harare, Zimbabwe, The Health Research Unit Zimbabwe, Harare, Zimbabwe, [3]LMU University, Institute of Infectious Diseases and Tropical Medicine, Munich, Zimbabwe, [4]Baines Occupational Health Services, Baines Occupational Health and Safety Group, Harare, Zimbabwe, [5]Ministry of Health and Child Care, TB, Harare, Zimbabwe, [6]Biomedical Research and Training Institute, The Health Research Unit Zimbabwe, Harare, Zimbabwe, [7]London School od Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, Zimbabwe, [8]Union Zimbabwe Trust, TB, Harare, Zimbabwe, [9]Ministry of Health and Child Care, National TB Programme, Harare, Zimbabwe, [10]The National University of Science and Technology, Department of Community Medicine, Harare, Zimbabwe, [11]The University of the Witwatersrand, School of Public Health, Division of Occupational Health, Witwatersrandsouth, South Africa
e-mail: akanksha.mimi@gmail.com

Background: Artisanal and small-scale miners (ASM) face a high burden of disease—including TB, HIV, silicosis, sexually transmitted infections, substance misuse, and exposure to mercury and cyanide toxicity. Despite growing awareness, healthcare interventions tailored for this group remain limited.
Design/Methods: We explored the perceptions of ASM and their representatives regarding a five-year screening intervention in Zimbabwe (KNTB). Using focus group discussions, we gathered insights from 31 participants, including ASM, ASM leaders/representatives, healthcare staff, academics, and national stakeholders.
Results: Participants unanimously agreed that screening activity was highly beneficial. However, fears surrounding the screening process and the potential for positive TB or HIV results were evident. To address these concerns, participants stressed the importance of sensitisation initiatives led by ASM leadership and peer-officers. Stigma was identified as a factor that reduced HIV testing uptake relative to TB testing.
Additionally, traditional beliefs and religious practices significantly influenced health-seeking behaviour, with many ASM believing that diseases including silicosis were easily treatable with simple measures e.g "staying out of dust for a week" or "drinking milk". For TB diagnosis, challenges centred on diagnostic results not being available on the same day.
For those requiring treatment for HIV, maintaining continuity of care was a significant challenge due to the mobile nature of their occupation and access to transportation. Treatment adherence was further complicated by ASM "feeling well" after initial treatment doses, unaware of the consequences of not completing courses. Further themes are summarised in Figure 1.

Figure 1.Diagram summarising themes and sub-themes from focused group discussions with 31 participants.

Conclusions: There is a critical need for targeted health screening and comprehensive care for this vulnerable group. Whilst the KNTB model showed considerable promise, expanding such interventions to reach ASMs in other regions and addressing additional health priorities will require enhanced collaboration between the mining sector, the Ministry of Health, and other stakeholders.

EP11-805-19 Effectiveness of TB treatment in individuals exposed to silica or with silicosis: A systematic review

M. Achayo,[1] N. Siegfried,[2] D. Rees,[3,4] R. Ehrlich,[5]
[1]Mwitikio wa Kudhibiti Kifua Kikuu na UKIMWI Tanzania (MKUTA), Programs, Dar es Salaam, United Republic of Tanzania, [2]University of Cape Town, Epidemiology, Cape Town, South Africa, [3]University of the Witwatersrand, Occupational Health, Johannesburg, South Africa, [4]National Institute for Occupational Health, Occupational Medicine and Epidemiology, Johannesburg, South Africa, [5]University of Cape Town, Division of Occupational Medicine, Cape Town, South Africa
e-mail: rodney.ehrlich@uct.ac.za

Background: Tuberculosis is a global problem affecting large numbers of silica-exposed workers. Both silica exposure and silicosis increase the risk of active tuberculosis. Some studies have suggested that silica exposure and silicosis are associated with unsuccessful TB treatment outcomes and increased relapse. Current evidence is based on a mix of clinical trials and observational studies with inconsistent results.
This systematic review aimed to examine the potential modifying effect of silica exposure alone or of silicosis on TB treatment outcomes.
Design/Methods: We conducted a systematic review of randomized and nonrandomized controlled trials, cohort and case-control designs published 1970-2023. Eligible studies investigated outcomes among silica-exposed individuals or (separately) those with silicosis receiving

TB treatment. We searched PubMed, Web of Science and Scopus on 10-03-2024. We conducted risk of bias (ROB) assessments appropriate to study design: 1) ROB In Non-Randomized Studies – of Intervention (ROBINS-I), 2) ROB In Non-Randomized Studies – of Exposures (ROBINS-E) and 3) ROB tool for randomized trials (RoB 2).
Results: Six studies met the inclusion criteria, all involving individuals with silicosis. The pooled odds ratio (OR) for treatment failure/delayed conversion for individuals with silicotuberculosis versus those with TB alone was 2.86 (95% CI: 1.73-4.74; N=3), the corresponding estimate for mortality OR: 2.45 (95% CI: 0.58-10.39; N=2), and for TB relapse OR: 1.19 (95% CI: 0.01-135.53; N=2). High risk of bias or "some concerns" were noted in five of the six studies, due to possible confounding, loss to follow up, missing data, and/or concerns about exposure or outcome measurement.
Conclusions: The evidence base on treatment outcomes in silicosis is sparse and suffers from high risk of bias. However, the direction is towards significantly poorer outcomes than for TB alone. Randomised or high-quality follow-up studies are long overdue to strengthen the evidence base for this neglected question.

EP11-806-19 Reaching behind bars: Mobile TB van initiative for central region district prison TB eradication in Malawi

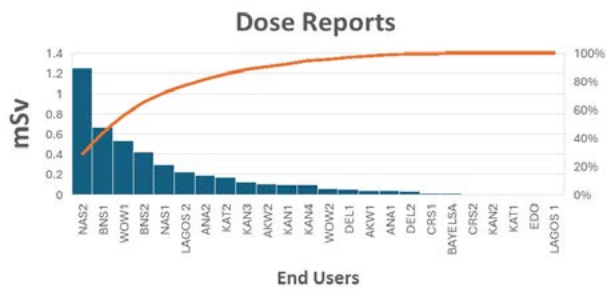
P. Chimalizeni,[1] K. Mbendera,[1] T. Mwenyemkulu,[1] M. Mmanga,[1] [1]National TB and Leprosy Elimination Program (NTLEP) Malawi, Preventive, Lilongwe, Malawi

Background and challenges to implementation: Tuberculosis prevalence is very high in prisons due to several factors like congestion and poor nutrition. This poses significant a public health risks. Central region district prisons face unique challenges in TB diagnosis, treatment and prevention due to resource constraits and overcrowing. The studying districts are nkhotakota prison and Kasungu prison district prisons.
The objective is to evaluate the impact of a Mobile TB Van on TB screening and detection among inmates in central region prison districts.
Intervention or response: A mobile TB Van equipped with digital Chest –Ray GeneXpert and other diagnostic tools , visit the prisons every six months for mass TB screening . All the prisoners undergo Chest X Ray despite no sign. Those with symptoms or those having high CAD score submit sputum for geneXpert.
Those diagnosed with TB are initiated TB treatment, care, follow up and education.
Results/Impact: During the year 2024 we screened 994 prisoners 69 presumptives (6.9%) and 7 TB cases (10%) of the presumptives. We had screened 23 prison staff with no presumptives.
Conclusions: The Mobile TB van significantly improved TB screening and detection among inmates in central region prison districts of Kasungu and Nkhotakota. This innovative approach can be replicated in other prison settings to reduce the burden of TB and improve health outcomes among this vulnerable population.

EP11-808-19 Radiation protection and safety of end users of the portable digital X-ray (PDX) machines for TB screening in Nigeria: Experience of KNCV Nigeria

E. Chukwu,[1] A. Izokpu,[1] C. Dimkpa,[1] M. Sheshi,[1] B. Odume,[1] E. Ubochioma,[2] O. Sesere,[2] K. Ebarekor Ekpen,[3] M. Fila,[1] M. Tukur,[4] O. Chukwuogo,[1] S. Useni,[1] [1]KNCV Tuberculosis Foundation Nigeria, Programs, Abuja, Nigeria, [2]National TB Buruli Ulcer and Leprosy Control Program NTBLCP, Programs, Abuja, Nigeria, [3]KNCV Tuberculosis Foundation Nigeria, Monitoring and Evaluation, Abuja, Nigeria, [4]KNCV Tuberculosis Foundation Nigeria, Programs, Kano, Nigeria
e-mail: echukwu@kncvnigeria.org

Background and challenges to implementation: Radiation safety is a concern for all, radiation from diagnostic imaging modalities such as Xray machines are minor contributors to the cumulative dose exposures of healthcare personnel. However, frequent ionizing radiation exposure during TB screening with PDX may be a potential risk of serious illnesses and death if safety measures are neglected.
Intervention or response: KNCV Nigeria supported the deployment of PDX platforms for TB screening, and engaged radiographers dispensing ionizing radiation on average, screen above 50 persons daily. Although radiation emission of PDX is low compared to conventional Xray machines, KNCV Nigeria provided regular retraining of all the end users, mandates wearing of TLD badges under the lead apron and ensured that all radiographers wear appropriate PPE and use the exposure strings provided by the manufacturers **(Delft, MinXray and Fuji)**. Reading from the TLD is obtained every quarter and recorded as a monitoring measure for all end users.



Results/Impact: For employee of 18 years or above, the dose limit for the whole body is 100mSv over five consecutive years and no one year must exceed 50mSv. We

obtained and analysed the dosimeter report for 4 consecutive quarters, the highest accumulated dose was 1.25mSv against annual limit of 20mSv. This result was achieved through multiple approach ranging from equipment design, training and compliance with radiation safety enforced on all end users by KNCV.

Conclusions: The combination of multiple approach ranging from retraining of end users on safety, fidelity to manufacturers instructions and use of exposure strings along with enforcing the use of protective devices has ensured the safety of all the end users of the PDX machines, hence the dose measurement over one calendar year has remained negligeable. The use of PDX for TB screening should be encouraged as it contributes close to zero risk to the end users.

EP12 Leveraging AI across the TB care cascade: From hotspot detection to treatment success

EP12-809-19 Leveraging eCBSS data for geospatial mapping of TB hotspots and optimising the integrated TB case finding (CAST+) intervention in Eastern Uganda

C. Brianwong,[1] D. Cherotin,[2] J. Bakyawa,[2] D. Kiragga,[3]
[1]Baylor Foundation Uganda, Medical and Psychosocial, Mbale, Uganda, [2]Baylor Foundation Uganda, Strategy Development, Monitoring and Evaluation, Mbale, Uganda, [3]Baylor Foundation Uganda, Executive Director's Office, Kampala, Uganda
e-mail: clarkjoshua001@gmail.com

Background and challenges to implementation: The Ugandan Ministry of Health developed the CAST+ strategy to find missing TB patients through 5-day biannual door to door community screening for TB, leprosy, HIV, malaria, malnutrition, antenatal care and immunization status. The first nationwide campaign was conducted September 2022, covering all villages.

However, this intervention has proven costly with variable results. In 2020, Uganda adopted the electronic case-based surveillance system (eCBSS) for TB surveillance and program reporting that provides patient level data and place of residence.

We describe how eCBSS data was used to develop geospatial maps to define TB hotspots for targeted CAST+ Campaigns.

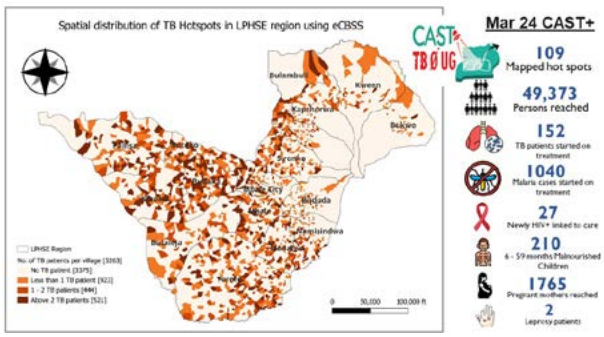
Intervention or response: Prior to the CAST+ campaign in March 2024, USAID LPHS-E scaled up eCBSS to 93% (166 out of 178) of the Diagnostic and Treatment Units (DTUs) in the Bukedi and Bugisu regions and supported entry to 103% (6992 out of 6860) of the patient backlog.

This data was then used to map TB hotspots using Geographic Information System technology, which were prioritized and actively screened during the CAST+ campaign in March 2024.

A hotspot was defined as any village with more than two TB patients in the past year (March 2023 to February 2024).

Results/Impact:

- There was a 41% drop in unit cost of identifying a TB patient from $66 in September 2022 to $37 in March 2024.
- The March 2024 campaign cost $5,783, a significant reduction from the $50,678 spent in the September 2022 campaign.
- During the March 2024 CAST+ campaign, 155 TB patient from the 109 mapped hotspots were diagnosed and started on treatment, compared to 764 TB patients identified in all villages in Sept 2022 with similar yield of 2.0% and 1.9% respectively.



Conclusions: Utilizing eCBSS data for geospatial mapping enables TB programs to accurately identify hotspots, pinpoint high-burden areas, and effectively guide resource allocation for targeted community TB interventions.

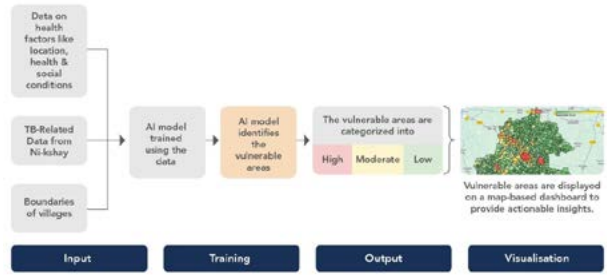
EP12-810-19 AI-powered vulnerability mapping for TB as a guiding tool for active case-finding activities

U. Singh,[1] R. Rao,[1] A. Chaudhary,[2] V. Yadav,[3] S. Kalia,[3] P. Soni,[4] B.R. Preetham,[5] M. Chavan,[6] S. Sekhar,[5] P. Balraj,[3] M. Kulkarni,[5] N. Agrawal,[6] [1]Ministry of Health and Family Welfare, Government of India, Central TB Division, New Delhi, India, [2]Wadhwani Institute for Artificial Intelligence, Central TB Division - AI Unit, Ministry of Health and Family Welfare, Govt. of India, New Delhi, India, [3]Wadhwani Institute for Artificial Intelligence, Solutions, New Delhi, India, [4]Wadhwani Institute for Artificial Intelligence, Engineering, New Delhi, India, [5]Wadhwani Institute for Artificial Intelligence, Machine Learning, New Delhi, India, [6]Wadhwani Institute for Artificial Intelligence, Deployment, New Delhi, India
e-mail: aparna@wadhwaniai.org

Background and challenges to implementation: India's National Tuberculosis Elimination Programme (NTEP) deploys Active Case Finding (ACF) to systematically screen at-risk vulnerable populations, aiming for early Tuberculosis (TB) identification and reduced transmission.

Traditionally, mapping areas with these populations relies heavily on the local knowledge of healthcare staff. Consequently, despite NTEP's intensified efforts to screen all the at-risk vulnerable individuals, unreported Persons with TB (PwTB) might be missed if they reside in areas not covered during ACF activities, thus continuing disease transmission. To support NTEP's ongoing intensified efforts, an innovative AI tool has been developed to identify areas likely harboring undiagnosed individuals, aiming to enhance ACF outcomes.

Intervention or response: Wadhwani AI has developed a novel AI-based vulnerability mapping tool. It integrates over 20 open-source datasets encompassing geographical, socio-demographic, and economic factors with anonymized PwTB location coordinates from Ni-kshay portal (a web-based, case-based real-time surveillance system under NTEP). To ensure accuracy, a data pipeline was developed to standardise and perform necessary transformations to make these datasets usable at varied resolutions. The AI model generates vulnerability predictions at a highly granular 500x500 meter tile level. These are then aggregated to the village/ward level, providing actionable insights compatible with NTEP's operational structure.



Results/Impact: The developed AI tool utilises more than 11.6 million geospatial tiles to provide village/ward-level vulnerability for all districts nationwide. To validate the tool's effectiveness, a retrospective analysis compared village rankings generated by the AI tool to the PwTB reported in the villages. It yielded 71% accuracy in identifying the top 20% of vulnerable villages (in descending order of PwTB notified) within the selected dataset.

Conclusions: The AI tool's initial model and technical infrastructure provide a promising foundation for supporting NTEP's ACF activities in the early detection of PwTB. Furthermore, the underlying methodology holds potential for adaptation for other infectious diseases.

EP12-811-19 Effectiveness of systematic screening of TB amongst key vulnerable populations using AI-enabled X-ray machines in Lagos State, Nigeria

V. Aganaba,[1] O. Daniel,[2] A. Opeyemi,[3] O. Olupitan,[3] A. Agbaje,[3] C. Mensah,[4] E. Oboku,[5] B. Odume,[6] O. Sokoya,[7] O. Chijioke- Akaniro,[8] J. Ssekitooleko,[9] J. Kimeu,[9] [1]Institute of Human Virology Nigeria, Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria, Lagos, Nigeria, [2]Institute of Human Virology Nigeria, Program Coordinating Unit (PCU), Lagos, Nigeria, [3]Institute of Human Virology Nigeria, Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria,, Abuja, Nigeria, [4]Institute of Human Virology Nigeria, Office of the COO, Abuja, Nigeria, [5]KNCV, Programs, Lagos, Nigeria, [6]KNCV, Programs, Abuja, Nigeria, [7]Lagos State Ministry of Health, Lagos State TB & Leprosy Control Program, Abuja, Nigeria, [8]National TB and Leprosy Control Programme, Public health, Abuja, Nigeria, [9]The Global Fund to Fight AIDS, Tuberculosis and Malaria ,, Global Health Campus, Geneva, Nigerian Country Team, Geneva, Switzerland
e-mail: oadebayo@ihvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) is a significant public health challenge in Nigeria, particularly among vulnerable populations. Traditional screening methods are often limited by resource constraints, leading to delayed diagnosis and increased transmission.

The integration of Artificial Intelligence (AI) into TB active case finding through mobile X-ray systems offers a promising solution to enhance early detection and treatment outcomes.

This study aims to evaluate the effectiveness of systematic screening using AI-enabled mobile X-ray machines on TB detection rates among key vulnerable populations in Lagos State, Nigeria.

Intervention or response: A comparative cross-sectional study was conducted amongst Key vulnerable population (prisoners) in Lagos State. The outcome of screening activities done using CAD4TB AI-enabled mobile X-ray machines were compared with screening done using the WHO-recommended four-symptom screen (W4SS), from June to December 2023.

The CAD4TB software is designed to detect TB-related anomalies in chest X-rays, providing real-time diagnostic support to healthcare providers.

Data on TB presumptives, detection rates, treatment initiation rate, and patient demographics were collected and analyzed.

Results/Impact: Of the 1,750 people screened, 625 were screened using A.I enabled mobile X-ray device, with 32 TB presumptives and 24 TB cases. The other 1,123 people were screened verbally using W4SS of which 230 were identified as TB presumptive and 13 cases bacteriologically diagnosed.

Mode of Screening	# Screened	# Presumptive	#Presumptive Evaluated	#TB Diagnosed	NNS	NNT
AI – enabled screening	625	32	32	24	26	1
W4SS Screening	1,123	230	230	13	86	18
Total	1,750	262	262	37	47	7

Conclusions: Systematic screening using AI-enabled X-ray machines significantly improved early TB detection and treatment initiation rates amongst key vulnerable populations. AI-enabled Chest X-ray machines in active TB case findingis an effective approach to reducing TB burden. Efforts should focus on deploying digitalized A.I-enabled X-ray machines to high burden settings, especially amongst key vulnerable populations.

EP12-812-19 Leveraging AI to enhance TB detection among asymptomatic individuals: A comparative analysis from community screening in Ladakh, India

T. Thinles,[1] U. Singh,[2] D. Spalzes,[3] S. Chandra,[4] P.K. Yadav,[4] L. Aravindakshan,[4] K. Venkatesan,[4] P. Kapoor,[4] S. Joshi,[4] U. Mohan,[4] K. Vijay,[4] Y. Malhotra,[4] [1]Administration of Union Territory of Ladakh, Department of Health and Medical Education, Ladakh, India, [2]Government of India, Ministry of Health and Family Welfare, New Delhi, India, [3]Administration of Union Territory of Ladakh, National Health Mission, Ladakh, Ladakh, India, [4]Government of India - WHO Country Officer for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India
e-mail: yadavp@rntcp.org

Background and challenges to implementation: Tuberculosis (TB) screening under national programs often relies on symptom-based screening, potentially missing cases in asymptomatic individuals. Artificial Intelligence (AI) tools offer a novel opportunity to augment TB detection by identifying individuals with atypical chest x-ray (CXR) presentations.

This study evaluates the effectiveness of an AI solution in detecting TB among asymptomatic individuals during a community-based screening.

Intervention or response: An AI-assisted CXR screening tool was deployed from July 2024 to March 2025 in Leh, Ladakh. A comprehensive schedule for area-specific screening activities was developed and disseminated to peripheral healthcare facilities. Community health workers conducted prior community sensitization and awareness campaigns.

All individuals aged 14 years and above were systematically screened, regardless of symptomatic presentation. Sputum samples were collected from individuals with symptoms as well as those identified with abnormalities on CXR flagged by AI-tool.

Results/Impact: Out of 10,209 individuals screened, 458 were detected with symptoms, while 47 asymptomatic individuals (0.5%) were flagged by AI-tool for abnormal CXR findings. Sputum samples were collected from 451 (98%) symptomatic individuals and 44 (94%) AI-identified individuals for nucleic acid amplification test (NAAT) confirmation. Among symptomatic individuals, 20 out of 451 (4.4%) were found positive for TB. Among AI-identified asymptomatic, 2 out of 44 (4.5%) tested positive for TB *(Table 1)*. Statistical analysis using Fisher's Exact Test showed no significant difference in TB positivity rates between two groups ($p \approx 1.00$). This indicates that the AI-tool identified TB-positive cases at a rate comparable to conventional symptom-based screening.

Table 1. Community- Level TB screening activity profile - Leh, Ladakh, India

Indicators	N	(%)
Total population	135232	
Total screened	10209	7.5%
TB symptomatic	458	
Sputum testing among symptomatic	451	
TB positive among symptomatic	**20**	**4.4%**
TB asymptomatic (flagged by AI as symptomatic)	47	0.5%
Sputum testing done among asymptomatic flagged by AI	44	
TB positive among asymptomatic	**2**	**4.3%**

Conclusions: The AI-assisted tool demonstrated a promising ability to detect TB among asymptomatic individuals at a rate equivalent to symptomatic screening. Reinforcing its potential as a valuable adjunct to routine TB screening, particularly for early detection in asymptomatic cases. Integrating AI tools into community TB screening activity may improve case detection and support TB elimination efforts by expanding reach of effective screening.

EP12-813-19 Using artificial intelligence software to improve TB screening efficiency: Comparison between intensified case finding in public facilities and the wow interventions in Kano State, Nigeria

J. Jacob,[1] M. Tukur,[2] [1]National Open University of Nigeria, ACF, Bauch, Nigeria, [2]ABU Zaria, Programs, Kano, Nigeria

Background and challenges to implementation: AI-based CAD tools like CAD4TB improve TB screening efficiency in high-burden areas like Kano, Nigeria. This study assesses CAD4TB's role in reducing GeneXpert wastage by accurately identifying presumptive TB cases in ICF and WoW interventions.
Intervention or response: KNCV Nigeria's TB LON 1&2 project operates in 14 states, with two key interventions in Kano to find missing TB cases:
1. Facility-based screening (ICF) using trained ad-hoc staff, and;
2. Mobile community-based testing (WoW). Results from January–December 2021 were analyzed to compare their effectiveness.
Results/Impact: In 2021, the WoW intervention screened 40,681 people, diagnosing 727 TB cases, while ICF in public screened 1,122,066, diagnosing 5,847. WoW's AI-driven triaging showed a 4.7x higher yield, indicating greater efficiency by reducing unnecessary tests compared to ICF in public. This highlights WoW's precision in TB detection.
Conclusions: CAD4TB AI improves TB screening cost-efficiency by reducing false positives and cartridge waste. WoW's higher detection highlights AI's value in resource-limited settings like Nigeria, advocating for AI scale-up to optimize yield and cut costs.

EP12-814-19 Impactful use of handheld X-ray device for reaching the unreached population of tribal district Nandurbar in Maharashtra, India

M. Chavan,[1] M. Kadam,[2] R. Sonawane,[3] S. Sangale,[4] R. Vishwajeet,[2] A. Kadu,[2] K. Nagpurkar,[5] K. Khaparde,[2] S. Chandra,[2] [1]Government of Maharashtra National TB Elimination Programme, Zilla Parishad, Nandurbar, India, [2]Government of India-WHO Country Office, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [3]Government of Maharashtra, Zilla Parishad, Nandurbar, India, [4]Government of Maharashtra National TB Elimination Programme, Public Health Department, Pune, India, [5]Government of Maharashtra, State Technical Support Unit, National TB Elimination Programme, Pune, India
e-mail: kadua@rntcp.org

Background and challenges to implementation: To accelerate the effort in achieving the End TB targets for India new technological advancements are playing a pivotal role. The usage of new tool of Handheld X ray (HHX) devices in TB screening has expedited the progress in TB Elimination strategies for Nandurbar district of Maharashtra. It is a tribal district with limited access to health services which makes it extremely challenging for people to reach health facility.
Intervention or response: This cross-sectional study involved conducting 113 TB screening camps over a four-month period (December-2024 to March-2025) across the district in different villages. Two HHX machines were deployed to facilitate doorstep screening, particularly targeting vulnerable populations. Digital X-rays were remotely interpreted by radiologists through a secure digital transfer system. Individuals with abnormal chest X-rays were further evaluated using NAAT (Nucleic Acid Amplification Testing) to confirm TB diagnosis.
Results/Impact: As part of the intervention, 8592 chest X-rays were offered using handheld X-ray (HHX) devices across 113 screening camps. The initiative contributed to a notable increase in TB case notification rates—from 75/lac/year during Dec 2023–Mar 2024 to 114/lac/year during Dec 2024–Mar 2025—representing a 52% rise in

public sector TB notifications. The increase in TB notification is **statistically significant** ($p< 0.05$). This indicates that the observed rise is attributed to the effectiveness of the intervention. This included an additional yield of 224 TB cases compared to the same period in the previous year.

The screening also facilitated early detection of two malignancies and several other respiratory conditions, underscoring the broader diagnostic value of the intervention.

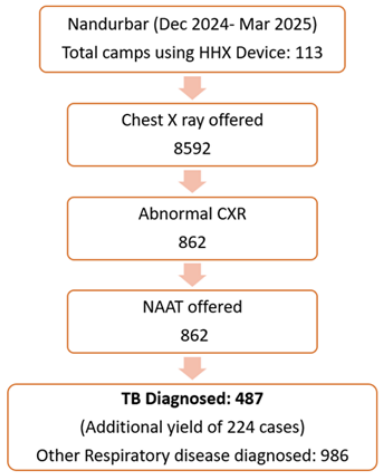


Figure 1. Nandurbar district TB screening camp Dec 2024 - Mar 2025.

Conclusions: The use of HHX machines among vulnerable populations significantly enhanced early TB case detection, resulting in a substantial additional yield and contributing to a statistically significant increase in notification rates. The portability of the device proved critical in reaching remote and underserved areas, improving healthcare access.

EP12-815-19 Bridging diagnostic gaps in rural Nigeria: The role of AI-supported PDX-CAD in TB detection

E.E. Ajumuka,[1] W. Yekumah,[1] V. Edjobayire,[1]
[1]KNCV, Technical, Abuja, Nigeria
e-mail: docajumuka@yahoo.com

Background and challenges to implementation: Tuberculosis remains a serious health issue in Nigeria, especially in rural areas with limited healthcare access. To tackle this, the TB LON project and STOP-TB Partnership introduced the AI-powered PDX-CAD machine for faster, more accurate diagnosis.

Despite challenges like tough terrain, power issues, and training needs, the team's dedication is paying off. This innovative tool is now bringing life-saving TB testing to hard-to-reach communities and helping close long-standing gaps in care.

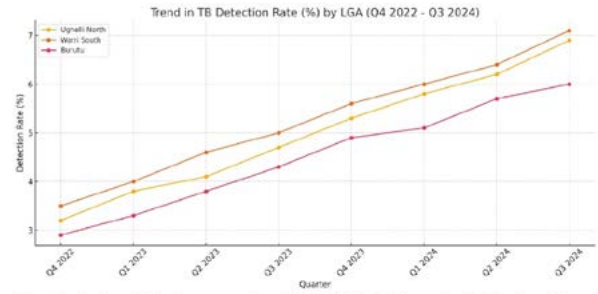
Intervention or response: A mixed-methods approach was adopted to assess the implementation, challenges, and impact of the AI-supported PDX-CAD system in improving tuberculosis detection in underserved rural areas of Nigeria. It focused on selected rural communities across three high-burden rural LGAs (Ughelli North, Warri South and Burutu) in Delta state, Nigeria where the PDX-CAD was deployed. These sites were chosen based on TB burden and accessibility.

Quantitative data were collected retrospectively from project registers between September 2022 and September 2024. Key indicators included the number screened, presumptive identified, and TB cases confirmed using PDX-CAD.

Qualitatively, Key Informant Interviews (KIIs) and Focus Group Discussions (FGDs) were also conducted with community members, including TB patients and caregivers, to provide insight into community level acceptance, awareness, and access to TB screening services.

Results/Impact: Analysis of 26 KIIs and 9 FGDs identified key themes. Barriers included unreliable electricity, internet issues, staff resistance to AI tools, and logistical difficulties. While strong community health worker involvement, hands-on support, and integration with TB programs helped things run smoothly. Users reported faster, more accurate TB diagnosis. Community members appreciated convenience and speed. Recommendations for scale-up include expanding training for frontline workers, and conducting community sensitization to promote early care-seeking and treatment initiation.

Trend analysis was conducted to evaluate changes in TB detection rates. Between September 2022 and September 2024, 18,476 individuals were screened and 1,215 (14.8% of screened) Presumptive identified. Analysis showed increase in the number of confirmed TB cases over the two-year period, particularly in the first 12 months. Detection rates improved from 4.2% in Q4 2022 to 7.6% in Q3 2024, indicating increased case finding and possibly improved awareness and access to screening.



Warri South shows the highest upward trend, Ughelli North follows closely behind and Burutu, while improving, lags slightly, reflecting infrastructure and accessibility challenges.

Conclusions: AI-supported PDX-CAD has significantly enhanced TB detection in rural Nigeria. Scaling up this innovation, alongside infrastructure improvements and community engagement can transform early diagnosis and save more lives.

EP12-816-19 Evaluating diagnostic accuracy and cost-effectiveness of AI-based CAD (QURE) for TB screening in Guinea

A.S. Magassouba,[1,2] A.A. Touré,[3] Y. Sylla,[4] B.D. Diallo,[4] S. Camara,[2] V. Veronese,[5] J. Campbell,[6] A.M. Bangoura,[7] K. Koura,[8] C.S.C. Merle,[5] [1]The Union, Tuberculosis, Conakry, Guinea, [2]National Tuberculosis Control Program, Research and Training, ConakryGuine, Guinea, [3]Gamal Abdel Nasser of Conakry, Public Health, Conakry, Guinea, [4]Gamal Abdel Nasser University of Conakry, Public Health, Conakry, Guinea, [5]WHO TDR, Research, Geneva, Switzerland, [6]McGill University Health Centre, Division of Clinical and Translational Research, Montreal (Quebec), Canada, [7]National Tuberculosis Control Program, Management, ConakryGuine, Guinea, [8]The Union, Tuberculosis, France, France
e-mail: aboubakar.magassouba.consultant@theunion.org

Background and challenges to implementation: In Guinea, tuberculosis (TB) screening with chest X-rays (CXR) is often inaccessible due to few trained radiologists. Thus, direct microbiologic testing is common for people with TB symptoms. AI-driven computer-aided detection (CAD) tools may overcome access barriers to CXR in Guinea and help triage individuals for microbiologic testing. We assessed the diagnostic accuracy of CAD and cost-effectiveness of implementing CAD-based triage of symptomatic individuals compared to universal GeneXpert testing in Guinea.

Intervention or response: Individuals with TB symptoms who presented to 16 sites in Conakry, Guinea between 1 May and 31 October 2024 received CXR and GeneXpert testing. We compared the diagnostic performance of CAD (QureAI) to GeneXpert using sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) overall and by subgroups (age, sex, and HIV status). Receiver operating characteristic (ROC) analysis was used to calibrate CAD scores, and Youden's Index to identify an optimal threshold. The cost-effectiveness of CAD-based triage (GeneXpert if CAD-positive) compared to universal GeneXpert testing was estimated.

Results/Impact: Among 1,095 participants screened, 167 (15.3%) had TB according to GeneXpert. CAD achieved an AUC of 0.96 (95% CI: 0.94–0.98) at an optimized threshold of 0.405, with an overall sensitivity of 88%, specificity of 92%, PPV of 67%, and NPV of 98%. Sensitivity was highest among females and those under 30 years, and reached 100% for people with HIV; specificity was ~92% across all subgroups. In this cohort, CAD-based triage would save $11,100 but miss 20 people with TB compared to universal GeneXpert. Thus, the incremental cost per additional TB diagnosis with universal GeneXpert was $555.

Conclusions: CAD has good diagnostic accuracy and has potential as a triage test in Guinea. CAD-based triage would save money compared to universal GeneXpert, but at the expense of missing TB diagnoses; its cost-effectiveness will be influenced by TB prevalence.

EP12-817-19 Using AI to improve reported treatment adherence under the National TB Elimination Programme (NTEP) in India

U. Singh,[1] R. Rao,[1] A. Chaudhary,[2] V. Yadav,[3] H. Kohli,[3] S.D. Chaudhari,[3] G. Tom,[4] A. Reddy,[4] P. Balraj,[3] H. Kataria,[5] N. Agrawal,[6] [1]Ministry of Health and Family Welfare, Government of India, Central TB Division, New Delhi, India, [2]Wadhwani Institute for Artificial Intelligence, Central TB Division - AI Unit, Ministry of Health and Family Welfare, Govt. of India, New Delhi, India, [3]Wadhwani Institute for Artificial Intelligence, Solutions, New Delhi, India, [4]Wadhwani Institute for Artificial Intelligence, Machine Learning, New Delhi, India, [5]Wadhwani Institute for Artificial Intelligence, Engineering, New Delhi, India, [6]Wadhwani Institute for Artificial Intelligence, Deployment, New Delhi, India
e-mail: aparna@wadhwaniai.org

Background and challenges to implementation: Under the National Tuberculosis Elimination Programme (NTEP), all persons with tuberculosis (PwTB) are issued a 'Treatment card,' a paper-based recording form available at health facilities (public/private). These cards document services like administered drugs (fixed-dose combinations), diagnostics, co-morbidities, treatment adherence, and treatment outcomes.

While field-level treatment supporters and healthcare workers manually update treatment adherence on these cards using coded symbols as per standard formats, digitizing this adherence data in real-time into the Ni-kshay portal (a web-based, case-based real-time surveillance system under NTEP) faces challenges.

Furthermore, existing patient-centric digital adherence tools suffer from variable uptake and engagement issues, especially during later treatment phases, leading to underreporting of adherence information on Ni-kshay.

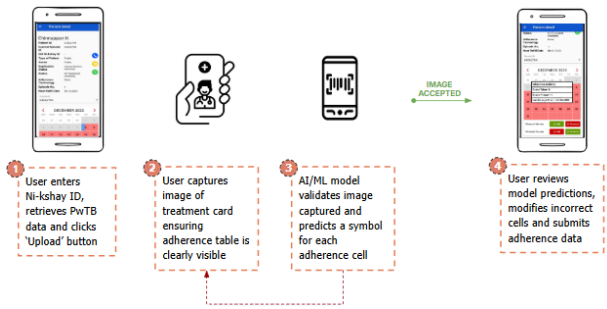
Intervention or response: To address this, Wadhwani AI developed an AI-powered tool for healthcare workers. This tool interprets the symbols marked on the Treatment cards to streamline adherence reporting. Healthcare workers can periodically upload smartphone images of the cards.

The AI tool then validates the image, identifies the symbols to interpret, and calculates cumulative adherence since the treatment initiation, as per the Ni-kshay portal. Human-in-loop is incorporated if the tool fails to analyse symbols due to errors.

Results/Impact: The AI tool successfully detected the adherence table on the card and extracted the data from the cells.

Evaluated on 140 cards, the model achieved an overall accuracy of 97% in correctly identifying the cells and classifying symbols. The symbol classifier in the AI tool had an accuracy of 97%, while the table detector has a mean Average Precision (mAP) of 0.99.

Sensitivity was high for supervised doses (96%), missed doses (95%), and blank cells (98%), and moderate for unsupervised doses (76%).



Conclusions: The AI tool can facilitate accurate and rapid digitization of treatment card adherence data. Its implementation is expected to substantially improve the completeness and timeliness of treatment adherence reporting within the national Ni-kshay portal.

EP12-818-19 Outcomes of TB screening of immigrants using AI-enabled digital X-rays at the Lagos-Abidjan corridor

A. Oboku,[1] T. Osatuyi,[1] E. Chukwu,[1] B. Odume,[2]
[1]KNCV Nigeria, Programs, Lagos, Nigeria, [2]KNCV Nigeria, Programs, Lagos State, Nigeria
e-mail: ednaoboku@gmail.com

Background and challenges to implementation: The Lagos-Abidjan corridor is a high-mobility route in West Africa with an increased risk of tuberculosis (TB) transmission among migrants due to poor access to screening and treatment services. The challenge of early TB detection in this mobile population prompted the deployment of the mobile X-ray van equipped with digital AI-enabled X-ray systems to improve screening efficiency.
Intervention or response: A TB screening campaign targeting immigrants was conducted at the Lagos-Seme border during the flag-off of the cross-border TB active case finding activity. A parallel screening algorithm combining the WHO four-symptom screen (W4SS) and artificial intelligence (AI)-enabled digital chest X-rays was adopted. Individuals with symptoms or CAD4TB scores ≥40 were classified as presumptive and submitted sputum for bacteriological testing using GeneXpert. Radiologists reviewed chest X-ray images via the XMAP platform, and case confirmation was conducted by medical officers.
Results/Impact: A total of 278 immigrants were screened. Of these, 36 individuals were identified as TB presumptives (29 through W4SS and 7 through CAD4TB score ≥40). Four TB cases were diagnosed, yielding an 11% case detection rate—one bacteriologically confirmed and three clinically diagnosed.
The intervention provided integrated care by offering both TB and HIV screening, reducing missed opportunities for diagnosis. The deployment of AI tools improved presumptive identification, especially among asymptomatic individuals.

Conclusions: The use of AI-enabled digital X-rays during the flag-off TB screening campaign at the Lagos-Abidjan corridor is relevant for reaching mobile, high-risk populations. Integrating digital tools with W4SS enhances TB case finding, reduces the incidence of missing TB cases and promotes cross-border collaboration. This model is scalable for broader regional implementation across similar mobile communities.

EP13 Electrifying TB: Using digital tools across the care cascade

EP13-819-19 Implementation of the TB electronic monitoring system in Uganda

M. Nakawooya,[1] G. Amanya,[1] A. Mulindwa,[1] E. Quinto,[1] R. Byaruhanga,[1] E. Tweyongeire,[1] L. Henry,[1]
[1]Ministry of Health, Uganda, National TB and Leprosy Program, Kampala, Uganda
e-mail: mabelprecious451@gmail.com

Background and challenges to implementation: For years, Uganda's National TB and Leprosy Program (NTLP) relied on paper-based data collection and DHIS2 aggregate reporting, prone to errors and limited access to real-time patient-level information. Recognizing the need for a robust TB surveillance system, the Ministry of Health (MOH), in collaboration with partners, developed eCBSS to improve data accuracy, facilitate patient monitoring, and enhance program performance. The system enables real-time data capture at health facilities, ensuring that all TB and leprosy cases are tracked throughout the continuum of care.
Intervention or response: The NTLP, supported by stakeholders, piloted eCBSS in 99 health facilities between January and June 2021. Based on its success, a nationwide rollout followed, expanding to 1,511 facilities by December 2024, covering 72% of TB Diagnostic Units. Key interventions included capacity building through extensive training sessions equipped health workers with skills in system use, Regional Support Structures through district leadership, mentorship, peer-to-peer learning, and virtual webinars strengthened system adoption. DHIS2 was still in use to gauge the amount of data being captured electronically.

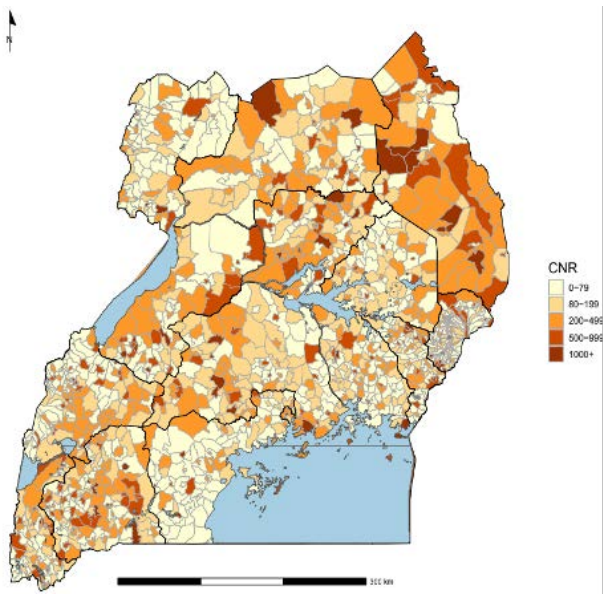


Figure. eCBSS Hot spots at subcounty level FY2023/2024.

Results/Impact: 80% of persons with TB reported in DHIS2 are now captured in eCBSS, enhancing data accuracy. The eCBSS has facilitated the mapping of TB hotspots guiding targeted interventions; the system improved data timeliness, completeness, and precision, leading to better patient outcomes.
Conclusions: Implementing eCBSS has strengthened TB surveillance in Uganda by providing patient-level data. Continued expansion, integration, and stakeholder engagement will ensure sustainability and improve TB prevention and care efforts. The system serves as a model for digital health transformation in disease surveillance.

EP13-820-19 Enhancing TB prevention and care in Maharashtra: Insights from Expand ELEVATE project through automated data analysis

S. Sangale,[1] N. Gaikwad,[1] Q. Toufique,[2] A. Date,[3] P. Nadol,[3] C. Ho,[3] D. Kambhampati,[4] S.K. Sarangi,[4] D. Balasubramanian,[4] I. Thior,[5] L. Mueller,[5] H. Sandhu,[2]
[1]Government of Maharashtra, Public Health Department, Pune, India, [2]Centers for Disease Control and Prevention(CDC), Division of Global HIV and TB(DGHT), Delhi, India, [3]Centers for Disease Control and Prevention (CDC), Division of Global HIV and TB(DGHT), Atlanta, United States of America, [4]PATH, Infectious Disease, Delhi, India, [5]PATH, Primary Health Care, Seattle, United States of America
e-mail: dbala@path.org

Background and challenges to implementation: The TB *Mukt Panchayat* (TBMP) initiative under National Tuberculosis Elimination Programme (NTEP) empowers *Panchayat*, India's rural self-governance system at village council level, to combat TB through improved ownership. *Panchayats* are screened annually using six NTEP criteria to be declared TB-free for a year.
The Expand ELEVATE (Engaging Local Experts for Validating and Analyzing TB data to End-TB in India, E2), a data management project to support TB elimination activities, supported TB elimination efforts in Maharashtra by automating TB-free status eligibility analysis.
Intervention or response: In Maharashtra, with 27,888 *Panchayats* across 34 districts, manual data compilation and analysis for progress review routinely required days and wasn't accurate.
In September 2024, E2 developed an automated digital dashboard to streamline monthly collation and analysis, generating state-level dashboards with district-level dropdown lists (Figure-1).
From September 2024 to February 2025, E2 provided monthly technical assistance to review progress and take programmatic actions. Additionally, E2 trained two state NTEP staff to replicate and utilize the tool for future needs.

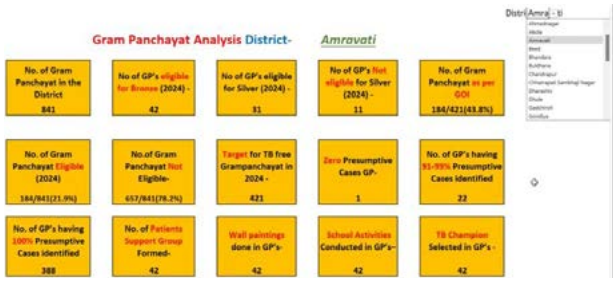

Figure 1. Snapshot of TB Free Panchayat dashboard for Maharashtra state, India.

Results/Impact: The automated digital tool improved efficiency by reducing data collation and analysis time from three to one day, eliminated errors, and enabled quick decision making. Timely planning and execution led to a cascade of prompt actions in districts. In Maharashtra, 7,402 (27%) *Panchayats* were declared TB-free in 2025, compared to 2,251 (8%) in 2024.

Additionally, staff acquired skills in designing similar tools and using them in other aspects of the program for prompt decision-making, leading to more effective health interventions.

Conclusions: The TBMP initiative, supported by the E2 project, demonstrated the effectiveness of data automation and capacity-building in improving TB data management using data at a local level result in making real gains in ending TB on the ground. By emphasizing timely data for decision-making and empowering local staff with smart data tools, the project further strengthened TB elimination efforts.

EP13-821-19 Improving DHIS2 TB data quality across regions in Uganda

M. Nakawooya,[1] G. Amanya,[1] A. Mulindwa,[1] R. Byaruhanga,[1] E. Quinto,[1] E. Tweyongeire,[1] L. Henry,[1] [1]Ministry of Health, Uganda, National TB and Leprosy Program, Kampala, Uganda
e-mail: mabelprecious451@gmail.com

Background and challenges to implementation: The National TB and Leprosy Program (NTLP) relies on an electronic-based health management information system (eHMIS) based on District Health Information Software 2 (DHIS2) for TB reporting and programmatic decision-making. However, data quality issues such as incomplete reports, inconsistencies between paper-based and electronic records, and duplicate entries have hindered accurate reporting. To address these challenges, the NTLP and stakeholders initiated a multi-pronged approach to enhance data integrity across MOH regions.

Intervention or response: A structured data quality improvement strategy was adopted in 2023 focusing on Pre-Data Collection Meetings involving training and sensitization sessions before routine data collection cycles to ensure correct data capture and reporting, Desk Reviews through routine analysis of DHIS2 data to identify anomalies, missing reports, and inconsistencies and shared out on a weekly, monthly and quarterly basis. Data Validation Meetings where regional-level engagements involving district biostatisticians and TB focal persons to reconcile discrepancies. Data Cleaning through systematic removal of duplicate cases and correction of misclassified data entries. Remote Support which involve virtual mentorship, troubleshooting, and refresher training for health workers to enhance DHIS2 proficiency.

Results/Impact: These interventions led to significant improvements in TB data quality. Completeness of reports increased from 88% in 2020 to 98% in 2024, and discrepancies between DHIS2 and facility-level data reduced by 33%. The engagement of biostatisticians and focal persons fostered greater ownership and accountability in TB data reporting.

Conclusions: A combination of desk reviews, validation meetings, data cleaning, remote support, and structured pre-data collection meetings has proven effective in improving TB data quality in DHIS2. These interventions should be sustained and scaled up to ensure continuous data integrity and facilitate evidence-based TB programming.

EP13-822-19 Digitising TB care: Advancing person-centred approaches through T-bu Lite in Nakuru County, Kenya

G. Onyango,[1] A. Gathee,[2] B. Ulo,[1] M. Githiomi,[3] N. Barasa,[4] A. Ndombi,[2] [1]Amref Health Africa, Global Fund TB Project, Nairobi, Kenya, [2]Amref Health Africa, AICS GF 5% TB Project, Nakuru, Kenya, [3]National TP and Leprocy Program, ICT, Nairobi, Kenya, [4]Nakuru County, Department of Health, Nakuru, Kenya
e-mail: gregorybrn8@gmail.com

Background and challenges to implementation: Kenya bears a high TB burden. To strengthen TB data capture and verification, the National Leprosy and TB Program (NLTP), in collaboration with Amref and supported by the Global Fund, developed TIBU—an application used by Sub County TB and Leprosy Coordinators (SCTLCs) nationwide. However, with over 4,000 TB treatment sites, monthly mentorship and data verification remain unfeasible.

Moreover, TIBU is not a point-of-care system, resulting in continued reliance on paper tools and increased workload for healthcare workers, impacting patient-centred TB care.

Intervention or response: To address these gaps, T-bu Lite—an application integrated with TIBU—was piloted by Amref and the Nakuru County Department of Health, with support from the Italian Agency for International Cooperation, starting December 2023. Imple-

mented in 20 facilities, the system enables real-time data access for timely, patient-centred-decisions. Facilities were equipped with computers and internet routers, and healthcare workers were trained on TIBU for data entry and use. Key features include real-time data capture, reduced documentation burden, and SMS appointment reminders to enhance patient adherence.

Results/Impact: The proportion of TB patients notified-within-one month rose from 69% in 2022 to 93% in 2024. In pilot sites, 70% of sputum follow-ups were updated in 2024, compared to 54% in non-pilot sites. Treatment outcome updates within-one-month in Nakuru County increased from 70% in 2022 to 96% in 2024. SCTLCs now dedicate more time to mentorship, while healthcare workers focus on quality care. The system has improved data accuracy and timeliness, enhancing facility-level decision-making.

Conclusions: The digitization of TB data through the TIBU system has demonstrated promising results in improving patient-centred care in Nakuru. Reducing the reliance on paper-based tools and enabling real-time data access, has enhanced case notification, treatment outcomes updates, and overall efficiency in TB management. This approach serves as a model for regions aiming to improve TB care through digital health solutions.

EP13-823-19 Integrated genomic and epidemiological surveillance of TB in Germany, 2020-2024: Results from three cities

T. Domaszewska,[1,2] T. Houwaart,[3] V. Dreyer,[4,5] I. Friesen,[6] M. Kuhns,[6] L. Bös,[1] W. Haas,[1] S. Niemann,[4,7,6] S. Kröger,[1,2] TTU-TB 02.812 Study Group [1]Robert Koch Institute, Infectious Disease Epidemiology, Berlin, Germany, [2]German Center for Infection Research (DZIF), partner site Hannover-Braunschweig, Berlin, Germany, [3]Robert Koch Institute, Genome Competence Centre, Berlin, Germany, [4]Research Center Borstel, Molecular and experimental Mycobacteriology, Borstel, Germany, [5]German Center for Infection Research (DZIF), partner site Hamburg-Lübeck-Borstel-Riems, Borstel, Germany, [6]Research Center Borstel, Leibniz Lung Center, Supranational and National Reference Center for Mycobacteria, Borstel, Germany, [7]German Center for Infection Research (DZIF), partner site Hamburg-Lübeck-Borstel-Riems, Borstelger, Germany
e-mail: domaszewskat@rki.de

Background: Tuberculosis (TB), particularly the emergence of drug resistant *Mycobacterium tuberculosis* complex (MTBC) strains, remains a major public health challenge. Whole genome sequencing (WGS) of MTBC isolates combined with classical epidemiology enhances comprehensive TB surveillance, including monitoring of resistance levels and impact of migration on transmission. Local public health authorities (LHAs) in Hannover, Hamburg, and Frankfurt/Main, the Robert Koch Institute and the National Reference Center for Mycobacteria delivered a comprehensive set of integrated molecular and epidemiological data.

Design/Methods: Key epidemiological parameters of the patients notified within the TB notification system were linked with WGS results, including information on molecular clusters. We present descriptive analysis of the data from 2020-2024.

Results: 1,293 culture-positive TB cases were notified from the study sites; WGS data was linked to 909 (70%) of them. 332/909 (37%) of these cases were part of 175 molecular clusters, which also involved cases notified by other LHAs, and without linked epidemiological data (Table 1).

Among 175 clusters, 157 (90%) included cases born outside of Germany (n=354), five of them with children below the age of 15 (n=7). Further six clusters involved children born in Germany (n=8). Of the cases born abroad with available information (n=325), 35% developed TB within two years, 38% within 3-9 years, and 26% within ten or more years upon arrival in Germany. Drug-resistant TB was identified in 46 clusters (26%), involving 156 cases, including two clusters with pre-XDR-TB (n=9) and one cluster with XDR-TB (n=1).

Table 1 Number of cases in the detected molecular clusters by year and region; n (%).

District/Year	2020	2021	2022	2023	2024	NA[1]	Total
Region Hannover	3 (5.3%)	19 (28.4%)	9 (11.5%)	13 (9.5%)	5 (4.1%)	0 (0.0%)	49(6.3%)
Frankfurt am Main	16 (28.1%)	15 (22.4%)	14 (17.9%)	17 (12.4%)	14 (11.4%)	0 (0.0%)	76 (9.8%)
Hamburg	38 (66.7%)	32 (47.8%)	36 (46.2%)	53 (38.7%)	22 (46.8%)	0 (0.0%)	207 (26.8%)
Other districts	0 (0.0%)	1 (1.5%)	19 (24.4%)	54 (39.4%)	56 (45.5%)	0 (0.0%)	130 (16.9%)
Unlinked cluster cases[1]	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	309 (100.0%)	309 (40.1%)
Total	57 (100.0%)	67 (100.0%)	78 (100.0%)	137 (100.0%)	123 (100.0%)	309 (100.0%)	771 (100.0%)

[1]For all cases with missing link between epidemiological and molecular information, assignment to district and notification year was not possible. Those cases are presented as "unlinked cluster cases".

Conclusions: The identification of clusters spanning multiple regions and occurring long after migration highlights the critical role of WGS in nationwide TB surveillance. Integrating epidemiological and molecular data enhances the detection of transmission and events specific to risk groups or settings, making it a crucial tool for modern TB surveillance. These insights support the development of targeted interventions, ultimately strengthening transregional TB control efforts.

EP13-824-19 Advancing TB monitoring: Digitalisation of Nepal's National Tuberculosis Programme

L.R. Joshi,[1] S.R. Tiwari,[2] M.N. Khanal,[3] A. Shrestha,[1]
[1]Save the Children/Global Fund-Tuberculosis Program, Program Management Unit, Thimi, Bhaktapur, Nepal, [2]National Tuberculosis Control Center, Program Management, Thimi, Bhaktapur, Nepal, [3]National Tuberculosis Control Center, Planning, monitoring, evaluation & research Section, Thimi, Bhaktapur, Nepal
e-mail: lokjoshi11@gmail.com

Background and challenges to implementation: Nepal's National Tuberculosis Program (NTP) has made significant progress in digitalizing its data management system to improve TB surveillance and program performance. The initiative aims to ensure real-time, case-based data capture and reporting across service delivery points.
Intervention or response: The NTP developed the National Tuberculosis Program Management Information System (NTPMIS), leveraging local expertise and integrating it within the DHIS2 Tracker platform. As of 2024, this system is functional in 6,241 DOTS centers (eTB Register), 117 GeneXpert labs, 29 Drug-Resistant TB (DRTB) treatment centers, and 2 culture and DST labs.
A separate PPM system captures case data from pharmacy referral interventions and is linked to the eTB register. Biometric systems have been introduced at GeneXpert and DRTB sites to reduce duplicate entries and improve patient tracking.
Aggregated reporting tools were also developed to monitor partner contributions and TB Free Initiative. Centralized data security is ensured through three-tier server backups at National Information Data Center (Kathmandu), Disaster Recovery Office-DRO (Hetauda), and National Tuberculosis Control Center (NTCC).
Results/Impact: Over 300,000 clint records are managed annually through NTPMIS, significantly improving data quality and traceability. While full integration with the national Health Management Information System (HMIS) has been for GeneXpert and DRTB data, 80% integration has been reached for drug-sensitive TB (DSTB), with full alignment expected by 2025. However, only 5% of Designated Microscopic Centers (DMCs) currently use digital tools due to infrastructure gaps.
Conclusions: Nepal's digital transformation in TB surveillance marks a pivotal achievement in public health, enabling real-time reporting, enhancing data use, and improving service delivery.
Continued investment in robust infrastructure, seamless interoperability, and cloud migration is expected to further amplify the program's effectiveness and sustainability, while acknowledging that although a formal data protection policy is not yet established, significant efforts are in place to safeguard patient information and ensure privacy.

EP13-825-19 Improvement of TIBULIMS connectivity solution in Kenya with integration with DELFT's CAD4TB machines in Kenya

E. Muriithi,[1] M. Githiomi,[1] Delft Imaging Team
[1]National Tuberculosis, Leprosy and Lung Disease Program, Monitoring and Evaluation, Nairobi, Kenya

Background and challenges to implementation: Kenya's National Tuberculosis Program (NTP) has utilized GxLIMS for GeneXpert data management since 2014. However, the introduction of new WHO-recommended diagnostics (WRDs) in 2022 necessitated an upgraded TIBULIMS platform to integrate GeneXpert/Ultra, TrueNat, and CAD4TB. The Delft Light ultra-portable X-ray machines with CAD were integrated into TIBULIMS, but limitations of the existing Thirona (CAD4TB) system—restricted module variables, lack of national-level data access, minimal customization, and absence of remote CXR reading—hindered TB screening and monitoring. This led to the TIBULIMS-CAD4TB integration.
Intervention or response: The Kenya National TB Program developed TIBULIMS using Agile methodology to create an integrated diagnostic platform. This unified solution connected all WHO-recommended diagnostics (GeneXpert, TrueNat, and CAD4TB-enabled X-rays) into a single system. The development process emphasized stakeholder engagement and rigorous validation to ensure the platform met operational needs while maintaining flexibility for future adaptations.
Results/Impact: TIBULIMS has transformed TB diagnostics in Kenya, delivering real-time screening results within minutes of image capture and enabling remote radiologist interpretations within ≤1 hour for same-day clinical decisions. The system seamlessly correlates AI-generated CXR results with laboratory and clinical data, enhancing diagnostic accuracy. Operational improvements include 24/7 equipment monitoring and one-click reporting, reducing administrative workload by 60%. Unified dashboards now provide national-level visibility, geographic mapping of screening coverage, and facility-specific metrics, empowering program managers with actionable insights.
Conclusions: TIBULIMS-CAD4TB Integration has significantly improved data quality and accessibility, consolidating screening data from all sites into interactive dashboards. This integration showcases how digital health technologies can address implementation challenges in resource-limited settings, optimizing diagnostic efficiency, clinical workflows, and program monitoring. Its success serves as a model for other national TB programs aiming for integrated diagnostic data systems.

EP13-826-19 Enhancing timely monitoring and follow-up of drug-resistant TB: Implementing a digital laboratory information system in Uganda

J. Kabugo,[1] S. Ssebirumbi,[1] H. Ssentamu,[1] J. Namutebi,[1] V. Veronese,[2] [1]NTRL-Uganda, NHLDS, Kampala, Uganda, [2]World Health Organization, Research & Training in Tropical Diseases (TDR), Geneva, Switzerland
e-mail: ksolomonjoel@gmail.com

Background: In Uganda, more than 100,000 people were diagnosed in 2024 with Tuberculosis (TB), of which approximately 85% were started on TB treatment. Barriers such as transcription errors, incomplete data, and lack of sample tracking hinder TB diagnosis, routine monitoring of patients and treatment follow-up in Uganda. Using courier systems, emailing and localized laboratory information systems delays results dispatch, making it hard to initiate patients on the right medication due to lack of timely diagnostic results.

We upgraded the Tuberculosis Laboratory Information System (TB-LIS) at the National TB Reference Laboratory (NTRL) to address these gaps and align with WHO's digital health targets for TB elimination.

Design/Methods: Using the RE-AIM framework, we conducted implementation research to deploy an agile, custom-built TB-LIS connecting NTRL to two referral hospitals (January–April 2024). Data from 346 sample requests, questionnaires, and key informant interviews were analyzed to assess pre/post-implementation impact. Convenience sampling ensured representation across roles (clinicians, lab staff) and genders.

Results: The system was successfully installed at two referral hospitals. Sample tracking using the system was at 100% (346/346), reducing TB sample rejection rates by 1.3 times (pre-implementation was at 1.1% (8/681), while post was at 0.87% (3/346). Data completeness improved from 89% to 100% for demographics and laboratory indicators.

Timely access to results was at 100% (346/346) on the same day compared to 96% (654/681) ≥5 days before installation. Key barriers included unstable power, expensive internet and increased workload, while the availability of computers and computer literacy were key facilitators.

Conclusions: The TB-LIS enhanced connectivity between NTRL and MDR-TB sites, enabling real-time result access and patient profiling. Scaling this system nationally could reduce diagnostic inequities and support the WHO's End TB Strategy and address connectivity gaps.

EP13-827-19 Multi-country consortium data systems - setup, challenges, and solutions: A case study of the Start4All initiative

O.M. Akinwande,[1] J. Read,[1] [1]Liverpool School or Tropical Medicine, Global Health Trials Unit, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: olusegun.akinwande@lstmed.ac.uk

Background and challenges to implementation: The Start4All initiative aims to enhance tuberculosis (TB) case detection, implemented across seven countries through a multi-centre cross-sectional study, involving presumptive TB cases identified in healthcare facilities and active case-finding (ACF) efforts. It targeted diverse populations, such as internally displaced persons (IDPs), refugees, and nomads. Implementing a standardised data collection and management system across multiple countries presented challenges, including country-specific database preferences, data harmonisation, real-time quality assurance, and varying work weeks and time zones that disrupted real-time monitoring, coordination, and data submission.

Table 1: Study Sites and Target Populations

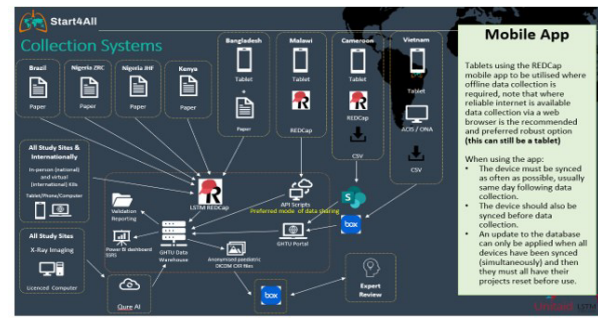
	Country	No Study sites	Region	Category	Key Population	Rec Target
1	Bangladesh	7	South Asia	ACF/SHF	Slum, Rural, Semi-Urban	3000
2	Brazil	3	South America	SHF	Rural, Semi-Urban	639
3	Cameroon	5	West Africa	ACF/SHF*	Rural, Semi-Urban	3300
4	Kenya	2	East Africa	SHF	Rural, Semi-Urban	1400
5	Malawi	3	East Africa	SHF	Rural, Semi-Urban	1200
6	Nigeria-ZRC ~ North-Central	3	West Africa	SHF	Rural, Semi-Urban	1700
7	Nigeria-JHF ~ North-East	6	West Africa	ACF	IDPs, Refugees, Nomads	2000
8	Vietnam	4	Southeast Asia	ACF/SHF*	Rural, Semi-Urban	3000
		33				**16239**

*recruiting children

Table 2: Data Collection & Transmission Plan

	Country	Data Collection & Collation Plan	Transmission Channel	Cadence
1	Bangladesh	Paper forms → LSTM REDCap Tablet → LSTM REDCap		Real-time
2	Brazil	Paper forms → LSTM REDCap		Real-time
3	Cameroon	Tablet → Local REDCap → LSTM	via SharePoint	Bi-weekly
4	Kenya	Paper forms → LSTM REDCap		Real-time
5	Malawi	Tablet → Local REDCap → LSTM	via API	Real-time
6	Nigeria-ZRC	Paper forms → LSTM REDCap		Real-time
7	Nigeria-JHF	Paper forms → LSTM REDCap		Real-time
8	Vietnam	Paper forms → ACIS / ONA → LSTM	via BOX	Bi-weekly
Cameroon + Vietnam		Peads DICOM images	via BOX	

Figure 1: Data Systems Schema



Intervention or response: A structured data collection framework was established using electronic data capture (EDC) systems such as REDCap and ACIS/ONA, and data manipulation and visualisation tools including MS-SQL, Visual Studio (VS), SQL Server Reporting Services (SSRS), and PowerBI. A hybrid paper-based and electronic transmission approach accommodated country-specific preferences.

Key interventions:
- Addressed data ownership concerns by providing real-time access to collected data and established API-based data sharing for interoperability.
- Standardising data-sharing protocols, CSV file exchange, and cadence agreements.
- Developed structured data systems assessment checklist to evaluate DM infrastructure and ensure compliance with (GCP) standards.
- Implemented secure, real-time sharing of X-ray DICOM files
- Addressed culture result entry challenges by integrating remote access for laboratory personnel and streamlining data entry at centralised locations.
- Established staggered data collection and transmission schedules to accommodate different work weeks and ensure timely reporting across time zones.
- For quality control (QC), SSRS was configured to send an automatic data query report to all sites at the same time weekly.

Results/Impact:
- 75% of sites achieving real-time data sharing.
- 100% QC & 70% query resolution rate within seven days.
- Secure X-ray image sharing improving diagnostic workflow.
- Reduced culture data turnaround time (TAT) through centralised entry.

Conclusions: This initiative provides a scalable model for cross-country TB programs, highlighting the need for adaptive data management frameworks to enhance real-time data integrity and operational efficiency.

EP13-828-19 Optimising electronic medical records to strengthen TB/HIV service delivery: A multi-phase redesign and evaluation of impact in Southern Nigeria

E. Ezieke,[1] C. Okolo,[2] L. Adams,[3] O. Esosuakpo,[2] O. Onyedinachi,[4] A. Adegboye,[1] A. Eyo,[4] [1]Excellent Community Education Welfare Scheme, Prevention Care and Treatment, Uyo, Nigeria, [2]Excellent Community Education Welfare Scheme, Strategic Information, Uyo, Nigeria, [3]Excellent Community Education Welfare Scheme, Information Technology, Uyo, Nigeria, [4]Excellent Community Education Welfare Scheme, Prevention Care and Treatment, Abuja, Nigeria
e-mail: EEzieke@ecews.org

Background and challenges to implementation: The ECEWS ACE-5 project uses the LAMIS electronic medical records (EMR) system to report key TB/HIV indicators. However, evolving program priorities and increased patient volumes revealed documentation challenges. Ambiguities in the TB module and overlapping data fields led to duplicate entries, confusion across screening, treatment, and prevention components, ultimately reducing data quality and weakening program monitoring.

Intervention or response: In May 2024, the project partnered with DATA.FI Nigeria to review and redesign the TB/HIV module in phases for improved functionality and reporting efficiency.

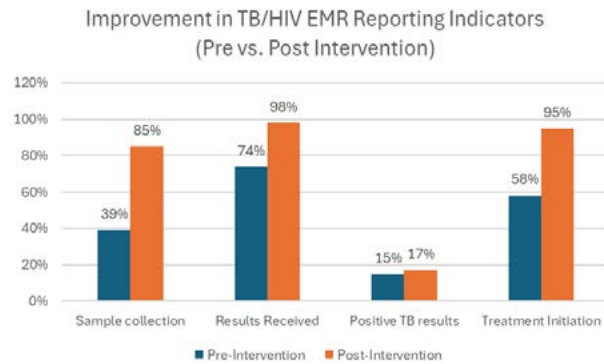
Phase 1: A participatory approach was adopted, engaging the LAMIS Community of Practice and ACE (Accelerating Control of Epidemics) project leads.

Phase 2: The system was redesigned to clearly separate TB screening, treatment, and prevention sections. Auto-population features were introduced to reduce data entry time and duplication and streamline data flow within the EMR.

Phase 3: Following approval, the upgraded module was deployed across all ACE-supported sites, accompanied by comprehensive staff training.

A comparative analysis of data from 225 facilities in Akwa Ibom and Cross River States was conducted, comparing five months pre-intervention period (April–August 2024) to five months post-intervention period (October 2024–February 2025) on the EMR, assessing key TB/HIV indicators.

Results/Impact: The post-intervention analysis showed significant improvements in TB/HIV data reporting across 225 facilities. Sample collection increased from 39% (1,344/3,477) to 85% (2,363/3,021), a 46% improvement. TB test results improved from 74% (989/1,344) to 98% (2,511/2,563), a 24% increase. The proportion of clients with documented positive TB results rose from 15% (149/989) to 17% (424/2,511). TB treatment initiation improved from 58% (86/149) to 95% (402/424), indicating enhanced reporting quality.



Conclusions: This intervention demonstrates the value of collaborative EMR optimization in strengthening TB/HIV service delivery. A well-designed and user-friendly EMR system is essential for improving data quality, facilitating real-time monitoring, and achieving better health outcomes in resource-limited settings.

EP14 Enhancing TB diagnosis and case finding among children

EP14-829-19 Enhancing childhoodTB detection in Bangladesh: The role of government hospitals and strategic screening initiatives

F.M.M. Haque,[1] Z. Nasreen,[2] M.A.H. Khan,[3] S. Yeasmin,[4] R.S. Banu,[5] A. Akhter,[6] MAH. Salim,[7] Divisional TB Expert group [1]National TB Control Program, Monitoring and Evaluation, Dhaka, Bangladesh, [2]Directorate General of Health Services, Health Service Division, Dhaka, Bangladesh, [3]National TB Control Program, Admin, Dhaka, Bangladesh, [4]National TB Control Program, Monitoring And Evaluation, Dhaka, Bangladesh, [5]National TB Control Program, Program, Dhaka, Bangladesh, [6]National TB Control Program, Coordination, Dhaka, Bangladesh, [7]Harvard Medical School, Department of Social Medicine, Dhaka, Bangladesh
e-mail: tonmoy.ndc@gmail.com

Background and challenges to implementation: Childhood Tuberculosis(TB) remains underdiagnosed globally due to nonspecific symptoms and diagnostic challenges, particularly in children under five. In Bangladesh, children aged 0–14 accounted for only 3.39% of total TB notifications in 2021. To address this gap, the national TB program introduced strategic measures—including facility-based Active Case Finding (ACF) and stool testing—to improve pediatric-TB detection.
Intervention or response: Government strengthened systematic screening in public health facilities, particularly in outpatient departments, pediatric wards, and nutrition units. Stool testing was rolled out as a non-invasive diagnostic tool for young children. A notable proportion of TB in children under five was identified after the referral from government hospital, underlining their central role in early detection and emphasizing the crucial role of government hospitals in initiating referrals and facilitating accurate diagnosis,
Results/Impact: From Q1-2023 to Q4-2024, childhood-TB cases in children aged 5–14 years showed a steady increase from 1718 in Q1-2023 to 2817 in Q4-2024 (64% growth). Cases in children aged 0–4 years grew by 45%. Referrals from government hospitals shows significant rise for both age, with a 35% increase for 5–14 years and 36% for 0–4 years. Over 50% of total under-five children were diagnosed with TB after being referred from government hospitals in 2023 and 2024 which was below 45% during year 2022. The national proportion of childhood-TB increased from 3.39% in 2021 to 5.29% in 2024, marking significant gains in pediatric-TB detection.
Conclusions: The expansion of facility-based screening and adoption of stool testing significantly boosted childhood-TB case detection in Government hospitals of Bangladesh emerging as key diagnostic hubs, particularly for the child-TB. Efforts should focus on ensuring equitable access to diagnostic services, enhancing community awareness, and investing in continuous capacity building for healthcare professionals to improve TB diagnostics. These steps will help sustain and scale the gains in childhood-TB detection.

EP14-830-19 Leveraging community-based models and private sector engagement to improve paediatric TB detection in Sokoto State, Nigeria

S. Msheliza,[1] A. Agbo,[1] T. Adetiba,[2] A. Agbaje,[2]
[1]The Leprosy Mission Nigeria, Programs, Abuja, Nigeria, [2]Institute of Human Virology Nigeria, Programs, Abuja, Nigeria
e-mail: samism01@yahoo.com

Background: Childhood tuberculosis (TB) remains underdiagnosed in rural Nigeria due to limited diagnostic infrastructure and delayed care-seeking. In Sokoto State, access to chest X-rays—vital for pediatric TB diagnosis—is lacking at most primary health facilities, resulting in underreporting and delayed treatment. To address this, a community-based intervention was implemented in 2023 to improve pediatric TB case detection. The initiative was supported by the Global Fund to Fight AIDS, Tuberculosis and Malaria, with the Leprosy Mission Nigeria as the Sub-Recipient and the Institute of Human Virology Nigeria (IHVN) as the Principal Recipient, under the Public-Private Mix (PPM) grant. Diagnosed cases were linked to private health facilities for care and follow-up.
Design/Methods: A structured biweekly transport model was used to convey children with presumptive TB from rural health centers to urban diagnostic facilities equipped with X-ray technology. To improve participation, meals were provided to address nutritional barriers. Simultaneously, outreach campaigns—delivered through local health workers and traditional town criers—were conducted to raise TB awareness, improve early case identification, and encourage caregiver engagement.
Results: The intervention significantly improved childhood TB detection, with all confirmed cases linked to private facilities. Monthly diagnostic referrals rose from 50 to over 250 children. Pediatric TB notifications increased by 239%, from 936 in 2022 to 3,170 in 2023. The contribution of childhood TB to overall notifications grew from 7.5% to 16%. Over 15,000 households were reached through community engagement, resulting in a 60% rise in presumptive TB referrals. Caregivers cited transport and nutritional support as key enablers for accessing diagnostic services.
Conclusions: This Global Fund-supported intervention demonstrates that integrated community transport, nutritional support, and private sector engagement can substantially enhance pediatric TB detection in underserved settings, offering a scalable model for replication.

EP14-831-19 Advancing TB detection in children with stool test: KNCV Nigeria experience

N. Nwokoye,[1] O. Chukwuogo,[1] C. Ogbudebe,[1] S. Useni,[1] S. Balogun,[1] V.-L. Ovoh,[1] T. Theodore,[1] B. Odume,[1]
[1]KNCV Nigeria, Technical, Abuja, Nigeria
e-mail: nnwokoye@kncvnigeria.org

Background and challenges to implementation: The Simple One-Step (SOS) Stool-based Xpert method is increasingly used in Nigeria for diagnosing childhood tuberculosis (TB). This approach is beneficial because it can identify TB in children who have difficulty providing quality sputum samples. The collection procedure is non-invasive, and testing is done at the primary health facilities, owing to its low biosafety requirements and user friendliness. We reviewed the contribution of the stool-based Xpert test to TB detection in Children across 14 KNCV-supported states.
Intervention or response: The low childhood TB notification in Nigeria necessitated the roll-out of the stool-based Xpert method. KNCV Nigeria, in partnership with the National TB and Leprosy Control program of Nigeria, decentralized stool testing to the primary health facilities and private sector where individuals first seek help. The capacity of the health care workers and laboratory staff were built on sample collection, transportation, and the stool processing procedure. Four-and-a-half-year retrospective data (July 2020 -January 2025) on stool tests performed for children aged 0- 14 years was downloaded from DHIS2 and analyzed using SPSS.
Results/Impact: In the period under review, a cumulative number of 138,358 stool samples from children with presumed TB across 14 States were evaluated using the SOS method. A total of 6,450 children were detected to have TB and 6426(99.6%) were put on treatment. The TB yield recorded was 5%.

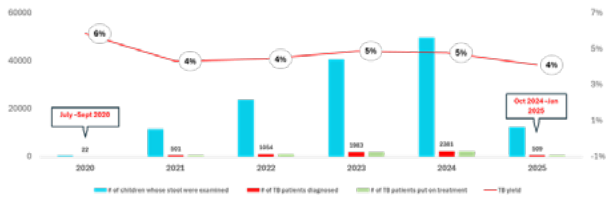


Fig 1: Stool test result from July 2020 – Jan 2025.

Conclusions: The SOS method has proven to be simple, robust and reliable, contributing to increased bacteriological confirmation and rifampicin resistance profile in TB cases in children.

EP14-832-19 Exploring role of CXR CAD for paediatric TB detection: A retrospective evaluation of CXR CAD performance in children and adolescents in Myanmar

T. Maung,[1] H.T. Oo,[1] A.M. Thu,[1] A.P.S. Phoo,[2] K.Z. Thann,[2]
[1]Myanmar Medical Association, TB Program, Yangon, Myanmar,
[2]PATH, Myanmar Country Program, Yangon, Myanmar
e-mail: drtnmg@gmail.com

Background and challenges to implementation: Diagnosing TB in children is complex due to non-specific symptoms, limited bacteriological confirmation, and restricted access to radiology expertise. In Myanmar, chest X-ray (CXR) plays a vital role in pediatric TB diagnosis. To address diagnostic challenges and expand access to radiological screening, Computer-Aided Detection (CAD) software was introduced into TB services. However, evidence on CAD performance in pediatric populations remains limited, particularly for detecting classic features like hilar lymphadenopathy. Myanmar Medical Association implemented qXR version 3.2 in routine pediatric TB screening. This abstract presents a retrospective evaluation of its performance and early findings from a blinded exercise using version 4.2.
Intervention or response: From March 2023 to May 2024, 1,150 children aged 6–14 were referred for CXR from 99 GP clinics across 12 Yangon townships. CAD interpretation using qXR 3.2 was integrated into routine TB workflows. Each image was independently reviewed by three expert radiologists, blinded to CAD results, with consensus (≥2 of 3 agreement) used as the reference standard. Final TB diagnoses were made by trained clinicians. A subset of images was re-evaluated using qXR 4.2 under blinded comparison.

Metric	Measure (95% CI; n = 1150)		
Sensitivity	18.18% (15.95% - 20.41%)		
Specificity	98.38% (97.65% - 99.11%)		
Positive predictive value	51.43% (48.54% - 54.32%)		
Negative predictive value	92.74% (91.24% - 94.24%)		
AUC	0.58 (0.54 - 0.62)		
Statistic/ Metric	Children & young adolescents (n = 1150)	Children (n = 530)	Young adolescents (n = 620)
Agreement rate	23.91%	20.94%	26.45%
Cohen's kappa	0.01 (p=0.004)	0.006 (p=0.169)	0.02 (p=0.004)

Table 1: Results of qXR version 3.2

Results/Impact: qXR 3.2 flagged 3% of cases as presumptive TB versus 79% by radiologists, showing 18.2% sensitivity, 98.4% specificity, and AUC 0.58. As shown in Table1, agreement with radiologists was low overall (23.9%, $\kappa = 0.01$), and even lower among younger children (20.9%, $\kappa = 0.006$) than young adolescents (26.5%, $\kappa = 0.02$). Hilar lymphadenopathy was missed in 72% of discordant cases.

qXR 4.2 showed improved sensitivity (26.8%), specificity (94.6%), and agreement (κ = 0.04), though pediatric-specific features remained under-detected.
Conclusions: While CAD expands TB screening access, current tools remain limited in pediatric populations. Improvements in qXR 4.2 are promising, and findings support progressive CAD integration with clinical oversight. Continued refinement and validation in children are essential before broader use in TB programs.

EP14-833-19 Treatment decision algorithms to detect paediatric pulmonary TB in unstable settings: Experience in South Sudan

L.F. Nyikayo,[1] B.Y. Lual,[1] E. Briskin,[2] L. Moreto-Planas,[3] B. Tut,[4] P.J. Panyuan,[5] H. Huerga,[6] TB ALGO PED Study Group [1]MSF- Malakal, Medical, Malakal, South Sudan, [2]Epicentre, Field Epidemiology and Training, Paris, France, [3]MSF -OCBA, Medical, Barcelona, Spain, [4]MSF-OCBA, Medical, Juba, South Sudan, [5]MOH, NTLP, Juba, South Sudan, [6]Epicentre, Field Epidemiology and Training, Brussels, Belgium, Belgium
e-mail: msfe-malakal-research@barcelona.msf.org

Background and challenges to implementation: South Sudan's estimated incidence of tuberculosis (TB) is 227 per 100,000 people. In 2022 the WHO to recommend new treatment decision algorithms (TDAs) for pediatric pulmonary TB. Médecins Sans Frontières (MSF) supports 2 hospitals in Malakal, including pediatric wards and inpatient therapeutic feeding centers, as surrounding areas face instability, with frequent population movements. MSF implemented the TDA without x-ray in these two facilities in January 2024.
Challenges included high population mobility, high demand for human resources and training, and some clinician perceptions of over-treatment.
Intervention or response: To account for high population mobility and frequent early discharge against medical advice, laboratory tests (GeneXpert, TB-LAM) were ordered as soon as presumptive TB was identified at initial assessment for all children (instead of only for those at high risk of rapid TB progression), and follow-up visits started as soon as 5 days after initial assessment (instead of the 7-14 days recommended by the TDA). To support TB treatment continuation once initiated, health promotion teams increased calls and home visits.
To address high human resource demands, one TDA implementation focal-person was identified, supporting continuous refresher training.
Results/Impact: From January to December 2024, 264 children under 10 years were identified with presumptive TB, and 125 (47%) were started on TB treatment. Staff found the TDAs easy to use and helpful; however, in the absence of the focal person, the TDAs were less used and TB treatment initiation rates dropped.
Conclusions: We recommend adapting the model of care to the context, for success along the care continuum, including training and consensus-building while implementing the TDAs, and linkages to ensure treatment is completed once initiated. While having a focal person is valuable, decentralizing responsibility for algorithm use across clinicians from implementation start may support the sustainable use of the TDAs.

EP14-834-19 Traditional birth attendants are major contributors to finding childhood TB: Comparative analysis of childhood TB case-finding across TB LON 3 interventions in Oyo State

A. Ricketts,[1] O. Adedayo,[2] O. Daniel,[3] A. Agbaje,[3] B. Olaniyi,[3] S. Akingbesote,[3] C. Uzoigwe,[3] C. Mensah,[4] M. Pedro,[5] R. Eneogu,[6] [1]Institute of Human Virology Nigeria, PCT, Ibadan, Nigeria, [2]Institute of Human Virology Nigeria, Strategic Information, Ibadan, Nigeria, [3]Institute of Human Virology Nigeria, PCT, Lagos, Nigeria, [4]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [5]Institute of Human Virology Nigeria, Strategic Information, Lagos, Nigeria, [6]United State Agency for International Development, TB/HIV Office, Abuja, Nigeria
e-mail: aricketts@ihvnigeria.org

Background and challenges to implementation: Tuberculosis remains a disease of public health concern in Nigeria as a leading cause of death across all age groups. Children are particularly more vulnerable and the mortality among this age group is disproportionately high. Early diagnosis and treatment are crucial for better outcomes, effective management, and control of TB among children. With the increased drive for optimal diagnosis of childhood TB, it is important to assess which interventions yielded CTB optimally.
Intervention or response: A comparative analysis of childhood TB yield from different interventions was conducted using IHVN TB LON 3 project data. The period of review for this study is January 2024 to December 2024. The interventions selected for this study are special population, community, public health facilities, private health facilities, traditional birth attendants (TBAs), stand-alone laboratories (SALs), proprietary patent medicine vendors (PPMVs). Selected metrics for the analysis are 'total number of children screened', 'total number of presumptive children evaluated', 'total number of cases diagnosed', 'total number of childhood TB cases diagnosed' 'Childhood TB yield', 'number needed to screen (NNS)', 'number needed to test (NNT)', 'total number of TB cases', 'proportion of CTB cases diagnosed among total diagnosed'.
Results/Impact: The analysis revealed that the intervention that is most efficient in childhood TB case detection is traditional birth attendants. From the table below, it is

observed that the TBA intervention has the highest CTB yield (15%). Furthermore, the TBA intervention is also shown to have the lowest NNS (80) and NNT (7) among all interventions. This infers that in terms of TB cascade efficiency, TBA intervention was unsurpassed for the period.

Interventions	Children (0-14) Screened	Presumptive Children (0-14)	Cases (0-14) diagnosed	CTB Yield	CTB NNS	CTB NNT	Total Cases (Adult TB +CTB)	Proportion of CTB cases
Community	21748	1653	122	7%	178	14	2266	5%
PPMVs	3989	559	43	8%	93	13	826	5%
Private Health Facilities	32047	1631	50	3%	641	33	1151	4%
Public Health facilities	308430	7487	349	5%	884	21	4834	7%
SALs	3796	73	3	4%	1265	24	77	4%
Special Population	170	24	2	8%	85	12	108	2%
TBAs	1685	144	21	15%	80	7	246	9%

Conclusions: TBAs have potential to be game changers in childhood TB case detection. Allocating more resources and scaling up TBA interventions in programs can significantly increase CTB case detection.

EP14-835-19 Overcoming barriers to childhood TB detection: Scaling up childhood TB case detection through integrated facility and community-based interventions in Niger State, Nigeria

D.S. Hananiya,[1] I. Isah,[2] D. Philip,[2] O.A. Fadare,[3] O. Olarewaju,[4] S. Dimang,[4] O. Chijioke-Akaniro,[4] E. Ubochioma,[4] [1]WHO Nigeria, UCN/Field Presence Cluster, Minna, Nigeria, [2]Ministry of Secondary and Tertiary Health, Niger State, Department of Public Health, Minna, Nigeria, [3]WHO Nigeria, UCN Cluster, Abuja, Nigeria, [4]Federal Ministry Of Health, Department of Public Health, Abuja, Nigeria
e-mail: drhananiya@gmail.com

Background and challenges to implementation: Nigeria remains among the top contributors to the global childhood tuberculosis (TB) burden, with an estimated 59,000 children (0–14 years) developing TB annually (Global TB Report, 2024). Diagnosing TB in children, particularly those under five years, is challenging. The National Strategic Plan targets a 15% contribution of childhood TB to total notifications; however, Niger State recorded only 2.5% in 2022, the lowest nationally. This highlighted critical gaps in child TB detection requiring innovative and targeted approaches.
Intervention or response: A multisectoral strategy was implemented in 2023–2024 to improve childhood TB detection. Key activities included stakeholder engagement to identify barriers, capacity building for health facility staff and community TB workers, collaboration with the State Nutrition Programme to enhance screening coverage. Outreach screening was intensified in child clinics, schools, orphanages, internally displaced persons (IDP) camps, etc. Stool sample testing using Gene Xpert was scaled up, with laboratory scientists retrained and sample referral systems strengthened. Uptake of free chest X-rays were promoted through social mobilization, National Childhood TB Testing Week commemorated according to NTP guidance.
Results/Impact: Childhood TB notifications increased from 151 in 2022 to 256 in 2023 (70% increase) and 532 in 2024 (108% increase). The proportion of childhood TB among total TB cases rose from 2% in 2022 to 5% in 2024, despite a 4,000-case increase in overall TB notifications.
A total of 862 stool samples were tested in 2024 across five Gene Xpert sites, yielding 17 positive results (2% positivity rate). Stool testing contributed to 3% of total childhood TB diagnoses. Males accounted for 56% of childhood TB cases and females 44%.

Childhood TB Notification in Niger State			
	2022	2023	2024
Total persons with diagnosed	6440	8104	10405
Absolute Number of Children	151	256	532
proportion of children	2%	3%	5%

Sex disaggregation of Childhood TB (0-14yrs)			
	2022	2023	2024
Male	51%	60%	57%
Female	49%	40%	43%

Conclusions: Integrated facility and community-based interventions, including collaboration with the nutrition programme, scale-up of stool testing, and nationwide testing initiatives, significantly improved childhood TB detection in Niger State. This approach offers a scalable and context-appropriate model for similar high-burden, low-resource settings.

EP14-836-19 Innovative approach to finding missing child TB cases in Nigeria: An account of the national child TB testing week

O. Chijioke-Akaniro,[1] O. Urhioke,[1] A. Omoniyi,[2] O. Olarewaju,[1] M. Etolue,[1] O. Fabunmi,[1] U. Udechukwu,[1] O. Omosebi,[1] E. Ubochioma,[1] S. Labaran,[1] [1]National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Nigeria, Department of Public Health, Abuja, Nigeria, [2]WHO Country office, Nigeria, UCN, Communicable and Non-Communicable disease, Abuja, Nigeria
e-mail: ocakaniro@gmail.com

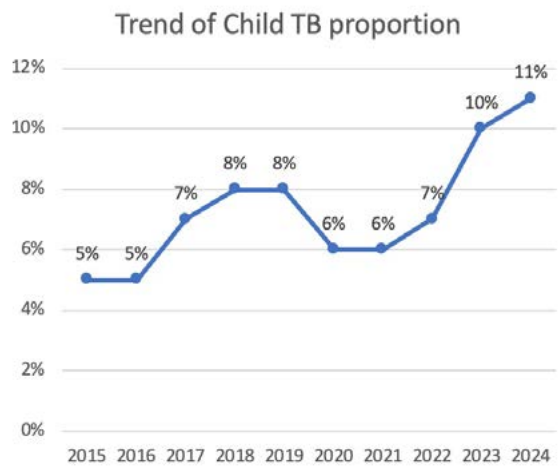
Background and challenges to implementation: Nigeria notified 285,561 tuberculosis (TB) cases in 2022 with children accounting for only 7% which is far from the 14% national strategic plan target. This study demonstrates the impact of the innovative national child TB testing week on childhood TB notification in Nigeria. This exercise was conducted in May 2023 across 36 states and the federal capital territory.
Intervention or response: A pre-mapping of all child health care or congregate settings was done in all 36+1 states including immunization clinics, post-natal-wards,

child-friendly-centres, orphanages, nursery and primary schools, and nutrition clinics. A team made up of state/LGA TB programme officers, partners and community health workers were mobilized to create awareness on the testing locations. Then a general consent was obtained from caregivers for symptomatic screening of children or screening with X-ray for TB.

Presumptive had their sputum/stool collected, packaged, and moved to GeneXpert centres for testing. Caregivers of children with confirmed TB were contacted and children started on TB treatment. The national TB programme (NTP) recording tools were used for documentation, from which data was aggregated

Results/Impact: At the end of one week, 1,231,436 children were seen, 636,369 (52%) screened for TB, 177,570 (28%) presumptive TB were identified, 159,783 (90%) were tested, and 7,806 (5%) TB cases were diagnosed and started on treatment. Number Needed to Screen was 82 and Number Needed to Test was 20.

This exercise resulted in an 11% childhood TB contribution in Q2 2023 and overall, childhood TB contribution increased from 7% in 2022 to 10% at the end of 2023. In 2024, similar event was held and has further improved child TB contribution from 10% in 2023 to 11% in 2024.



Conclusions: The child TB testing week is an innovative approach that has demonstrated the potential of increasing childhood TB notification in low resource settings.

EP14-837-19 Assessing CAD performance in detecting TB in paediatric chest radiographs

Z.Z. Qin,[1] S. Gelaw,[2] A. Klosovsky,[1] T.S. Egzertegegne,[3] N.L. Leyso,[2] [1]International Organization for Migration, Migration Health Division, Geneva, Switzerland, [2]International Organization for Migration, Migration Health Division, Manila, Philippines, [3]International Organization for Migration, IOM Africa Regional Teleradiology Centre, Nairobi, Kenya
e-mail: zqin@iom.int

Background: Tuberculosis (TB) detection in pediatric populations presents unique challenges due to differences in radiographic presentation compared to adults. This study evaluated the performance of computer-aided detection (CAD) software in detecting TB in chest radiographs (CXRs) of children under 15 years.

Design/Methods: Utilizing a case-control dataset of 1,476 pediatric CXRs divided equally into three age groups: under 5 years, 5–10 years, and 10–15 years, we evaluated three CAD software against an expert radiological reference standard (RRS). Software was only evaluated on CXR from children in the age group that the CAD software is recommended for use.

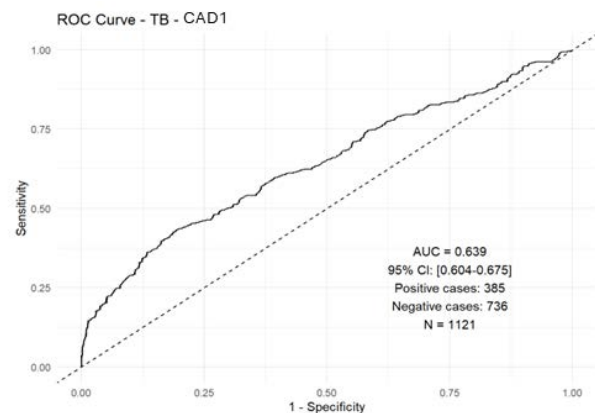
The area under the Receiver Operating Characteristic curve (AUC-ROC) was calculated for each software and CAD abnormality score distributions were generated for each of the three age categories, where relevant.

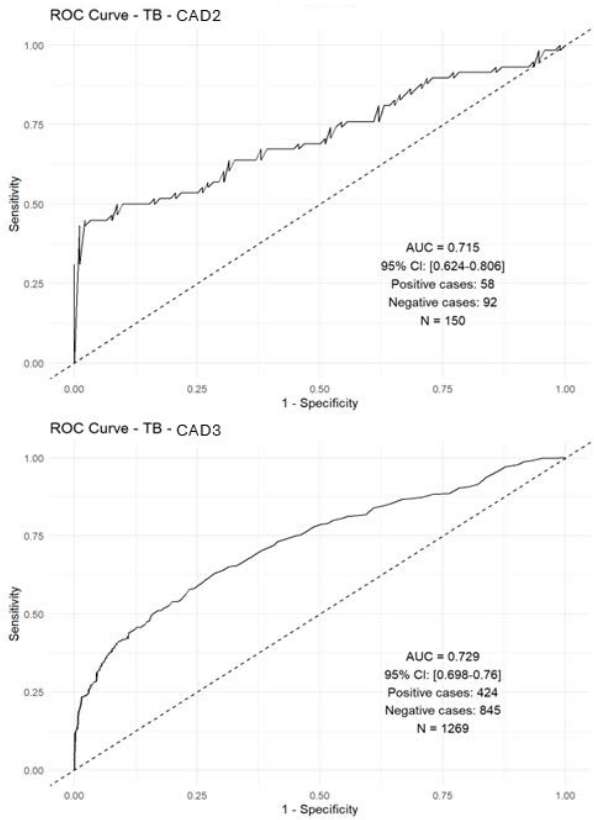
Results: CAD3 demonstrated the highest overall ability to detect TB with an AUC-ROC of 0.729 (95% CI: 0.698–0.760) in children aged 3 years and older.

CAD1 showed moderate performance with an AUC-ROC of 0.639 (95% CI: 0.604–0.675) in children aged 4 years and above.

This was surpassed by CAD2 (AUC-ROC: 0.715 [95% CI: 0.624–0.806]), but the latter software was only evaluated in individuals aged 14 years and older.

CAD3 generally allocated very low abnormality scores across age groups, while CAD1 tended to allocate higher abnormality scores to the youngest age group (<5 years old), despite this group having the lowest number of TB cases according to the RRS.





Conclusions: The accuracy of CAD for detecting pediatric TB varies widely across software, with CAD2 demonstrating promising accuracy. Further research is needed to evaluate CAD in pediatric populations for the development of evidence-based policy.

EP14-838-19 The current landscape of artificial intelligence-assisted chest radiography for paediatric TB: A scoping review

I. Aulianisa,[1] D.K. Ryuk,[1] M. Yang,[1] J. Son,[1] W. Shreeya,[1] D.-E. Kim,[1] M. Kohli,[2,1] H. Sohn,[1] [1]Seoul National University College of Medicine, Department of Preventive Medicine, Seoul, Republic of Korea, [2]FIND, Evidence and Policy, Geneva, Switzerland
e-mail: irinaaulia@snu.ac.kr

Background: Tuberculosis (TB) remains a major cause of death among children, particularly in resource-limited settings. While computer-aided detection (CAD) systems are increasingly used for TB screening, pediatric-specific evidence remains scarce. This scoping review provides an overview of the current literature on CAD tools for pediatric chest radiography and highlights research gaps.
Design/Methods: Using Arksey and O'Malley's framework, we searched five databases (PubMed, Cochrane, Scopus, Embase, Web of Science) for studies published between 2000 and 2024. Eligible studies reported on CAD systems applied to pediatric chest X-rays (ages 0–18). Screening and data extraction were conducted using Covidence and Excel. Data included study design, age group, setting, CAD product, reference standard, and outcomes. Results followed PRISMA-ScR guidelines.
Results: Out of 9,190 records retrieved, 389 studies were relevant, and 158 included pediatric data. Only nine (2.3%) focused exclusively on children. Most studies assessed diagnostic performance or algorithm development, primarily using CAD4TB (Delft, NL).
The most commonly used datasets were Shenzhen, Montgomery, and NIH, with pediatric representation of 9.42%, 3.63%, and 3.2%, respectively. The highest reported accuracy was 98% from an ensemble machine learning model, while JF CXR-1 demonstrated the best overall performance (sensitivity 94.2%, specificity 91.2%, AUC 0.98).
Only one study used a Microbiological Reference Standard (MRS), while most others relied on radiological interpretation. Key challenges included limited pediatric datasets, inconsistent labeling, and underrepresentation of children in model training and validation.

Author (Year)	Tool/Study Focus	Pediatric Data	Gold Standard	External Validation	Performance
Mouton (2010)	Prototype System	High	N/A	Low	Not reported
Tezoo (2012)	Prototype Model	High	Low	Low	Not reported
Padash (2022)	Systematic Review	Moderate	N/A	N/A	N/A
Palmer (2023)	CAD4TB	Moderate	Low	Low	AUC 0.72; Sens ~72%, Spec ~66%
Yang (2023)	JF CXR-1	High	Moderate	Moderate	AUC 0.98; Sens 94.2%, Spec 91.2%
Amin (2023)	Qure.ai	Moderate	Low	Low	F1 0.88; Acc 98% (TB class)
Capellán-Martín (2023)	Custom DL Model	High	Low	Low	Not reported
Edem (2024)	CAD4TBv7	High	High	Low	Sens 50.3%, Spec 98%, AUC ~0.70
Capellán-Martín (2024)	Tool Comparison	High	Low	Low	Not reported

Evidence Gap Map of Pediatric TB-CAD Studies: Diagnostic Tools, Data Representation, and Reported Performance (2010–2024)

This table summarizes nine studies on pediatric TB-CAD, highlighting key areas such as pediatric data use, diagnostic reference standards, external validation, and reported performance. "High" means strong evidence, such as use of pediatric-specific data or microbiological confirmation. "Moderate" indicates partial or mixed data. "Low" reflects limited evidence or methodological issues. "N/A" means the study did not apply or report a standard. Reported metrics include AUC, sensitivity, specificity, accuracy, or F1-score. The color coding helps identify strengths and gaps in the current research to guide future work.

Conclusions: Current evidence on pediatric TB-CAD remains limited and methodologically inconsistent. There is a pressing need for age-appropriate, validated datasets and standardized diagnostic frameworks. Future research should prioritize clinical implementation, inclusive population representation, and harmonized reporting to improve the use of CAD in pediatric TB detection and care.

EP15 Prevent to end: Catalysing implementation of TB preventive treatment

EP15-839-19 India's experience of programmatic implementation of TPT for contacts of people with drug-resistant

R. Taralekar,[1] V. Dhawan,[2] C. Das,[3] S. Chandra,[1] L. Mehandru,[1] S. Suryawanshi,[1] U. Singh,[2] [1]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [2]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [3]National Aids Control Organisation, (NACO), New Delhi, India
e-mail: taralekarr@rntcp.org

Background and challenges to implementation: India's National TB Elimination Programme (NTEP) introduced TB Preventive Treatment (TPT) for contacts of drug-resistant TB (DR-TB) patients in 2022. Provider hesitancy and low access to TB infection (TBI) test, Isoniazid (H)/ Fluoroquinolone (FQ) Drug Susceptible Testing (DST) were initial challenges in the roll out. The implementation experiences and outcomes of DR-TB patient contacts provided TPT under NTEP were documented to inform strategies for future scaling up.
Intervention or response: After ruling out TB, contacts were offered 6 months of daily levofloxacin (6Lfx) for FQ-susceptible MDR-TB exposure or 4 months of daily rifampicin (4R) for isoniazid mono/poly-resistant TB (Hr-TB) with Rifampicin-susceptible exposure. Provider hesitancy was tackled through advocacy and evidence-based communication. Screening used symptoms, chest X-ray, upfront NAAT, and TBI tests. Access to Line Probe Assay improved DST for Isoniazid and FQ. Resources for drugs, TBI tests, funds, and nutrition were ensured. Community engagement promoted adherence with $3 incentives for supporters. A TPT module in Ni-Kshay enabled real-time tracking of TPT care from enrolment to outcomes.
Results/Impact: Between Jan ,22 and Dec ,24, 3,534 MDR/RR-TB patient contacts were started on the 6Lfx regimen, achieving 89% treatment success among 1,770 initiated in 2023. Additionally, 2,432 Hr-TB patient contacts were placed on the 4R regimen from Jan ,23 to Dec ,24, with 79% success among 1,424 initiated in 2023. Scaling up TPT was supported by TB screening during active case finding, TBI and H/FQ testing, advocacy, digital tools, and community engagement. Long-term follow-up to monitor break-through TB and resistance amplification is ongoing.
Conclusions: India's experience demonstrates that with adequate resources, digital tools, advocacy and community engagement, TPT for DR-TB contacts can be effectively scaled. Continued efforts will be key to achieving higher TPT coverage and completion to enable accelerated incidence reduction on DR-TB among contacts.

EP15-840-19 Opportunities for optimising routine delivery of TB preventive treatment for people living with HIV in high-burden TB settings

L. Chimoyi,[1] S. Ginindza,[1] B. Nonyane,[2] C. Mulder,[3] A. Bedru,[4] N. Kawaza,[5] K. Shearer,[2] G. Churchyard,[6,7] C. Hoffmann,[8] V. Chihota,[6,7] [1]The Aurum Institute, Implementation Research Division, Johannesburg, South Africa, [2]Johns Hopkins, Bloomberg School of Public Health, Baltimore, United States of America, [3]KNCVTB Plus, TB, Hague, Netherlands, [4]KNCVTB Plus, TB, Addis Ababa, Ethiopia, [5]The Aurum Institute, Global Division, Harare, Zimbabwe, [6]The Aurum Institute, Executive Division, Johannesburg, South Africa, [7]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa, [8]Johns Hopkins, Medicine and Public Health, Baltimore, United States of America
e-mail: lchimoyi@auruminstitute.org

Background: Short-course TB preventive treatment (TPT) regimens including the weekly three-month Isoniazid and Rifapentine (3HP) are safer with higher completion rates in clinical trials. However, few descriptions from programmatic settings exist. We descriptively summarized TPT outcomes**.**
Design/Methods: From 2021-2023, we conducted a 24-month observational cohort study of people living with HIV (PLHIV) either initiating or refilling antiretroviral treatment (ART) in nine health facilities in Ethiopia, South Africa and Zimbabwe. Socio-demographic and clinical data were collected at enrolment. During follow-up, TB symptoms and TPT-side effects were reported to study staff. TPT initiation, completion, and TB diagnoses were abstracted from clinic records.
A subset of participants used an electronic dose monitoring (EDM) box to track completion. Sputum-based microbiological TB investigations were done on all participants at 12-and 24-months post-enrollment.
Results: We enrolled 2,095 participants, mostly female (n=1,489;71.1%), with a median age of 42 years (interquartile range:35-50). 1,828(87.3%) were established on ART and 1,312(62.6%) had no prior TPT history. We identified 1,075 TPT-naïve PLHIV who initiated TPT [3HP:613(57.0%) and 6H/12H:462(43.0%)] within one week of enrolment. Of these, 59/1,075(5.5%) reported TB symptoms. During follow-up, a total of 241 TPT-related side-effects were reported by 156(14.5%) PLHIV [3HP (n=190/613(31.0%)) and 6H/12H (n=51/462(11.0%))].
Treatment interruption was reported by 250(23.3%) PLHIV and most reported forgetting to take TPT (n=90;36.0%). TPT completion was documented for 955(88.8%) and semi-objectively assessed via EDM for 366/734(49.9%).
Fourteen TB diagnoses were made; incidence rate of 0.74(95%CI:0.44-1.25)/100 person-years. Of these, 10(71.4%) were microbiologically confirmed and were all asymptomatic whereas four (28.6%) were clinically diagnosed.

Conclusions: In programmatic settings, TPT was well tolerated, but common treatment interruptions highlighted the need for patient-centered strategies to minimize them. Additionally, objective measurement of TPT completion is needed to address overreporting. Most TB in this TPT-exposed population was asymptomatic, leading to missed diagnoses, suggesting alternative approaches to standard symptom screening towards improving timely diagnosis.

EP15-841-19 TPT refusal rates and barriers among people who are HIV-negative TB contacts aged 5 years and above

L. Mutti,[1] D. Siameka,[1] I. Mwaba,[1] M. Kagujje,[1] P. Mwaba,[1] R. Chimzizi,[2] C. Chanda,[3] M. Mputu,[3] A. Mubanga,[3] K. Zimba,[4] N. Kasese-Chanda,[4] M. Muyoyeta,[1] [1]Center for Infectious Disease Research in Zambia, Tuberculosis, Lusaka, Zambia, [2]USAID LEAP Project, Tuberculosis, Lusaka, Zambia, [3]Ministry of Health Zambia, National Tuberculosis and Leprosy Program, Lusaka, Zambia, [4]United States Agency for International Development (USAID) Zambia, Health Office, TB/HIV, Lusaka, Zambia
e-mail: lilungwe.mutti@cidrz.org

Background: In 2019, the National Tuberculosis program (NTP) updated guidelines recommending TB Preventive Treatment (TPT) among contacts to TB cases ≥ 5 years. However, uptake in this group remained low. In 2024, with support from USAID TBLON project, NTP commenced TPT surge to increase uptake among contacts ≥5 years.

We reviewed data collected from contacts who declined TPT to determine refusal rates and to identify barriers to uptake in this population.

Design/Methods: The surge was conducted between November 2024 and January 2025 in 89 public health facilities across 8 provinces in Zambia. Documented contacts to TB patients diagnosed between June and October 2024 were followed up for TB screening. Those eligible were initiated on TPT, except where TPT was unavailable. Individuals who declined TPT were administered a standard TPT decline form. We report descriptive summary statistics in proportions and frequencies.

Results: Of the 20,103 contacts identified, 19,710 (98.1%) were eligible for TPT and 14,248 (72.3%) were initiated. TPT refusal rate was 2% (462/19,710). Among those who refused, 383(83%) had a documented decline form: 202 (53%) were female, 137 (36%) aged 25-49 years, and 190 (50%) attained secondary level education. A total of 344 (90%) had previously heard about TPT.

Reported reasons for refusal included concern about side effects 125(33%), fear of stigma 75(20%), currently taking other medication 61(16%), low perceived risk of developing TB 48(13%), and lack of understanding of the benefits of TPT 32(8%). Overall, 134(35%) individuals reported being discouraged from taking TPT by family members (89, 66%), friends (30, 22%), neighbors (4, 3%) and church members (4, 3%).

Background and challenges to implementation: In 2019, the Zambia National Tuberculosis and Leprosy Program (NTLP) updated guidelines recommending TB Preventive Treatment (TPT) among HIV-negative TB contacts ≥ 5 years. However, uptake in this group remained low. In 2024, with support from USAID TBLON project, NTLP launched TPT surge to increase uptake among contacts ≥5 years. We reviewed data collected from contacts who declined TPT to determine refusal rates and identify barriers to uptake in this population.

Intervention or response: TPT surge was conducted between November 2024 and January 2025 in 89 public health facilities across 8 provinces in Zambia. Documented contacts of TB patients diagnosed between June and October 2024 were followed up for TB screening. Those eligible were screened and initiated on TPT, except where unavailable. Individuals who declined TPT were administered a standard TPT decline form. TPT decline was defined as refusing to initiate TPT despite receiving TB prevention counselling. We analyzed refusal rates using descriptive summary statistics.

Results/Impact: Of the 20,103 contacts identified, 19,710(98.1%) were eligible for TPT and 14,248(72.3%) were initiated. TPT refusal was 2% (462/19,710) and among those who refused, 383(83%) had a documented decline form: 202(53%) were female, 137(36%) aged 25-49 years, and 190(50%) attained secondary-level education and 344(90%) had previously heard about TPT.

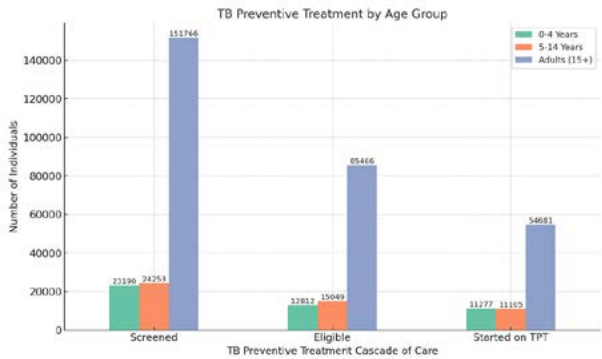
Reported reasons for refusal included concern about side effects 125(33%), fear of stigma 75(20%), currently taking other medication 61(16%), low perceived risk of developing TB 48(13%), and lack of understanding of the benefits of TPT 32(8%). A total of 134(35%) individuals reported being discouraged from taking TPT by family members (89, 66%), friends (30, 22%), neighbors (4, 3%) and church members (4, 3%).

Conclusions: TPT refusal among ≥ 5 contacts was generally low and driven by modifiable factors. Social influences played a role in reduced uptake. Strengthening health education and community engagement is essential to improve TPT acceptance among eligible contacts.

EP15-842-19 Scaling up TB preventive treatment: Expanding coverage to all age groups, including people without HIV

M.T. Rahman,[1] A. Khan,[2] O. Ramis,[3] M.I. Bakker,[4] M. Brouwer,[5] T. Garg,[1] B. Kirubi,[6] J. Creswell,[7] [1]Stop TB Partnership/UNOPS, TB REACH, Geneva, Switzerland, [2]UNOPS, TB, Chicago, United States of America, [3]UNOPS, TB, Barcelona, Spain, [4]KIT Institute, Centre for Applied Spatial Epidemiology, Amsterdam, Netherlands, [5]PHTB Consult, TB, Haren, Netherlands, [6]Stop TB Partnership/UNOPS, TB REACH, Stockholm, Sweden, [7]Stop TB Partnership/UNOPS, Innovations & Grants Team, Geneva, Switzerland
e-mail: toufiqr@stoptb.org

Background and challenges to implementation: Tuberculosis preventive treatment (TPT) traditionally prioritizes children under five and people with HIV, leaving older children (5-14 years) and adults significantly underserved. However, guidelines from the World Health Organization now recommend TPT coverage to all age groups, and expanding TPT to these groups is critical. This review analyzes multi-country implementation outcomes under the TB REACH initiative.
Intervention or response: Between Q1 2023 and Q2 2024, routine programmatic data from 18 TB REACH projects were aggregated and analyzed across 13 countries. Key cascade indicators—number screened verbally for TPT, eligible, and initiated on TPT—were systematically evaluated by three age groups (0-4, 5-14, and 15+ years). Nine projects included testing for TB infection, while others relied on ruling out active TB for eligibility based on in-country guidelines. Chi-square tests were performed to assess the expanded coverage across age groups statistically.



Results/Impact: A total of 199,209 individuals were screened, with notable expansions in older children and adults: 23,190 (11.6%) aged 0-4, 24,253 (12.2%) aged 5-14, and 151,766 (76.2%) adults aged 15+. Of these, 113,327 individuals were identified as eligible for TPT, including significant numbers from older age groups (5-14: 15,049; Adults: 85,466). A total of 77,063 (68%, Range: 11-15,343) initiated TPT, demonstrating effective enrolment strategies in older populations (5-14: 11,105; Adults: 54,681). Projects used TB infection tests in 24,732 individuals and confirmed 6,112 with TB infection. Chi-square analysis showed significant enrolment differences ($p<0.001$), highest in adults, followed by 5–14-year-olds, and lowest in under-fives. Five different TPT regimens were used across the 18 projects, including 3HP (n=17), 6H (n=15), 3HR (n=7), 4R (n=2), and 1HP (n=2).
Conclusions: Expanding TPT beyond traditional target age groups is feasible and achievable through strategic enrolment and tailored approaches. Continued advocacy, strengthened data collection, and ongoing monitoring will be essential to maintain and enhance these outcomes across diverse global settings.

EP15-844-19 Improving systematic TPT prescription using QuantiFERON®-TB Gold test results in Ukraine

V. Shukatka,[1] L. Skoklyuk,[1] T. Ivanenko,[1] A. Bogdanov,[1] M. Germanovych,[1] N. Zherebko,[1] K. Gamazina,[1] G. Dravniece,[1] [1]PATH, STBCEU, Kyiv, Ukraine

Background and challenges to implementation: Ensuring continuous and barrier-free access to tuberculosis infection (TBI) diagnostics and TB preventive treatment (TPT) is essential for reducing both TB transmission and incidence. Until 2021, the primary method for diagnosing TBI in Ukraine was the tuberculin skin test, which was used inconsistently, and access to QFT-Gold test was not widely established. Improved, patient-centered approaches for prescribing and supporting TPT were needed.
Intervention or response: From October 2021–September 2022, the USAID-funded, PATH-led Support TB Control Efforts in Ukraine (STBCEU) project engaged private laboratories to ensure continuous access to QFT-Gold testing for TBI diagnosis in 17 project regions. STBCEU conducted training and mentorship for regional TB specialists on improved TB case detection, rationalization for patient selection, short TPT regimens benefits, TPT referral algorithms, test result tracking, clinical management, clinical mentoring on interpreting QFT-Gold test results, patient management strategies, and TPT prescription protocol establishment, especially for TPT in QFT-negative persons older than five.
Results/Impact: From October 2021–December 2024, 11,613 individuals at high risk for TB were referred for QFT-Gold testing. Among the 9,836 tested, 1,976 (20.1%) had positive results. TPT was prescribed to 1,922 individuals, of whom 1,503 tested positive with the QFT test, while 419 tested negative.
The percentage of negative QFT patients over 5 years old receiving TPT declined from 18% to 0.4%, increasing to 4.3% due to testing initiation in 5 new regions and currently remains at 2.4%.

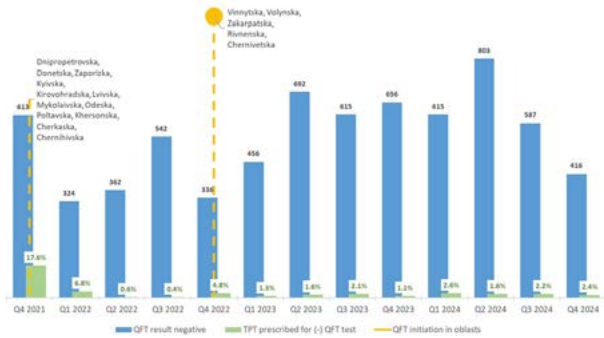


Figure 1: Percentage for TPT prescription for people above 5 years old with negative QFT test

Conclusions: The STBCEU-supported introduction of QFT-Gold testing significantly improved TBI diagnostics and TPT access for high-risk populations in Ukraine. Enhancing clinical decision-making and reduction of inappropriate TPT prescriptions has enabled a more effective, patient-centered approach to TB control. Continued expansion of testing and healthcare professional training is vital to sustain positive outcomes and further reduce TB rates.

EP15-846-19 Attrition among people with TB from contact screening until TB preventive therapy initiation: Programmatic challenges and bottlenecks in high-burden TB settings

S. Faisal,[1] A. Rab,[2] K. Farough,[1] R. Farrukh,[1] G. Haider,[1] M. Shoaib,[1] F. Irfan,[3,4] [1]Greenstar Social Marketing, TB Program, Islamabad, Pakistan, [2]Greenstar Social Marketing, Health Services, Karachi, Pakistan, [3]Michigan State University, Department of Neurology & Ophthalmology, College of Osteopathic Medicine, Institute of Global Health, East Lansing, United States of America, [4]Manhattan Strategy Group, Health, Bethesda, United States of America
e-mail: sobiahina@gmail.com

Background and challenges to implementation: Provision of TB preventive treatment (TPT) to infected and exposed individuals is a key strategy for halting the TB epidemic. Despite the aggressive programmatic roll out of TPT across the globe and availability of user friendly 3HP regimen, the uptake is still 21% among the estimated eligible households at global level, and 3.2% in Pakistan.
This study was conducted to determine the attrition of household contacts of bacteriologically positive (B pos) TB patients before TPT initiation at different stages of programmatic implementation.
Intervention or response: This cross-sectional study analysed the TPT programmatic implementation data of Public Private Mix models (PPM) in 28 districts of Pakistan, from November 2024 till February 2025. The TPT implementation included verbal screening of household (HH) contacts of bacteriologically confirmed TB patients followed by further screening through x ray to rule out TB disease. TPT was offered to all eligible and TB disease-free HH contacts through general physician clinic, large private hospitals, non-government organization (NGO) led hospitals and parastatal hospitals.
Results/Impact: During the study period, among 12 559 bacteriologically confirmed TB patients, 50 172 HH contacts (4 per index case) were identified. Among these, 27237 (54%) were verbally screened by field team, 957 (3.5%) were identified as TB presumptive, of these 396 (41%) were diagnosed with TB. Among the 26280 HH contacts who did not have TB symptoms, 5861 (22.3%) were further screened through x ray, among which 5683 (97%) started TPT. Pre-treatment attrition of 46% and 77.7% was observed at the step of verbal screening and x ray screening to rule out active TB disease.

Programmatic stages		GP model	Large private hospitals	NGO led hospitals	Parastatal hospitals	Total
B pos TB patients	n	8479	3640	178	262	12559
HH contacts	n	32846	15411	720	1195	50172
HH contacts verbally screened	n (%)	20488 (62%)	5937 (39%)	583 (81%)	229 (19%)	27237 (54%)
Presumptive TB among screened	n (%)	644 (03%)	289 (05%)	7 (01%)	17 (07%)	957 (3.5%)
TB patients diagnosed among presumptive	n (%)	248 (39%)	134 (46%)	5 (71%)	9 (53%)	396 (41%)
Eligible for TPT after verbal screening	n	19844	5648	576	212	26280
X ray screened to rule out disease	n (%)	2820 (14%)	2769 (49%)	160 (28%)	112 (53%)	5861 (22%)
HH contacts started TPT among screened	n (%)	2673 (95%)	2750 (99%)	156 (98%)	104 (93%)	5683 (97%)

Conclusions: TPT attrition is mainly observed at two steps; contacts screened by field team, and x ray screening to rule out disease. These programmatic challenges and barrier in access to TPT must be addressed through strategic interventions.

EP15-847-19 Identifying missed opportunities in tuberculosis preventive treatment care cascade: Analysis of programme data from Maharashtra, India

A. Mundra,[1] T. Bhatnagar,[2] M. Das,[3] S. Sangale,[4] H. Patil,[5] A. Raut,[1] A. Kadu,[6] R. Paradkar,[7] S. Gupta,[1] B. Garg,[1]
[1]Mahatma Gandhi Institute of Medical Sciences, Community Medicine, Wardha, India, [2]ICMR National Institute of Epidemiology, School of Public health, Chennai, India, [3]FIND, Monitoring and evaluation, New Delhi, India, [4]Public health department, Maharashtra, State TB office, Pune, India, [5]Public Health Department, Maharashtra, District TB Office, Wardha, India, [6]World Health Organization, NTEP technical support network, Pune, India, [7]Zila Parishad, Public Health Department, Wardha, India
e-mail: anuj.mundra87@gmail.com

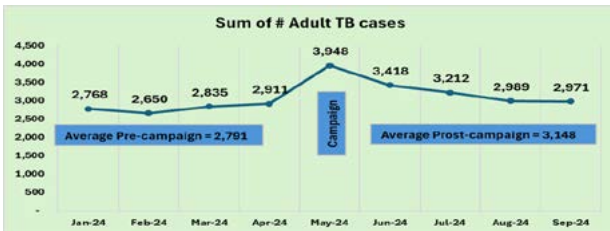
Background: Tuberculosis infection is a condition when a person harbours the bacilli without having signs of active disease. In India, approximately 70% of household contacts of people with pulmonary tuberculosis have the infection. The national tuberculosis elimination programme recommends preventive treatment to household contacts of all people with pulmonary tuberculosis after ruling out active disease. Maharashtra is one of the bigger states in India with high tuberculosis burden.
Design/Methods: We analyzed the state programme data to describe the tuberculosis preventive treatment care cascade for household contacts of all notified people with pulmonary tuberculosis for the year 2023 in Maharashtra.
Results: Contact tracing was done for 84% of the 1,33,167 notified people with pulmonary tuberculosis. A total of 4,06,291 household contacts were enlisted out of whom 3,86,224 (95%) were screened for symptoms of tuberculosis. 185502 (45%) household contacts were listed as eligible for tuberculosis preventive treatment, of whom 101325 (55%) were initiated on tuberculosis preventive treatment. While 41,480 (41%) of those initiated on treatment successfully completed it, treatment outcomes were not recorded for around 57,191 (56%) of them. Tuberculosis preventive treatment completion as well as recording of treatment outcomes was lesser for 6H regimen, among contacts of those seeking care from private sector and clinically diagnosed people with tuberculosis.
Conclusions: Reasons for losses from the cascade need to be identified and addressed. Addressing missing data will further help in understanding programme performance. Frontline workers may be trained and utilized to capture real time data using simpler tools.
Aligning the annual India TB report with the guidelines by including household contacts of all notified persons with pulmonary tuberculosis instead of only microbiologically positive ones may improve treatment outcome recording among clinically diagnosed cases.
The capacity building, monitoring, and supportive supervision need further strengthening to improve the provision of tuberculosis preventive treatment care.

EP16 Finding the missing people with TB: Lessons learned from and across Nigeria

EP16-848-19 Unintended gains: How childhood TB awareness campaigns boosted adult TB case finding

P Alu,[1] O Daniel,[2] M Pedro,[1] R Agbaje,[3] C Mensah,[4] P Dakum,[3] R Eneogu,[5] S Labaran,[6] [1]Institute of Human Virology Nigeria, Strategic Information, Lagos, Nigeria, [2]Institute of Human Virology Nigeria, Programs, Lagos, Nigeria, [3]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [4]Institute of Human Virology Nigeria, Office of the COO, Abuja, Nigeria, [5]United States Agency for International Development (USAID), HIV/AIDS & TB Office, Abuja, Nigeria, [6]National Tuberculosis & Leprosy Control Programme, Federal Ministry of Health, Abuja, Nigeria
e-mail: paul.ozed96@gmail.com

Background: Tuberculosis (TB) remains a significant public health challenge globally, particularly in high-burden countries like Nigeria. While targeted interventions often focus on specific population groups, there is growing evidence that awareness campaigns designed for one demographic can have broader, unintended benefits. In May 2024, a targeted Childhood TB Awareness Campaign was implemented, aiming to improve awareness, diagnosis, and treatment of TB in children under 15.
However, post-intervention data revealed an unexpected outcome—an increase in TB case detection among adults during the same period.
This study explores the secondary impact of a Childhood Tuberculosis (TB) Awareness Campaign on non-childhood TB case finding in Southwestern Nigeria in 2024.
Design/Methods: Using data from TB LON 3 project implemented by Institute of Human virology Nigeria (IHVN) with the support from USAID implemented in 4 Southwestern states of Lagos, Ogun Osun and Oyo State of Nigeria TB notification data were analyzed four months before and after the campaign.
Results: Findings showed a 41% increase in adult TB case notification on the month of campaign from an average of 2,791 to 3,948 cases and 13% from 2,791 to and average case of 3148 cases post-campaign. Many adult cases were identified after individuals attended health facilities with their children or engaged in community-based TB education activities.



The campaign's widespread messaging on TB symptoms and treatment reduced stigma and prompted more adults to seek testing. Community involvement and caregiver participation were key drivers of this ripple effect.
Conclusions: Although designed for children, the awareness campaign had a positive spillover effect on adult TB detection. This underscores the potential of child-focused interventions to benefit broader populations.
Future TB programs should integrate family-centered and community-wide messaging to maximize impact. Leveraging such unintended outcomes can strengthen TB case finding and support Nigeria's goal of reducing TB burden across all age groups.

EP16-849-19 Optimizing tuberculosis (TB) screening services using innovative strategies: Insights from TB LON 1&2 project implementation in Bauchi State, Nigeria

H. Ibrahim,[1] M. Tukur,[2] S. Mafwalal,[3] G. Zephaniah,[4] M. Bajehson,[2] B. Odume,[5] C. Ogbudebe,[6] O. Chukwuogo,[5] Y. Ahmed,[7] D. Sulaiman,[8] [1]KNCV Nigeria, Strategic Information, Bauchi, Nigeria, [2]KNCV Nigeria, Programs/Technical, Kano, Nigeria, [3]KNCV Nigeria, Programs/Technical, Bauchi, Nigeria, [4]KNCV Nigeria, Strategic Information, Kano, Nigeria, [5]KNCV Nigeria, Programs/Technical, Abuja, Nigeria, [6]KNCV Nigeria, Strategic Information, Abuja, Nigeria, [7]Bauchi State Agency for Control of Malaria HIV, Tuberculosis Leprosy, Monitoring and Evaluation, Bauchi, Nigeria, [8]Bauchi State Agency for the Control of Malaria HIV, Tuberculosis Leprosy, Programs/Technical, Bauchi, Nigeria
e-mail: habusafwan@gmail.com

Background and challenges to implementation: Tuberculosis remains a public health concern in Nigeria, particularly in rural underserved communities, where undiagnosed TB cases continue to pose a major challenge to TB prevention and care due to poor health seeking behaviour and limited access to healthcare services especially in remote and hard-to-reach populations. These undiagnosed TB cases continue to contribute to increased missing TB cases gap in Nigeria and globally.
We present results of innovative strategies from the TB LON 1&2 project in Bauchi state Nigeria targeted at optimizing TB screening services to find the missing TB cases.
Intervention or response: KNCV Nigeria, adopted innovative active TB case finding strategies aimed at bolstering TB control efforts under TB LON 1&2 project across the twenty LGAs in Bauchi state. These included Intensified Case Finding activities in public and private facilities using dedicated TB screening officers at service delivery points; Patent medicine vendors and Standalone laboratories engagement, Contact Investigation, Community TB screening in schools, facilities and hard to reach communities using EWORS, ACF in Special Populations and Active case finding using a mobile diagnostic unit, the wellness on wheels truck.
Results/Impact: Between June 2020 and December 2024, a total of 4,113, 856 persons were screened (98% screening coverage), 307,297 (7%) presumptive were identified with (97%) of them evaluated. A total of 24,661 TB cases (8%) were diagnosed, of this number 1710(7%) were children and 24,550 (100%) were placed on treatment across all the interventions.

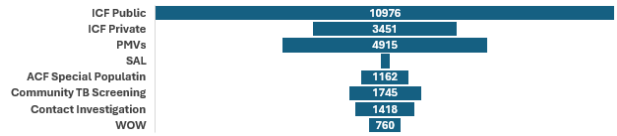


Fig1: TB Case contribution by Intervention.

Since introduction of the project in Bauchi state, a consistence increase in TB case notification has been observed from 4430 in 2020 to 14083 in 2024 representing a 318% increase.
Conclusions: The project has successfully demonstrated an innovative model to improve TB case finding in poor communities and hard-to-reach populations, thereby improving the overall TB case notification in the State.

EP16-850-19 Optimizing TB active case finding in Nigeria: Comparative analysis of screening models across four States

M. Yashim-Ankut,[1] O. Adebayo,[1] E.J. Ikeh,[1] M. Osime,[1] T. Hosle,[1] O. Olupitan,[1] C. Mensah,[2] P. Dakum,[3] E. Ubochioma,[4] C. Adesigbin,[4] J. Kimeu,[5] M. Zamzu,[5] Global Fund NTHRIP Team [1]Institute of Human Virology Nigeria (IHVN), Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria, [2]Institute of Human Virology Nigeria (IHVN), Office of the COO, Abuja, Nigeria, [3]Institute of Human Virology Nigeria (IHVN), Office of the CEO, Abuja, Nigeria, [4]National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Public Health Department, Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Nigerian Country Team, Geneva, Switzerland
e-mail: myashimankut@ihvnigeria.org

Background and challenges to implementation: Nigeria's TB Active Case Finding (ACF) strategies vary widely across states in scope and efficiency. With limited public health resources, understanding which models deliver the highest yield is critical for national program optimization. This paper compared TB ACF implementation models in four Nigerian states—Kaduna, Kogi, Niger, and the Federal Capital Territory (FCT)—and identified approaches that balance scale, efficiency, and resource use.
Intervention or response: A retrospective review of ACF data from January to December 2024 was conducted. Data from each state were analyzed for total individu-

als screened, presumptive cases evaluated, TB diagnoses made, and number of community TB health workers (CTHWS) deployed. Descriptive statistics and inferential tests (ANOVA, Pearson's correlation, and linear regression) were performed to assess inter-state differences and predictors of diagnostic yield.

Results/Impact: Four distinct models emerged:

1. Kaduna (High-Volume High-Yield): Screened 226,133 individuals and diagnosed 11,848 TB cases (yield: 9.3%). Strong correlation (r = 0.95) between presumptive evaluations and diagnoses, with quarterly improvements and an average of 115 CTHWS.
2. Kogi (Precision-Targeted): Highest diagnostic efficiency (10.2% yield), screening 63,382 and diagnosing 5,029 cases with a mean of only 48 CTHWS.
3. Niger (Inefficient Scale): Despite screening 229,632 individuals, only 5,083 cases were diagnosed (yield: 7.6%), with a consistent 150 CTHWS indicating possible inefficiencies ($p < 0.01$ vs. Kaduna/Kogi).
4. FCT (Under-Resourced): Screened 23,824 and diagnosed 820 cases (7.9% yield), hampered by a sharp workforce decline from 226 to 35 CTHWS.

ANOVA confirmed significant differences in yield across states ($F = 9.87$, $p < 0.01$). Presumptive evaluations predicted 90% of diagnostic outcomes ($R^2 = 0.90$).

Conclusions: Kogi's precision model offered the highest efficiency, while Kaduna's scale model achieved the greatest absolute yield. Findings support integrated strategies that balance scale with targeting for effective ACF implementation.

EP16-851-19 Revolutionizing tuberculosis case finding in rural Nigeria: Unleashing the power of digital innovation and community engagement

C. Dimkpa,[1] B. Odume,[2] O. Chukwuogo,[2]
[1]KNCV Nigeria, Community ACF, Bauchi, Nigeria,
[2]KNCV Nigeria, Programmes, Abuja, Nigeria
e-mail: dimkpababington@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a significant public health challenge in Nigeria, with many cases going undetected. This study compares the roles of health facility-based and community-based active case-finding (ACF) strategies in increasing TB yield in Bauchi State, Nigeria. We introduce EWORS (Early Warning and Response System), a digital tool/guidance system, to determine key hotspots for screening itineraries in rural communities.

Intervention or response: The study employed a mixed-methods approach, combining facility-based TB surveillance with community-based ACF activities. We utilized EWORS to identify high-risk communities (hotspots) for TB transmission. For ACF activities, the Wellness on Wheels (WOW) mobile diagnostic truck was deployed to Tudun Wadan Daniya, a high-risk community in Bauchi metropolis. Mass sensitization, community mobilization, and collaborative efforts with local healthcare providers were implemented to enhance TB case finding.

Results/Impact: The findings demonstrate that community-based ACF activities, strengthened by facility-based TB surveillance and digital tools like EWORS, can significantly improve TB case detection. In two weeks, we screened 1488 individuals, identified 71 presumptive TB cases, and diagnosed 39 new TB cases (21 bacteriologically confirmed and 18 clinically diagnosed). All diagnosed cases were enrolled on treatment.

Attendees	Screened for TB	Presumptive identified & Evaluated	Diagnosed & notified TB cases	Bacteriological	Clinical	Enrolled on treatment
1488	1488	71	39	18	21	39

Conclusions: This study highlights the complementary roles of facility-based and community-based ACF strategies in enhancing TB case finding in rural Nigeria. The integration of digital tools like EWORS and community-based interventions can optimize TB case detection, particularly in high-risk communities. Our findings inform the development of innovative, community-focused TB control programs in resource-constrained settings.

EP16-852-19 Community-driven approach to improve tuberculosis case detection: Experience from AMAC'A', Federal Capital Territory, Nigeria

O. Ekwueme,[1] D. Bello,[2] D. Hananiya,[3] A. Okagbue,[1] O. Sesere,[1] S. Dimang,[1] O. Akaniro,[1] E. Ubochioma,[1] V. Ombeka,[1] C. Adesigbin,[1] S. Labaran,[1] [1]Federal Ministry of Health, Public Health Department, Abuja, Nigeria, [2]FCT Health and Human Services Secretariat, AMAC Area Council, Abuja, Nigeria, [3]World Health Organisation, North Central Zonal Office, Minna, UCN/Field Presence Cluster, Minna, Nigeria
e-mail: obiomaekwueme@gmail.com

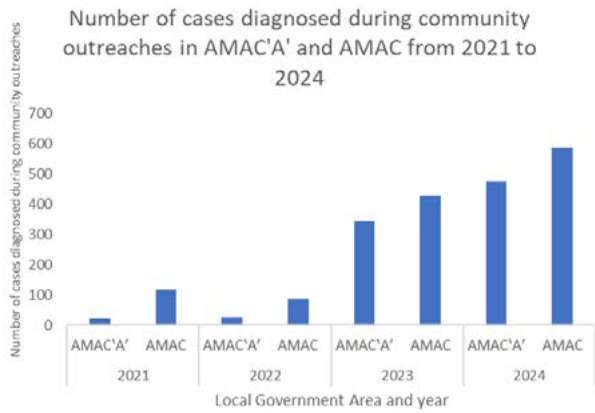
Background and challenges to implementation: Tuberculosis (TB) remains a leading public health concern globally. Without treatment, 50% of individuals with active TB may die. Nigeria ranks sixth among countries with high TB burden and holds the highest TB burden in Africa. In 2024, of an estimated 499,000 TB cases, only 405,000 were notified, leaving a gap of 94,000 undetected cases and sustaining community transmission of TB. Despite ongoing efforts, TB treatment coverage in the Federal Capital Territory (FCT) was 24% in 2024.

Intervention or response: To address the low TB case detection rate, the TB Local Government Supervisor (TBLS) of Abuja Municipal Area Council (AMAC)'A' implemented a community-based intervention. AMAC, one of six area councils in the FCT, is subdivided into five admin-

istrative units. On resumption of duty in 2022, the TBLS in AMAC'A' recruited and trained 25–30 unemployed graduates quarterly as Community Volunteers (CVs). The CVs were deployed for monthly house-to-house sensitisation and community outreaches based on hotspot mapping.

Each outreach team comprises healthcare workers of various cadres. Outreach activities include: health education, basic clinical services, sputum collection for GeneXpert testing, and contact investigation (CI). CVs receive mentoring, refresher trainings, and incentives to maintain motivation.

Results/Impact: In 2024, 27 community outreaches were conducted in AMAC'A'. In this same year, there were 3,463 presumptives and 478 TB cases diagnosed (56% were males-269/478 and 91% were adults-436/478). CI linked 403 index cases to 1,673 contact persons and 1,224 eligible contacts were initiated on TB Preventive Therapy (TPT). In AMAC'A', the CV-led strategy contributed 81% (478/587) of TB cases detected during community outreaches in AMAC and AMAC contributed to 69% (2540/3,679) of the TB cases notified in FCT.



Conclusions: The AMAC'A' CV model boosted TB case detection and TPT uptake. This scalable approach demonstrates the impact of grassroots involvement in bridging TB notification gaps.

EP16-853-19 Boosting tuberculosis case finding in Nasarawa state, Nigeria through strong partnerships with community-based organizations and community stakeholders

C. Osakwe,[1] S. Ovye,[2] Q. Ogbuji,[3] S. Isah,[1] O. Odume,[1] K. Abdulazeez,[1] [1]Initiative for Prevention and Control of Diseases, Tuberculosis Control, Mararaba, Nigeria, [2]State Ministry of Health, Lafia, Nasarawa State, Tuberculosis and Leprosy Control, Lafia, Nigeria, [3]Association for Reproductive and Family Health, TB/HIV Unit, Abuja, Nigeria
e-mail: chijiosakwe@yahoo.com

Background and challenges to implementation: Tuberculosis (TB) case finding in Nasarawa State, Nigeria has remained stable over the years even though less than 70% of the TB cases in the State has been identified. This non-increase in case finding in the state is mainly because of the concentration of TB case finding activities to health facilities only.

Intervention or response: To boost TB case finding in the State, Initiative for Prevention and Control of Diseases (IPCD) with funding from the Global fund embarked on aggressive TB activities in communities in all the 13 local government areas (LGAs) of the State. Between 2021 and 2024, a total of 10 community-based organizations (CBOs) and 238 community TB workers (CTWs) were mobilized to carryout TB awareness campaigns, house to house case search and contact investigation of diagnosed TB cases in 2,067 communities in the State.

Results/Impact:

	2021	2022	2023	2024	Total
Number communities visited	215	343	507	1002	2067
Number community members screened	44800	84744	61309	108738	299592
Number presumptive TB	7356	19039	23557	19674	69626
Number TB cases diagnosed	675	1765	2234	1652	6326
Number TB cases started on treatment	675	1721	2194	1652	6242
% Contribution to State Case Finding	16%	32%	30%	21%	25%

TB Case Finding through Community TB Active Case Finding Efforts, Nasarawa State, Nigeria, 2021 - 2024.

The aggressive TB active case finding activities in the communities resulted in the screening of 299,592 community members and the identification of 69,626 of persons with presumptive TB, with 6,326 TB cases diagnosed and 6,242 cases commenced on TB treatment. These cases represent a 25% contribution of TB cases from targeted TB active case finding in the communities over a 4-year period. This contribution has resulted in the increase of TB cases in the State from 4,261 in 2021 to 7,687 in 2024.

Conclusions: Engagement of CBOs to saturate communities with aggressive TB active case finding activities can result in the detection of TB cases than would have been missed from routine passive TB case finding activities.

EP16-854-19 Early experiences from the large-scale deployment of portable digital X-rays for active TB screening in Nigeria

M. Sheshi,[1] E. Chukwu,[1] K. Ekpen,[1] O. Sesere,[2] E. Ubochioma,[2] C. Ogbudebe,[1] O. Chukwuogo,[1] B. Odume,[1] [1]KNCV Nigeria, Programs, Abuja, Nigeria, [2]National Tuberculosis Leprosy and Buruli Ulcer Control Program, Gran Management Unit, Abuja, Nigeria
e-mail: msheshi@kncvnigeria.org

Background and challenges to implementation: Nigeria has made significant strides in TB control in the past 5 years, with treatment coverage improving from 27% to 70% within this period, with concomitant reduction in TB mortality rates. In 2021, with funding from USAID, Nigeria piloted the use of ten portable digital X-rays (PDX) for TB screening with impressive results, and this has significantly improved TB case finding particularly in remote areas with limited healthcare infrastructure and expertise. With support from Global Fund, an additional 370 PDX platforms has been procured for TB screening across all states in Nigeria.
Intervention or response: KNCV Nigeria supports the NTP to ensure effective deployments of these procured platforms. Adequate planning with all relevant stakeholders, development of a National guideline for the use of PDX platforms, trainings and efficient monitoring of the deployed platforms were carried out to ensure optimal use of these procured units. Field implementation of these PDX platforms commenced in October 2024, and this has been a learning process for such large-scale deployments, with improvements made in the implementation.
Results/Impact: Of the 370 procured PDX platforms, 190 platforms were prioritized for TB case finding in hotspot communities and hard to reach locations with minimal access to TB diagnostic services. Within the firs six months of implementation, a total of 154,056 persons have been screened for TB using these PDX platforms, with 3,321 persons diagnosed with TB.

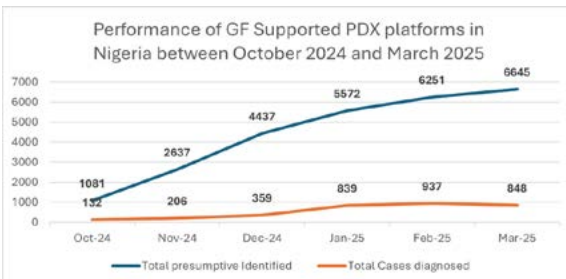


Figure-1: Presumptive and TB cases identified by PDX in Nigeria between October 2024 and March 2025.

Conclusions: The early experience using the PDX platforms in Nigeria has been rewarding as it has proven to be more efficient, sensitive, and specific than the symptom screening, with an average Number needed to screen (NNS) of 48 and number needed to test of 8. This massive deployment is a critical step toward improving TB prevention and care in the Nigeria

EP16-855-19 Experiences with chest X-ray mobile vans and artificial intelligence software in TB screening and diagnosis at hard-to-reach areas in Lagos Nigeria

T. Osatuyi,[1] E. Chukwu,[2] M. Sheshi,[2] O. Udunze,[1] B. Odume,[2] O. Sokoya,[3] [1]KNCV Nigeria, Tuberculosis, Lagos, Nigeria, [2]KNCV Nigeria, Tuberculosis, Abuja, Nigeria, [3]Lagos state Ministry of health, Directorate of Disease control, Lagos, Nigeria
e-mail: otaiwo@kncvnigeria.org

Background and challenges to implementation: WHO recommends chest X-ray (CXR) with artificial intelligence (AI) software interpretation in TB screening to improve TB case notification. In Lagos, CXR-AI has been extensively used in both public health facilities level and community TB screening, however, limited data exists on its use of mobile X-ray vans at the hard-to-reach areas in Lagos. This study investigates the utilization of CXR with CAD software within targeted outreach programs as a cost-effective strategy for early active TB case identification, particularly in hard-to-reach LGAs in Lagos like Ojo, Epe and Badagry LGAs.
Intervention or response: KNCV Nigeria supported the use of 3 mobile X-rays vans equipped with CAD software as part of the strategies for active TB case finding at the hard-to-reach LGAs. These machines were seamlessly integrated into targeted outreach programs, with screening algorithms devised to incorporate CXR alongside symptom screening for all outreach attendees. Quarterly outreaches were conducted across three designated LGAs. Clients above threshold scores of 40 were presumptive for TB, submitted sputum samples for microscopy and Xpert testing and were reviewed by clinicians, according to national guidelines.
Results/Impact: 10,396 people were screened for TB from January to December 2024, with 1,513 being presumptive for TB, yielding 328 (22% case yield) TB cases with 63% (206/328) clinically diagnosed. 314(96%) pulmonary TB cases were notified during the implementation period, being 42% higher than those notified from January to December 2023 (181 TB cases). Strong coordination with Community stakeholders and partners was key to successful implementation. Challenges included low level of logistic supports and limited funding and thus leading to seldom visits of mobile vans to hard-to-reach LGAs unlike frequent visits to proximity LGAs.
Conclusions: Use of CXR-AI was well integrated in hard-to-reach areas settings and seemed to have contributed to improved TB notification. Further interventions should consider a maximum funding for routine screening at hard-to-reach areas

EP16-856-19 Sustained impact of active community case finding on tuberculosis detection and notification trends in Benue State, Nigeria: A 13-year comparative analysis (2010–2023)

O. Odume,[1] C. Nwafor,[2] A. Meka,[2] C. Eze,[3] S. Tanze,[4] D. Ugo,[1] T. Adetiba,[5] O. Olupitan,[5] E. Ubochioma,[6] O. Chijioke- Akaniro,[7] J. Kimeu,[8] A. Reilly,[9] [1]REDAID-NIGERIA, Monitouring, Evaluation, Accountability and Learning (MEAL), Makurdi, Nigeria, [2]REDAID-NIGERIA, Programmes, Enugu, Nigeria, [3]REDAID-NIGERIA, Monitouring, Evaluation, Accountability and Learning (MEAL), Enugu, Nigeria, [4]REDAID-NIGERIA, Programmes, Makurdi, Nigeria, [5]Global Fund N-THRIP, Institute of Human Virology, Nigeria (IHVN), Programmes, Abuja, Nigeria, [6]National TB and Leprocy and Buruli Ulcer Control Programme Nigeria, Programmes, Abuja, Nigeria, [7]National TB and Leprocy and Buruli Ulcer Control Programme Nigeria, Monitouring and Evaluation, Makurdi, Nigeria, [8]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Programmes, Geneva, Switzerland, [9]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Monitouring and Evaluation, Geneva, Switzerland
e-mail: oluchi.f.odume@gmail.com

Background and challenges to implementation: Nigeria remains a high-burden tuberculosis (TB) country, with persistent gaps in case detection. To address this, Active Community Case Finding (ACF) was introduced in Benue State in 2010 to complement Passive Case Finding (PCF) and improve early TB diagnosis. However, the long-term impact and scalability of ACF remain underexplored. This study evaluates ACF's effectiveness over 13 years, focusing on implementation challenges and outcomes.

Intervention or response: A retrospective review of TB notification data (2005–2023) from the Benue State Tuberculosis and Leprosy Control Program was conducted. The study was divided into pre-ACF (2005–2009), early ACF (2010–2017), and advanced ACF (2018–2023). Quantitative data from 2013 to 2023 were analyzed using Join-point regression to assess trends.

The study also considered high-risk groups, such as HIV-positive individuals, and the scalability of the ACF approach.

Results/Impact: Prior to ACF implementation, TB detection rates stagnated below 30 per 100,000, missing the national target. Following ACF's introduction, TB notifications increased by 50.47%, from 4,652 cases in 2018 to over 7,000 in 2023. Regression analysis revealed a significant upward trend ($p<0.05$), especially in high-burden communities like urban slums. While HIV co-infected individuals benefit from integrated screening in health facilities, ACF further identified undiagnosed TB cases in these populations. Improvements in program delivery during the advanced ACF phase (2020–2023) amplified these results.

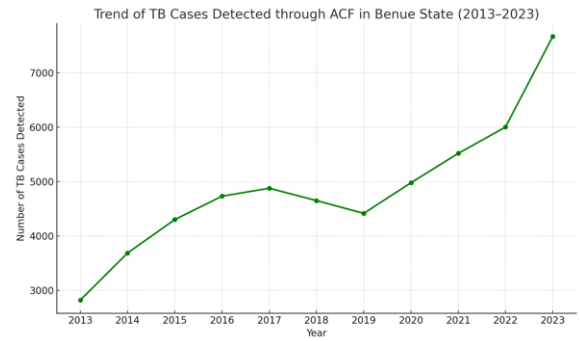

Figure 1.0: A graph showing notification trends from 2013–2023, with steady increases during the early ACF phase, a dip in 2018–2019, and a strong upward trend in the advanced phase.

Conclusions: ACF significantly improved TB case detection in Benue State. To sustain these gains, integrated co-funding, community-led surveillance, and innovations like AI-assisted screening are crucial. Lessons from Benue provide insights for TB control strategies in similar settings.

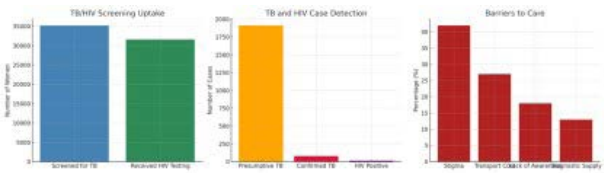
EP16-857-19 Eliminating missed diagnoses: Expanding TB/HIV testing for pregnant women in high-burden communities in Katsina State, Nigeria

P. Batur,[1] R. Abi,[1]
[1]KNCV Nigeria, Programme, Katsina, Nigeria

Background and challenges to implementation: Tuberculosis (TB) and HIV remain persistent public health challenges in Katsina State, Nigeria. Pregnant women are particularly vulnerable, facing elevated risks of co-infection, maternal complications, and vertical transmission. Despite availability of TB and HIV services within antenatal care (ANC), multiple barriers—including stigma, financial hardship, and limited diagnostic infrastructure—contribute to missed diagnoses. In response, the KNCV Community Public-Private Mix (CPPM) grant, supported by the Global Fund, implemented community-based active case finding (ACF) to strengthen TB and HIV screening, early diagnosis, and care linkage among pregnant women in high-burden communities.

Intervention or response: A combined retrospective-prospective cohort design was used to evaluate the program's impact. Community health workers (CHWs) conducted household visits, symptom assessments, and mobile HIV testing. TB screening employed symptom checklists, chest X-rays, and GeneXpert MTB/RIF testing. Data were gathered on screening uptake, positivity rates, treatment initiation, and barriers to service access. In-depth interviews with participants explored perceptions of community screening and health-seeking behaviors.

Results/Impact: Of the 35,225 pregnant women screened for TB, 31,612 (89%) also received HIV testing. Among them, 1912 (5%) had presumptive TB and 78 were confirmed TB-positive. HIV testing identified 14 positive cases (0.28%), some of whom had TB co-infection. Linkage to treatment was high: 94% of TB-positive and 100% of HIV-positive women were enrolled in appropriate care pathways. Reported barriers included stigma (42%), transport costs (27%), lack of awareness (18%), and insufficient diagnostic tools (13%).



Conclusions: Community-based TB/HIV screening significantly enhances early case detection and maternal health outcomes in underserved settings. Integrating mobile diagnostics and ANC-linked screening, while addressing social barriers, is critical. Government and partner-led expansion of this approach will be vital for sustaining gains and reducing maternal TB/HIV burden in Nigeria.

EP16-858-19 One goal, many paths: Transforming TB case finding through multi-sector approaches in Nigeria

O. Daniel,[1] A. Agbaje,[2] C. Mensah,[3] P. Dakum,[3] C. Uzoigwe,[1] M. Pedro,[4] B. Olaniyi,[1] A. Alege,[5] R. Eneogu,[6] D. Nongo,[6] S. Labaran,[7] O. Akaniro,[7] [1]Institute of Human Virology Nigeria, Prevention Care and Treatment, Ikeja, Nigeria, [2]Institute of Human Virology Nigeria, Office of the CEO, Ikeja, Nigeria, [3]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [4]Institute of Human Virology Nigeria, Strategic Information, Ikeja, Nigeria, [5]Society for Family Health, Community, Ikeja, Nigeria, [6]United States Agency for International Development, HIV/AIDS & TB Office, Abuja, Nigeria, [7]National Tuberculosis, Leprosy and Buruli Ulcer Control Program, Public Health, Abuja, Nigeria
e-mail: odaniel@ihvnigeria.org

Background: Achieving TB epidemic control in high-burden countries like Nigeria requires intensified case-finding through diversified service delivery models. The USAID TB-LON 3 Project implemented a multi-pronged strategy across community, public facility, and private-sector platforms in Lagos, Ogun, Oyo, and Osun States to boost TB case detection.
Design/Methods: We analyzed TB case notification data across three key intervention areas—Community Active Case Finding (ACF), Intensified Case Finding in Public Facilities, and Public-Private Mix (PPM)—from 2021 to 2024, focusing on year-on-year performance and contributions to overall case notification increaments.
Results: Total TB notifications rose from 21,991 in 2021 to 40,690 in 2024, marking an 85% increase.

- **Community ACF** contributed significantly with a 56% rise (from 7,808 to 12,158), reflecting the success of targeted outreaches in underserved areas, including IDP camps, urban slums, and high-risk special populations.
- **Public Facility interventions** recorded a 67% increase (from 10,752 to 17,983), highlighting the impact of health worker mentorship, screening intensification, and optimized diagnostic linkages.
- **PPM interventions** achieved the most dramatic growth with a 207% increase (from 3,431 to 10,549), showcasing the effectiveness of private-sector engagement, especially among the formal and informal private providers.

Period	Year 2021 Notification	Year 2022 Notification	Year 2023 Notification	Year 2024 Notification	% Increase in Notification
ACF Community	7,808	8,054	10,158	12,158	56%
Public Facility	10,752	13,475	13,455	17,983	67%
Private Facilities	3,431	7,625	8,980	10,549	207%
Total	21,991	29,154	32,593	40,690	85%

Conclusions: The strategic expansion of TB services across community, public, and private platforms significantly improved TB case detection in Southwest Nigeria. Each modesl demonstrated unique strengths—community ACF expanded reach to hidden populations, public facility interventions improved service quality, and PPM unlocked new case pools. These results affirm the importance of integrated, multi-platform approaches for sustainable TB service scale-up and epidemic control.

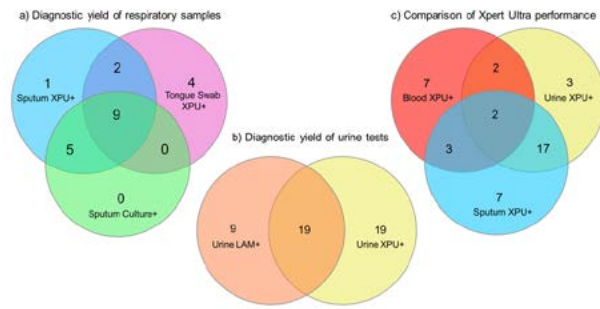
EP17 Improving diagnostic yield for TB: Methods and innovations

EP17-859-19 High diagnostic yield of sputum and non-sputum tuberculosis tests in an emergency centre in Cape Town, South Africa

A. van der Westhuizen,[1] S. Minnies,[1] S. Shologu,[1] D.L. Mbu,[1] R. Shing,[2] C. Kibamba,[3] D.J. van Hoving,[4] R. Nathavitharana,[5] G. Theron,[1] [1]Stellenbosch University, Division of Molecular Biology and Human Genetics, Cape Town, South Africa, [2]Boston University, Department of Emergency Medicine, Boston, United States of America, [3]Stellenbosch University & Khayelitsha Hospital, Division of Emergency Medicine, Cape Town, South Africa, [4]Stellenbosch University, Division of Emergency Medicine, Cape Town, South Africa, [5]Beth Israel Deaconess Medical Center & Harvard Medical School, Division of Infectious Diseases, Boston, United States of America
e-mail: drananjavdw@gmail.com

Background: Undiagnosed tuberculosis (TB) and mortality is common in people in emergency centres in South Africa, especially amongst people living with HIV (PLHIV). Prospective data on the yield of non-sputum tests are needed, including incremental benefits in the context of strengthened sputum collection efforts.
Design/Methods: We enrolled adults (≥18 years) with TB symptoms or risk factors (PLHIV, previous TB, close contacts) presenting to an emergency centre in Khayelitsha, Cape Town.
We compared diagnostic yields of respiratory (sputum: Xpert MTB/RIF Ultra (XPU), culture, tongue swabs: (XPU), urine (AlereLAM, XPU) and blood (XPU) tests and did a head-to-head XPU comparison across specimen types.
Results: Among 266 participants, 114 (43%) had ≥1 positive test. 69/114 (61%) were routinely diagnosed (44, 3, 3, and 11 exclusively positive on sputum, urine AlereLAM, blood culture, and other extrapulmonary samples respectively; 11 positive from multiple sample types). 45/114 (39%) were identified exclusively through study testing (5 sputum-, 14 urine-, 10 blood-, 2 tongue swab-positive, 14 positive by multiple tests). Sputum was routinely collected in 147/266 (55%). The study obtained expectorated sputum from an additional 57, of whom 12/57 (21%) were positive. Routine invasive sampling (lumbar puncture, thoracentesis, pericardiocentesis) led to 13 positive diagnoses; 7 of which were also diagnosed using non-invasive study tests, suggesting invasive sampling could be reduced.
Amongst study tests, of 21 positive respiratory samples, 4 (19%) were exclusively tongue swab-positive. Of 47 urine-positives, 9 (19%) were AlereLAM-positive alone, and 19 (40%) urine XPU-positive alone. Among 41 XPU-positive cases, 7 (17%) were exclusively blood-positive (Figure).

Figure 1: Maximizing diagnostic yield of sputum and non-sputum-based testing



Conclusions: Our findings underscore the high TB burden in emergency settings, the value of multiple sputum collection attempts and the synergistic benefits of different tests on non-sputum specimens, which could reduce invasive sampling. The incremental diagnostic yield of non-sputum-based tests provides key insights for integrated diagnostic algorithms to improve treatment.

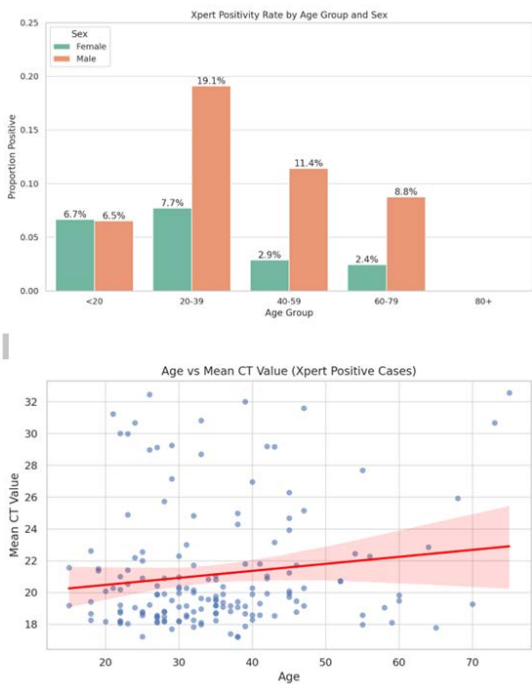
EP17-860-19 Analyzing the effect of demographic factors on Xpert positivity and cycle threshold values in tuberculosis testing

T.T. Eliya,[1] T. Wingfield,[2] N. Kontogianni,[2] R. Akpakpan,[3] E. Emeka,[4] J. Bimba,[5] M. Iwakun,[6] P. Adogo,[1] B. Adeyanju,[1] A. Ojo,[7] H. Geraldine,[8] H. Dachor,[1] [1]Bingham University Karu, Nigeria, Zankli Research Center, Karu, Nigeria, [2]Liverpool School of Tropical Medicine (LSTM), Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland, [3]National Tuberculosis Leprosy and Buruli Ulcer Conrol Programme (NTBCLP), Public Health, Abuja, Nigeria, [4]Federal Ministry of Health, Abuja, Laboratory Services Department, Abuja, Nigeria, [5]Bingham University, Nasarwa State, Zankli Research Center, Karu, Nigeria, [6]Bingham University Karu, Zankli Research Center, Karu, Nigeria, [7]FCT Tuberculosis Leprosy and Buruli Ulcer Control Programme (FCT TBLCP), Public Health Department, Health service and Environment, Abuja, Nigeria, [8]Asokoro District Hospital, Abuja, Medical Laboratory Unit, Abuja, Nigeria
e-mail: iliya.taryuta@binghamuni.edu.ng

Background: Tuberculosis (TB) remains a major global health concern. The Xpert MTB/RIF assay is a widely used molecular diagnostic tool that provides rapid detection of TB and estimates bacterial load via cycle threshold (CT) values. Understanding how demographic factors influence Xpert positivity and CT values may guide effective TB screening strategies.
This study seeks to explore the effect of age and gender on Xpert positivity and CT values among individuals tested for TB..
Design/Methods: A cross-sectional approach was utilized to enroll 1,705 consented participants across three health facilities. Sputum samples and demographic data were collected. Xpert MTB/RIF test was performed on sputum samples, and results including CT values for five

genetic probes were documented. Xpert positivity rates were compared across age groups and gender. While linear regression analyzed the relationship between age and CT values among positive cases.

Results: Out of the 1,705 samples analyzed, Xpert positivity was significantly higher among males ($p < 0.001$), particularly those aged 20–39. Positivity rates decreased with age, with the lowest rates observed in females aged 60 and above. No significant difference was found in CT values between males and females ($p = 0.15$). A weak positive correlation ($r = 0.14$) between age and mean CT value was observed among positive cases, suggesting a lower bacterial load in older individuals.



Conclusions: Gender and age significantly influence Xpert TB positivity rates, with young adult males showing the highest risk. CT values, however, remain consistent across demographics. These findings support the need for age- and gender-targeted TB screening strategies to enhance early case detection and resource allocation in high-burden settings

EP17-861-19 Who, what, and how much: Sputum scarcity amongst people requiring tuberculosis testing across multiple countries

W. Nwamba,[1,2] A. Okunola,[1,2] R. Crowder,[3] D. Christopher,[4] W. Worodria,[5] C. Yu,[6] Z. Palmer,[1,2] G. Ndlangalavu,[1,2] D. Naidoo,[1,2] A. Cattamanchi,[3,7] G. Theron,[1,2] [1]SAMRC Centre for TB Research, DSI-NRF Centre of Excellence for Biomedical TB Research, Cape Town, South Africa, [2]Stellenbosch University, Biomedical Sciences, Cape Town, South Africa, [3]University of California San Francisco, Center for Tuberculosis and Division of Pulmonary and Critical Care Medicine, California, United States of America, [4]Christian Medical College, Department of Pulmonary Medicine, Vellore, India, [5]World Alliance for Lung and Intensive Care, ., Kampala, Uganda, [6]De La Salle Medical and Health Sciences Institute, Department of Internal Medicine, Dasmariñas, Philippines, [7]University of California Irvine, Division of Pulmonary Diseases and Critical Care Medicine, UnCalifornia, United States of America
e-mail: wdube@sun.ac.za

Background: Tuberculosis (TB) diagnostic evaluation often excludes people who cannot naturally produce sputum (sputum-scarce), yet their prevalence, characteristics, and impact on test performance remain poorly understood.

Design/Methods: We analysed adults with presumptive pulmonary TB enrolled in a multi-country diagnostic study (Cohort A, n=2224), studies in South Africa with similar eligibility criteria (Cohort B, n=2179), and unselected antiretroviral therapy (ART) initiators irrespective of respiratory symptoms (Cohort C, n=297). All participants were required to give at least two sputa for Xpert MTB/RIF or Xpert MTB/RIF Ultra (Ultra) and MGIT960 culture, and information on whether people could naturally make sputum (expectorate) or required sputum induction was recorded.

Results: Sputum-scarcity was observed in 13% (618/4700) of participants. Female sex [(adjusted odds ratio (aOR): 1.57 (95% confidence interval (CI): 1.02, 1.86); p<0.001], recruitment site [aOR: 1.05 (1.00, 1.12); p=0.031] and TB-positive individuals on ART [aOR: 2.78 (1.02, 5.53); p=0.044] were positively associated with sputum-scarcity, whereas smoking [aOR: 0.58 (0.46, 0.74); p<0.001], previous TB [aOR: 0.78 (0.63, 0.96); p<0.014], night sweats [aOR: 0.51 (0.43, 0.61); p<0.001], and low TBscoreII [aOR: 0.66 (0.56, 0.79); p<0.001] were negatively associated. Among confirmed TB cases, 12% (96/830) were sputum-scarce. The sensitivity and specificity of Ultra were lower among sputum-scarce participants [73% (54, 88) vs. 89% (84, 93); p=0.035 and 99% (98, 99) vs. 100% (99, 100); p=0.111], respectively.

Conclusions: Sputum-scarce people are more likely to be female, TB-positive individuals on ART and individuals with lower disease burden. Sputum scarcity demonstrates significant geographical variation and has a significant impact on diagnostic accuracy. These findings highlight the need for an extra effort and alternative TB diagnostic strategies.

EP17-862-19 Enhancing tuberculosis microscopy diagnosis and external quality assurance using telepathology in Kenya: A case of Meru County

J. Magiri,[1] D. Memeu,[2] J. Gituma,[3] B. Mutuku,[4] J. Marcomic,[5] B. Ulo,[6] [1]Kenya Methodist University, School of Health Sciences, Nairobi, Kenya, [2]Kenyatta University, School of Pure and Applied Sciences, Meru, Kenya, [3]Jomo Kenyatta University of Science and Technoloy, School of Health Science, Nairobi, Kenya, [4]Kenya Methodist University, School of Health Sciences, Meru, Kenya, [5]Moi University, School of Health Sciences, Nairobi, Kenya, [6]Moi University, School of Medicine, Nairobi, Kenya

Background and challenges to implementation: Meru County is among top three TB high burden Counties in Kenya having reported 3,995 new patients in 2024, 70% of which were bacteriologically confirmed. The Kenya TB Guideline recommends molecular diagnosis as the first test, with follow-up microscopy for confirmed patients to monitor treatment. It also recommends Drug-resistant TB patients to have monthly microscopy follow ups as well as Quarterly TB microscopy EQA through blinded slide rechecking.

However, traditional microscopy faces challenges such as limited access to qualified microscopists, delayed results, and diagnostic errors. Telepathology offers an innovative solution, improving diagnostic accuracy by connecting health facilities with expert microscopists remotely.

Intervention or response: In February 2025, Meru Teaching and Referral Hospital, in partnership with Meru University of Science and Technology, piloted telepathology integration into TB diagnosis by re-analyzing 76 follow-up smears from Quarter 4 of 2024. High-resolution images were transmitted to centralized microscopists for review in order to assess telepathology's potential for diagnosis and microscopy EQA.

Results/Impact: Results reviewed that smear thickness 77%, size 62%, evenness 69% and result accuracy 100%. CAPA was instituted and prompt EQA feedback provided to facilities in real time while enhancing objectivity in quality assessments.

Conclusions: Telepathology in TB microscopy diagnosis and EQA re-checking enhances diagnostic accuracy, supports professional development, and strengthens global TB control efforts, ensuring more reliable diagnosis and improved TB case detection and management and can be applied in Kenya.

EP17-863-19 Incremental yield of the addition of tongue swab to sputum molecular testing for tuberculosis in South African adult primary healthcare clinic attendees

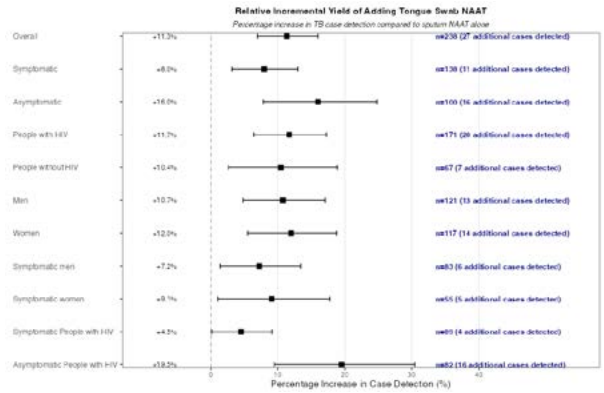
R. Berhanu,[1] L. Lebina,[2] A. David,[3] L. Genade,[4] M. Milovanovic,[5] F. Swanepoel,[4] S.V. Omar,[6] B. Nonyane,[7] M. Mohlamonyane,[8] S.-A. Meehan,[9] L. Scott,[3] N. Martinson,[4] TUTT-Plus Study Group [1]Vanderbilt University Medical Center, Department of Medicine, Division of Infectious Diseases, Nashville, TN USA, South Africa, [2]Africa Health Research Institute, Clinical Trials Unit, Durban, South Africa, [3]University of the Witwatersrand, Wits Diagnostics Innovation Hub, Health Sciences Research Office, Faculty of Health Sciences, Johannesburg, South Africa, [4]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa, [5]African Potential Group, Research, Johannesburg, South Africa, [6]National Institute for Communicable Diseases, Centre for Tuberculosis, National & WHO Supranational TB Reference Laboratory, Johannesburg, South Africa, [7]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States of America, [8]University of the Witwatersrand, Perinatal HIV Research Unit, Polokwane, South Africa, [9]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Stellenbosch, South Africa
e-mail: rebecca.h.berhanu@vumc.org

Background: Sputum molecular testing is the WHO-recommended first-line diagnostic for pulmonary tuberculosis, but sputum can be challenging to collect and poses nosocomial transmission risks. Tongue swabs' ease of collection could expand TB testing access and increase diagnoses, despite lower sensitivity.

Design/Methods: Adults with TB risk factors (living with HIV [PWH], recent TB history, TB contact) from ten South African primary healthcare clinics in three provinces had sputum and tongue swab collected, irrespective of symptoms. Sputum was tested on either Xpert MTB/RIF Ultra ('Ultra'), MAX MDR-TB, or Cobas MTB, and tongue swabs with Ultra.

The primary outcome was incremental yield of tongue swab as an add-on test to sputum, defined as the percentage of additional individuals with TB detected when using both sputum and tongue swab tests compared to sputum alone.

Results: Among 7,940 participants (78% PWH, 25% reported TB symptoms), 96% were able to expectorate sputum. Valid results were available from 85% of sputum specimens versus 97% of tongue swabs ($p<0.001$). Overall, 265 (3.3%) individuals were diagnosed with TB, 100 (1.3%) by sputum only, 138 (1.8%) by both methods, and 27 (0.3%) by tongue swab only. The incremental yield of tongue swab in addition to sputum was 11.3% (95% CI 7.0%-16.1%), this varied non-significantly by province with the most prominent increase of 30% seen in KwaZulu-Natal. The overall number needed to test to identify one additional individual with TB is 294 (202 – 428).



Conclusions: The incremental yield of adding tongue swab to standard of care sputum molecular testing was modest though non-significant regional variation existed. Tongue swab testing may still be of benefit in high prevalence communities and settings where sputum collection is challenging. Implementation research should study use cases for tongue swabs to screen and test for TB in populations currently missed by sputum-based testing.

EP17-864-19 Use of TB-LAMP assay for active case finding of pulmonary tuberculosis in Nepal

A. Shimouchi,[1,2] R. Gopali,[1,2] B. Maharjan,[2] Y. Shrestha,[1] Y. Hirano,[3] P. Shrestha,[4] I. Onozaki,[3,5] S. Mitarai,[6] K. Okada,[3,5]
[1]Japan Anti-Tuberculosis Association (JATA), Nepal Office, Kathmandu City, Nepal, [2]Japan-Nepal Health and Tuberculosis Association (JANTRA), Director's Office, Kathmandu City, Nepal, [3]Japan Anti-Tuberculosis Association (JATA) HQ, International Program, Tokyo, Japan, [4]National Tuberculosis Control Centre, Nepal, Director's Office, Kathmandu City, Nepal, [5]The Research Institute of Tuberculosis, JATA, International Cooperation, Tokyo, Japan, [6]The Research Institute of Tuberculosis, JATA, Department of Bacteriology, Tokyo, Japan
e-mail: bjmaharjan28@gmail.com

Background: As only half of estimated TB cases are registered in Nepal, symptomatic screening as active case finding (ACF) has been carried out in 42 out of 77 districts in the country. In addition, Xpert MTB/RIF has been introduced and expanded nationwide. As a result, the number of sputum test significantly increased. However, smear microscopy is a still most commonly used tool and overall smear positivity has been reduced from 8.6% to 3.3% in the last 7 years.
In this situation, this study aims to evaluate the loop mediated isothermal amplification for TB(TB-LAMP) to compare diagnostic yield rate of pulmonary TB with smear microscopy.
Design/Methods: Participants in the study were presumptive TB patients detected separately by symptomatic screening and chest X-ray screening regardless of symptoms. Smear microscopy and TB-LAMP assay were performed using Xpert MTB/RIF Ultra as the microbiological reference standard assay.
Results: A total of 1231 presumptive TB patients were enrolled in the study from January 2024 to January 2025. More than half of presumptive TB patients were male (56.4%) and more than half (55.4%) were age of 45 or over. Out of them, 800 completed smear microscopy, TB-LAMP and Xpert Ultra assay.
Positivity of each test was 3.9%, 9.9% and 13.1%, respectively. When compared with Xpert Ultra as the reference, sensitivity of smear microscopy and TB-LAMP was 28.6% (95% CI 20.8-37.8) and 73.3% (95% CI 64.2-80.9), respectively.
The specificity, positive predictive value (PPV), negative predictive value (NPV) and kappa value were 99.9% (95% CI 99.2-100), 93.8% (95% CI 79.9-98.3), 90.2% (95%CI 87.9-92.1), 0.41 (95% CI 0.38-0.44) and 99.7% (95%CI: 99.0-99.9%), 97.5% (95%CI: 91.2-99.3), 96.1% (95%CI: 94.4-97.3), 0.82 (95% CI 0.78-0.85), respectively.

		Xpert Ultra	Xpert Ultra	
		Positive	Negative	Total
Smear microscopy	Positive	30	1	31
	Negative	75	694	769
TB-LAMP	Positive	77	2	79
	Negative	28	693	721
Total		105	695	800

Table Agreement between smear microscopy, TB-LAMP and Xpert Ultra assay.

Conclusions: TB-LAMP showed higher sensitivity and would replace smear microscopy effectively in ACF. Cost-effectiveness study should be done to ascertain the applicability of TB-LAMP in Nepal.

EP17-865-19 Evaluating optimal functionality of the GeneXpert machine as a point-of-care diagnostic tool for tuberculosis in Nigeria: Lessons from KNCV, Cepheid Authorized Service Provider

C. Ehimanre,[1] H. Ahmad,[1] A. Adeyomoye,[1] T. Panda,[1] A. Muhammad,[1] I. Agazie,[1] S. Adeshina,[1] P. Ajiboye,[1] [1]KNCV Tuberculosis Foundation, Laboratory Service, Abuja, Nigeria
e-mail: christopher.ehimanre@kncvtbc.org

Background and challenges to implementation: Nigeria bears one of the world's highest tuberculosis (TB) burdens, making accurate and timely diagnosis is critical for TB control. The GeneXpert MTB/RIF or Ultra assay facilitates rapid detection of Mycobacterium tuberculosis and rifampicin resistance within 70 minutes.

However, effective nationwide deployment requires robust technical support, trained users, and adequate infrastructure elements often lacking in resource-limited settings.

Intervention or response: In 2014, Cepheid appointed KNCV Tuberculosis Foundation as the Authorized Service Provider (ASP) in Nigeria. Initially supporting fewer than 100 GeneXpert machines, KNCV now oversees over 540 systems. Key Interventions include:

- Routine and on-demand training for end users
- Troubleshooting support, annual calibrations, and preventive maintenance.
- A network of trained "super-users" providing decentralized technical assistance.
- Facility level mentorship to advocate for infrastructure improvement, including ventilation, air conditioning, and power stability.

Results/Impact: Service data and user feedback revealed that many machine failures resulted from end user errors, including inadequate cleaning of cartridge bays and filters, mishandling of cartridges, and poor adherence to standard operating procedures (SOPs).

Additionally, Infrastructural deficiencies such as poor ventilation, non-functional air conditioning, and unreliable power supply has led to overheating, test interruptions, and sample loss.

The deployment of super-users and the implementation of responsive service protocols significantly reduced machine downtime and improved overall reliability.

KNCV's approach underscores the interconnected role of user behavior, technical competence, and environmental readiness in sustaining diagnostic performance.

Strengthening decentralized support structures, continuous user training, and enhanced collaboration with facility management have been pivotal in improving machine uptime and diagnostic reliability.

Conclusions: KNCV's decentralized, capacity-building model offers a scalable solution for sustaining GeneXpert performance in Nigeria. Continued investment in training and infrastructure is essential to maintaining diagnostic effectiveness and supporting national TB seeking sustainable solutions to optimize TB diagnostics.

EP17-866-19 Evaluating the cost-effectiveness of integrating TB LAMP and GeneXpert for tuberculosis diagnosis in Kaduna State, Nigeria

C. Igwetu,[1] H. Ma'ab Baffa,[1] M. Tukur,[1] [1]KNCV Nigeria, Technical and Program Department, Federal Capital Territory, Nigeria
e-mail: cigwetu@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) is a major public health concern in Nigeria, with approximately 467,000 cases reported in 2023. As one of the top 30 high-burden TB countries, Nigeria accounts for 87% of global TB cases. Limited diagnostic coverage and a 70% funding shortfall exacerbate the problem. GeneXpert, while effective, is costly and requires stable infrastructure, which is often lacking in rural areas. To address this, Nigeria adopted a revised diagnostic algorithm, using TB LAMP as the primary screening tool, reserving GeneXpert for confirming rifampicin resistance in positive cases. TB LAMP is more affordable ($5 vs. $10) and suitable for low-resource settings.

Intervention or response: In 2024, KNCV Nigeria, in collaboration with the National Tuberculosis, Leprosy and Buruli Ulcer Control Programme (NTBLCP), deployed TB LAMP in six primary healthcare facilities in Kaduna State. Under the new algorithm, all presumptive TB cases were initially tested with TB LAMP, with only positive results undergoing further GeneXpert testing for drug resistance. Laboratory staff were trained, and results were documented using national TB reporting tools.

Results/Impact: Between January and June 2024, a total of 2,145 presumptive TB samples were tested using TB LAMP, identifying 358 positive cases. These cases underwent additional testing with GeneXpert. The combined testing strategy cost $14,305, compared to $21,450 if GeneXpert had been used for all samples, resulting in a savings of $7,145 (33%).

Month	January	February	March	April	May	June	Total
Presumptive evaluated	330	300	408	252	390	465	2145
Positive cases diagnosed	55	52	58	45	79	69	358

Conclusions: Using TB LAMP as the primary diagnostic tool reduces costs while maintaining quality. It is recommended for high-burden, resource-limited settings and should be scaled nationally to improve diagnostic coverage and optimize funding.

EP17-867-19 A prospective multicentre diagnostic accuracy study of the Truenat MTB Plus/COVID-19 assay for simultaneous detection of TB and COVID-19

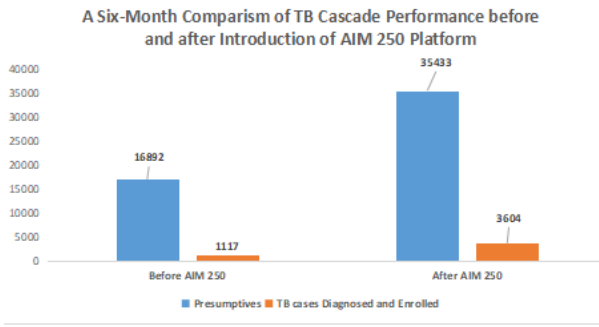
H. Tootla,[1] R. Székly,[2] M. Patidar,[3] M. Joloba,[4] C. Ugarte-Gil,[5,6] M. Purohit,[3] H. Cox,[7] C. Zamudio,[6] W. Ssengooba,[8] A. Penn-Nicholson,[9] [1]University of Cape Town, Medical Microbiology, Cape Town, South Africa, [2]FIND, Clinical Trials Unit, Geneva, Switzerland, [3]R. D. Gardi Medical College, Department of Pathology, Ujjain, India, [4]Makerere University, College of Health Sciences, Kampala, Uganda, [5]The University of Texas Medical Branch, Department of Epidemiology, Galveston, United States of America, [6]Universidad Peruana Cayetano Heredia, Instituto de Medicina Tropical Alexander von Humbold, Lima, Peru, [7]University of Cape Town, Medical Microbiology, Cape Town, Australia, [8]Makerere University, Department of Medical Microbiology, Kampala, Uganda, [9]FIND, TB Programme, Geneva, Switzerland
e-mail: adam.penn-nicholson@finddx.org

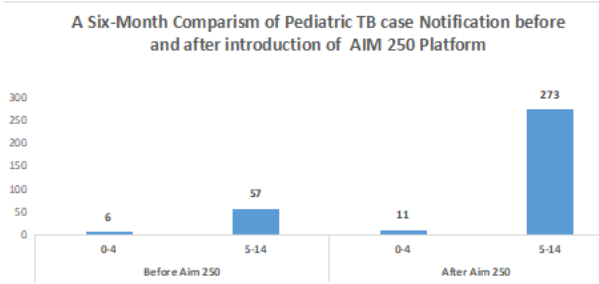
Background: The COVID-19 pandemic led to disrupted TB management. Overlapping symptoms, radiological findings and risk factors made differentiating TB and COVID-19 disease difficult. These challenges highlight the need for integrated testing strategies. The TruenatTM MTB-Plus/COVID-19 assay was developed to address this diagnostic gap.
Design/Methods: This was a prospective multicentre diagnostic accuracy study for the Truenat MTB-Plus/COVID-19 assay, using a combined sputum plus nasopharyngeal swab specimen for evaluation in a single multiplex assay.
Participants were adults with presumptive TB enrolled from Uganda, Peru, South Africa, and India between October 2022 and December 2023.
A microbiological reference standard of sputum GeneXpert Ultra and TB culture was used for TB, whereas national RT-PCR was used as a reference standard for COVID-19. Wilson's score method was used to determine the sensitivity and specificity.
Results: Of the 1928 participants enrolled, the median (IQR) age was 37 years (27-50), 359/1928 (18.6%) previously had TB, and 287/1928 (14.9%) were HIV-positive.
The overall prevalence of TB was 24.8% (476/1920) [95% CI 22.9-26.8%].
Prevalence of COVID-19 was 3.8% (73/1910) [3.1-4.8%] overall, and 4.7% (22/470) [3.1-7%] in those with confirmed TB.
Overall sensitivity of Truenat MTB-Plus/COVID-19 against TB was 79.8% (380/476) [CI 76.0-83.2%]. When comparing paired sampled, Truenat MTB-Plus/COVID-19 had a 9.5% (CI 6.5-13.1%) decrease in sensitivity against sputum TB culture compared to Xpert Ultra (82.8% [78.9-86.1%] vs 92.4% [89.4-94.5%], respectively).
Overall specificity of Truenat MTB-Plus/COVID-19 for TB was 98.9% (1428/1444) [CI 98.2-99.3%].
For COVID-19 detection, the overall sensitivity of Truenat MTB-Plus/COVID-19 assay compared to national site-specific RT-PCR was 64.4% (47/73) (52.9-74.4%), with specificity 99.2% (1814/1829) (CI 98.7-99.5%).
Conclusions: Although optimal diagnostic performance was not demonstrated, the potential for rapid development of tests that integrate TB diagnosis with detection of other relevant respiratory infections is highlighted.

EP17-868-19 Improving performance and efficiency through digital platforms: The Accelerated Implementation Methodology (AIM 250) experience in Kano State, Nigeria

A. Bello,[1] H. Baffa,[1] A. Okoh,[2] M. Said,[3] M. Sheshi,[2] M. Tukur,[1] M. Bajehson,[1] A. Adekunle,[4] T. Adetiba,[4] J. Ssekitoleko,[5] B. Odume,[2] [1]KNCV Nigeria, Programme, Kano, Nigeria, [2]KNCV Nigeria, Programme, Abuja, Nigeria, [3]KNCV Nigeria, M&E, Kano, Nigeria, [4]IHV Nigeria, Programme, Abuja, Nigeria, [5]Global Fund, Programme, Geneva, Switzerland
e-mail: abello@kncvnigeria.org

Background and challenges to implementation: The strength of a health system and ultimately the health of a population depends to a large degree on health worker performance. However, insufficient support to build, manage and optimize human resources for health in low- and middle-income countries results in inadequate health workforce performance, perpetuating health inequities and low-quality health services. We present result showcasing use of a digital platform in improving performance and supervision efficiency in Kano State.
Intervention or response: KNCV Nigeria implements the Global fund cycle 7 grant in Kano across 40 local Government Areas. In September 2024, AIM 250 digital platform was introduced to track key performance indicators, and ensure supervision to sites are being maximized. Open Data Kit (ODK) are filled on weekly and monthly basis to ensure compliance, a feedback system is sent on every Tuesday to review performance. Data was analyzed when AIM250 was not introduced Vs when it was introduced.
Results/Impact: From April to September 2024, 16,892 presumptive TB cases were identified and evaluated, leading to the diagnosis and enrollment of 1,117 TB cases. In October, the AIM 250 platform was introduced to enhance performance tracking, resulting in a remarkable increase in TB detection.From October to March the number of presumptive TB cases surged to 35,433 Presumptive TB with 3,604 cases diagnosed and enrolled, representing a 48% increase in presumptive identification and a 31% rise in TB diagnoses.
Additionally, childhood TB notification saw a significant improvement, rising from 63 to 283 cases, marking a 22% increase in pediatric TB case detection





Conclusions: Result shows significant improvement in key performance indicators following the introduction of AIM 250. This digital platform has proven effective in enhancing performance through structured weekly and monthly feedback mechanisms, addressing field implementation challenges. We recommend scaling up AIM 250 for broader implementation integrating it with existing health information systems in the country.

EP18 PLHIV - the continuum of TB care (prevention, diagnosis, treatment and post-treatment)

EP18-869-19 Universal TB testing with simultaneous TPT prescribing among people living with HIV in South Africa

K. Shearer,[1] L. Steiner,[1] N. Sabet,[2] B. Ncwana,[2] P. Biyela,[2] M. Ngema,[2] J. Golub,[1] T. Moloantoa,[2] N. Martinson,[2] C. Hoffmann,[1] [1]Johns Hopkins University, Center for Tuberculosis Research, Cape Town, South Africa, [2]University of the Witwatersrand, Perinatal HIV Research Unit, Soweto, South Africa
e-mail: Martinson@phru.co.za

Background: South African guidelines recommend targeted universal testing for tuberculosis (TUTT) for people living with HIV (PWH) starting antiretroviral therapy (ART). Modeling suggests that TUTT with simultaneous TPT (TUTT-PT), irrespective of TB symptom status, may reduce TB disease and death. We evaluated whether the TUTT-PT approach could increase TPT prescribing while not causing potential harms from provision of TPT to people with TB disease.
Design/Methods: We conducted a pilot evaluation of TUTT-PT in 5 clinics (3 intervention, 2 standard of care) in North West province, South Africa. In all clinics, a study nurse conducted a clinical evaluation with enrolled adult PWH starting or re-starting ART. In intervention clinics, an algorithm informed study nurses of whether to recommend TPT. Participants with severe TB symptoms (hemoptysis and/or fever) or specific contraindications were not recommended to receive TPT. Clinic nurses made the final TPT prescribing decision.
Results: Overall, 413 PWH were enrolled; 213 at intervention clinics and 200 at control clinics. The median (interquartile range) age was 37 (30, 45), 55% were female, and 32% had ≥1 TB symptom. TB testing was higher in intervention (99%) vs control (62%) clinics and, after excluding a one-month TPT stock-out period, TPT prescribing within 7 days of ART was also higher (intervention: 86%; control: 71%). Fifteen participants who started TPT were diagnosed with TB (10 intervention, 5 control); 8 switched to anti-TB treatment ≤7 days of sputum collection and 4 switched >7 days; 1 died, 1 withdrew, and 1 was hospitalized).
Conclusions: We achieved a high level of TB testing and TPT prescribing using the TUTT-PT approach, with successful switch from TPT to TB treatment in both arms for people diagnosed with TB disease. Routine rollout of a TUTT-PT approach could substantially increase TPT prescribing and decrease TB disease. A larger clinical trial should be considered.

EP18-870-19 Effect of secondary tuberculosis preventive therapy on posttreatment outcomes of people with HIV in Uganda

S. Makumbi,[1] G. Nabirye,[1] E. Sunyua,[1] L. Chaisson,[2] D. Dowdy,[3] B. Opiira,[4] C. Yoon,[2] F.C. Semitala,[5,6,7] [1]Infectious Diseases Research Collaboration, Kampala, Uganda, TB-Script, Kampala, Uganda, [2]University of California San Francisco, Division of Pulmonary and Critical Care Medicine, San Francisco, United States of America, [3]Johns Hopkins University, Departments of Epidemiology, International Health, and Medicine, Baltimore, United States of America, [4]Infectious Diseases Research Collaboration, Kampala, Uganda, Pharmacy, Kampala, Uganda, [5]Infectious Diseases Research Collaboration, Kampala, Uganda, Research, Kampala, Uganda, [6]Makerere University College of Health Sciences, Department of Medicine, Kampala, Uganda, [7]Makerere University Joint AIDs Program, Executive Management, Kampala, Uganda
e-mail: mshafic630@gmail.com

Background: Recurrent tuberculosis (TB) accounts for a substantial proportion of TB incidence among people with HIV (PWH) in high prevalent settings.
World Health Organisation (WHO) supports posttreatment or secondary TB preventive therapy (sTPT) for all PWH to prevent recurrence. In Uganda, a recent national campaign to scale-up TPT included sTPT for all PWH successfully completing TB treatment. We evaluated whether sTPT improves post-treatment outcomes of PWH
Design/Methods: From November 2020 to January 2023, we enrolled consecutive adults presenting to four clinics in Uganda for antiretroviral therapy (ART) initiation in a randomized trial comparing two WHO-recommended TB screening strategies (NCT04557176). Routine clinicians decided whether to initiate sTPT among participants completing treatment for TB. We compared individual characteristics and posttreatment outcomes among trial participants who received sTPT vs. no sTPT.

Table. Clinical characteristics and posttreatment outcomes of PWH, by sTPT status.

Demographic and clinical characteristics	sTPT[1] (n=154)	No sTPT (n=96)	p-value
Female sex	63 (41%)	38 (40%)	0.84
Age (median years [IQR])	35 (29-40)	35 (29-39)	0.66
Pre-ART CD4 count (median cells/uL [IQR])	107 (56-200)	115 (54-218)	0.69
Microbiologically-confirmed TB (initial episode)	102 (66%)	51 (53%)	0.04
Posttreatment outcomes			
TB recurrence and death	7 (5%)	6 (6%)	0.56
TB recurrence[2]	4 (3%)	1 (1%)	0.39
Died[3]	3 (2%)	5 (5%)	0.15
Time-under-observation (per 100 person-years)	2.19	1.8	
Incident rate of TB recurrence and death (per 100 py)	3.2 (95%CI: 1.5-6.7)	5.1 (95%CI: 2.3-11.3)	0.40[4]

[1]sTPT regimen (101 received IPT, 53 received 3HP); [2]TB recurrence was microbiologically-confirmed for 2 of 4 sTPT recipients and 0 of 1 non-recipients; [3]Cause of death attributed to active TB for 2 of 3 sTPT recipients and 2 of 5 non-recipients); [4]p-value for incident rate ratio.

Results: Of 1,719 total participants, 250 completed standard TB treatment, of whom 154 (62%) initiated sTPT. There was no difference in sex, median age, and median pre-ART CD4 cell-count by sTPT status (Table). However, participants who received sTPT were more likely to have microbiologically-confirmed TB (urine lipoarabinomannan- or sputum Xpert MTB/RIF Ultra-positive) than participants who did not receive sTPT (66% vs 53%, p=0.04). Four sTPT recipients (1%) developed recurrent TB and three (2%) died, versus one (1%) and five (5%) sTPT non-recipients, respectively. The adjusted incidence rate ratio of recurrent TB and mortality combined was 0.63 (95% CI: 0.2-1.9).
Conclusions: In Uganda, a country with high TB/HIV burden, routine sTPT did not improve posttreatment outcomes of PWH initiating ART who successfully completed TB treatment. Given the resource requirements of sTPT (e.g., drug costs, clinic workload), these resources may be more efficiently re-allocated to other TB control activities.

EP18-871-19 Kynurenine-to-tryptophan ratio is a suitable blood-based screening tool for active tuberculosis in pregnant women living with HIV

C. Gascua Adu-Gyamfi,[1,2] L. Makhathini,[2] G. Montepiedra,[3] N. Salazar-Austin,[4] A. Gupta,[5] M. Suchard,[6] [1]University of the witwatersrand, School of Physiology, Johannesburg, South Africa, [2]National Institute for Communicable Diseases, Centre for vaccines & Immunology, Johannesburg, South Africa, [3]Harvard University, T. H. Chan School of Public Health, Boston, United States of America, [4]Johns-Hopkins University, Department of Paediatrics, Marryland, United States of America, [5]Johns-Hopkins University, Department of Medicine, Marryland, United States of America, [6]University of the witwatersrand, School of Pathology, Johannesburg, South Africa
e-mail: clementgascua@yahoo.com

Background: For pregnant women living with HIV (PwLHIV), concurrent tuberculosis (TB) increases the risk of miscarriage, as well as maternal and infant mortality. Recently, we reported that K/T ratio is a suitable blood-based TB test in adults, children and PwLHIV. Indoleamine 2,3-dioxygenase (IDO) breaks down tryptophan into kynurenines, and IDO activity mediates fetal-maternal tolerance at the placenta. We investigated whether the stage of pregnancy affects the use of IDO activity as a screening tool for TB disease in PwLHIV. Additionally, we assessed IDO activity as a marker of isoniazid preventive therapy (IPT) response among PwLHIV during pregnancy or the postpartum period.
Design/Methods: We measured plasma kynurenine and tryptophan concentrations in PwLHIV enrolled in TB APPRISE by ELISA. TB APPRISE enrolled PwLHIV during second trimester and followed them until 44 weeks postpartum. Participants were randomized to receive IPT either during the antepartum or postpartum period. Six women developed TB at antepartum. IDO activity was calculated as the Kynurenine:Tryptophan (K/T) ratio.

Results: There was no significant difference in K/T ratio measured in the second trimester compared to third trimester of pregnancy (median, 0.106 [interquartile ranges (IQR) 0.077-0.138] versus 0.096 [IQR 0.062-0.133], P < 0.6098). K/T ratio significantly decreased in all women at postpartum compared to the antepartum period (median 0.135 [IQR 0.106-0.175] versus 0.033 [IQR 0.028-0.042], P < 0.0001). Pregnant women who received IPT during pregnancy exhibited decreased K/T ratio compared to those who received IPT at postpartum period (P = 0.0074). In postpartum period, plasma K/T ratio was elevated in women who developed TB at the time of diagnosis compared to controls (P < 0.0001).
Conclusions: Our results show no variation in plasma K/T ratio during pregnancy but significant decreases in postpartum period among PwLHIV. Plasma K/T ratio should be further evaluated as an initial TB screening test to assess its impact on patient care.

EP18-872-19 Diagnostic accuracy of point-of-care ultrasound for tuberculosis disease among inpatients with HIV: A prospective cohort study in Ghana

J. Åhsberg,[1,2,3] S. Bjerrum,[1,2,4] V.J. Ganu,[5] P. Puplampu,[6] M. Lartey,[6] I. Somuncu Johansen,[1,2] C. Borbjerg Laursen,[7,8]
[1]University of Southern Denmark, Research Center of Infectious Diseases, Department of Clinical Research, Odense, Denmark, [2]Odense University Hospital, Mycobacterial Centre for Research Southern Denmark, MyCRESD, Department of Infectious Diseases, Odense, Denmark, [3]Statens Serum Institut, International Reference Laboratory of Mycobacteriology, Copenhagen, Denmark, [4]Copenhagen University Hospital Rigshospitalet, Department of Infectious Diseases, Copenhagen, Denmark, [5]Korle Bu Teaching Hospital, Department of Medicine, Korle Bu, Ghana, [6]Medical School, College of Health Sciences, University of Ghana, Department of Medicine & Therapeutics, Accra, Ghana, [7]Odense University Hospital, Department of Respiratory Medicine, Odense, Denmark, [8]University of Southern Denmark, Odense Respiratory Research Unit (ODIN), Department of Clinical Research, Odensedede, Denmark

Background: Timely detection of HIV-associated tuberculosis (TB) is challenged by non-specific symptoms and a high prevalence of paucibacillary and extrapulmonary disease. Point-of-care ultrasound (POCUS) may support early TB diagnosis. This study assessed the diagnostic accuracy of POCUS features for TB among inpatients with HIV.
Design/Methods: This prospective study was conducted at Korle Bu Teaching Hospital, Ghana (Jan 2020–Jan 2022, NCT04122404), enrolling inpatients with advanced HIV or symptoms suggestive of TB. Study procedures included POCUS, clinical assessment, and TB testing with 8-week follow-up. POCUS assessment of the heart, lungs, and abdomen for signs suggestive of TB were performed as index test. Diagnostic accuracy was evaluated against 8 weeks composite reference standard (CRS) including microbiologically confirmed (eMRS) and clinical TB. Primary outcome was the accuracy of individual and combined POCUS features against CRS. Secondary analyses included associations between POCUS features and 8-week TB status.
Results: Among 107 patients (median age: 42 years (IQR 34-51), 56.1% female, 45.8% newly diagnosed with HIV) TB prevalence ranged from 47.0% (47/100, eMRS) to 56.1% (60/107, CRS). Having any effusion (pericardial, pleural or ascites) was commonly observed (78/107, 72.9%), however unspecific for TB (Table 1 against CRS).
Complex pericardial effusion (6/107, 5.6%) and severely impaired left ventricular function (8/107, 7.6%) had moderate rule-in value for TB.
Pneumothorax and complex ascites were uncommon (3/107, 2.8%, respectively) but 100% specific for TB. The FASH and FLUS protocols detected 75.0% and 81.7% of TB cases respectively, but had low specificity.
A combination of either complex pericardial effusion, severely impaired LV function, pneumothorax, or complex ascites had strong rule-in potential (sensitivity 25.0%, specificity 93.6%) and an adjusted OR of 5.49 (95% CI 1.42–21.22) for TB.

POCUS features	POCUS positive n=107 (CRS+ n=60 / CRS− n=47)	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)	PLR (95% CI)	NLR (95% CI)
Complex pericardial effusion (presence of septations/ fibrin strands)	6 (5/1)	8.3 (2.8-18.4)	97.9 (88.7-99.9)	83.3 (35.9-99.6)	45.5 (35.6-55.8)	3.92 (0.47-32.40)	0.94 (0.86-1.02)
Severely impaired LV function (eyeballing)	8 (6/2)	10.0 (3.8-20.5)	95.7 (85.2-99.5)	75.0 (34.9-96.8)	44.9 (34.8-55.3)	2.30 (0.49-10.87)	0.94 (0.85-1.04)
Complex pleural effusion (presence of septations/ fibrin strands)	11 (7/4)	11.7 (4.8-22.6)	91.5 (79.6-97.6)	63.6 (30.8-89.1)	44.8 (34.6-55.3)	1.37 (0.43-4.41)	0.97 (0.85-1.10)
Pneumothorax (absence of lung sliding, absence of B-lines, and if detected, the presence of the lung point)	3 (3/0)	5.0 (1.0-13.9)	100.0 (92.5-100.0)	100.0 (29.2-100.0)	45.2 (35.4-55.3)	NA	0.95 (0.90-1.01)
Complex ascites (presence of septations)	3 (3/0)	5.0 (1.0-13.9)	100.0 (92.5-100.0)	100.0 (29.2-100.0)	45.2 (35.4-55.3)	NA	0.95 (0.90-1.01)
Any effusion (pericardial effusion and/or pleural effusion and/or ascites)	78 (46/32)	76.7 (64.0-86.6)	31.9 (19.1-47.1)	59.0 (47.3-70.0)	51.7 (32.5-70.6)	1.13 (0.89-1.43)	0.73 (0.39-1.36)
FASH (Focused Assessment with Sonography for HIV-associated TB, Heller et al.)	76 (45/31)	75.0 (62.1-85.3)	34.0 (20.9-49.3)	59.2 (47.3-70.4)	51.6 (33.1-69.8)	1.14 (0.88-1.46)	0.73 (0.41-1.33)
FLUS (14-zone focused lung ultrasound)	93 (49/44)	81.7 (69.6-90.5)	6.4 (1.3-17.5)	52.7 (42.1-63.1)	21.4 (4.7-50.8)	0.87 (0.76-1.00)	2.87 (0.85-9.71)
Any of the four best performing individual POCUS features to rule in TB (Any of complex pericardial effusion, severely impaired LV function, pneumothorax, or complex ascites)	18 (15/3)	25.0 (14.7-37.9)	93.6 (82.5-98.7)	83.3 (58.6-96.4)	49.4 (38.7-60.2)	3.92 (1.20-12.74)	0.80 (0.68-0.94)

Conclusions: Among admitted patients with HIV, complex pericardial effusion, impaired LV function, pneumothorax, or complex ascites were suggestive for TB and should prompt further investigation and early treatment.

EP18-873-19 People living with HIV have increased plasmacytoid dendritic cells and systemic inflammation if they have history of pulmonary TB

M. Ward,[1] Y. Joseph,[2] P. Zumbo,[3] A. Apollon,[2] E. Dumont,[2] A. Alonso,[1] D. Fitzgerald,[1] J. Pape,[1,2] K. Dupnik,[1] [1]Weill Cornell Medicine, Internal Medicine, New York, United States of America, [2]GHESKIO, Medicine, Port au Prince, Haiti, [3]Weill Cornell Medicine, Applied Bioinformatics Core, New York, United States of America

Background: People living with HIV who have history of TB have worse outcomes, including increased all-cause mortality and risk for recurrent TB. We hypothesized that persistent immune deficits could explain these outcomes. To assess for persistent immunologic changes after TB cure in people living with HIV we sequenced peripheral immune cells to identify candidate immune cell subsets followed by confirmatory studies to investigate the relevance of these subsets.
Design/Methods: We completed Cellular Indexing of Transcriptomes and Epitopes by Sequencing (CITE-Seq) of PBMC of people living with HIV with (n=6) or without (n=3) TB history at GHESKIO Centers in Haiti. CITE-Seq analysis included differential gene expression and principle components and pathways analyses. Confirmatory studies on an expanded cohort (n=29) included dendritic cell subtyping by flow cytometry and cytokine quantification using an 18-plex Th1/Th2 panel. Twoway comparisons were with non-parametric tests and tobit regression with Bonferroni correction.
Results: There was over-representation of the Hallmark gene set, "genes regulated by NF-kB in response to TNF" in the PBMC population as well as in individual immune lineages. TNF levels were higher in the TB group (p=0.002). There were 68 differentially expressed genes in the dendritic cells with over-representation of pathways important for response to TB: response to hydrogen peroxide, oxidative stress, and reactive oxygen species. In an expanded cohort of 29 people with HIV, there was a larger percentage of plasmacytoid dendritic cells by flow cytometry (p=0.011). and increased plasma IL-6, IL-12p70, IL-15, IL-2, IFN-alpha, and TNF in the TB history group (n=18) compared to people with no history of TB (n=11).
Conclusions: A proinflammatory milieu and immune cell gene expression mediated by TNF persist in people living with HIV even years after TB. If the differences are preexisting risk factors or establish during the natural history of HIV and TB is still to be determined.

EP18-874-19 Implementing data linkage to qualify trends of unfavorable TB-HIV outcomes in Brazil (2013–2023)

J.N.d.B. Silva Júnior,[1] Y.B.d. Costa,[1] L.H. Arroyo,[1] F.L.R. Vega,[1] D. Arakaki,[1] M.R.L. Ferreira,[1] K. Andrade,[2] T. Benoliel,[1] A.R.P. Pascom,[1] P.F. Palha,[3] D.M. Pelissari,[1] F. Dockhorn,[1] [1]Ministry of Health, Department of HIV/AIDS, Tuberculosis, Viral Hepatitis and Sexually Transmitted Infections, Brasília, Brazil, [2]PAHO/WHO - Brazil, Coordination of Communicable Diseases and Environmental , Brasília, Brazil, [3]University of São Paulo, Department of Maternal-Child and Public Health Nursing at the Ribeirão Preto School of Nursing, Ribeirão Preto, Brazil
e-mail: nildoenfer@hotmail.com

Background: Unfavorable treatment outcomes in tuberculosis (TB), such as death and loss to follow-up, remain disproportionately high among people living with HIV and AIDS (PLWHA). However, underreporting of HIV status in TB surveillance systems may lead to biased estimates. This study analyzes the impact of database linkage between TB and HIV systems on trend analysis of unfavorable outcomes among people with TB-HIV co-infection in Brazil.
Design/Methods: We analyzed national surveillance data on TB cases diagnosed between 2013 and 2023. Two datasets were compared: one using only HIV status reported in TB notifications, and another enhanced through probabilistic linkage with the national HIV/AIDS and Mortality Information Systems. Unfavorable outcomes were defined as death and loss to follow-up. Annual proportions of unfavorable outcomes among PLWHA were calculated, and trends assessed using Prais-Winsten regression.
Results: A total of 91,580 TB-HIV co-infection cases were identified through linkage, a 17.5% increase compared to the dataset without linkage. Across all years, the proportion of unfavorable outcomes was consistently higher in the linked dataset. A significant declining trend in unfavorable outcomes was observed in the linked data (–0.83 percentage points per year; $p < 0.001$). No significant trend was found in the unlinked data (–0.14 percentage points per year; $p = 0.564$), suggesting temporal stability.

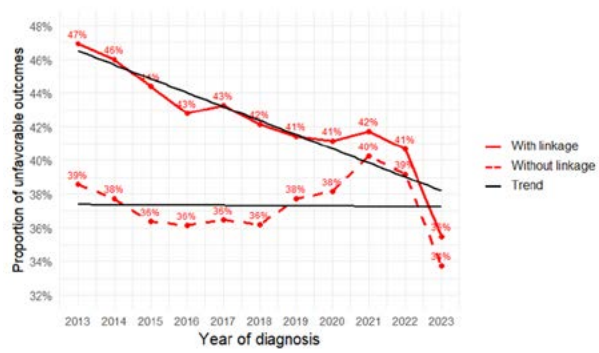


Figure 1. Proportion of unfavorable outcomes among people with tuberculosis-HIV coinfection by year, according to the use of database linkage.

Conclusions: Database linkage increased the sensitivity of TB-HIV co-infection surveillance by identifying additional PLWHA not registered in the TB national system. This integration improved the estimation of unfavorable outcomes and revealed trends not visible in isolated datasets. In contexts where health information systems remain fragmented, adopting routine data linkage is crucial to strengthen epidemiological surveillance by identifying patterns, trends, and gaps that might otherwise go unnoticed and guide more effective, targeted public health interventions.

EP18-875-19 Integrating self-care into TB-HIV management: Addressing mental health challenges for persons infected with TB-HIV co-morbidities in Kano State, Nigeria

J. Adizue,[1] J. Anyanti,[2] S. Adamu,[1] [1]Society for Family Health, Programs, Federal Capital Territory, Nigeria, [2]Society for Family Health, Program, Federal Capital Territory, Nigeria
e-mail: Jadizue@sfhnigeria.org

Background: HIV and Tuberculosis (TB) remain major public health challenges, often compounded by stigma, leading to severe mental health burdens for co-infected individuals. These challenges negatively affect social relationships and treatment adherence. This study explores the role of self-care in improving treatment outcomes for individuals with TB-HIV co-morbidities, emphasizing a person-centred approach within existing health programs.

Self-care refers to the ability of individuals, families, and communities to maintain health, prevent disease, and manage illness with or without healthcare support. This study evaluates self-care awareness among TB-HIV patients and its impact on treatment outcomes.

Design/Methods: A mixed-methods approach was employed, involving 201 participants across seven local government areas in Kano State, Nigeria, over a period of two month from October to December 2024. Quantitative data on demographics, service utilisation, and treatment adherence were collected through structured surveys. Qualitative insights were obtained via in-depth interviews with patients, healthcare providers, treatment supporters, community leaders, and CBOs. Data triangulation was used to assess barriers, facilitators, and overall program impact.

Results:

- Awareness of self-care was mixed, with 53.33% of respondents having prior knowledge. Among them, 57.14% associated self-care with self-management, while awareness of self-awareness (28.57%) and self-testing (14.29%) was lower.
- About 80% recognized the link between self-care and quality of care in health facilities, highlighting its potential for integration into TB-HIV programmes.
- Stigma and discrimination (60%) were the biggest barriers to HIV care access, followed by distance to healthcare facilities (15%).
- Self-stigma (84%) was a major mental health challenge, leading to social withdrawal and fear of status disclosure.

Conclusions: Integrating self-care into TB-HIV services is essential for improving access and mental health outcomes.

Recommendations include expanding mental health training for healthcare workers, integrating psychological support, and enhancing data collection for monitoring and evaluation.

EP18-876-19 Predictors of post tuberculosis treatment mortality among people living with HIV: An observational cohort study, Andhra Pradesh, India, 2024

R. Allam,[1] M. Thogarucheeti,[2] S. Attada,[3] N. Chava,[4] J.K. Kurada,[4] G. Ramesam,[4] R.p. Kumar,[4] V. Yeldandi,[4] R.P. Poluru,[4] C. Sriramulu,[2] P. Nadol,[1] K.P. Yepuru,[2]
[1]U.S. Centers and Disease Control and Prevention, Division of Global HIV and TB, Delhi, India, [2]Andhra Pradesh State AIDS Control Society, Care Support and Treatment Division, Vjayawada, India, [3]Andhra Pradesh State AIDS Control Society, Department of Health and Familywelfare, Vjayawada, India, [4]Society for Health Allied Research & Education India, Department of Research, Hyderabad, India
e-mail: qdj4@cdc.gov

Background: Tuberculosis (TB) among People Living with HIV (PLHIV) is associated with poor treatment outcomes compared to those without HIV and has implications for TB control. India's national guidelines recommend post anti-TB treatment (ATT; 6-9 months of daily multi-drug regimen) follow-up every six months for two years from the last date of ATT. Limited data is available on post ATT mortality and predictors among PLHIV in India.

Design/Methods: We analysed secondary program data from 14 antiretroviral therapy (ART) clinics located in three high-burden districts of Andhra Pradesh. We included PLHIV aged >15 years who completed ATT successfully during January 2017–December 2021.

We followed-up for two years from ATT completion and monitored four-symptom TB screening, nucleic acid amplification test result for recurrent TB; CD4 and HIV-1 viral load for ART monitoring; TB prevention therapy (TPT) initiation start and completion for primary and secondary prophylaxis and calculated post TB treatment mortality rate (MR) per 100 person-years (PY).

We used multi-variable Cox proportional hazard models and calculated adjusted hazard ratios (AHR) to determine predictors of post TB treatment mortality.

Results: The 3,357 PLHIV meeting the inclusion criteria accounted for 5,594PY of follow-up. A total of 510 PLHIV died during follow-up (MR:9.1 per 100 PY, 95%CI:8.34-9.94). Select variables, such as HIV treatment interruption during follow-up (AHR:34.03, 95%CI: 16.-72.15), no exposure to secondary prophylaxis of isoniazid after ATT (AHR:3.84, 95%CI:3.07-4.80), HIV viral load ≥1,000 copies/ml during follow-up (AHR:2.80, 95%CI:1.97-3.99), no exposure to dolutegravir based regimen during follow-up (AHR:2.16, 95%CI:1.65-2.83), and baseline CD4 count ≤200 cells/mm3 (AHR:1.22, 95%CI:1.01-1.48), were associated with significantly higher risk of post TB treatment death.
Conclusions: ART clinic staff may focus on modifiable risk factors, such as preventing HIV treatment interruption, enabling viral load suppression, and ensuring initiation of secondary TPT to reduce post TB mortality among PLHIV.

EP19 Adult lung - burden and care of lung conditions

EP19-878-19 Clinico-radiological spectrum of respiratory post-acute COVID-19 in adults in Lusaka, Zambia: A cross-sectional study

L. Kajimanga,[1] C. Sinyangwe,[1] N. Naik,[1] K. Mateyo,[1]
[1]University of Zambia / University Teaching Hospital-Adult, Internal Medicine, Lusaka, Zambia
e-mail: lobinak34@gmail.com

Background: As the COVID-19 pandemic progressed, it became evident that some individuals continued to experience respiratory symptoms post-acute illness. However, these symptoms remain poorly characterised, particularly in low-resource settings. Despite the global burden of COVID-19, data on its long-term pulmonary effects in Zambia are lacking. This study aimed to describe the clinical and radiological patterns of respiratory post-acute COVID-19 at the University Teaching Hospital (UTH) in Lusaka, Zambia.
Design/Methods: A cross-sectional study was conducted from October 2022 to May 2024 among adults attending the UTH respiratory clinic with persistent or new respiratory symptoms at least 12 weeks after acute COVID-19. 45 participants were included. Categorical variables were reported as frequencies and proportions; continuous variables as means (±SD) or medians (IQR). Associations with abnormal chest CT features were analysed using t-tests, Chi-squared, or Fisher's exact tests.
Results: 66.7% were female. The mean age and BMI were 54 years and 29 kg/m² respectively. Pre-existing comorbidities were present in 88.9% of participants. Dyspnoea (60.0%) and chest pain (48.9%) were the most common symptoms. A total of 6.7% remained on supplemental oxygen. Abnormal spirometry was found in 68.1% of patients; 54.4% had a restrictive pattern. Chest CT abnormalities included intralobular lines or reticulations (46.7%), ground-glass opacities (37.8%), filling defects (8.1%), and consolidations (4.4%). Age ($p<0.0001$), oxygen therapy during acute illness ($p=0.015$), and abnormal spirometry ($p=0.05$) were significantly associated with abnormal CT findings.
Conclusions: Older age, prior oxygen therapy, and impaired lung function increase the likelihood of radiological sequelae post-acute COVID-19..

EP19-879-19 Determinants of COVID-19 mortality and temporal trends according to the health regions of São Paulo, Brazil

T. Barbosa,[1] A. Aparecida Monroe,[1] A. Fehr Tártaro,[1] B. Fornaziero Vigato,[1] H. Sávio Dias Moura,[1] J. Soares Tenório de Araújo,[1] M. Eduarda Pagano Pelodan,[1] N. Zini,[1] R. Junior,[1] T. Kehinde Ayandeyi Teibo,[1] V. Chicalo António Caripa,[1] R. Alexandre Arcencio,[1]
[1]Universidade de São Paulo, Enfermagem em Saude Publica, Ribeirão Preto, Brazil

Background: To understand the pandemic, it is essential to analyze the characteristics of different regions. In São Paulo, a strategic Contingency Plan was implemented to manage the outbreak and its consequences.
This context underscores the significance of identifying the determinants of COVID-19 mortality and analyzing temporal trends in each DRS within the state.
Design/Methods: This research employs an ecological study design where data on confirmed cases and mortality due to COVID-19 were collected from February 2020 to December 2021.
In addition, social and health indicators were analyzed to understand their relationship with the determinants of the disease. The GAMLSS was utilized to identify significant determinants of COVID-19 outcomes.
Results: The analysis revealed an increase in deaths from chronic diseases alongside a decrease in the overall mortality rate from COVID-19.
Notably, there was an observed relationship between the percentage of older adults in the urban population and increased COVID-19 mortality, as well as the effect of vaccination rates.

μ	Estimate	Std. Error	t value	Pr(>|t|)	Relative Increase (%)
(Intercept)	-2,28E+00	6,71E-01	-3.391	0.000743 ***	-
V2	-1,37E+00	6,53E-01	-2.091	0.036939 *	-74,59%
V4	2,06E-04	8,38E-04	0.246	0.805826	-
V5	8,27E-02	1,69E-02	4.902	1.23e-06 ***	8,62%
V9	2,35E-02	3,57E-03	6.572	1.11e-10 ***	2,38%
V10	-9,30E-01	8,71E-01	-1.068	0.286068	-
V11	2,68E-02	4,41E-03	6.075	2.25e-09 ***	2,72%

*Table 1 - Final model adjusted to identify factors associated with COVID-19 mortality in São Paulo. *p=0.03; ***p<0.0001*
*Legend: V2= deaths from non-transmissible chronic diseases; V3= percentage of the population 0-14 years; V4= percentage of population 15-60 years; V5= percentage of population 61 or older; V9= percentage of urban population; V10= Gini index (divided by 100) and V11= vaccination (calculation of the total applied doses of the 2nd dose of the vaccine against COVID-19 divided by population *100).*

Conclusions: This study highlights the importance of a variety of factors—such as behavioral, genetic, economic, demographic, and environmental—when identifying high-risk subgroups for complications and mortality due to COVID-19. Due to the diversity of individuals and regions, implementing targeted regional policies that reflect local population dynamics and socioeconomic conditions is crucial. This research can guide future health interventions, promoting equity and addressing the diverse needs of different populations.

EP19-880-19 Influence of pneumopathy on the survival of people with COVID-19 in Brazil (2021–2024)

R.J. Rosa,[1] L.P. Ferezin,[1] M.C.T.d. Campos,[2] E.C. Maraus,[1] H.S.D. Moura,[1] N.M. Ribeiro,[1] V.C.A. Caripa,[1] A.L.T. Vinci,[1] W.O.B. Bernardi,[1] T.K.A. Teibo,[1] M.D.P.S. Gallardo,[3] R.A. Arcêncio,[1] [1]University of São Paulo at Ribeirão Preto School of Nursing, Department of Nursing, Ribeirão Preto, Brazil, [2]University of Brasília, Department of Nursing, Brasília, Brazil, [3]Autonomous University of Madrid, Department of Nursing, Madrid, Spain
e-mail: ricardo@eerp.usp.br

Background: The interaction between viral infection and chronic respiratory diseases can exacerbate clinical severity. Therefore, the objective of this study was to analyze the influence of pre-existing pneumopathies on the survival time of individuals diagnosed with COVID-19 in Brazil between 2021 and 2024.
Design/Methods: This is a cross-sectional study. The data used in this study were obtained from the Coronavirus Panel, made available by the Brazilian Ministry of Health, covering the period from February 2021 to December 30, 2024. For the survival analysis, the Kaplan-Meier method was used to estimate the cumulative probability of survival over time for two groups (with and without pneumopathy). The comparison between the survival curves was performed using the log-rank test to determine whether there was a significant difference between the groups.
Results: The sample included 583,446 COVID-19 cases, distributed between 50.7% men and 49.3% women. In terms of age, 62.9% were aged 60 or over, 32% were aged 30-59 and 5% were aged 18-29. As for race/color, 60.2% were white, 38.7% black/brown, 1% Asian and 0.2% indigenous.
Figure 1 presents the Kaplan-Meier survival curves. In 2021 and 2023, a significant difference between the groups is observed ($p < 0.0001$), indicating that individuals with pneumopathy had a lower probability of survival over time compared to those without the condition.
However, in 2022 and 2024, the p-values were 0.83 and 0.25, respectively, indicating no significant difference between the groups in both years.

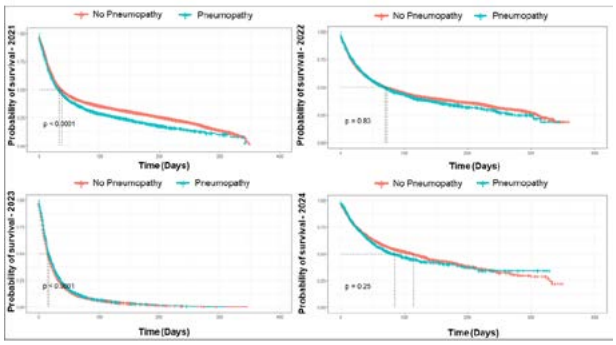

Figure 1 – Kaplan-Meier analysis of individuals with and without pneumopathy (2021-2024).

Conclusions: This study showed a significant difference in survival time among individuals who tested positive for COVID-19, comparing those who died with those who were discharged.
In addition, the presence of pneumopathy was associated with a tendency for the clinical condition to progressively worsen, resulting in a greater likelihood of death.

EP19-881-19 What is it if it's not TB? Infections causing a similar clinical picture and their morbidity and mortality

S.F. Weber,[1,2,3] A. Glaser,[4] B.R. Adegbite,[5] J.B.P.A.A. Abdul,[5] C.S. Gouleu,[5] V. Rickerts,[6] C.M. Denkinger,[1,3] M.P. Grobusch,[4,5,7,8] A.A. Adegnika,[5,4,8] S. Bélard,[4,8] and the NoTB study group (Micheska Epola Dibamba Ndanga, Guy Arnault Rogue Mfoumbi Ibinda, Jean-Ulrich Muandze Nzambe, Michael Lanzer, Frank Tobian, Fabrice Mbaïdiguim, Andréa Rosine Oméra Obele Ndong ,Jean Ronald Edoa) [1]Heidelberg University Hospital, Infectious Diseases and Tropical Medicine, Heidelberg, Germany, [2]University Hospital Heidelberg, Parasitology, Heidelberg, Germany, [3]German Center for Infectious Disease Research (DZIF), Partner site Heidelberg, Heidelberg, Germany, [4]University Hospital Tübingen, Institute of Tropical Medicine, Tübingen, Germany, [5]Centre de Recherches Médicales de Lambaréné, CERMEL, Lambaréné, Gabon, [6]Robert Koch Institute, FG 16 Mykologie, Berlin, Germany, [7]Amsterdam University Medical Centers, Center of Tropical Medicine and Travel Medicine, Amsterdam, Netherlands, [8]German Center for Infectious Disease Research (DZIF), Partner site Tübingen, Tübingen, Germany

Background: Pulmonary infections causing tuberculosis symptoms like cough or hemoptysis may be due to non-tuberculous mycobacteria (NTM), fungi, or parasites and may contribute to TB overdiagnosis or co-infection. Clinically diagnosed TB is associated with unfavourable outcomes.
This study investigated the prevalence and outcomes of non-TB infections in patients with presumed pulmonary TB in Lambaréné, Gabon.

Design/Methods: From 09/2024 to 02/2025 we enrolled consenting hospitalized adult patients with a positive WHO TB symptom screen undergoing TB evaluation (Xpert Ultra) in Lambaréné, Gabon. A questionnaire assessed medical and exposure history (TB, fungi, paragonimiasis).
Diagnostics included mycobacterial and fungal sputum cultures (SDA, 5-day incubation), stool and sputum parasitology, cryptococcal serum and histoplasma urine lateral flow antigen (LFA) tests, and HIV testing. Two-month outcomes were assessed via phone follow-up.
Results: A total of 103 participants were enrolled (median age 44 (IQR 30.5;58.5); 59% female). HIV prevalence was 29%; 19% had prior pulmonary TB. Fungal exposure was reported by 39% (most commonly: 63% excavations, 43% bat contacts), and 7% consumed raw/undercooked crabs as a risk factor for paragonimiasis.
Confirmed TB was diagnosed in 31%, clinical TB in 6%, and "NoTB" in 62%. Likely NTM were detected in 12% (of these 58% in the NoTB-group). LFAs were positive for histoplasmosis in 6% and cryptococcosis in 3% (mostly in NoTB). No paragonimus eggs were detected.
Overall 2-month mortality was 12% (12/97). In confirmed TB it was 14% (4/29), in clinical TB 0% (0/6) and 11% (7/64) in NoTB.
Conclusions: Fungal (9%) and NTM (12%) infections were frequent in presumptive TB patients and mortality in TB and NoTB exceeded 10%. Identification of cultured fungi and specific fungal PCRs (*Histoplasma, Blastomyces*) for final fungal classification are pending. Further analyses including sequencing of cultured NTM-strains, stool and sputum PCR for *Paragonimus* and metagenomics on sputum will be applied to better differentiate clinically relevant infections.

EP19-882-19 Prevalence and clinical implications of *Aspergillus* infection in a PeruvianTB cohort

A.E. Madden,[1] C.-C. Huang,[2,1] R.I. Calderon,[3] L.W. Lecca,[4,1] M. Mendoza,[4] N.B. Ponce,[4] G.R. Rocha,[4] Q. Tan,[1] K. Tintaya,[4] X. Tovar,[1] Z. Zhang,[2] M.B. Murray,[1,5,2] [1]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States of America, [2]Brigham and Women's Hospital, Division of Global Health Equity, Boston, United States of America, [3]Advanced Research and Health, Advanced Research and Health, Lima, Peru, [4]Socios En Salud, Socios En Salud, Lima, Peru, [5]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States of America
e-mail: alicia_madden@hms.harvard.edu

Background: Chronic pulmonary aspergillosis (CPA) is a prevalent but underrecognized form of post-tuberculosis lung disease. CPA presents with symptoms similar to those of tuberculosis (TB) and may be frequently misdiagnosed as TB. We estimated the prevalence of anti-

Aspergillus antibody positivity and CPA in a tuberculosis cohort in Lima, Peru and investigated the clinical impact of *Aspergillus* infection among those receiving TB treatment.

Design/Methods: Between October 2020 and February 2022, we enrolled and followed persons diagnosed with tuberculosis in Lima, Peru. We obtained serum samples at the time of TB diagnosis and again after 2 months of treatment and tested these for IgG antibodies against *Aspergillus* species. Participants were considered microbiologically negative for TB if their sputum smear, culture, and GeneXpert results were all negative.

Results: Among 1,998 individuals (mean age = 37.9 years, range 14-90) , 5.4% were anti-*Aspergillus* antibody positive and 4.3% met the clinical criteria for CPA at baseline. Those with positive *Aspergillus* serology were older (mean age = 54.6 years) and more likely to have a history of previous TB disease (aOR = 3.79) .

Five (0.3%) initially anti-*Aspergillus* antibody negative participants were positive at 2 months, and nine (10%) initially antibody positive participants reverted to negative serostatus. Among microbiologically negative patients, both *Aspergillus* positivity and CPA prevalence were higher at 8.1% and 6.3% respectively. Participants with positive *Aspergillus* serology showed less clinical improvement at 2 months of treatment and had lower rates of cure or treatment completion.

Conclusions: This is the largest suspected TB cohort to be evaluated with anti-*Aspergillus* serology. Our preliminary findings indicate that among those who are microbiologically negative for TB at the time of diagnosis, 6% or more may have CPA instead. CPA is an underrecognized differential diagnosis for TB and *Aspergillus* positivity may be predictive of poor response to TB treatment.

EP19-883-19 Adopting an integrated approach to lung health: A case study in Murang'a County, Kenya

V. Wanjohi,[1] L. Irungu,[2] I. Kathure,[3] I. Umuro,[3] B. Mwangi,[1] D. Karambi,[1] P. Kimani,[1] S. Olwande,[1]
[1]Clinton Health Access Initiative, Infectious Diseases, Nairobi, Kenya, [2]Muranga County Government, TB and Lung Health, Nairobi, Kenya, [3]Division of TB and Other lung Diseases, Division of TB and Other lung Diseases, Nairobi, Kenya
e-mail: irungu4@gmail.com

Background and challenges to implementation: In Kenya, respiratory diseases account for 25% of outpatient visits. Gaps remain in identifying at-risk TB and other lung diseases individuals. Barriers include absent integrated guidelines, siloed workflows, limited access to advanced diagnostics, inadequate healthcare worker training, and insufficient funding, resulting in missed diagnoses and reduced case detection rates. An accelerated approach is imperative in developing an integrated lung health guideline with standardized algorithms and screening protocols.

Intervention or response: The Division of TB and Other Lung Diseases in Kenya is implementing the iPACT (Integrated Program for Asthma, COPD, and TB) project in a phased approach, starting with three high-burden counties. A three-day pilot implementation was conducted in Muranga County, launched on World TB Day through community-based outreaches and two prison centers. Community health promoters mobilized the community, and symptomatic screening administered at triage. Symptomatic patients received chest X-rays using the AI-powered digital X-ray. Spirometry was used to differentiate other chronic lung diseases.

Results/Impact: A total of 1393 patients were screened, with males being 91% (1277). About 33% (464) of the total screened were symptomatic and were offered CXR with AI. Lung abnormalities detected were suggestive TB at 29% (137), lung nodules 2% (8), 21% (98) abnormal features suggestive of other lung diseases, and 15% (60) had both suggestive TB and other lung abnormalities. Spirometry tests (98) were administered to only patients with abnormal other lung diseases,13% (13) showed features of Asthma, 7% (7) COPD, 1% (1) mixed obstructive and restrictive, and 3% (3) PTLD. MTB detected were 18% (36). Patients were linked to appropriate care.

Conclusions: An integrated approach with improved screening and diagnostic workflows and tools improves early detection of TB and other lung diseases. This approach addresses diagnostic and case management gaps through comprehensive standardized protocols and optimized patient referral pathways, indicating it is an essential model with the potential for scale-up.

EP19-884-19 Metabolic disorders and clinical outcomes in AECOPD: A multi-centre cohort study

J. Pu,[1] [1]West China Hospital of Sichuan University, Department of Respiratory and Critical Care Medicine;2.State Key Laboratory of Respiratory Health and Multimorbidity, Chengdu, China
e-mail: 3273396213@qq.com

Background: The coexistence of hypertension, diabetes, dyslipidemia, and obesity (collectively termed ‚metabolic dysfunction') is prevalent in chronic obstructive pulmonary disease (COPD) patients, yet its impact on acute exacerbation (AECOPD) outcomes remains poorly understood. We aimed to investigate the association between metabolic dysfunction and clinical prognosis in hospitalized AECOPD patients.

Design/Methods: In this prospective multi-center study, we enrolled 11,165 AECOPD patients from ten Chinese medical centers, stratified by metabolic dysfunction status (present: n=4,503; absent: n=6,662). Primary outcomes

included in-hospital mortality, ICU admission, and mechanical ventilation requirement. Cox proportional hazards models were adjusted for age, sex, BMI, and smoking status.

Results: Patients with metabolic dysfunction were older (75.2±9.7 vs 70.8±10.3 years, p<0.001), had higher BMI (23.1±4.5 vs 20.6±3.5 kg/m², p<0.001), and greater comorbidity burdens (coronary heart disease: 18.3% vs 7.3%; heart failure: 16.3% vs 8.7%; cerebrovascular disease: 9.1% vs 3.8%; all p<0.001).

After multivariable adjustment, metabolic dysfunction showed no significant association with in-hospital mortality (aHR=1.49, 95%CI:0.90-2.47, p=0.124), ICU admission (aHR=1.02, 95%CI:0.83-1.25, p=0.849), invasive mechanical ventilation (aHR=1.06, 95%CI:0.80-1.42, p=0.673), or non-invasive ventilation (aHR=1.02, 95%CI:0.89-1.16, p=0.766).

Conclusions: Metabolic dysfunction was not independently associated with short-term adverse outcomes in AECOPD patients after adjustment for confounders.

EP19-885-19 Strengthening chronic respiratory diseases detection through a targeted Moonlight Outreach in Muthurwa, Nairobi, Kenya

S. Olwande,[1] P. Kimani,[1] B. Mwangi,[1] V. Wanjohi,[1] D. Karambi,[1] I. Kathure,[2] I. Umuro,[2] E. Mueni,[3] C. Ngunu,[3]
[1]Clinton Health Access Initiative, Infectious Diseases & Lung Health Program, Nairobi, Kenya, [2]National Leprosy Tuberculosis and Lung Disease Program,Kenya, National Leprosy Tuberculosis and Lung Disease Program,Kenya, Nairobi, Kenya, [3]Nairobi City County Government, Health, Nairobi, Kenya

Background and challenges to implementation: Kenya faces a high burden of respiratory diseases, including tuberculosis (TB), asthma, chronic obstructive pulmonary disease (COPD), and post-TB lung disease (PTLD). Limited access to screening services, especially among high-risk populations, worsens the situation. Muthurwa, a densely populated area in Nairobi, is a hotspot for respiratory diseases, particularly TB, due to overcrowded, poorly ventilated guest houses. Economic challenges and low awareness further delay healthcare-seeking. In response, a moonlight outreach was organized to provide accessible screening for chronic lung conditions and promote early detection in the community.

The outreach, held on World TB Day, targeted guest house residents living in high-risk conditions. As part of an integrated lung health initiative, it piloted a revised Integrated Algorithm for Screening Lung Conditions. This included digital chest X-rays (dCXR) with AI for diagnostics. Participants were referred for TB testing or further evaluation for asthma, COPD, PTLD, or lung cancer. A Chronic Lung Conditions Assessment Form was used to assess symptoms and comorbidities.

Intervention or response: In March 2025, the outreach was conducted over two nights. Community Health Promoters (CHPs) mobilized residents for screening using portable dCXR with AI. Clinical assessments and GeneXpert testing were conducted for symptomatic individuals. Health education on early diagnosis, treatment, smoking cessation, and prevention was also provided.

Results/Impact: A total of 336 individuals participated, with 99% (332) undergoing chest X-ray screening. Of those, 72% (239) had normal results. About 10% (33) had abnormal findings suggestive of TB and were further investigated, leading to 44% (15) being diagnosed.

Additionally, 18% (60) had abnormal X-rays suggestive of other lung conditions and were clinically diagnosed with asthma (10), COPD (12), PTLD (8), and suspected lung cancer (5).

Conclusions: The outreach enhanced early detection of chronic respiratory diseases and linkage to care. Scaling such initiatives and improving diagnostics is key to addressing respiratory disease burdens in high-risk settings

EP19-886-19 Assessing integrated lung health services in selected primary healthcare facilities (PHC) in North-Central Nigeria: Findings from a 2023-2024 pre-implementation baseline survey

K. Ojobor,[1] C. Atori,[2] J. Odu,[3] U. Ralph-Opara,[4] G. Yisa,[1] A. Toyin,[1] C. Uzoama,[2] M. Endalkachew,[4] S. Neri,[5] J. Cresswell,[6] A. Latif,[7] O. Chijioke-Akaniro,[8] [1]Project HOPE Nigeria, Programs, Minna, Nigeria, [2]Project HOPE Nigeria, Programs, FCT, Nigeria, [3]Project HOPE, Ontario, Canada, Programs and Technical, Ontario, Canada, [4]Project HOPE Washington, DC, Global Health, Washington, United States of America, [5]Project HOPE, Namibia, Programs and Technical, Windhoek, Namibia, [6]STOP TB Partnership, Geneva, Innovations & Grants, Geneva, Switzerland, [7]Mercy Corps, Pakistan, Programs, Islamabad, Pakistan, [8]NTBLCP Nigeria, M & E, FCT, Nigeria
e-mail: KOjobor@projecthope.org

Background and challenges to implementation: In Nigeria, there is an estimated TB burden of 499,000 in 2023; 13 million estimated to be living with asthma, and pneumonia accounts for 12% of all under-five deaths annually. All three of these conditions may present with similar clinical symptoms. In North-central Nigeria, treatment coverage for TB remains low, at 62%. Given the overlap in symptomatic presentation of Tuberculosis (TB), asthma, and pneumonia and the integrated health service delivery mandate of PHC, we conducted a facility baseline assessment to identify service delivery gaps in respiratory care. We will use the information to inform our program with the intent of using an integrated care program to improve diagnosis and treatment of these three conditions.
Intervention or response: A mixed-method baseline assessment was conducted in three high-burden Local Government Areas (LGAs) in Niger State, as part of the integrated lung health EXALT project. These LGAs have a TB treatment coverage ranging from 41% to 58%. Within these LGAs, 15 PHCs were randomly selected as assessment sites. Healthcare facility data was gathered from facility registers and equipment and medicines were observed. The data was entered into Excel and analyzed using descriptive statistics. Additionally, qualitative interviews with 15 healthcare workers explored perspectives on service availability and quality.
Results/Impact: We assessed 15 health centers in Niger state. We found knowledge and resource gaps across all facilities. Major findings include: 50 to 100% of HCWs lacked training in Tuberculosis, Asthma and Pneumonia. 67% of facilities had no microscope or anti TB medicines. There were no nebulizers at any facility.
Conclusions: The assessment revealed significant gaps in case detection, knowledge and diagnostic resources. This confirms our assumptions and will help define our interventions to improve diagnosis and treatment of these conditions ultimately enhancing lung health services at PHC level.

EP19-887-19 Factors associated with increased mortality among people with lung cancer in Tanzania and Uganda

G.I. Soka,[1] I. Najjingo,[2] S. Namiiro,[2] S.G. Mfinanga,[1] E. Ngadaya,[1] F. Schummacher,[3] J. Hale,[4] J. Willis,[5] B. Kirenga,[2] S. Gerson,[5] [1]National Institute for Medical Research-Nimr Muhimbili Center, Research, Dar Es Salaam, United Republic of Tanzania, [2]Makerere University Lung Institute, Research, Kampala, Uganda, [3]Case Western Reserve University, Case Comprehensive Cancer Center, Case Western, United States of America, [4]Case Western Reserve University, Research, Case Western, United States of America, [5]Case Western Reserve University, Case Western Reserve University, Case Western, United States of America
e-mail: gracesoka@gmail.com

Background: Lung cancer is the most prevalent cancer globally and the leading cause of cancer-related deaths, accounting for 1.8 million deaths worldwide. In sub-Saharan Africa, the incidence and mortality rates are approximately 128.2 and 87.2 per 100,000 people, respectively. Mortality rates vary due to multiple factors, including HIV. Understanding these determinants is crucial for creating targeted interventions in Tanzania and Uganda. This study aims to identify factors associated with increased mortality among lung cancer patients in these countries, focusing on the impact of HIV co-infection.
Design/Methods: Individuals ≥ 18 years with biopsy-proven lung cancer were enrolled in the study since 2022. Data on sociodemographic, clinical and comorbidities,

diagnostic and treatment outcome were recorded. Kaplan Meier was used to assess for difference in survival rates by HIV status. Cox hazard proportion hazard regression analysis was done to assess factors associated with increased mortality among lung cancer patients.

Results: A total of 289(48.2%) lung cancer biopsy-confirmed patients were enrolled in the study. Majority, 157(54.3%) were under 60 years of age, 159(55%) women, 129(44.8%) peasant 207(71.8%) non-smokers and 21(7.3%)were HIV positive. Firewood/logs 138(48.08%) and charcoal 95(33.1%) were the major cooking fuels. Majority were diagnosed at stage (III and IV), and 162(56.1%) have died. From the regression analysis; stage at diagnosis, having history of smoking, progressively severity of symptoms and HIV positive were the major causes of death among these patients.

Conclusions: Late-stage diagnosis, HIV co-infection, smoking history, and worsening symptoms were key factors linked to higher lung cancer mortality in Tanzania and Uganda emphasizing the significant impact of HIV co-infection. The study highlights the need for early detection, increased awareness, and targeted interventions addressing these factors to reduce mortality. Further research is warranted to explore the interplay between these factors and to develop region-specific guidelines for lung cancer management in the context of HIV.

EP19-888-19 Detection to neglect: Gaps in care for non-TB lung conditions revealed by integrated chest X-ray screening in underserved communities in Nigeria

J.N. Ekwu,[1] C. Ugwu,[1,2] J.S. Bimba,[3] [1]Zankli Research Centre, Bingham University, Karu, Nigeria, Zankli Research Centre, Karu, Nigeria, Nigeria, [2]Liverpool School of Tropical Medicine, UK, Community Medicine, Karu, Nigeria, [3]Bingham University, Community Medicine/Zankli Research Centre, Karu, Nigeria
e-mail: ekwujames@gmail.com

Background: Nigeria is ranked sixth among the 30 high-burden countries for tuberculosis and continues to face the high burden of Chronic respiratory diseases (CRDs) and cardiovascular diseases (CVDs), with gaps in early detection, management options, and data showing ongoing transmission and sustained incidence, especially in underserved, rural communities.

Therefore, an integrated, decentralized, and culturally sensitive approach to screening and care is needed to address this public health challenge.

Design/Methods: An integrated screening programme was conducted in underserved, remote communities using a Chest X-ray (CRX) machine with AI capabilities to detect lung and heart abnormalities indicative of TB, CRDs, and CVDs. Individuals with X-ray results suggestive of Tuberculosis were subjected to further analysis using GeneXpert and linked to community facilities providing TB services. All those with X-ray abnormalities indicative of CRDs and CVDs were referred to tertiary facilities for confirmatory diagnosis and appropriate linkage to care.

Results: Of the 3006 persons screened for TB and non-TB abnormalities, 1017(34%) had abnormal CXR results (Opacity 47%, Nodule 26%, emphysema 21%), with 16% suggestive of TB (Cavity 2%, fibrosis 15%), while 35% had abnormalities indicative of CRDs and CVDs (emphysema 21%, blunted costophrenic angle 9%, cardiomegaly 15%, vascular calcifications 11%, Pleural effusion 7%, Tracheal shift 5%); with a 99% enrollment rate for TB care while only about 2% of non-TB conditions referred to tertiary facilities linked to care.

Although case detection increased due to integrated screening, access to care remained a significant challenge, as over 98% of individuals referred for CRD and CVD care at tertiary facilities were unable to enroll in treatment due to transportation barriers and the high cost of accessing care.

Conclusions: While integrating screening improves case detection, there is a need to bridge the gaps in decentralized, integrated, and affordable health care to improve health outcomes among underserved communities, affording individuals universal health coverage.

EP20 Messaging that matters: Effective communication for TB elimination

EP20-889-19 Could content creation be the hope of TB diagnosis? Insights from KNCV Nigeria's Wellness on Keke initiative

K. Anadi,[1] E. Nwokoro,[2] M. Meribe,[1] O. Kene-Eneh,[1] O. Chukwuogo,[2] B. Odume,[2] [1]KNCV Nigeria, Communication, Abuja, Nigeria, [2]KNCV Nigeria, Programs, Abuja, Nigeria
e-mail: kanadi@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge in Nigeria, with a significant gap between estimated incidence and reported cases. This study explored the potential of content creation to improve TB diagnosis rates within the context of KNCV Nigeria's Wellness on Keke (WoK) initiative, a mobile health program designed to reach underserved populations.
The study aimed to determine if strategically developed content can enhance TB awareness, reduce stigma, and encourage individuals to seek timely diagnosis through the WoK initiative.
Intervention or response: This study utilized an extended literature review approach to explore the potential of content creation, through an investigation of previous successful TB campaigns that have utilized content creation in Nigeria and similar settings.
The analysis focused on identifying effective content formats, potential delivery methods, and the specific opportunities and challenges of delivering content via the WoK platform.
Results/Impact: The analysis indicated substantial potential for utilizing tailored content creation strategies; for example, leveraging storytelling and engaging trusted community figures such as the Keke drivers themselves, were highlighted as particularly promising approaches. Evidence from other successful TB campaigns in Nigeria underscored the effectiveness of employing multi-channel communication strategies, utilizing local languages, and sharing relatable personal narratives.
Finally, the study identified several specific challenges to implementing these content strategies within the mobile WoK framework, such as the existing digital divide, variations in literacy levels among target populations, the crucial need for cultural sensitivity in messaging, and possible logistical challenges inherent in a mobile initiative.
Conclusions: The findings of this study revealed that despite potential challenges, content creation can encourage timely healthcare-seeking behavior for TB and thus improve diagnosis rates.
Thus, integrating targeted, culturally relevant content creation into the WoK initiative and broader strategies offers considerable potential „hope" for enhancing TB diagnosis in Nigeria.

EP20-890-19 360-degree communication campaign to mobilize communities to undergo early testing for Tuberculosis in India

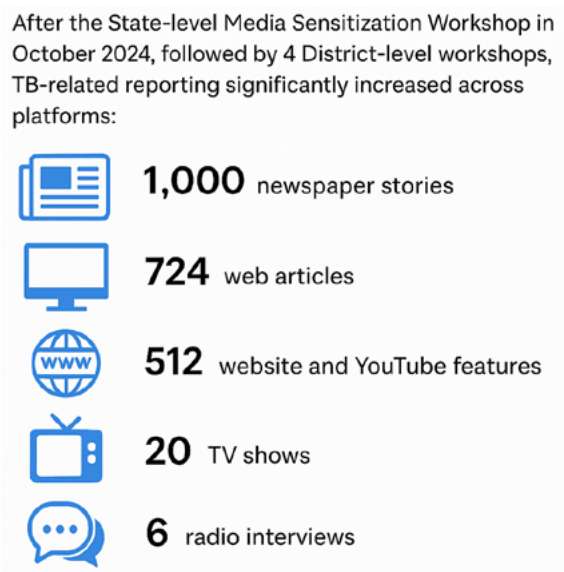
N. Kumar,[1] A. Bhardwaj,[2] P. Bordoloi,[3] S. Sharma,[4] U. B Singh,[4] [1]Ministry of Health and Family Welfare, Government of India, Central TB Division, New Delhi, India, [2]The International Union Against Tuberculosis and Lung Disease, ACSM NTSU, New Delhi, India, [3]World Health Organisation, GOI-WHO TB TSN, New Delhi, India, [4]Ministry of Health and Family Welfare, Central TB Division, Delhi, India
e-mail: ashish.bhardwaj@theunion.org

Background and challenges to implementation: The National Tuberculosis Elimination Programme endeavors a TB-free India by, targeting decline in annual TB incidence rate, decline in death due to TB and Zero catastrophic expenditure due to TB
Though TB incidence and mortality rates have decreased since 2015, challenges such as stigma, diagnostic gaps, and undernutrition require intensified efforts through community-centric approaches. A focused Information, Education and Communication, IEC campaign was necessitated as the National TB Prevalence Survey [1] highlighted that 64% people who showed symptoms did not seek care.
[1] National TB Prevalence Survey in India 2019 – 2021
Intervention or response: A 100-day intensified campaign for TB Elimination in India's high prevalence districts[1]. Focused IEC activities were undertaken to leverage all communication platforms and ensure impactful outreach for increasing awareness, reducing stigma, and encouraging community participation in TB detection drives. Engagement though social media and editorial media helped in increasing salience and motivating vulnerable people to undergo TB Testing.
[1] Shortlisted basis high death rates, testing gaps and high TB incidence) across 33 States/UTs, including high-burden of TB disease and mortality due to TB, tribal, mining, and aspirational districts.
Results/Impact: A 360-degree targeted IEC campaign was released to increase awareness, negate stigma and increase people's participation for TB Elimination. Focused activities included 1,94,185+ awareness activities, 62,981 stigma reduction activities, 59,853 sensitization & stigma reduction activities with students and teachers, 24,322 activities were held with opinion leaders, community influencers, religious organizations, 8,467 Mid-media and local IEC awareness Sessions, Editorial Media coverage that included 5,755+ articles in Print /Electronic Media and Conversations around #TBMuktBharat on twitter yielded 10,904 Mentions by 4,891 Unique Authors.
Conclusions: The 100-day intensified campaign emphasized on people's movement to increase TB awareness among general population and motivate vulnerable individuals and symptomatic cases to undergo TB testing, prevention and treatment.

EP20-891-19 Bridging the TB knowledge gap: The impact of media in Himachal Pradesh, India

G. Beri,[1] Y.P. Sharma,[1] R. Kumar,[1] L.R. Sharma,[1] A. Bhardwaj,[2] S. Savita,[3] A. Singh,[4] [1]Department of Health and Family Welfare, National Health Mission, Shimla, India, [2]National Task Force, TB, Shimla, India, [3]International Union Against TB and Lungs Disease, ACSM-NTSU, Shimla, India, [4]International Union Against TB and Lungs Disease, ACSM-NTSU, Delhi, India
e-mail: SUNIL.SAVITA@THEUNION.ORG

Background and challenges to implementation: TB is a serious public health problem in India requiring a comprehensive strategy engaging different stakeholders including community to achieve elimination. Lack of awareness among general population on TB warrants the use of mass media to drive large-scale behavioural change to improve diagnosis, treatment and prevention.
Intervention or response: A media advocacy & sensitization meeting was organized in the state of Himachal Pradesh in October 2024 which had participation from 43 journalists. To drive sustainability and maintain momentum, four media workshops at district level were organized which were attended by 110 journalists. They were sensitized about reporting on TB, programme updates and encouraged to use their platform to be the eyes and ears of the programme in ensuring TB services reach the last mile stakeholder



Results/Impact: After these 5 workshops TB-related reporting improved significantly, both qualitatively and quantitatively across platforms at State and District levels From October 2024 to March 2025, there were 1,000 newspaper stories, 724 web articles, 512 website and YouTube features, 20 TV shows, 6 radio interviews, and 450 social media/Youtube reports. Organic coverage ranged from 3 to 30 stories per month. This extensive media engagement played a key role in raising awareness about TB symptoms, services, and early treatment—contributing to improved health-seeking behaviour across Himachal Pradesh and strengthening community support for TB elimination efforts.
Conclusions: After the media sensitization workshops in HP, media has emerged as a critical catalyst in the people's movement against TB with a sustained increase in coverage on TB across versatile platforms. It indicates that a comprehensive and transparent sensitization of media journalists on TB helps in having sustainable engagement. Furthermore, these media outputs were free and organic, making them more credible and effective, and underlining the potential of this intervention to be scaled up to national and global levels.

EP20-892-19 Organizing site visits for journalists to provide firsthand, experiential insight into TB program interventions

N. Kumar,[1] H. Mir,[2] R. Sankar,[2] S. Ravishanker,[2] U. Singh,[3] [1]Ministry of Health and Family Welfare, Government of India, Central TB Division, New Delhi, India, [2]Global Health Strategies, Tuberculosis, New Delhi, India, [3]Ministry of Health and Family Welfare, Central TB Division, New Delhi, India
e-mail: sravishanker@globalhealthstrategies.com

Background and challenges to implementation: In line with the National Strategic Plan, India's National TB Program (NTP) has implemented several innovative strategies to improve access to quality, affordable TB care. Showcasing these initiatives is essential – not only to raise public awareness and encourage greater service uptake, but also to reinforce stakeholder commitment and morale. Mainstream media plays a pivotal role in promoting evidence-based discourse around program achievements.
Intervention or response: In March 2025, the NTP organized experiential learning visits for journalists from leading Indian media outlets. These visits, conducted at the close of India's specialized 100-Day Intensified TB Elimination campaign, showcased decentralized service delivery, innovative screening and diagnostic approaches, and community engagement strategies.
The visits were held in Uttar Pradesh – India's most populous state with nearly 26% of the national TB burden and Meghalaya – a remote northeastern state with challenging terrain.
Results/Impact: Journalists from eight major Indian national outlets participated and gained firsthand exposure to different program interventions and community engagement approaches. These included decentralized TB service delivery models through community-level Ayushman Aarogya Mandirs (Primary Healthcare Centres), community screening drives using AI-enabled portable

X-rays, and involvement of TB survivors as champions. Interactions with patients, healthcare workers, and local administrators deepened their understanding of local contexts, leading to more informed and impactful reporting. Following the two visits, over 150 media reports were published highlighting key aspects of India's TB response and serve to generate greater awareness about TB symptoms, available services, and address myths and misconceptions, thus reducing stigma, and encouraging healthcare seeking behaviour.

Conclusions: Experiential visits provide journalists with a unique opportunity to witness on-ground realities, understand sociocultural contexts, and engage with cutting-edge approaches to service delivery. By connecting journalists directly with on-ground realities, such initiatives strengthen public awareness and community engagement – key to sustaining TB elimination efforts.

EP20-893-19 From silence to strength: A 100-day tuberculosis-awareness drive utilizing community radio, newspapers, and television broadcasts under IMPACT-India in Chandigarh Union Territory (UT) and Punjab, India

N.K. Sinha,[1] R. Gangula,[2] M. Sharma,[3] A. Das,[3] V. Joseph,[3] P. Kapoor,[4] R. Dasari,[2] R. Begum,[3] R. Bhaskar,[5] B.S. Kushwaha,[6] S.K. Mattoo,[6] U.B. Singh,[6] [1]TB Alert India, Program Management, Chandigarh, India, [2]TB Alert India, Program Management, Hyderabad, India, [3]KHPT, Programs, New Delhi, India, [4]Office of the World Health Organization (WHO) Representative to India, WHO Country Office, Communicable Diseases, Chandigarh, Punjab, India, [5]Office of Director Health Services, Government of Punjab, Chandigarh, India, [6]Central TB Division, Ministry of Health and Family Welfare, New Delhi, India
e-mail: rameshdasari@tbalertindia.org

Background and challenges to implementation: Tuberculosis (TB) remains a significant public health challenge in India, with stigma, misinformation, and delayed diagnosis continuing to hinder progress towards TB elimination. Traditional IEC (Information, Education, and Communication) efforts often fall short in reaching grassroots populations.

In this context, community and mass media platforms have emerged as powerful tools to engage the public, drive awareness, and reduce stigma, particularly in underserved regions.

Intervention or response: Under the Integrated Measures for Prevention and Care in TB (IMPACT)-India Project, TB Alert India leveraged mass media to amplify TB awareness across Chandigarh-UT and Punjab. Over six months, more than 200 newspaper articles, 5 Television interviews, and FM Radio Chitkara's 100-day segment "Meri Kahani, Meri Zubaani" (My Story, My Voice), aired from December 9, 2024, to March 24, 2025, reached an estimated 3 million listeners. The segment featured survivor stories and expert insights, driving community engagement. The Governor of Chandigarh-UT honored TB Champions for inspiring change within the community. This strategic media advocacy significantly bolstered awareness, engagement, and solidarity in the fight against TB. The data from Ni-kshay (India's digital TB surveillance system) was extracted and analysed.

Results/Impact: The media-driven advocacy campaign boosted awareness and health-seeking behavior over six months, leading to a 13% increase in TB notifications across Punjab. The five intervention districts - Ludhiana, Jalandhar, Patiala, Moga, and Firozpur recorded a 21.3% rise, while Chandigarh-UT saw a 22% increase. Compared to October–March 2023–2024 and 2024–2025, these gains reflect impactful community engagement in TB prevention and care, reaching millions statewide.

Medium	Reach/Impact
Radio	FM Radio Chitkara reached over 3 million rural listeners through its 100-day broadcast initiative.
Television	Over 10 million viewers watched the TB-related news coverage on various TV channels.
Newspapers	Publications like local news paper Punjab Kesari, Jagbani and The Times of India reached a daily readership of 2 million people.
TB Notifications	-TB notification in Punjab increased by 13%. - Intervention districts in Punjab recorded an exclusive increase of 21.3%. - In Chandigarh-UT, TB notifications rose by 22%.

Table-1: Showing Reach and Impact of Media-Driven Advocacy.

Conclusions: The IMPACT-India Project highlighted the power of media-led, community driven advocacy amplified the reach of TB awareness campaigns. By mainstreaming the voices of TB survivors and experts, and recognizing them publicly normalized the TB conversations destigmatizing TB created a scalable model for public health communication in India.

EP20-894-19 Smartphone and social media use among people living with tuberculosis: A key for less resource intensive IEC

A. Kadam,[1] P. Kadam,[2] Y. Gao,[3] A. Kakrani,[4] S. Kakade,[2] P. Tayde,[2] A. Gupte,[3] M. Barthwal,[2] PTLD Study Team
[1]Johns Hopkins Center for Infectious Diseases in India, Medicine, Pune, India, [2]Dr. D. Y. Patil Medical College, Hospital and Research Centre, Pulmonary Medicine, Pune, India, [3]Boston University School of Public Health, Global Health, Boston, United States of America, [4]Dr. D. Y. Patil Medical College, Hospital and Research Centre, Medicine, Pune, India
e-mail: akadam2@jhmi.edu

Background: Though resource intensive, IEC (Information, Education, and Communication) is crucial for effective tuberculosis (TB) program implementation. Digital health technologies can make IEC less resource intensive. Though there is sufficient literature on use of digital health technologies in TB, majority were on TB diagnosis and treatment adherence using mHealth applications, text messaging, calls or videocalls.
Though telecom industry being fast evolving, the scientific literature on smartphone access and use among people with tuberculosis (PWTB) is limited and not assessed periodically. We explored smartphone use among PWTB to identify potential social media platforms for IEC.
Design/Methods: We enrolled 30 adults (≥18 years) with drug-sensitive pulmonary TB at treatment initiation in an ongoing study from public TB clinics in Pune, India. Sociodemographic and smartphone use questionnaires were administered by trained staff at enrolment. Descriptive statistics were used to summarise the data.

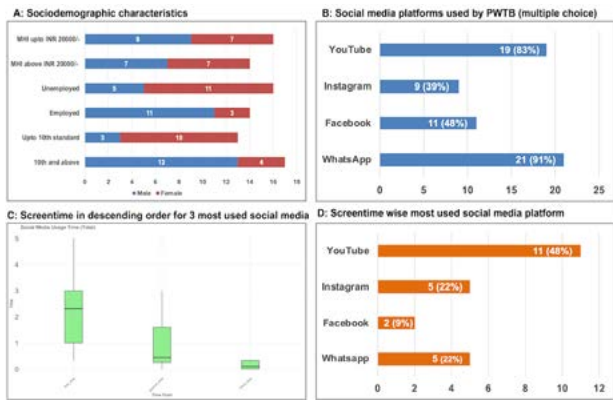


Figure. Sociodemographic characteristics and social media use among people with tuberculosis.

Results: Of 30 PWTB, 14 (47%) were female, 24 (80%) owned a smartphone and all of them had internet access. The primary internet was mobile internet for 22 (92%). The median screentime of social media use among PWTB was 3.1 hours per day (IQR 1.5, 4.7). Among 96% (23/24) who were using social media, 21 (91%) were using WhatsApp, 19 (83%) YouTube, 11 (48%) Facebook and 9 (39%) Instagram. When ranked by screentime, the maximum time spent on a single application (2.3 hours, IQR 1.0, 3.0) by 11 (48%) on YouTube whereas by 5 (22%) each on WhatsApp and Instagram.
Conclusions: Though majority PWTB were using WhatsApp and YouTube, based on screentime YouTube was the most used social media platform. Standalone mHealth applications are important for IEC but a scoping review by Giebel GD et al (2023) comprehensively assessed their challenges and barriers. Hence, IEC additionally needs to be integrated in social media platforms used by PWTB.

EP20-895-19 Tuberculosis education and communication in the digital era: Mixed-methodology study to assess perspectives of healthcare professionals and other stakeholders

K. Dasgupta,[1] S. Sangale,[2] A. Kadu,[1] K. Khaparde,[3] S. Chandra,[3] Y. Wadgave,[4] S. Patil,[5] A. Kale,[2] [1]Government of India - WHO Country Office for India, TB Technical Support Network, National Tuberculosis Elimination Programme - Technical Support Network, New Delhi, India, [2]Government of Maharashtra, National TB Elimination Programme, Pune, India, [3]Government of India- WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [4]FIND, Access, Pune, India, [5]MGM Medical College, Community Medicine, C. Sambhajinagar, India
e-mail: kadua@rntcp.org

Background: Among the challenges faced in India's efforts to eliminate tuberculosis, is identifying and bridging inadequacies in awareness and perceptions about the disease, its diagnosis, treatment, prevention and other services, in different groups such as the public, healthcare professionals, other healthcare staff and stakeholders. As per the last national tuberculosis prevalence survey (2021), 55% of symptomatic individuals across the country either ignored their symptoms or couldn't recognise them. It is also vital for healthcare providers to stay updated with relevant information. Advocacy, communication and social mobilisation (ACSM) interventions are directed at bridging such gaps.
A key challenge in planning and implementing these is their impact evaluation. A feedback mechanism incorporating the same is likely to significantly help shape ACSM interventions to be more target-specific and resource efficient.
Design/Methods: Quantitative: Survey to assess perceptions regarding tuberculosis IEC and digital media usage for the same, among physicians and other medical professionals actively dealing with tuberculosis in everyday practice. 152 responses were collected, and convenience sampling is being continued to strengthen the study. **Qualitative**: Thematic analysis of challenges and ways ahead in planning and implementing ACSM interventions, explored through FGD and KII.

Results:

Practice area	Rural: 39 (25.6%)	Urban & semi-urban: 113 74.4%)		
Source of knowledge/updates about tuberculosis (mutually inclusive)	Formal medical education: 141 (92.7%)	CMEs, trainings & workshops: 113 (74.3%)		
Preferred modes to receive updates/ information about tuberculosis (mutually inclusive)	Offline such as CME/training/ workshop, etc: 107 (70.3%)	Online training sessions: 87 (57.2%)	Social media platforms (Message apps, Instagram, X, YouTube, Facebook): 85 (55.9%)	
Perception of tuberculosis awareness among general public	Inadequate: 93 (61.2%)	Adequate: 48 (31.6%)	Can't say: 11 (7.2%)	
Perception of tuberculosis awareness among other healthcare professionals	Inadequate: 59 (38.8%)	Adequate: 93 (61.1%)		
Most effective platform for tuberculosis IEC to public as per perception (mutually exclusive)	Social/digital media: 46 (30.2%)	Awareness sessions or display at public sites: 36 (23.6%)	Print or mass media: 28 (18.4%)	Others- Door-to-door campaigns (15), Educational institute/ workplaces: (7), one-on-one interactions with healthcare provider (5), and three more
Average hours spent on social media (self)	Less than 1 hour: 37 (24.3%)	1-2 hours: 67 (44%)	2-6 hours: 45 (29.6%)	More than 6 hours: 3
Average hours spent on social media by average beneficiary/ patient (perception)	Less than 1 hour: 16 (10.5%)	1-2 hours: 52 (34.2%)	2-6 hours: 62 (40.7%)	More than 6 hours: 22 (14.4%)
Maximum time spent on (social media platform, 4 options)	YouTube: 54 (35.5%)	Instagram: 41 (26.9%)	Facebook: 34 (22.3%)	X: 6 None of these: 17
Stakeholder groups to be involved in tuberculosis IEC	Healthcare professionals: 121 (79.6%)	Community health staff & volunteers: 111 (73%)	Media-persons, politicians, community leaders and influencers: 94 (61.8%)	People affected personally: 89 (58.5%) NGOs and civic associations: 87 (57.2%)

Conclusions: Our findings suggest a need to revisit certain strategies employed in tuberculosis IEC for the public as well as healthcare and ancillary professionals. The role of digital media is widely perceived to be evolving and significant, reflecting a need for more investment. Collaboration between IEC on tuberculosis and other public health concerns such as air pollution, antimicrobial stewardship, airborne infection control, lung cancer screening and tobacco control, is deemed useful, as is involvement of more diverse stakeholder groups. Lack of understanding of target audience, poor impact visibility, as well as scope for better financial planning, and identification and motivation of facilitating groups, were among the major challenges identified for effective IEC.

EP20-896-19 Barriers and facilitators of tuberculosis treatment among Cameroon refugees in Nigeria: A mixed-methods study

S. Abdulkarim,[1] S. John,[2] C. Smyth,[3] A. Versfeld,[4]
[1]Gombe State Ministry of health, Planning, Reserach and Statistics, Gombe, Nigeria, [2]Adamawa State ministry of Health, Planning Research and Statistics, Adamawa, Nigeria, [3]Stop TB Partnership, Challenge Facility for Civil Society (CFCS), Geneva, Switzerland, [4]Stop TB Partnership, Challenge Facility for Civil Society (CFCS),, Eastern Cape, South Africa
e-mail: drsurajkwami@gmail.com

Background: Refugees globally face a disproportionately high burden of tuberculosis (TB) and significant barriers to healthcare. Nigeria currently hosts large numbers of refugees displaced by the unrest in Southern Cameroon. To support improved TB care, Janna Health Foundation and Sufabel Community Development Initiative conducted research to identify care access barriers as perceived by refugees with TB receiving treatment in public facilities in Taraba State. This paper seeks to showcase findings on care access barriers to TB services experienced by Refugees in Taraba State.
Design/Methods: A 15-item Likert-scale questionnaire was developed based on eight semi-structured interviews with religious and community leaders, eight focus group discussions with healthcare providers and people affected by TB, and 25 individual interviews with people with TB. Trained refugee peers administered the questionnaire to 130 participants (66 women, 64 men) across three local government areas (LGAs) while they waited for treatment in public facilities.
Results: The most commonly reported individual barriers were hunger (93.0%), lack of money for transport (92.3%), and inability to pay service costs (90.8%). Health system barriers included fear of disease transmission (70.0%), stigma from healthcare workers (60.0%), lack of potable water (55.0%), and medication stockouts (51.0%). Interpersonal barriers included community stigma (70.0%), lack of clothing deemed appropriate (55.8%), and language challenges (54.6%).
Overall, 60.8% (n=79) identified at least 10 of the listed items as barriers to care.
Conclusions: Findings underscore the compounded barriers faced by Cameroonian refugees navigating TB care—where poverty, displacement-related vulnerability, and systemic health service gaps intersect. Addressing these challenges requires integrated approaches that link TB care with food security, financial protection, and stigma reduction, both within facilities and communities. Strengthening health systems to be inclusive of displaced populations, and enabling affected communities to shape responses, is essential to building equitable and resilient TB care in displacement settings.

EP20-897-19 Effect of community awareness, screening, diagnosis, and treatment campaigns on TB care in Uganda

R. Mulebeke,[1] [1]Mildmay Research Centre Uganda, Research, Kampala, Uganda
e-mail: mulebeker@gmail.com

Background: SETTING: Eight districts in central Uganda with 105 health facilities.
OBJECTIVE: To evaluate the effectiveness of the community awareness, screening, testing, diagnosis, and treatment (CAST-TB) campaigns on the number of people screened for, presumed to have, and diagnosed with TB disease.
Design/Methods: We designed a quasi-experimental study and utilized Bayesian Structural Time-Series analysis for counterfactual predictions over 24 months (12 months before vs 12 months during intervention). The intervention was the CAST-TB campaigns. The outcomes included the number of people screened for, presumed to have, and diagnosed with TB disease.
Results: The intervention led to a 36% (95% credible interval [CrI] 8.4–65, P = 0.005) increase in the number of people screened for TB disease (1,194,257 observed vs 875,211 predicted), a 29% (95% CrI 5.3–52, P = 0.01) increase in the number of people presumed to have TB disease (25,784 observed vs 19,997 predicted), and a 49% (95% CrI 25–75) increase in the number of people diagnosed with TB disease (2,566 observed vs 1,719 counterfactual).

Outcome	Number screened for TB disease	Number presumed to have TB disease	Number diagnosed with TB disease
Intervention period	1,194,257	25,784	2,566
Counterfactual (95% CI)	875,211 (629,329–1,115,424)	19,997 (15,374–24,726)	1,719 (1,281–2,137)
Percentage increase, % (95% CI)	36 (8.4–65)	29 (5.3–52)	49 (25–75)
P-value	0.005	0.01	<0.0001

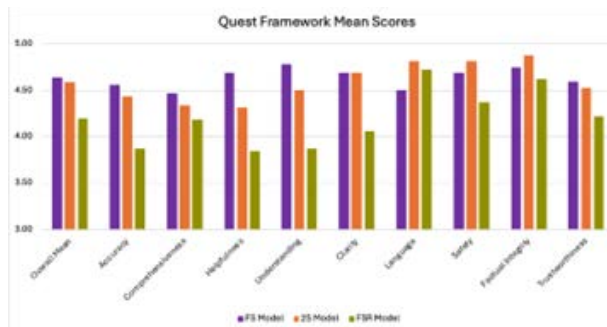
Table 2. Effect of CAST-TB campaigns on the study outcomes.

Conclusions: We found the CAST-TB campaigns improved the number of people screened for, presumed to have, and diagnosed with TB disease. Our evidence provides the data needed to support the Uganda MoH's effort to scale up the CAST-TB campaigns across the country.

EP20-898-19 Enhancing TB treatment: Developing and evaluating Spanish-language LLM chatbots for real-time support, accuracy, and empathy

S. Iribarren,[1] H. Jakher,[1] D. Galdamez,[1] D. Filienko,[2] A. Vidrio,[1] Y. Rodrigues,[1] J. Roberti,[3] M. Nizar,[2] P. Carmiol-Rodriguez,[1] C. Kwanin,[1] M. De Cock,[2] W. Yuwen,[4] [1]University of Washington, Biobehavioral Nursing and Health Informatics, Seattle, United States of America, [2]University of Washington, Computer Science and Systems, Tacoma, United States of America, [3]Institute of Clinical Effectiveness and Healthcare Policy, Research, Buenos Aires, Argentina, [4]University of Washington, Nursing and Healthcare Leadership Program, Tacoma, United States of America
e-mail: sjiribar@uw.edu

Background: TB treatment adherence is challenged by healthcare access barriers, provider shortages, and prolonged treatment with side effects. Digital adherence technologies (DATs) offer real-time monitoring but often lack 24/7 support, integrated mental health care, and tailored solutions for Spanish-speaking populations. Our team developed TB Treatment Support Tools (TB-TSTs), a DAT integrating a mobile app, linkage to treatment supporters, and an objective adherence test. To enhance scalability, we developed and validated a Spanish-language, large language model (LLM)-powered chatbot for real-time TB treatment support.
Design/Methods: Using a convergent mixed methods approach, we developed six chatbot models with various training techniques, including zero-shot learning, few-shot learning (FS), and retrieval-augmented generation (RAG). A two-step classification process identified queries requiring empathy. Internal evaluations refined chatbot responses, while external evaluations by ten Spanish-speaking TB experts assessed chatbot accuracy, comprehensiveness, and linguistic appropriateness (QUEST framework, 1-5 scale). Empathy was rated separately (0-2 scale). Thematic analysis identified areas for improvement.
Results: The FS chatbot performed best (4.64/5), followed by 2S (4.59/5) and FSR (4.20/5) (Figure 1).



Empathy scores ranked FS highest (1.77/2), outperforming 2S (1.54/2) and FSR (0.97/2). Challenges included overly technical language, difficulty distinguishing latent

from active TB, and occasional vague responses. FS and 2S models conveyed warmth and engagement, though FS sometimes lacked empathy, and 2S did not always tailor responses.

Conclusions: LLM-powered chatbots show promise for TB support, with all top models scoring ≥4 across evaluation dimensions. FS outperformed others, while RAG introduced inconsistencies. Future work will refine chatbot responses, integrate mental health interventions, and incorporate personalized patient profiles to improve knowledge retention. Iterative evaluations with TB experts and survivors will optimize accuracy and empathy, establishing a scalable, culturally adaptable AI-driven TB support tool for future clinical trials and external funding.

EP21 TB contact screening across the age spectrum

EP21-899-19 Active tuberculosis in household contacts of central Ethiopia: Whole genome sequencing based genomic diversity, transmission dynamics and drug resistance pattern analysis

G. Abegaz,[1] A. Cabibbe,[2] B. Ayano,[1] A. Simie,[1] G. Yadu,[1] G. Tadesse,[3] W. Sabiti,[4] K. Moghaddasi,[2] I. Iannucci,[2] D. Cirillo,[2] S. Abdela,[5] B. Gumi,[6,7] [1]Ethiopian Public Health Institute, Tuberculosis research unit, Addis Ababa, Ethiopia, [2]IRCCS San Raffaele Scientific Institute, Emerging Bacterial Pathogens, Milan, Italy, [3]Ethiopian Public Health Institute, Infectious disease directorate, Addis Ababa, Ethiopia, [4]st .Andrews university, Infection and Global Health, St andrews, United Kingdom of Great Britain and Northern Ireland, [5]Ethiopian Public Health Institute, Laboratory service directorate, Addis Ababa, Ethiopia, [6]Addis Ababa university, Aklilu lema institute of pathobiology, Addis Ababa, Ethiopia, [7]Addis Ababa university, Pathobiology, Addis AbabaETETHIO, Ethiopia
e-mail: gech1365@gmail.com

Background: Mycobacterium tuberculosis complex genotyping improved the understanding of transmission dynamics and is used to support or refute transmission assumptions between epidemiologically linked cases.
This study aimed to analyse genomic diversity, transmission dynamics and drug resistance mutation in epidemiologically linked pulmonary TB patients and their household contacts in central Ethiopia.

Design/Methods: The study was conducted from January 2023 to December 2023 at randomly selected public health facilities in the central part of Ethiopia. A total of 50 genomes from Pulmonary TB patients and their Household contacts were considered for WGS analysis using the MTBSeq pipeline and Ridom SeqSphere software for drug resistance and genotypic analysis(SNP distance cut-off of 12).

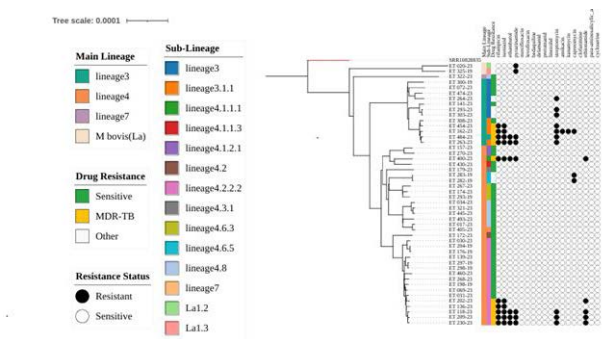


Figure 1. Phylogenetic tree constructed by pairwise distance (maximum likelihood) of 47 *Mycobacterium tuberculosis* isolates including SRR10828835 as reference genome.

Results: Through the analysis of successful WGS data from 48 isolates, we discovered that most of the isolates were part of lineages L4 (Euro-American, 33/48; 68.75%)

and L3 (Delhi-CAS, 12/48; 25.0%), with the Euro-American (L.4.2.2) being the most prevalent sub-lineage (16/48; 33.33%). Tuberculosis caused by *M. bovis* represented 4.17% (2/48). Among the 48 isolates, approximately one-fifth were found to be at least MDR-TB (10/48; 20.83%). The transmission analysis revealed 4 related events, resulting in an overall clustering rate of 17.02% (8 out of 47). Almost 75% (3 out of 4) of the clustered strains came from the same household, while 25% were from non-index household contacts. Three of the 10 index-HHC pairs with valid WGS analysis share the exactly matched genome. We have also identified previously unreported mutations linked to resistance Amikacin and Ethioniamid.
Conclusions: Individuals residing in areas with a high burden of tuberculosis are at risk of contracting the disease from sources beyond their homes. Genomic sequencing gives insights into the epidemiological patterns of TB, leading to better strategies for target groups at high risk of unnoted TB transmission.

EP21-900-19 Application of RNA sequencing in school tuberculosis outbreak response: A nested case-control study in Shanghai, China

X. Xiao,[1] Z. Li,[1] J. Chen,[1] Z. Wu,[2] X. Shen,[1] [1]Shanghai Municipal Center for Disease Control and Prevention, Division of Tuberculosis and HIV/AIDS Prevention, Shanghai, China, [2]Shanghai Municipal Center for Disease Control and Prevention, Research Management Department, Shanghai, China
e-mail: xiaoxiao@scdc.sh.cn

Background and challenges to implementation: Students are a key population for tuberculosis (TB) prevention and control in China. As active TB cases in schools can rapidly trigger outbreaks. To curb transmission, timely screening of student contacts—including detecting active cases and identifying latent tuberculosis infections (LTBI)—is critical. Globally, no reliable method can predict the risk of progression from LTBI to active TB. This study aimed to evaluate the role of RNA sequencing (RNA-seq) in case prediction and targeted intervention.
Intervention or response: During a school TB outbreak in Shanghai, baseline venous blood samples were collected from all 10 students with LTBI. All close contacts of the index case were followed for one year. After active TB cases emerged during follow-up, baseline blood samples from cases and matched controls (1:4 ratio by sex, age, and exposure level) underwent RNA-seq. Differentially expressed genes were enriched and analyzed via Kyoto Encyclopedia of Genes and Genomes (KEGG).
Results/Impact: A 19-year-old female student's failure to seek timely medical care led to the outbreak. Among 36 close contacts, 10 (27.8%) tested positive for TB infection, and two (20.0%) progressed to active TB. RNA-seq combined with cluster analysis identified the two secondary cases three months earlier than traditional methods. KEGG enrichment analysis revealed that differentially expressed genes in the two secondary cases, compared to LTBI controls, were predominantly enriched in pathways related to bactericidal functions and immune regulation.

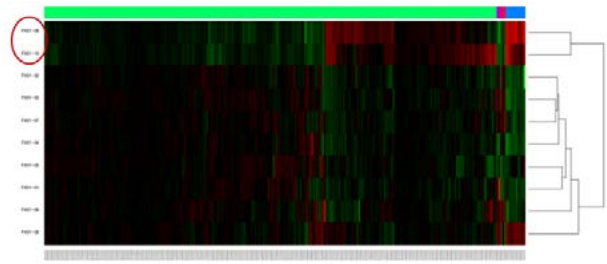

Figure 1 The tree diagram of cluster analysis for 10 students with latent tuberculosis infection.

Conclusions: RNA-seq demonstrates potential for identifying high-risk individuals who progress to tuberculosis during TB outbreaks, thereby enabling early intervention to disrupt transmission. This technology could serve as a strategic tool for targeted TB prevention and control in school settings.

EP21-901-19 Reasons for non-enrollment of household contacts in a multinational MDR-TB preventive treatment clinical trial

S. Kanade,[1,2] M. Kendall,[3] L. Aaron,[3] S. Kim,[4] N. Linda,[5] A. Van Grack,[6] M. Hughes,[3] G. Churchyard,[7] A. Gupta,[8] A. Hesseling,[9] S. Swindells,[10] H. Mugerwa,[11] [1]Byramjee Jeejeebhoy Government Medical College, Clinical Research Site, Pune, India, [2]Center for Infectious Diseases in India, Clinical Research, PuneIn, India, [3]Harvard T.H. Chan School of Public Health, Biostatistics, Boston, United States of America, [4]Frontier Science Foundation, Biostatistics, Brookline, United States of America, [5]ACTG, Network Coordinating Centre, Bethesda, United States of America, [6]ACTG, Network Coordinating Centre, Washington, United States of America, [7]Aurum Institute, Head Office, Parktown, South Africa, [8]Johns Hopkins University, Department of Medicine, Baltimore, United States of America, [9]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Cape Town, South Africa, [10]University of Nebraska Medical Center, Department of Internal Medicine, Omaha, United States of America, [11]Joint Clinical Research Centre, Research, Kampala, Uganda
e-mail: skanade1@jhmi.edu

Background: Household contacts (HHCs) of people with Multi-Drug Resistant Tuberculosis (MDR-TB) are at high risk of developing tuberculosis disease. We describe the reasons HHCs did not enroll into ACTG A5300B/IMPAACT 2003B/PHOENIx (NCT03568383), an ongoing cluster-randomized trial evaluating efficacy and safety of Delamanid versus Isoniazid for tuberculosis preventive treatment (TPT).

Design/Methods: All HHCs of enrolled MDR-TB index participants were enumerated and approached for the study. Reasons for non-enrollment were collected. High-risk groups were children <5 years old, HHCs ≥5 years who were living with HIV, and HHCs ≥5 years who had a positive test of tuberculosis infection. Difference in participation by risk group was analysed using Chi-Square Test.

Results: We enumerated 8378 HHCs of 1927 MDR-TB index participants from 13 countries from July 2019–January 2025. 1715 (20%) declined screening and 2374 (28%) screened out (ineligible). Screened HHCs who did not enroll had a median age of 26 years; 57% were females, 6% were <5 years old, 5% were living with HIV (PLWH), and 38% had a positive test for TB infection. Of 2374 screened and deemed ineligible, 1317 (55%) were not in a defined high-risk group, 180 (8%) had active tuberculosis disease, and 105 (4%) had laboratory abnormalities. Of 4272 confirmed eligible for the trial, 298 (7%) opted not to enroll. Reasons for non-enrollment varied by country and by high-risk group (see Table). PLWH were more likely to screen out (p<0.0001). Children <5 years old were less likely to enroll despite being eligible (p<0.0001).

Table: Reasons for non-enrollment of HHCs in the PHOENIx MDR-TB preventive treatment trial

		Range of Prevalence by Country		High-Risk Group*		
	Prevalence	Lowest	Highest	Age<5 years	Living with HIV	LTBI
Number of HHCs Enumerated	**8378**					
Declined screening (% of enumerated)	20%	Zimbabwe (0%)	Vietnam (84%)			
Number of HHCs Screened	**6663**			**542**	**460**	**4077**
Failed screening (% of screened)	36%	Peru, Uganda (32%)	Vietnam (55%)	18%	27%	15%
Number of HHCs Eligible	**4272**			**446**	**338**	**3468**
Not enrolled due to accrual pause (% of eligible)	1%	Botswana, India, Kenya, Vietnam, Zimbabwe (0%)	Brazil, South Africa, Tanzania (2%)	1%	2%	1%
Opted not to enroll (% of eligible)	7%	Tanzania (1%)	India (22%)	11%	3%	6%

Abbreviations: HHC, household contact; LTBI, latent TB infection

*High risk group, defined hierarchically from left to right, were eligible for study participation; remaining HHCs were not eligible for the study. Risk group was unknown for those who did not screen.

Conclusions: Characterizing reasons for non-enrollment provide understanding of the trial population and the eventual generalizability of results. Knowing reasons for screen failures and subsequent non-enrollment among those screened for this trial of household contacts is important to minimize gaps in future implementation of TB contact management.

EP21-902-19 Perceptions of universal TB testing among persons with TB and household contacts in Lesotho, South Africa and Tanzania

M. Matete,[1] S. Mwanyonga,[2] K. Mlalama,[2] F. Mboniswa,[2] R. Pelusa,[3] L. Ndelwa,[2] J. Nagudi,[3] T. Ntshiqa,[3] R. Mukora,[3] K. Velen,[3] S. Charalambous,[3] L. Tsope,[3] [1]Jhpiego, Programs, Maseru, Lesotho, [2]Nation Institute of Medical Research, Social Sciences, Mbeya, United Republic of Tanzania, [3]The Aurum Institute, Implementation Research Division, Johannesburg, South Africa
e-mail: Manthomeng.Matete@jhpiego.org

Background: Universal TB testing (UTT) is a strategy that includes TB testing of all contacts of persons with TB (PWTB) regardless of symptoms. It is critical to explore perceptions and acceptability of any intervention prior to full scale implementation for maximum success and improve patient outcomes. We describe perceptions of UTT among PWTB and their household contacts (HHCs) in three high-burden TB countries.

Design/Methods: We conducted in-depth interviews (IDIs) with PWTB and HHCs who were randomly selected from those enrolled in the CUT-TB trial conducted in Lesotho, South Africa, and Tanzania. IDIs were conducted between November 2023-December 2024. Interviews were audio-recorded, transcribed verbatim, translated, and thematically analysed using Quirkos software.

The interview guide explored four key themes: outcomes of TB testing, drivers and facilitators of stigma, stigma marking, and the health and social impact of TB at individual, interpersonal, and community levels. A deductive coding approach, guided by the Consolidated Framework for Implementation Research (CFIR), was used to analyse perceptions of UTT.

Results: We interviewed 135 participants: 75 PWTB and 60 HHCs. The mean age of participants was 43.9 and 52% were male. Participants highlighted the importance of TB testing even in the absence of symptoms, supporting UTT approach, although perceptions varied across groups. PWTB supported testing of HHCs but feared being identified as the source for community contact tracing due to fear of stigma and judgment. HHCs acknowledged the value of TB testing and indicated that perceived personal risk of TB influenced their willingness to be tested.

Participants preferred home-based testing over facility visits due to factors such as transport costs, time constraints, stigma, proximity to health facilities, and limited resource.

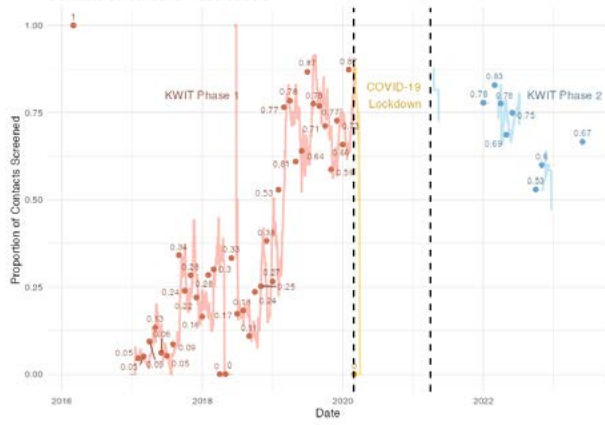
Conclusions: UTT was generally acceptable to participants and when combined with efforts to incorporate contacts' testing preferences and stigma reduction interventions in communities, may offer a useful approach to improve TB outcomes.

EP21-903-19 Resilient TB contact tracing amid crisis: Evaluating household-based screening during the COVID-19 pandemic

A. Brumwell,[1] K. Le Roux,[2] M. Wilson,[3] B. van de Water,[4] M. Brooks,[5] [1]University of Washington School of Public Health, Department of Global Health, Seattle, United States of America, [2]University of Cape Town, Department of Family Medicine, Cape Town, South Africa, [3]Advance Access & Delivery South Africa, n/a, Durban, South Africa, [4]Boston College, Connell School of Nursing, Boston, United States of America, [5]Boston University, School of Public Health, Department of Global Health, Boston, United States of America
e-mail: brumwell@uw.edu

Background: Effective tuberculosis (TB) elimination depends on identifying and treating high-risk groups, such as household contacts. Contact tracing is essential for TB elimination but is vulnerable to disruptions, including those caused by the COVID-19 pandemic.
This study assessed the pandemic's impact on TB contact tracing and evaluated whether household-based strategies can sustain screening efforts during crises.
Design/Methods: We analyzed two phases of a TB program in the King Sabata Dalindyebo sub-district, Eastern Cape, South Africa. Phase one (March 2016–March 2020) primarily used passive, facility-based screening. Phase two (April 2021–June 2023) relied on active, household-based screening supported by mobile chest x-ray units. We reviewed records of household contacts and compared the proportions screened.
An interrupted time-series analysis assessed screening trends for before, during, and after COVID-19 disruptions, adjusting for seasonality, facility type, and household clustering.

Figure 1. Monthly Proportion & 30-Day Rolling Average of Proportion of Household Contacts Screened for Tuberculosis



Results: In phase one, 38.5% (2945/7652) of contacts were screened; in phase two, 71.1% (1588/1139, OR=3.9) were screened. Screening peaked at 87% in February 2020 but dropped to 0% in March 2020 with COVID-19 onset. Screening resumed at 81% in April 2021 but declined to 67% by June 2023.
Screening odds increased monthly overall (OR=1.09, p<0.01), but declined during phase two (OR=-1.19, p=0.04), indicating reduced sustainability over time.
Conclusions: The COVID-19 pandemic severely disrupted TB contact tracing. However, household-based screening rapidly restored high screening levels, demonstrating resilience during public health emergencies. The subsequent decline highlights the need for sustained investment and support to maintain program effectiveness. To ensure continuity of TB services during future disruptions, policymakers should institutionalize flexible household-based screening models within national TB elimination strategies.

EP21-904-19 Scoring the silent threat: Age-specific risk models for pediatric TB contacts

M. Akyildiz,[1] A. Madan,[1] F. Amanullah,[2] H. Hussain,[3] A. Malik,[3] M. Brooks,[1] [1]Boston University School of Public Health, Global Health, Boston, United States of America, [2]Boston Children's Hospital, Pediatrics, Boston, United States of America, [3]Interactive Research & Development-Global, Tuberculosis, Singapore, Singapore
e-mail: mbbrooks@bu.edu

Background: Children exposed to tuberculosis (TB) at home are at increased risk of developing TB disease. Diagnosing TB in children is challenging due to nonspecific symptoms, paucibacillary disease, and a lack of sensitive diagnostic tools. Because current strategies are limited, we derived risk scores to predict TB disease in child household contacts of pediatric TB patients.
Design/Methods: We analyzed data from a large active screening program in Kotri, Pakistan, including child household contacts of adult and pediatric TB patients. The dataset included demographic information, clinical symptoms, and medical history, and was stratified by age: 0-4, 5-9, and 10-14 years. Univariable and multivariable logistic regression identified significant TB predictors for each group.
Risk scores were calculated using regression coefficients and standard errors. Receiver Operating Characteristic curve analysis determined optimal diagnostic thresholds; discriminatory properties were calculated, maintaining sensitivity at 85%.
Results: Of 3,014 child household contacts, 390 (12.9%) were diagnosed with TB: 203 (52.1%) aged 0-4, 138 (35.4%) aged 5-9, and 49 (12.6%) aged 10-14. Predictors retained in the multivariable models included cough, weight loss, weight percentile, and appetite; fever and BCG scar presence were also included in the 5-9 and 10-14 year models. Discriminatory properties for each model were as follows:
0-4 years: 85% sensitivity, 71% specificity, 39.7% PPV, 95.6% NPV

5-9 years: 85% sensitivity, 77% specificity, 32.1% PPV, 97.6% NPV
10-14 years: 85% sensitivity, 77% specificity, 21.2% PPV, 98.1% NPV

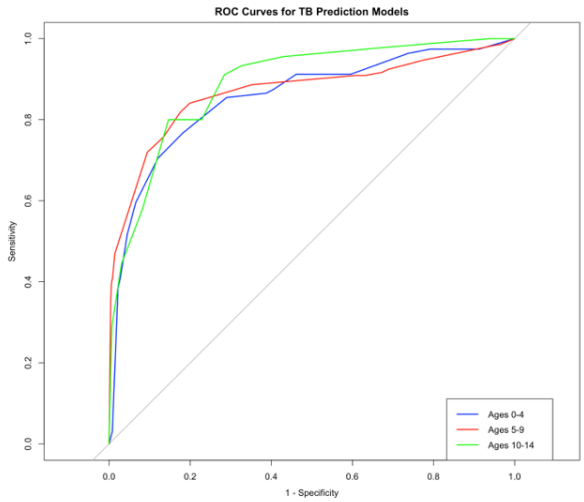


Figure 1. Receiver Operating Characteristic (ROC) Curves for TB Prediction Models in Child Household Contacts

Conclusions: These age-specific risk scores demonstrated high discriminatory performance and should be operationalized into clinical tools to improve screening of child contacts. Further external validation is underway to support wider implementation in Pakistan and similar settings.

EP21-905-19 Chest X-ray operational barriers in school-based pulmonary tuberculosis screening in China: A cross-sectional study

B. Wu,[1] Y. Yu,[2] M. Wang,[2] J. Yin,[2] [1]Chongqing Public Health Medical Center, Tuberculosis Department, Chongqing, China, [2]Chongqing Municipal Institute of Tuberculosis, Tuberculosis Department, Chongqing, China
e-mail: 957571316@qq.com

Background: In China, school-based pulmonary tuberculosis (PTB) control programs mandate PTB screening for high school students. While chest X-ray (CXR) serves as a primary screening modality, operational challenges persist in community-level medical and healthcare institutions, particularly regarding the absence of standardized external quality control mechanisms for CXR interpretation. Preliminary evidence suggested potential underdetection of PTB cases in school settings due to inconsistent CXR reading quality, which may contribute to ongoing TB transmission. This study addresses critical PTB detection gap in implementing large-scale school CXR screening programs.
Design/Methods: This was a cross-sectional study which was conducted among high school students between January 2022 and December 2022 in Chongqing, China. Participating radiologists and doctors underwent standardized training in CXR interpretation protocols. Symptom-based screening and immunological tests were prioritized, with abnormal results triggering CXR examinations. A comparative analysis was conducted between CXR results from the team that has undergone standardized training and those from community-level medical and healthcare institutions in 2021.
Results: PTB screening was conducted among 24,577 Senior 1 and Senior 2 students in Chongqing using CXR between January 2022 and December 2022 in Chongqing, China. The PTB detection rate reached 57 per 100,000 population through systematic CXR screening, significantly exceeding the 2021 baseline rate of 34.8 per 100,000 recorded by community-level medical and healthcare institutions (P<0.001). This discrepancy highlights potential case underreporting in routine surveillance systems.
Conclusions: Our findings substantiate CXR's critical role in school-based PTB control while revealing operational vulnerabilities:
1. Interobserver variability in CXR interpretation may create PTB detection gap;
2. Absence of regular EQC undermines screening reliability.
We propose institutionalizing radiologist competency certification for PTB screening in school students and establishing regional CXR audit panels to standardize diagnostic criteria.

EP21-906-19 Evaluating the impact of clinical contact tracing on tuberculosis case finding and preventive treatment in Lagos State, Nigeria: A pilot study

P. Alu,[1] O. Daniel,[2] M. Pedro,[1] A. Agbaje,[3] F. Muritala,[4] C. Mensah,[5] P. Dakum,[3] R. Eneogu,[6] S. Labaran,[7] M. Toriola,[1] A. Okungbure,[2] B. Shokunbi,[1] [1]Institute of Human Virology Nigeria (IHVN), Strategic Information, Lagos, Nigeria, [2]Institute of Human Virology Nigeria (IHVN), Programs, Lagos, Nigeria, [3]Institute of Human Virology Nigeria (IHVN), Office of the CEO, Abuja, Nigeria, [4]Institute of Human Virology Nigeria (IHVN), Strategic Information, Abuja, Nigeria, [5]Institute of Human Virology Nigeria (IHVN), Office of the COO, Abuja, Nigeria, [6]United States Agency for International Development (USAID), HIV/AIDS & TB Office, Abuja, Nigeria, [7]National Tuberculosis & Leprosy Control Programme, Federal Ministry of Health, Abuja, Nigeria
e-mail: paul.ozed96@gmail.com

Background and challenges to implementation: Nigeria with a population of over 220 million has one of the highest burdens of TB in the world and 6th highest contributor to the global TB incidence. The Nigerian National TB management and Control Guideline recommends all household and close contacts of bacteriologically diagnosed TB patients be evaluated for TB. However, contact

tracing of bacteriologically positive cases has not produced the expected yield as part of the broader efforts to meet the 2030 TB target to eliminate TB epidemic as outlined in UN SDGs. We piloted the contact tracing of clinical TB Case to see its impact on TB cases finding and preventive treatment.

Intervention or response: The TB LON 3 project implemented by Institute of Human Virology Nigeria (IHVN) with the support from USAID piloted Contact Tracing of clinically diagnosed TB case in public facilities from June to August 2024 in Lagos State Southwestern Nigeria.

Results/Impact: During the study period, a total of 973 index TB cases were contact traced, of which 249 (26%) were clinically diagnosed patients, 3,493 contacts were identified among the index cases, out of which 955 (26%) were contacts of the clinically diagnosed index cases and were all screened for TB, 196 presumptive cases were identified and evaluated, 21 TB cases were reported and started on treatment, contributing 24% of the total TB cases. With an NNT and NNS of 45 and 9 respectively showing high efficiency. In terms of TPT, 203 (8%) were contact of clinically diagnosed index cases.

Table 1: Bacteriological and clinical cascade from contact investigation, June to August 2024.

	June		July		August		Total		
	Bacteriological	Clinical	Bacteriological	Clinical	Bacteriological	Clinical	Bacteriological	Clinical	% Contribution
Number of Index TB cases contact traced	336	100	330	82	307	67	973	249	26%
Number of contacts identified	1114	340	1144	298	1235	310	3493	948	27%
Screened	1098	340	1144	300	1233	315	3475	955	27%
Presumptives	237	101	277	54	232	41	746	196	26%
Presumptive evaluated	237	101	277	54	232	41	746	196	26%
Cases diagnosed	20	11	36	4	32	6	88	21	24%
Treatment/notified	19	11	36	4	30	6	85	21	25%
Total enrolled on TPT	680	155	809	6	981	42	2470	203	8%
Number Needed to Screen	55	31	32	75	39	53	39	45	
Number Needed to Test	12	9	8	14	7	7	8	9	

Conclusions: The findings from this study highlight the potential of clinical contact tracing bridging gaps in TB case finding and preventive treatment, particularly in high-burden areas like Lagos State. Scaling this approach can accelerate progress toward achieving the 2030 TB elimination targets, reducing TB morbidity and mortality in Nigeria.

EP21-907-19 Strain discordance among household index-secondary patient pairs with tuberculosis disease

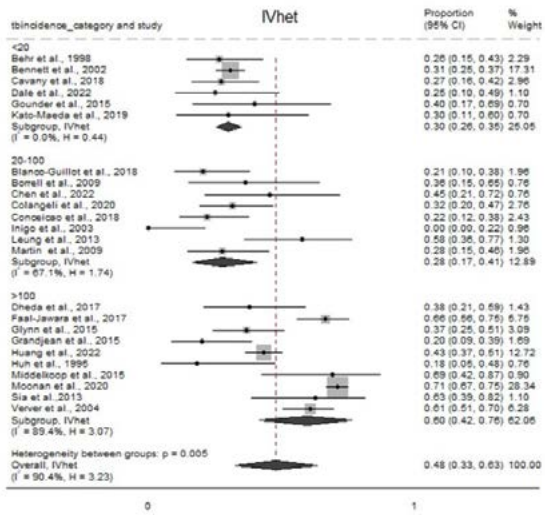
M. Chipinduro,[1,2,3] T. Yates,[4,5] R.W. Aldridge,[4,6] B. Khozoee,[7] J.R. Winter,[8] F. Tanser,[9,10,11,12] I. Ibrahim Abubakar,[13,14] K. Kranzer,[1,15,16,17] [1]Biomedical Research and Training Institute, The Health Research Unit - Zimbabwe, Harare, Zimbabwe, [2]Midlands State University, Department of Pathology, Gweru, Zimbabwe, [3]Ludwig Maximilian University, Center for International Health, Munich, Germany, [4]University College London, Centre for Public Health Data Science, Institute of Health Informatics, London, United Kingdom of Great Britain and Northern Ireland, [5]University College London, Division of Infection and Immunity, Faculty of Medicine, London, United Kingdom of Great Britain and Northern Ireland, [6]University of Washington, Institute for Health Metrics and Evaluation (IHME), Seattle, United States of America, [7]Royal Free Hospital, Royal Free London NHS Foundation Trust, London, United Kingdom of Great Britain and Northern Ireland, [8]Arcturis Data, Data Science, Corsham, United Kingdom of Great Britain and Northern Ireland, [9]Africa Health Research Institute (AHRI), Tanser Group, Durban, South Africa, [10]Stellenbosch University, Centre for Epidemic Response and Innovation (CERI), School of Data Science and Computational Thinking, Stellenbosch, South Africa, [11]University of KwaZulu-Natal, School of Nursing and Public Health, Durban, South Africa, [12]University of Kwa-Zulu Natal, Centre for the AIDS Programme of Research in South Africa (CAPRISA), Congella, South Africa, [13]University College London, Faculty of Population Health Sciences, London, United Kingdom of Great Britain and Northern Ireland, [14]University College London, MRC Clinical Trials Unit, London, United Kingdom of Great Britain and Northern Ireland, [15]London School of Hygiene & Tropical Medicine, Department of Clinical Research, London, United Kingdom of Great Britain and Northern Ireland, [16]Ludwig Maximilian University, Division of Infectious Diseases and Tropical Medicine, University Hospital, Munich, Germany, [17]German Center for Infection Research, (DZIF), Munich, Germany
e-mail: mchipinduro@gmail.com

Background: We describe the prevalence of *Mycobacterium tuberculosis* complex strain discordance among household index-secondary patient pairs with active tuberculosis and estimate the proportion of all tuberculosis in each community attributable to recent household transmission.

Design/Methods: We conducted a systematic review and meta-analysis whereby MEDLINE, EMBASE, Global Health, Web of Science and POPLINE databases were searched with updated searches on 26 January 2024. We included molecular epidemiology studies describing ≥10 pairs of individuals with a history of household contact; where both individuals had active tuberculosis that was strain typed using mycobacterial interspersed repetitive units–variable number of tandem repeats (MIRU-VNTR), restriction fragment length polymorphisms (RFLP)

or whole genome sequencing (WGS). Studies using low resolution strain typing techniques – 12 or 15 loci MIRU-VNTR – or undertaken during tuberculosis outbreaks were considered high-risk for bias. Pooled estimates of strain discordance were estimated using an inverse variance heterogeneity model. The proportion of all tuberculosis attributable to recent household transmission was estimated as the product of strain concordance and the proportion of all cases in the community with history of household exposure to a putative index case.

Results: Of the 28 studies reviewed, four (14%) were excluded due to high risk of bias. The remaining 24 studies included 1,493 pairs, 718 with discordant strain types. Prevalence of strain discordance was 0.48 (95%CI, 0.33-0.63; I^2 = 90%). Prevalence was greater in high (0.60, 95%CI 0.42-0.76) than low or moderate tuberculosis incidence settings (0.30, 95%CI 0.26-0.35; 0.28, 95%CI 0.17-0.41). Less than 10% of all tuberculosis disease was attributable to recent household transmission.



Forest plot using the IVhet model showing the proportion of household index-secondary patient pairs with discordant *Mycobacterium tuberculosis* complex strain type stratified by TB incidence (per 100,000 population per year)

Conclusions: Household transmission contributes minimally to the overall TB burden. Clustering of tuberculosis patients within households likely reflects both household transmission and shared risk factors for TB disease. Interventions to interrupt community transmission and for improved social protection in vulnerable households and communities should be prioritised.

EP22 The challenge of extrapulmonary TB

EP22-908-19 Clinical profile and outcomes of children with tuberculous meningitis at Kenyatta National Hospital: A six-year retrospective study

J. Masinde,[1] [1]University of Nairobi, Paediatrics and Child Health, Nairobi, Kenya
e-mail: naliakajoy04@students.uonbi.ac.ke

Background: Tuberculous meningitis (TBM) is a devastating form of extra pulmonary tuberculosis, with significant morbidity and mortality in children, especially in high-burden countries like Kenya.

This study aimed to evaluate the clinical profile and outcomes of children with TBM at Kenyatta National Hospital (KNH), Kenya's largest referral hospital.

Design/Methods: We conducted a retrospective cohort study of children aged 0-15 years diagnosed and treated for TBM at KNH between January 2018 and December 2023. Using a consensus case definition, patients were classified as having definite, probable, or possible TBM. Data on socio-demographic characteristics, clinical presentation, diagnostic evaluation, treatment, and outcomes were extracted from medical records and analyzed.

Results: Of 100 eligible children, none had definite TBM, 29% (29) and 71%(71) had probable and possible TBM, respectively. The median age was 2.2 years , with 72% (72) being <5 years. Males predominated at 68% (68), and 67% (67) had a history of contact with someone with TB. Most children, 81% (81), presented with advanced disease (stage II or III). Symptoms included cough 53 (53%), fever 85% (85), lethargy 51% (51) and seizures 77% (77). Among 65 children who had CSF analysis, 96.9% (63) had elevated proteins, mean protein 988.4. ESR was elevated in 83.3 % (30/36).

Neuroimaging was done in 89% (89) of patients, 91% (81) abnormal findings, hydrocephalus 53.9% (48) and 34.8 % (31) basal meningeal enhancement. 93% (93) started on anti-tuberculosis medications and corticosteroids 83% (83). Outcomes were poor with 33% (33) mortality. Among survivors, 55% (55) developed neurological sequelae.

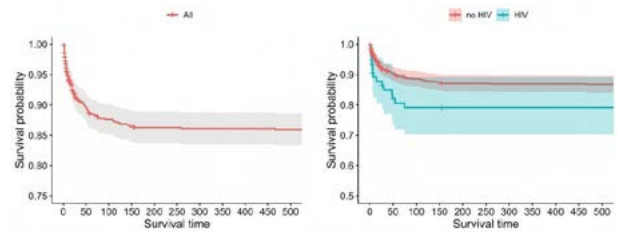
Conclusions: TBM affects mostly children <5 years with high rates of late diagnosis. The mortality rate (33%) is higher than reported studies from other regions.

Our findings show the urgent need for earlier diagnosis and improved management protocols for pediatric TBM in resource-limited settings to reduce devastating consequences of this disease.

EP22-909-19 Long-term survival and prognostic determinants of tuberculous meningitis in a high-migration metropolis: A decade-long bidirectional cohort study

L. Fu,[1] Q. Chen,[2] Y. Dong,[3] Y. Gao,[4] G. Deng,[1] [1]Southern University of Science and Technology/Shenzhen Third People's Hospital, Pulmonary Diseases Department, Shenzhen, China, [2]Southern University of Science and Technology/Shenzhen Third People's Hospital, Neurologic Surgery, Shenzhen, China, [3]University of Science and Technology of China, Graduate School, Hefei, China, [4]Capital Medical University/Beijing You'an Hospital, Hepatology, Beijing, China
e-mail: flk1981@qq.com

Background: Tuberculous meningitis (TBM) has high global mortality (55-75%), but region-specific outcomes in urban settings with advanced medical systems are poorly characterized.
This study analyzes TBM in Shenzhen, China, a megacity with significant migrant populations and tiered healthcare infrastructure.
Design/Methods: This bidirectional cohort study analyzed clinical data from 715 hospitalized TBM patients admitted to Shenzhen Third People's Hospital between May 10, 2012 and October 10, 2022. Data collected during hospitalization, including surgical procedures and clinical outcomes, were evaluated.
A follow-up telephone survey was conducted in November 2023 to assess survival patterns using Kaplan-Meier analysis, stratified by HIV status.
Results: The study revealed distinct mortality patterns, with in-hospital mortality reaching 7.5% (54/715), significantly lower than global estimates (P<0.001). HIV co-infection emerged as a critical risk amplifier with a 3.4-fold increase in mortality (18.7% vs 6.3%, P=0.002). Temporal analysis identified a critical 30-day intervention window, with 77.8% of deaths occurring within this period (median survival: 24 days, IQR 14-29).
Therapeutic outcomes demonstrated a significant survival benefit from neurosurgical intervention, with external ventricular drainage (96.9% survival, n=32), ventriculoperitoneal shunting (92.9%, n=14), and Ommaya reservoir placement (100%, n=5) demonstrating superior post-discharge outcomes.
Comparative analysis revealed significantly lower mortality in the surgical versus non-surgical cohorts (5.6% vs. 8.9%; HR=0.28, P=0.04).
Longitudinal survival curves showed plateau characteristics beyond 100 days post-admission, with 2-year survival rates diverging significantly between HIV-negative (92.1%) and HIV-positive (76.3%) subgroups (log-rank P<0.001).
Multivariate Cox regression identified three independent predictors of mortality: treatment delay >7 days (HR=2.1), baseline Glasgow Coma Scale ≤12 (HR=3.8), and HIV co-infection (HR=2.6).



Conclusions: This study challenges the notion of uniformly poor TBM prognosis, showing that mortality can be reduced to <10% with early intensive care and staged surgery. By quantifying time-dependent risks and validating HIV-integrated protocols, it offers strategies for TBM management in migration-dense megacities, aligning with WHO urban TB control priorities.

EP22-910-19 GeneXpert (Xpert MTB/RIF) testing of extrapulmonary samples in Nepal: A five-year trends analysis from the National Tuberculosis Program

L.R. Joshi,[1] A. Shrestha,[1] S.R. Tiwari,[2] N.P. Shah,[3] P. Ghimire,[4] M. Hada,[4] P. Shrestha,[5] [1]Save the Children/Global Fund-Tuberculosis Program, Program Management Unit, Thimi, Bhaktapur, Nepal, [2]National Tuberculosis Control Center, Program Management, Thimi, Bhaktapur, Nepal, [3]National Tuberculosis Control Center, Clinical, Thimi, Bhaktapur, Nepal, [4]National Tuberculosis Control Center, Laboratory, Thimi, Bhaktapur, Nepal, [5]Bir Hospital, Respiratory Medicine, Kathmandu, Nepal
e-mail: lokjoshi11@gmail.com

Background and challenges to implementation: Extrapulmonary tuberculosis (EPTB) diagnosis is challenging due to the paucibacillary nature of samples and difficulty in specimen collection. Molecular diagnostic tools like GeneXpert (Xpert MTB/RIF) have improved the rapid and accurate diagnosis of both pulmonary and extrapulmonary TB.
This study analyzes the trends and diagnostic yield of extrapulmonary sample testing using GeneXpert in Nepal over the past five fiscal years.
Intervention or response: GeneXpert test data from FY 2019/20 to 2023/24 were extracted from the Nepal National Tuberculosis Program Management Information System (NTPMIS) and analyzed.
Key indicators included valid tests, EP samples tested, TB positivity in EP samples, the proportion of EP samples tested, and the proportion of drug-resistant TB (DRTB) among diagnosed EP cases.
Results/Impact: Between FY 2019/20 and FY 2023/24, the number of GeneXpert testing sites in Nepal increased from 72 to 117, with total tests rising by over 200%. EP sample testing increased substantially, from 474 tests in FY 2019/20 to 9,524 in FY 2023/24. The proportion of

EP samples tested with GeneXpert increased from 1% to 6.8%, reflecting a gradual rise in EP case detection. The positivity rate for EP samples remained comparable to sputum samples, ranging from 10% to 15% over the past three years. TB notifications from EP samples increased from 184 to 1,063.
Despite this rise in case detection, the prevalence of DRTB among EP cases declined from 8.7% in FY 2019/20 to 2.6% in FY 2023/24, indicating improved diagnostic coverage and earlier detection.
Conclusions: Significant increase in GeneXpert testing over the past five years has led to higher EP case notifications and a decline in drug-resistant TB prevalence among EP cases. These findings highlight the critical role of molecular diagnostics in improving TB control, especially for EPTB, and emphasize the need for continued investment in diagnostic infrastructure to sustain progress toward TB elimination.

EP22-911-19 Extrapulmonary tuberculosis in the Netherlands (1993-2022): Localization patterns and treatment outcomes

F. Procee,[1,2,3] J. Bosdriesz,[2,4,5] M. Prins,[2,4,5] S. Hermans,[1,5,3,6] F. Cobelens,[1,5,3] [1]Amsterdam University Medical Centers, Global Health, Amsterdam, Netherlands, [2]Public Health Service, Infectious diseases, Amsterdam, Netherlands, [3]Amsterdam University Medical Centers, Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, [4]Amsterdam University Medical Centers, Infectious diseases, Amsterdam, Netherlands, [5]Amsterdam University Medical Centers, Institute for Infection and Immunity, Amsterdam, Netherlands, [6]Amsterdam University Medical Centers, Center for Tropical Medicine and Travel Medicine, Amsterdam, Netherlands
e-mail: fprocee@ggd.amsterdam.nl

Background: Extrapulmonary tuberculosis (EPTB) accounts for a substantial proportion of TB patients in low-incidence countries, but comprehensive data on disease localization and associated determinants and treatment outcomes remain limited.
Design/Methods: The objectives are to explore anatomical localization patterns and treatment outcomes of EPTB in The Netherlands from 1993 to 2022, focusing on socio-demographic disparities. We analyzed national TB surveillance data from 1993-2022. Individuals diagnosed with EPTB were categorized by main localization and stratified by age, sex, country of birth, comorbidities, and treatment outcomes. Determinants of localization were examined using logistic regression.
Results: We included 17,666 EPTB patients, representing 51.9% of all TB patients. 58.7% were female and 71.5% were born outside the Netherlands. The most frequent countries of birth, were the Netherlands (28.5%), Somalia (15.9%) and Morocco (9.4%).
Pleural (28.6%) and peripheral lymph node TB (27.8%) were the most common localizations. Women had higher odds of lymph node (OR:2.02, 95%CI:1.88-2.17), intestinal (OR:1.35, 95%CI:1.17-1.54), urogenital (OR:1.20, 95%CI:1.00-1.43) and bone TB (OR:1.19, 95%CI:1.06-1.34).
Treatment success varied: primary and lymph node TB had high completion rates (>89.0%), while miliary (62.6%) and meningeal/central nervous system TB (72.8%) had the poorest mortality rates of 17.0% and 12.7%, respectively. Pleural TB had a high hospitalization rate (37.3%). Outcomes also differed by country of birth. Patients from Eritrea, Pakistan, Afghanistan and Ethiopia had higher cure rates (>88%) and lower mortality (<1%). Dutch-born patients accounted for the most EPTB deaths (3.1%), while Polish-born patients had the poorest outcome (62.5% cure, 8.9% mortality). Children under 14 had a high cure rate 93.8%, while those aged ≥65 had the highest mortality (6.5%).
Conclusions: EPTB treatment outcomes in the Netherlands vary by localization, age, sex and country of birth. Certain subgroups, such as Polish-born patients, had consistently poorer outcomes. These findings support the need for more tailored care strategies.

EP22-912-19 Beyond the lungs: Extrapulmonary tuberculosis as a risk for TB deaths in faith based health facilities in Kampala, Uganda (2020–2023)

L. Ocen,[1] S. Najjingo,[1] J. Muhangi,[1] H. Suubi,[1] R. Tamale,[1] G.H. Kyambadde,[1] D. Nabukeera,[2] [1]Uganda Episcopal Conference, Uganda Catholic Medical Bureau, Kampala, Uganda, [2]Uganda Protestant Medical Bureau, Uganda Protestant Medical Bureau, Kampala, Uganda
e-mail: locen@ucmb.co.ug

Background: Extrapulmonary TB (EPTB) poses unique diagnostic and management challenges potentially heightened by delayed and misdiagnosis. This study explored the TB mortality burden in high-volume faith-based hospitals in Kampala city, where annual TB mortality (6.0–8.7%) exceeds the national average (<5%).
Design/Methods: We conducted a retrospective cohort analysis of 3,967 TB patients registered during the period 2020 to 2023 in the electronic Case-Based Surveillance System (eCBSS) across six faith-based hospitals. Mortality rates (per 100 person-months) and survival probabilities (Kaplan-Meier) were stratified by TB-patient classification—pulmonary bacteriologically confirmed (PBC), pulmonary clinically diagnosed (PCD), and EPTB—with Cox proportional hazards models adjusting for age, sex, HIV status, time of outcome, and year of diagnosis.
Results: Overall, 286/3,967 (7.2%) died. Of the 3,967 patients registered, 7.6% (n=302) had EPTB. Out of the 286 total deaths, 39 (13.6%) had EPTB. Of all patient cat-

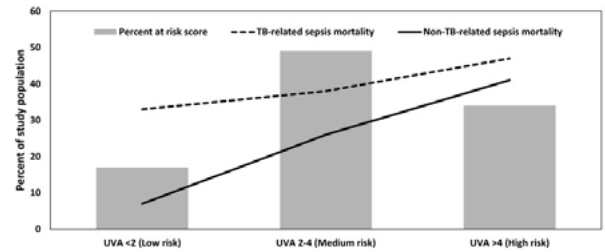
egories registered, EPTB exhibited the highest mortality rate (3.04 per 100 person-months, 95% CI: 2.21–4.15) compared to PCD (2.05, 95% CI: 1.70–2.46) and PBC (1.24, 95% CI: 1.04–1.47). Survival at 24 months was 0.82 for EPTB, 0.40 for PCD, and >0.90 for PBC (log-rank p<0.0001).
The adjusted hazard ratio (HR) for EPTB mortality was 2.60 (95% CI: 1.80–3.73, p<0.0001) versus PBC, with HIV co-infection (HR: 3.13 for newly tested positive) amplifying risk. Over half of the deaths (58.4%) occurred in the first month of treatment.
Conclusions: In high-volume, faith-based hospitals in Kampala, EPTB is a risk factor for TB mortality. The high mortality in the first month could be attributed to delayed or misdiagnosis. Enhancing EPTB-targeted diagnostics such as lateral flow LAM assays and molecular tests to address diagnostic gaps, especially in the first 28 days of diagnosis in these facilities, may reduce mortality among EPTB patients.

EP22-914-19 Tuberculosis-related sepsis is associated with increased in-hospital mortality across Universal Vital Assessment mortality risk score groups in adults in Mbarara, Uganda

M. Null,[1] M. Conaway,[2] R. Hazard,[3] L. Edwards,[4] K. Taseera,[5] R. Muhindo,[5] S. Olum,[6] A. Mbonde,[7] C. Moore,[1] [1]University of Virginia, Infectious Diseases and International Health, Charlottesville, Uganda, [2]University of Virginia, Public Health Sciences, Charlottesville, United States of America, [3]University of Washington, Anesthesia, Seattle, United States of America, [4]Stanford University, Engineering, Palo Alto, United States of America, [5]Mbarara University of Science and Technology, Medicine, Mbarara, Uganda, [6]Gulu University, Medicine, Gulu, Uganda, [7]Augusta University Medical College of Georgia, Neurology, Augusta, United States of America
e-mail: VGN6ET@uvahealth.org

Background: Tuberculosis (TB) is the leading cause of sepsis, which is the leading cause of global death with the highest burden found in Africa. The clinical Universal Vital Assessment (UVA) mortality risk score identifies patients at risk of in-hospital mortality in Africa. We determined the association between TB-related sepsis and in-hospital mortality stratified by UVA mortality risk score groups among participants with sepsis in Uganda.
Design/Methods: We analyzed data from adult participants with severe sepsis enrolled at the Mbarara Regional Referral Hospital in Uganda from October 2014 through May 2015. We compared in-hospital mortality between participants with and without TB-related sepsis in low, medium, and high UVA mortality risk score groups at 6 hours post-admission.
Results: Among 192 participants, the median (IQR) age was 34 (27-47) years, 99 (50%) were female, and 116 (59%) were living with HIV. The case fatality rate was 31%. There were 51 (27%) participants who were admitted with TB-related sepsis; 18 (9%) had a pre-admission TB diagnosis and 33 (17%) were newly diagnosed with TB. Of these 51, 21 (41%) died compared to 38 (27%) of 141 without TB (odds ratio [OR] 1.9, 95% confidence interval [CI] 0.97-3.7, p=0.06). The in-hospital mortality for participants with TB compared to those without TB in low, medium, and high UVA score risk groups was 33% vs. 7%, 38% vs. 26%, and 47% vs. 41%, respectively (Figure 1). Of the 33 with newly diagnosed TB, 11 (33%) died compared to 48 (30%) of 159 without newly diagnosed TB (OR 1.2, 95% CI 0.52-2.57, p=0.77).

Figure 1. The prevalence of UVA risk score groups at 6 hours post-admission and associated case fatality rates according to TB diagnosis among participants with sepsis in Uganda



Conclusions: Adults with TB-related sepsis were at higher risk of death compared to those without TB even after stratifying for severity of illness. A high index of clinical suspicion for TB, improved TB diagnostics, and more efficacious anti-TB therapies are urgently needed for patients with sepsis in Africa.

EP22-915-19 Lung versus genital symptoms: Which better predicts female genital tuberculosis?

D.S. Rahari,[1] K.K.K. Htet,[1] V. Chongsuvivatwong,[1]
[1]Prince of Songkla University, Department of Epidemiology, Hat Yai, Thailand
e-mail: dzerlina.rahari@gmail.com

Background: Female genital tuberculosis (FGTB) is a severe form of tuberculosis (TB) that generally occurs secondary to pulmonary or extrapulmonary TB (EPTB). It can spread directly from nearby organs or through hematogenous and lymphatic pathways from pulmonary TB. Genital symptoms may also be a predictor, but this suspicion has never been verified. Our study aimed to compare which preceding diagnosis is better for predicting FGTB between genital symptoms and lung symptoms.
Design/Methods: We retrieved records of FGTB (ICD-10 codes: A18.1, N74.0, N74.1, N77.0) from the Thailand national hospital admission database named the THIP database during 2017 to 2022. We applied a case-control

study design. For each of the above cases, we matched with four non-genital EPTB and four randomly chosen non-TB cases based on age, month and year of admission, and health region. A P-value <0.05 indicated a significant difference for each preceding disease.

Results: We identified 67 FGTB cases. Half of the patients were between 31 and 60 years old, and three-quarters were married or ever married. With a small sample size of some ICD-10 codes, FGTB had higher odds of having a previous genital problem admission (N73) than both EPTB and non-TB groups.

Such significant differences were also observed for N71, N80, and N93 when FGTB was compared against EPTB but not against non-TB. The odds of having a lung symptom admission in the past were not significantly different among the three groups.

Table 1 Top 5 of genital (N-code) and lung symptoms (J-code) preceding female genital tuberculosis (FGTB) compare to other extrapulmonary (EPTB) and non-tuberculosis (non-TB) diagnosis

ICD10	Diagnosis	67 FGTB	268 EPTB	OR (95% CI)*	268 non-TB	OR (95% CI)*
N73	Other female pelvic inflammatory diseases	6	0	N/A**	5	5.1 (1.3-22.02)**
N83	Noninflammatory disorders of ovary, fallopian tube and broad ligament	3	1	12.4 (0.97-656.7)	4	3.08 (0.4-18.7)
N71	Inflammatory disease of uterus, except cervix	2	0	N/A**	1	8.1 (0.4-484.8)
N80	Endometriosis	2	0	N/A**	4	2.02 (0.18-14.5)
N93	Other abnormal uterine and vaginal bleeding	2	0	N/A**	2	4.07 (0.29-57.04)
J10	Influenza due to identified seasonal influenza virus	1	0	N/A	2	2.01 (0.03-39.1)
J15	Bacterial pneumonia, not elsewhere classified	0	10	0 (0-1.7)	3	0 (0-9.7)
J17	Pneumonia in diseases classified elsewhere	0	7	0 (0-2.7)	0	N/A
J18	Pneumonia, organism unspecified	1	16	0.24 (0.005-1.6)	12	0.3 (0.007-2.3)
J45	Asthma	1	2	2.01 (0.03-39.1)	6	0.66 (0.01-5.6)

* 95% confidence limits computed by exact method
**statistically significant from two-tailed Fisher's exact test

Conclusions: Genital symptoms can be a better predictor for FGTB than lung symptoms. FGTB should be investigated more carefully in women hospitalized with genital problems in TB-endemic areas.

EP22-916-19 Prevalence and associated factors of active tuberculosis among IGRA-negative population

M.J. Fu,[1] C.R. Peng,[2] C.L. Bei,[3] H.M. Liu,[1] J.L. Wu,[4] [1]Changsha Central Hospital, Tuberculosis Intensive Care Unit, ChangSha, China, [2]University of South China, Changsha Central Hospital (affiliated with University of South China), ChangSha, China, [3]Changsha Central Hospital, Tuberculosis Diagnosis and Treatment Center, ChangSha, China, [4]Changsha Central Hospital, Clinical Laboratory Department, ChangSha, China
e-mail: 345480181@qq.com

Background: Tuberculosis (TB) remains a global public health challenge, necessitating early diagnosis. Although interferon-gamma release assays (IGRA) aid in detecting TB infection, current research predominantly focuses on evaluating the sensitivity and specificity of positive results for diagnosing latent tuberculosis infection (LTBI) and active tuberculosis (ATB), as well as investigating host-related factors and immunological mechanisms contributing to false-negative results.

In contrast, studies exploring diagnostic strategies for IGRA-negative populations with ATB remain limited, particularly regarding the identification of clinical characteristics and risk factors specific to this subgroup, highlighting the need to investigate prevalence and predictors in this population.

Design/Methods: This retrospective study analyzed 407 IGRA-negative patients from Changsha Central Hospital (September 2022–January 2023). Active TB prevalence was assessed, and potential predictors were identified through comparative analysis and multivariate logistic regression.

Results: The active TB prevalence was 13.27% (54/407), with 68.5% (37/54) confirmed microbiologically and 31.5% (17/54) clinically diagnosed. Pulmonary TB accounted for 83.3% (45/54), extrapulmonary TB for 5.6% (3/54), and combined cases for 11.1% (6/54). Key imaging features included lung cavitation (31.5%) and pleural effusion (31.5%).

Multivariate analysis identified seven independent predictors: occupation (social workers: OR=0.448, 95% CI: 0.222-0.904), weight loss (OR=2.944, 95%CI: 1.407-6.159), positive purified protein derivative (PPD) skin test (OR=5.758, 95%CI: 2.597-12.766), lung cavitation (OR=4.245, 95%CI: 1.946-9.263), pleural effusion (OR=2.851, 95%CI: 1.369-5.939), eosinopenia (OR=2.337, 95%CI: 1.109-4.925), and renal dysfunction (OR=2.561, 95%CI: 1.030-6.369).

Variables	β	S.E	Z	Waldχ²	P	OR	95%CI
social workers	-0.803	0.358	-2.241	5.021	0.025	0.448	0.222~0.904
weight loss	1.080	0.377	2.866	8.216	0.004	2.944	1.407~6.159
positive PPD skin test	1.751	0.406	4.309	18.566	0.000	5.758	2.597~12.766
lung cavitation	1.466	0.398	3.632	13.192	0.000	4.245	1.946~9.263
pleural effusion	1.048	0.374	2.799	7.834	0.005	2.851	1.369~5.939
eosinopenia	0.849	0.380	2.233	4.986	0.026	2.337	1.109~4.925
renal dysfunction	0.940	0.465	2.023	4.091	0.043	2.561	1.030~6.369

OR: Odds Ratio, CI: Confidence Interval

Table. Factors Associated with Active Tuberculosis Diagnosis in IGRA-Negative Populations: Multivariable Analysis

Conclusions: A non-negligible proportion of active TB occurs in the IGRA-negative individuals. Occupation, weight loss, lung cavitation, pleural effusion, TST positivity, eosinopenia (<0.05×10^9/L), and renal dysfunction may serve as independent predictors of active tuberculosis disease in the IGRA-negative population.

EP23 Unravelling Progress: The fallout of donor funding and accountability

EP23-917-19 Impact of USAID funding suspension on TB case detection in Cambodia: A critical setback

M. Chry,[1] C. Leng,[2] K. Mom,[3] S.C. Choub,[4] S.T. Kheang,[5] B. Heng,[5] C.Y. Huot,[6] S. Tuot,[7] [1]Cambodia Anti-Tuberculosis Association, TB program, Phnom Penh, Cambodia, [2]National Center for Tuberculosis and Leprosy Control (CENAT), Sub-Implementer of the GFATM, Phnom Penh, Cambodia, [3]Cambodia Anti-Tuberculosis Association, Management, Phnom Penh, Cambodia, [4]KHANA, Management, Phnom Penh, Cambodia, [5]Cambodian Health Committee, Management, Phnom Penh, Cambodia, [6]National Center for Tuberculosis and Leprosy Control, Management, Phnon Penh, Cambodia, [7]KHANA-Cambodia, Research, Phnom Penh, Cambodia

Background and challenges to implementation: Tuberculosis (TB) remains a significant public health concern in Cambodia, with an estimated 35% of TB cases undiagnosed due to limited access to diagnostic tools, insufficient healthcare resources, and gaps in service provision. Effective case detection is vital to reduce TB transmission, but challenges in screening efforts persist, especially in remote areas.

Intervention or response: The Community Mobilization Initiatives to End Tuberculosis (COMMIT) project, funded by USAID, was implemented to enhance TB case detection, prevention, and treatment in Cambodia. The initiative utilized community-based screening methods, including chest X-rays and Xpert MTB/RIF testing, to ensure early and accurate TB diagnosis. The project aimed to reach remote and underserved populations across 27 Operational Districts (ODs).

However, USAID terminated funding on January 25, 2025, significantly impacting TB screening activities in these regions.

Results/Impact: An analysis of TB case detection from Q1-2024 to Q1-2025 highlights the consequences of the funding disruption. In Q1 of 2024, when USAID was actively funding the program, 1,858 TB cases were detected, including 958 Bac+. Monthly detections were 581 in January, 578 in February, and 699 in March. After the funding suspension, case detection sharply declined. In January 2025, USAID-funded activities were still ongoing until January 25, resulting in 387 cases. However, after the suspension, case fell to 288 in February (50.17% decrease) and 214 in March (69.40% decrease), resulting in a 52.15% total decrease in detected cases compared to the previous year.

Conclusions: The suspension of USAID funding has led to a dramatic reduction in TB case detection, with over 50% fewer casesidentified in 2025 compared to 2024. This decline underscores the urgent need for alternative funding sources to maintain active screening programs and ensure continued TB case detection and control in Cambodia. Without immediate intervention, the disruption may hinder efforts to control TB and increase the risk of undiagnosed and untreated cases.

EP23-918-19 Enhancing performance management and accountability in TB program implementation: The AIM 250 experience

Q. Ogbuji,[1] R. Ogbonna,[2] B. Nwaogu,[1] O. Onitiju,[1] O. Olupitan,[3] T. Adetiba,[3] E. Ubochioma,[4] O. Akaniro,[5] R. Aoife,[6] [1]Association for Reproductive and Family Health, TB & HIV, Abuja, Nigeria, [2]Association for Reproductive and Family Health, TB & HIV, Lafia, Nigeria, [3]Institute of Human Virology, Nigeria (IHVN), Global Fund N-THRIP, Abuja, Nigeria, [4]National TB and Leprosy and Buruli Ulcer Control Programme, Global Fund Program Management Unit, Abuja, Nigeria, [5]National TB and Leprosy and Buruli Ulcer Control Programme, FMOH, Abuja, Nigeria, [6]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Grant Management Division, Geneva, Switzerland
e-mail: ogbonna.r@arfh-ng.org

Background and challenges to implementation: Nigeria has made commendable strides in strengthening its tuberculosis (TB) control program, particularly through expanded investments, strategic partnerships, and innovative interventions. However, like many large-scale public health programs, there remains room to enhance the consistency and timeliness of data reporting, accountability mechanisms, and real-time performance monitoring especially at sub-national levels where programmatic complexity increases.

Intervention or response: In response, the AIM 250 (working days) platform was introduced in early 2023 as a novel digital and performance accountability tool. The tool integrates a routine performance monitoring framework with adaptive intelligence and was anchored on weekly and monthly survey submissions by Cluster Coordinators and State Technical Officers (STOs). These surveys track key indicators, feeding into a centralized dashboard used for real-time supervision and gap identification. Quantitative data were collated and analyzed using Microsoft Excel, focusing on four primary metrics: Platform Adoption, Capturing Compliance, STO Adherence Rate, and Data Quality

Results/Impact: The results demonstrate a significant improvement in compliance and adoption after onboarding additional teams. Vantage Platform Adoption was initially low at 17% (Sept-Oct) but increased to 58% in Nov and 92% in Dec. Capturing Compliance rose from 44% in Sept to 67% in Dec, while Data Quality (Completeness) improved from 46% to 100% over the same period.

STO Adherence Rate remained stable at 83% initially but reached 100% in Dec. Similarly, Data Quality (Accuracy) improved from 76% in Oct to 95% in Dec. The structured reporting cycle and adaptive intelligence framework enabled state teams to track progress, identify gaps, and implement targeted interventions, leading to improved responsiveness and coordination.

Conclusions: AIM 250 has proven to be a transformative tool in TB program performance management, significantly enhancing data-driven accountability and managerial oversight.

The observed improvements in compliance and data quality following increased platform adoption highlight the importance of structured performance monitoring in optimizing program outcomes.

EP23-919-19 Leveraging the Multi-Sectoral Accountability Framework to accelerate TB elimination in Uganda: Political commitment, policy integration, and cross-sector collaboration

M. Mwesige,[1,2,3] H. Luzze,[1] N. Modi,[1] M.G. Nabukenya Mudiope,[2] E. Mbabazi,[4] A. Mulindwa,[1] [1]Ministry of Health, National TB and Leprosy Program, Kampala, Uganda, [2]Infectious Diseases Institute, Makerere University, Kampala, Uganda, Health Systems Strengthening, Kampala, Uganda, [3]Makerere University, School of Public Health, School of Public Health, Kampala, Uganda, [4]Office of the Prime Minister Prime, Minister's Delivery Unit (PMDU), Kampala, Uganda
e-mail: mathiusmwesige1@gmail.com

Background and challenges to implementation: In 2020, Uganda adopted the WHO Multi-Sectoral Accountability Framework for Tuberculosis (MAF-TB) to enhance political commitment, institutional accountability, and cross-sectoral collaboration in the fight against Tuberculosis. The Prime Minister championed Tuberculosis elimination, urging Ministries, Departments, and Agencies (MDAs) to integrate Tuberculosis interventions into Programme Implementation Action Plans (PIAPs). However, inadequate funding, poor coordination, persistent stigma, and slow policy adoption hindered full implementation, requiring ongoing political advocacy and reforms at the systems level.

Intervention or response: To operationalise MAF-TB, Ministry of Health (MoH), with support from USAID, WHO, and Global Fund, leveraged high-level political advocacy to establish the Prime Minister as a national TB champion. In response, 13 MDAs incorporated TB activities into 2024/25 work plans and budgets, allocating over UGX 1.8 billion towards workplace Tuberculosis service delivery interventions. MoH integrated TB screening into national HIV workplace policies and social protection schemes, widening access in occupational settings. Office of the Prime Minister facilitated intersectoral coordination, established accountability mechanisms, and organised annual stakeholder forums to align priorities, monitor progress, and strengthen multi-sector responsibility.

Results/Impact: High-level political commitment catalysed the national adoption of workplace TB interventions and resource mobilisation. 13 MDAs formally incorporated Tuberculosis programming into their sectoral plans and budgets. Over UGX 1.8 billion was allocated for workplace Tuberculosis activities in FY2024/25. 17,359 employees were screened; 6,770 presumptive cases were tested, identifying 192 tuberculosis-positive individuals, all linked to care. Tuberculosis was integrated into the National HIV Workplace Policy, leading to increased awareness and screenings among high-risk workforces. National Tuberculosis Stakeholders' Conference fostered cross-sector accountability and learning, enhancing the policy implementation momentum.

Conclusions: Uganda's implementation of MAF-TB exemplifies the transformative potential of political leadership, intersectoral policy reform, and integrated financing in accelerating the elimination of tuberculosis. By embedding tuberculosis interventions into workplace governance frameworks, Uganda offers a scalable, accountable model for sustainable Tuberculosis control and cross-sectoral impact.

EP23-920-19 Development of a multistakeholder accountability framework for tuberculosis control: A case study from Liberia

F. Ikhlaq,[1] S. Ahmad,[2] [1]NHS, Public Health, Birmingham, United Kingdom of Great Britain and Northern Ireland, [2]Tampere University, Finland, Public Health, Tampere, Finland
e-mail: fakhraikhlaq19@gmail.com

Background: Tuberculosis (TB) remains a leading cause of morbidity and mortality in Liberia, with an estimated incidence rate of 308 cases per 100,000 population and a treatment success rate of only 78% (WHO, 2023). Despite existing national strategies, Liberia faces persistent challenges in achieving WHO End TB targets, primarily due to fragmented stakeholder coordination, limited community engagement, and weak accountability mechanisms.

This study aims to develop a multistakeholder accountability framework to enhance TB control outcomes by fostering coordinated action and transparency among key actors.

Design/Methods: A qualitative case study design was utilized, incorporating 30 key informant interviews with representatives from the Ministry of Health, National Public Health Institute of Liberia (NPHIL), WHO, Global Fund partners, and community organizations.

The study also conducted a desk review of TB policies, National Strategic Plans, and surveillance reports (2018–2023). Thematic analysis identified accountability gaps, while pilot testing of the proposed framework assessed its impact on TB indicators over a 12-month period.

Results: Analysis revealed systemic gaps in governance, with 40% of stakeholders reporting unclear role delineations and 35% citing inadequate financial tracking mechanisms. Community engagement in TB care was limited, with only 25% of community health workers actively involved in case detection.

The proposed framework, incorporating structured governance models, performance monitoring, and community accountability forums, led to a 20% increase in case detection rates (from 67% to 87%) and improved treatment success rates to 90%. Stakeholder collaboration scores, assessed via standardized surveys, improved by 30%, reflecting enhanced coordination.

Conclusions: The implementation of a robust multistakeholder accountability framework significantly improved TB control outcomes in Liberia, demonstrating the critical role of coordinated governance, transparent reporting, and community participation.

Adoption of similar frameworks in comparable low-resource settings could accelerate progress toward global TB elimination targets, supporting resilient health systems in line with WHO's End TB Strategy.

EP23-921-19 Volatile funding in fight to tuberculosis: Dilemma in LMICs – Bangladesh context

M.F. Wahid,[1] R.S. Banu,[2] S. Islam,[3] [1]USAID LEAP Global, National Tuberculosis Control Programme, Dhaka, Bangladesh, [2]National Tuberculosis Control Program (NTP), Tuberculosis, Dhaka, Bangladesh, [3]BRAC, BRAC Health Programme, Dhaka, Bangladesh
e-mail: ferdous136@gmail.com

Background and challenges to implementation: Sustainable financing is prerequisite to achieve END TB target. Bangladesh is a TB high burden low- and middle-income country (LMIC) despite significant progress in TB prevention and care. This is mostly due to funding insufficiencies, which jeopardize TB targets, making affordability and accessibility difficult for disadvantaged groups. At the same time, there is a need to balance enhanced domestic resource mobilization with external assistance.

Intervention or response: This study focused to address mentioned funding challenges on financial constraints, donor dependence, and domestic funding barriers. It also explored potential solutions, including innovative financing and public-private partnerships to align with END TB target. During January to February 2025, desk review of National Program's Annual reports, National Strategic Plan (NSP), Joint Monitoring Mission (JMM) recommendations, Donor vs Domestic budget mapping, interviewing relevant focal persons from Government, implementing NGO Partners, Donor representatives were done.

Results/Impact: Findings indicate that, domestic funding is still limited to 39% and rest depends on external sources like The Global Fund and USAID. During last decade, domestic finance increased very slowly. Still there is 40% funding gap as per NSP. From 2021 to till date, commodities like molecular WHO-recommended rapid diagnostic (mWRD) tests, diagnostic kits, reagents, TB drugs, tuberculosis preventive treatment (TPT) drugs, capacity development, and an abundance of human resources funded by donors. Reducing donor dependency requires stronger domestic resource mobilization through increased government funding, corporate contributions, and private-sector investments. Innovative financing models like tax-based health financing, social health insurance, and results-based funding should be explored. Integrating TB services into Universal Health Care and ensuring strong political commitment are essential for sustainable, accessible, and affordable TB care.

Conclusions: Multifaceted strategy can address Bangladesh's TB financing issues, including more government sensitization for funding, sustainable financing mechanisms and increase private sector engagement. This scenario is more or less similar in all LMICs.

EP23-922-19 Health financing – The two-year planning cycle, simplified planning formats and conditionality-based incentives in India's TB program. Innovation from India

R. Rao,[1] V. Somasundaram,[2] S. Chandra,[2] S. Malviya,[1] U. Singh,[1] [1]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India
e-mail: vigneshwaranp@rntcp.org

Background and challenges to implementation: The National Health Mission (NHM) is key to achieving the National Health Policy and Sustainable Development Goal 3 (SDG-3). It focuses on improving primary health care, ensuring Universal Health Coverage (UHC), and

eliminating tuberculosis (TB). The National TB Elimination Program (NTEP) implements TB strategies at national and state levels through Programme Implementation Plans (PIPs). The disconnect between funding and state performance was a major challenge in Health financing, reducing accountability and results. .In 2022, NHM introduced reforms such as a two-year planning cycle and performance-based funding. The new, data-based approach showed strong results, leading to a countrywide increase in TB notifications from 70.2% in 2022 to 89.9% in 2024. This approach enhances state planning and effectiveness in TB elimination efforts.

Intervention or response: Given this background, in 2024, reforms were introduced for the PIPs such as (i) Two-Year Planning, (ii) Simplified Planning Format, (iii) Focus on Key Deliverables (iv) NTEP Key Conditionalities. NTEP performance was analyzed to assess this strategy's effectiveness using Ni-kshay data (India's TB digital surveillance system).

Results/Impact: After implementing the new strategy, TB notification data from 2021 to 2024 showed improved target achievement: 70.2% in 2022, 86.4% in 2023, and 89.9% in 2024—a total increase of 19.8 percentage points. Linking funding to performance through conditionality effectively enhanced the program, particularly in states of Ladakh, Uttar Pradesh, and Tripura.

Conclusions: India's performance-based funding model and enhanced planning system have significantly improved the TB program's performance. This approach promotes efficient resource use, accountability, and continuous improvement among states. As countries seek effective disease elimination strategies, this results-oriented model offers a strong global example.

EP23-923-19 Rethinking the TB funding landscape in Pakistan: From donor dependency to domestic leadership

S.S. Habib,[1] T. Masoud,[2] H. Bin Hamza,[2] W. Zulfiqar,[2] W. Jadoon,[2] N. Rafiq,[2] Z. Gardeezi,[2] S. Siddiqui,[1] [1]The Aga Khan University, Community Health Sciences, Karachi, Pakistan, [2]Ministry of National Health Services, Regulations and Coordination, (MoNHSRC), Islamabad, Pakistan
e-mail: shifa.habib@aku.edu

Background: Pakistan is the world's fifth highest TB burden country, with an estimated burden of 686,000 cases in 2023. Despite this, the domestic investment is only 5.5% of all TB financing (Global TB Report 2024). The Global Fund to Fight AIDS, Tuberculosis and Malaria (GFATM) remains the primary donor, contributing 32%, with a budget gap of 63%, undermining sustainability. A strategic review of GFATM funding in Pakistan was commissioned by Ministry of National Health Services, Regulation and Coordination, including an in-depth review of TB funding landscape.

Design/Methods: This financial review was embedded within a broad strategic review of GFATM in Pakistan. Desk-review of financial data provided by government, donors and development partners was conducted, followed by 232 key informant interviews. Financial quantitative analysis was conducted using MS Excel to assess funding flows and resource allocation and carry out fund flow mapping to identify and align funding sources

Results: GFATM has disbursed approximately USD 710 million for TB in Pakistan since 2004 (Figure-1), making it the largest source of TB funding. From 2016–2023, donor funds made up 80% of TB financing, while the government contributed around 20%. Fund absorption has improved over time, with ≥80% utilization in recent cycles. An approximately 15% of funding is allocated to human resources, 60% to pharmaceuticals, and less than 1% to communication. There is 100% reliance of donor funding for anti-TB medicines and 90% diagnostics are resourced by GFATM**.** The mandate for TB program governance lies with Country Coordinating Mechanism (CCM) and Common Management Unit (NTP), though both face structural challenges and weakened authority. The CMU relies on GFATM to pay its nearly 400 staff.

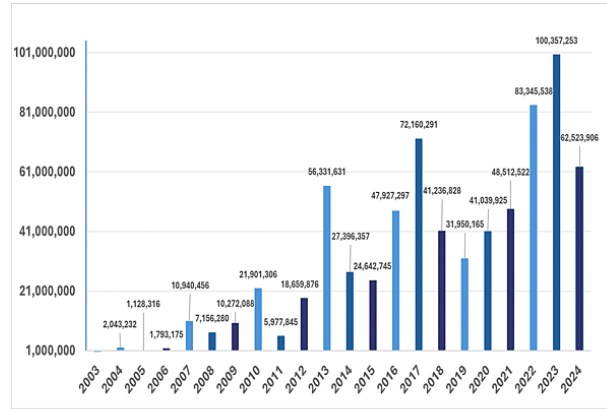


Figure 1 : TB funding by GFATM to Pakistan

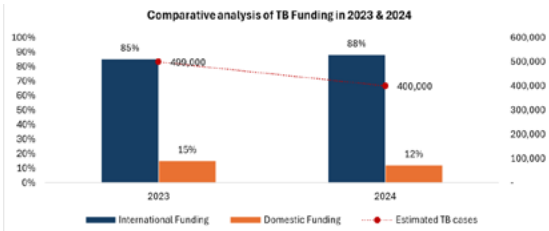
Conclusions: While donor support has expanded access and improved outcomes, increased government financing and stronger institutional ownership are urgently needed, especially in the face of recent donor freezes and shifting geopolitical priorities.

EP23-924-19 TB funding in Nigeria: The politics of resource allocation, donor dependence, and accountability challenges

V. Abel,[1] C. Amhanyobor,[1] I. Gordon,[2] B. Odume,[2]
[1]KNCV Nigeria, Finance and Operations, Abuja, Nigeria, [2]KNCV Nigeria, Technical/Programs, Abuja, Nigeria
e-mail: vabel@kncvnigeria.org

Background and challenges to implementation: With an estimated 499,000 cases reported in 2023, Nigeria ranks highest in tuberculosis (TB) burden in Africa and sixth globally. Despite this, the country's TB control efforts face significant financial challenges, with a funding gap of 60% in 2024. This study examines the political dynamics influencing TB funding in Nigeria, focusing on resource allocation, donor dependence, and accountability mechanisms.
Intervention or response: A comprehensive desk review of funding reports and relevant literature was conducted to analyze the trends and challenges in TB financing in Nigeria. The 2024 WHO Global Tuberculosis Report was examined to compare trends in TB financing and its influence on TB case notification.
Results/Impact: In 2024, Nigeria required $393 million for TB control; however, only 39.8% of this budget was funded, leaving a 60% unfunded gap of approximately $236 million. Domestic contributions accounted for 12%, a shortfall of 3% from a 15% contribution in 2023, while 88% came from international donors, a 2% increase from an 85% contribution in 2023. These findings reveal a heavy reliance on foreign aid, which poses sustainability risks for TB control programs. For instance, the suspension of U.S. health aid in early 2025 created a $5 million shortfall in Q1 2025 alone. Delays and inconsistencies in fund disbursement and the absence of specific TB legislation were cited as major threats to TB funding and efficient resource utilization.



Conclusions: Bridging Nigeria's TB funding gap and reducing donor dependence requires increased domestic investment and strong political commitment. The involvement of influential figures as TB advocates and ambassadors, such as the Nigerian First Lady, who has donated N2 billion ($1,285,718.88) from her foundation within one year to the fight against TB, has become exemplary. Establishing legal and institutional frameworks will also improve transparency and accountability in the disbursement of funds to achieve sustainable TB funding towards the ENDTB goals.

EP24 Frontiers in immunology and biomarkers - infection, disease risk and treatment monitoring

EP24-925-19 Impact of maternal helminth infection and *MTB* exposure on neonatal IgE, maternal and neonatal IgG immune profiles

M. Zewde,[1] S. Ali,[2] D. Fantahun,[3] M. Habtamu,[3]
[1]Armauer Hanson Research Institute, Mycobacteria and other Disease Department, Addis Ababa, Ethiopia, [2]St. Paul's Hospital Millennium Medical College, mycobacteria and other disease Research department, Addis Ababa, Ethiopia, [3]Armauer Hanson Research Institute, Mycobacteria and other Disease research Department, Addis Ababa, Ethiopia
e-mail: nanget2009@gmail.com

Background: Maternal helminth infections and Mycobacterium tuberculosis (*MTB*) exposure may influence maternal and neonatal immune responses, potentially impacting susceptibility to infectious and allergic diseases. This study investigates the relationship between maternal helminth infection, *MTB* exposure (via Quantiferon [QFT] testing), and immune profiles in mothers and neonates.
Design/Methods: A comparative cross-sectional study was conducted on 87 mothers, purposively grouped into helminth-infected (n=36) and helminth-negative (n=51) cohorts, and their neonates. Participants were further stratified by QFT status to assess *MTB* exposure. Stool samples were examined using a wet mount and kato-katz to identify helminth species and egg counts. *MTB*-specific IgG was measured in maternal venous and cord blood samples. Moreover, the total IgE levels of the neonates were measured. SPSS and Graph pad prism were used for data analysis, and Mann-Whitney U tests determined statistical significance ($P<0.05$)
Results: Among the helminth-infected group (n=36), *Taenia spp.* 13 (36.1%) and hookworm 12 (33.3%) were the predominant parasites. Of all QFT-tested participant mothers, 14 (16.1%) were QFT-positive and 63 (72.4%) were QFT-negative. Neonates born to helminth-infected mothers exhibited higher IgE levels than those of helminth-negative mothers ($P=0.04$). QFT-positive mothers were associated with lower neonatal IgE levels ($P=0.02$) and higher *MTB*-specific IgG levels ($P=0.01$). For hookworm-infected mothers, lower egg counts (<72 eggs/g stool) correlated with higher maternal IgG levels ($P=0.01$). However, egg counts did not significantly influence maternal IgG levels in Taenia spp. infected mothers.
Conclusions: Maternal helminth infection and *MTB* exposure significantly influence maternal and neonatal immune profiles. Helminth infection was linked to increased neonatal IgE, while maternal QFT positivity correlates with higher neonatal *MTB*-specific IgG. These findings highlight the complex interplay between maternal infec-

tions and neonatal immunity, emphasizing the need for further research to explore underlying mechanisms and their implications for susceptibility to infection and immune development

EP24-926-19 Regulation of TIM-3 expression in macrophages by IκBζ during Mycobacterium tuberculosis infection: Mechanisms and functional implications

Y. Niu,[1] Z. Tang,[1] Y. Feng,[1] M. Wu,[1] J. Zhang,[1] P. Tang,[1]
[1]The Fifth People's Hospitaof Suzhou /The Affiliated Infectious Diseases Hospital, Suzhou Medical College of Soochow University, Department of Tuberculosis, Suzhou, China
e-mail: yayanniu@163.com

Background: Macrophage (Mø) activation and their induction of type I immune responses are pivotal for host control of tuberculosis (TB); however, TIM-3 expression in Mø significantly suppresses their activation. Therefore, elucidating the regulatory factors and mechanisms governing TIM-3 expression in Mø holds critical innovative value for advancing TB prevention and therapeutic strategies.
Design/Methods: Using single-cell sequencing technology, RNA-seq, and other methods, we detected the expression levels of immune molecules and transcription factors associated with cellular characteristics and functions in various subpopulations of bone marrow-derived macrophage (BMDM) cells.
We further analyzed the correlation between IκBζ and TIM-3, as well as their associations with macrophage characteristics and functions.
Results: Single-cell sequencing analysis revealed that IκBζ expression levels are higher in pro-inflammatory M1-like Mø compared to M2-like Mø. Treatment with the cytokine IL-36γ significantly upregulated *Nfkbiz* (encoding IκBζ) and suppressed *Havcr2* (the gene encoding TIM-3) in TB antigen-stimulated Mø, accompanied by a marked increase in pro-inflammatory effector molecules and associated transcription factors.
Knockout of the *Nfkbiz* gene led to a significant rise in *Havcr2* expression and a pronounced decrease in pro-inflammatory effector molecules and transcription factors in TB antigen-stimulated macrophages.
Conclusions: IκBζ is a critical transcription factor that suppresses TIM-3 expression. Enhancing IκBζ through appropriate strategies, such as IL-36γ treatment, may inhibit TIM-3 expression, thereby mediating the enhancement of macrophage activation and effector functions.

EP24-927-19 Biomarkers for Asymptomatic TB Diagnostisis

M. Maseeme,[1] E. Wong,[2] A. Leslie,[2] [1]Africa Health Research Institute, Leslie Lab, Durban, South Africa, [2]Africa Health Research Institute, Basic and Translation Science, Durban, South Africa
e-mail: mahlatse.maseeme@ahri.org

Background: Tuberculosis (TB), continues to be a major global health challenge, particularly due to the difficulty in identifying asymptomatic. These individuals carry the bacteria without clinical symptoms but at risk of contributing to transmission. Current diagnostic tools like the Tuberculin Skin Test (TST) and Interferon-Gamma Release Assays (IGRAs) have limited ability to accurately identify and differentiate asymptomatic TB cases from latent cases. Recent advances in immunology suggest that addition of HLADR aid Mtb specific immune cell subsets ability to distinguish latency versus active disease including recent exposure, although this is promising is has not yet shown in asymptomatic TB and with and without HIV presence. Strengthening the evidence of HLADR in mtb specific biomarker drive efforts for this to get clinical test and use.
Design/Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from individuals with asymptomatic TB and matched community controls to investigate immune activation profiles. A T-cell antigen-specific activation assay was performed to assess functional immune responses. Panel of fluorescently labeled antibodies targeting activation markers and lineage-specific surface and intracellular proteins were used enabling the identification of unique immune subsets and activation patterns.
Results: In the absence of HIV co-infection, HLA-DR expression on M. tuberculosis-specific T cells effectively distinguished individuals with asymptomatic TB from community controls, indicating its potential as a diagnostic marker in HIV-negative populations. However, this discriminatory capacity was lost in the presence of HIV. Th17 cell subsets did not show significant differences between groups, irrespective of HIV status.
Interestingly, individuals with asymptomatic TB exhibited elevated levels of double-negative memory B cells compared to controls. Other lymphoid populations remain unchanged although there is elevated activation in the asymptomatic TB.
Conclusions: HLA-DR expression can distinguish asymptomatic TB in HIV-negative individuals, while broader immune profiles remain largely unchanged but with elevated antigen-specific inflammation in the asymptomatic TB.

EP24-928-19 Lens-free shadow imaging technology-based quantification of T cell activation for latent tuberculosis diagnosis

Y. Jang,[1] I. Lee,[1] H. Cheon,[2] G.I. Lee,[3,4] R. Nam,[3] L. Lee,[3] S. Kim,[3] H. Lee,[3] H. Yoon,[3] S. Seo,[1,5,6] S. Han,[5,7] H.S. Jun,[1,8]
[1]MetaImmuneTech Inc., R&D, Sejong, Republic of Korea, [2]Korea University, Smartcity Intelligent Healthcare Research Center, Sejong, Republic of Korea, [3]The Korean Institute of Tuberculosis · Korean National Tuberculosis Association, Laboratory Medicine Center, Cheongju, Republic of Korea, [4]The Korean Institute of Tuberculosis · Korean National Tuberculosis Association, Research&Development Center, Cheongju, Republic of Korea, [5]Korea University, Institute of Photonics and Materials, Sejong, Republic of Korea, [6]Korea University, Department of Electronics and Information Engineering, Sejong, Republic of Korea, [7]MetaImmuneTech Inc., QC&QA, Sejong, Republic of Korea, [8]Korea University, Department of Biotechnology and Bioinformatics, Sejong, Republic of Korea
e-mail: yyjang@metaimmunetech.kr

Background: Latent tuberculosis infection (LTBI) remains a significant global health challenge affecting approximately one-fourth of the world's population. Current diagnostic methods rely on T cell-based immunologic assays such as Interferon-Gamma Release Assay (IGRA), which detect memory T cell responses to *Mycobacterium tuberculosis*-specific antigens. However, these methods require extended incubation periods (>24 hours), expensive reagents, specialized equipment, and trained personnel, limiting their accessibility in resource-constrained settings. This study introduces a novel lens-free shadow imaging technology (LSIT) that quantifies T cell activation through label-free morphological analysis at the single-cell level, offering a rapid and cost-effective diagnostic alternative for LTBI detection.
Design/Methods: Peripheral blood samples were collected from QuantiFERON-TB Gold classified LTBI-positive and negative individuals. Blood samples were incubated in QuantiFERON-TB's Nil, TB antigen, and Mitogen tubes with added co-stimulatory antibodies (CD28/CD49d) for 6 hours at 37°C. Following incubation, $CD4^+$ T cells were isolated and analyzed on the LSIT platform. Morphological parameters were extracted from single-cell shadow images and compared between groups and stimulation conditions.
Results: All participants exhibited significant increases in LSIT-derived parameters (CMV, PPD, MMD, MMD_SD, WCM_SD) in the Mitogen group compared to Nil controls, validating general T cell responsiveness to stimulation. Notably, only LTBI-positive individuals showed significant increases in MMD_SD in the TB antigen group compared to Nil, indicating antigen-specific memory T cell activation.
Conclusions: This LSIT-based platform enables rapid, label-free, and quantitative assessment of T cell activation at the single-cell level through morphological analysis. The technology demonstrates strong potential as a cost-effective diagnostic tool for LTBI detection, especially in resource-limited settings. By eliminating the need for specialized reagents, reducing incubation time, and providing quantitative results, this approach may complement or improve upon current IGRA-based diagnostics, contributing to more effective tuberculosis control and prevention strategies.

EP24-929-19 Evaluation of absolute monocyte to lymphocyte ratio in peripheral blood as an index of tuberculosis in Lusaka, Zambia

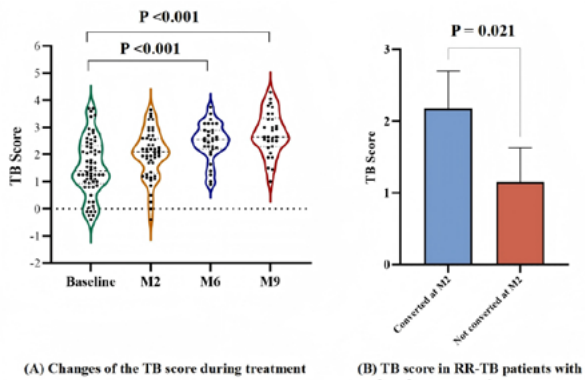
O. Makai,[1,2] K.J. Mateyo,[1] [1]University Teaching Hospital- Adult, Internal Medicine, Lusaka, Zambia, [2]University of Zambia, Internal Medicine, Lusaka, Zambia

Background: The diagnosis of Tuberculosis (TB) remains challenging, highlighting the need for improved diagnostic and screening tools. The Monocyte to lymphocyte ratio (MLR) has emerged as a potential marker for TB infection. However, evidence for its clinical utility remains inconclusive. This study aimed to evaluate the effectiveness of MLR in peripheral blood as a measure of active TB.
Design/Methods: A cross sectional study was conducted at three health facilities in Lusaka, Zambia. Participants were divided into four groups: HIV positive active TB patients (TB/HIVp), HIV negative active TB patients (TB/HIVn), HIV positive TB patients on treatment for more than two months (TxTB/HIVp) and healthy volunteers without active TB and HIV (HV). Blood samples were collected for Full blood count (FBC), white cell differential count (DC), and other tests. Data analysis was performed using Stata Version 18, employing descriptive statistics, logistic regression and ROC curves to evaluate the Monocyte to Lymphocyte ratio.
Results: 177 participants were analysed and categorised into four groups; 45 TB/HIVp, 42 TB/HIVn, 44 TxTB/HIVp and 46 HV. Active TB patients (TB/HIVp and TB/HIVn) had significantly higher median MLR values (0.41 and 0.35 respectively) compared to the TxTB/HIVp (0.142) and HV (0.13) groups. Significant differences were noted between TB/HIVp vs. TxTB/HIVp, TB/HIVp vs. HV, and TB/HIVn vs. HV. An MLR of >0.187 discriminated TB/HIVp from HV with 86.67% sensitivity, 82.61% specificity, 83.28% positive predictive value and 86% negative predictive value. An MLR >0.205 differentiated TB/HIVp from TxTB/HIVn with 77.8% sensitivity,70.4% specificity, 72.3% positive predictive value and 76% negative predictive value. Low BMI and low CD4 count were associated with higher MLR values.
Conclusions: Monocyte to lymphocyte ratio is significantly increased by active TB and is thus a potential biomarker for TB screening.

EP24-930-19 A novel blood-based 3-gene signature score for treatment monitoring in rifampicin-resistant tuberculosis: Preliminary results

Y. Zhang,[1] F. Sun,[1] Y. Li,[1] W. Zhang,[1] [1]Huashan Hospital, Fudan University, Department of Infectious Diseases, Shanghai, China
e-mail: evelyncheung@126.com

Background: A rapid, non-sputum-based test is urgently needed for tuberculosis treatment monitoring. We conducted a prospective cohort study to evaluate the performance of a blood-based 3-gene signature score (Xpert MTB-HR) for therapeutic monitoring in rifampicin-resistant tuberculosis (RR-TB).
Design/Methods: Patients aged 16–75 years with pulmonary RR-TB were prospectively enrolled and received a 9-month five-drug oral regimen comprising bedaquiline, linezolid, cycloserine, clofazimine, pyrazinamide, and a fluoroquinolone. Sputum cultures were obtained monthly, and venous blood was collected at baseline, month 2, month 6, and month 9 for the Xpert MTB-HR assay, which was performed according to the manufacturer's instructions. Cycle threshold for three genes (DUSP, GBP5 and KLF2) was obtained and the TB score was determined by: $(Ct_{GBP5} + Ct_{DUSP3})/2 - Ct_{KLF2}$.
Results: From May 2023 to February 2025, 67 patients were recruited. Thirty patients have completed treatment and no bacteriological failure has been reported so far. Two patients were lost to follow-up and three deaths occurred during treatment. The TB score gradually increased during treatment, with the most remarkable increase seen at month 6 (2.55 (IQR 2.20–2.90) vs. 1.40 (IQR 0.93–2.32), P <0.001) and month 9 (2.65 (IQR 2.29–3.35) vs. 1.40 (IQR 0.93–2.32), P <0.001) compared to baseline. The TB score at month 2 was higher in patients who achieved culture conversion compared to those with a positive culture ((2.18 (IQR 1.70–2.70)) vs. 1.15 (IQR 1.95–1.62), P = 0.021). The TB score demonstrated strong predictive performance for early culture conversion at month 2 compared with sputum culture, with an AUC of 0.812 (95% CI 0.666–0.958, P = 0.024). The optimal cut-off value was 1.30 with a sensitivity of 80.0% and a specificity of 81.0%.



(A) Changes of the TB score during treatment

(B) TB score in RR-TB patients with early culture conversion

Conclusions: This preliminary analysis suggested that the 3-gene TB score may serve as a biomarker for early culture conversion in RR-TB patients.

EP24-931-19 The value of platelet albumin ratio in monitoring treatment response and predicting time to culture conversion in patients with tuberculosis: A multicenter prospective study

Y. Li,[1] L. Song,[1] Z. Feng,[1] S. Ge,[1] F. Sun,[1] W. Zhang,[1]
[1]Huashan Hospital, Fudan University, Department of Infectious Diseases, Shanghai, China
e-mail: y_li11@fudan.edu.cn

Background: Identifying patients with tuberculosis (TB) at high risk of delayed culture conversion was challenging, particularly in resource-limited settings. We explored the value of platelet albumin ratio (PAR), an inflammation biomarker based on routine laboratory examinations, in monitoring treatment response and predicting time to culture conversion.
Design/Methods: This was a sub-study of a multicenter randomized controlled trial (NCT05401071) in China. Participants with drug-susceptible TB were randomly assigned to receive the standard regimen or 4-month regimens.. Sputum culture, platelet count and serum albumin tests were conducted at baseline and at week 1, 2, 3, 4, 6, 8, 12, 17, 21, and 26 after treatment initiation. Culture conversion was defined as two consecutive cultures, taken at least 14 days apart, being found to be negative. Cox proportional-hazards model was employed to analyze factors of delayed culture conversion and calculate the risk score. The median value of the risk score was used to classify low-risk or high-risk group of delayed culture conversion.

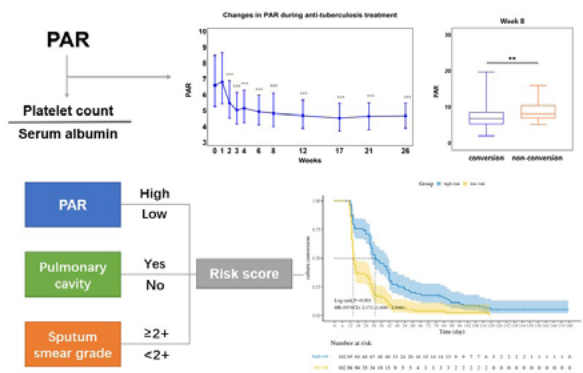


Figure1. PAR in monitoring treatment response and predicting time to culture conversion.

Results: A total of 204 patients with positive sputum culture were included, with the baseline median PAR of 6.58. The median PAR was significantly decreased at week 2 (5.48 vs. 6.58, P<0.001) compared to baseline and declined to 4.67 at week 26. The median baseline PAR of patients

without culture conversion at week 8 was significantly higher than patients with culture conversion (8.09 vs 6.72, P=0.003). Baseline PAR (aHR=0.90, 95%CI:0.85-0.95), cavity on pulmonary radiology (aHR=0.72, 95%CI:0.53-0.98), smear grade≥2+ (aHR=0.63, 95%CI:0.45-0.89) were independent risk factors of delayed culture conversion. The median time to conversion was 31 days (Interquartile range [IQR]: 14-44) in high-risk group, significantly longer than that (14 days, IQR:13-28, P<0.001) in low-risk group.
Conclusions: PAR significantly decreased after anti-TB treatment. The risk score based on baseline RAR, pulmonary radiology and sputum smear could identify patients at high risk of delayed culture conversion.

EP24-932-19 The value of SAT-TB in monitoring the early therapeutic efficacy of MDR/RR tuberculosis

X. Ma,[1] Y. Chen,[1] G. Ying,[2] Y. Yu,[2] [1]Hangzhou Red Cross Hospital, TB Diagnosis and Treatment Center, Hangzhou, China, [2]Zhejiang University of Traditional Chinese Medicine, Second Clinical Medical College, Hangzhou, China
e-mail: 26186761@qq.com

Background: MDR/RR tuberculosis treatment lack of rapid and effective monitoring methods. Current techniques, such as GeneXpert that cannot distinguish live from dead bacteria, MGIT™960 culture which required 42 days to get negative result, fail to meet the clinical demand for dynamic monitoring. SAT-TB detects the 16S rRNA that is highly expressed in live MTB, demonstrates potential in monitoring early therapeutic efficacy.
Design/Methods: A total of 125 MDR/RR-TB patients with baseline positive sputum MGIT™960 culture in Hangzhou Red Cross Hospital from January 2022 to October 2024 were included in the study. Sputum samples were collected from patients at the end of the first and second month of treatment. These samples were tested using sputum SAT-TB, acid-fast staining(AFS),and MGIT™960 culture. With MGIT™960 culture as the gold standard, the sensitivity, specificity, Kappa and AUC of ROC curve of SAT-TB and AFS were evaluated.
Results: Using MGIT™960 culture as the gold standard, The sensitivity of sputum SAT-TB and AFS in evaluating therapeutic efficacy was 87.1% and 54.8% at the end of the first month of treatment, with specificities of 100.0%and 98.9%. The Kappa values for SAT-TB and AFS were 0.910 and 0.626. The AUC values for sputum SAT-TB and AFS were 0.935 and 0.769(P=0.0006). At the end of the second month of treatment, the sensitivity of SAT-TB and AFS was 25.0%and 16.7%, with specificities of 100.0% and 98.2%. The Kappa values for sputum SAT-TB and AFS were 0.376 and 0.212. The AUC values for SAT-TB and AFS were 0.625 and 0.574 (P=0.2305).
Conclusions: At the end of the first month of treatment, sputum SAT-TB showed high consistency with MGIT™960 culture in evaluating therapeutic efficacy, indicating that sputum SAT-TB has certain application value in the early therapeutic efficacy evaluation of MDR/RR-TB.

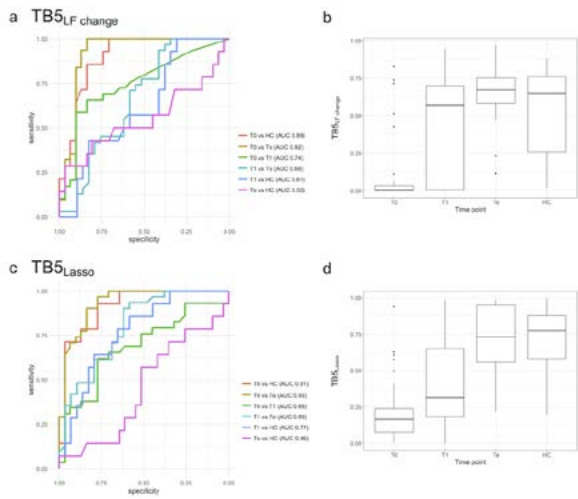
EP24-933-19 Multiparameter flow cytometry and machine learning identify a predictive blood-based immune signature for tuberculosis diagnosis and treatment monitoring

J. Eggeling,[1,2,3,4,5] J. Heyckendorf,[2,6] B. Kalsdorf,[1,2,3] D. Lewinsohn,[7] D. Schaub,[1,2,3] T. Schmidt,[8] M. Sester,[8] E. Tolosa,[9] C. Lange,[1,2,3] M. Reimann,[1,2,3] P. Sánchez Carballo,[1,2,3] DZIF-TB cohort study group [1]Research Center Borstel, Clinical Infectious Diseases, Borstel, Germany, [2]German Center for Infection Research, Tuberculosis Unit, Partner Site Hamburg-Lübeck-Borstel-Riems, Germany, [3]Lübeck University, Respiratory Medicine & International Health, Lübeck, Germany, [4]Schleswig-Holstein University Hospital, Pediatric Oncology and Rheumatology, Kiel, Germany, [5]Schleswig-Holstein University Hospital, Neonatology, Pediatric Pneumology and Neuropediatrics, Kiel, Germany, [6]Schleswig-Holstein University Hospital, Internal Medicine I, Kiel, Germany, [7]Oregon Health and Science University, Pulmonary, Allergy and Critical Care Medicine, Portland, United States of America, [8]Saarland University, Transplant and Infection Immunology, Homburg, Germany, [9]University Medical Center Hamburg-Eppendorf, Institute of Immunology, Hamburg, Germany
e-mail: jeggeling@fz-borstel.de

Background: There is increased interest in non-sputum-based biomarkers for the diagnosis and treatment monitoring of tuberculosis (TB).
Design/Methods: We conducted a prospective observational study in Germany, analyzing blood from 34 healthy controls (HC) and 51 TB patients at baseline (T0), after 14 days of therapy (T1), and at therapy end (Te). Using multiparameter flow cytometry, we profiled 386 immune cell populations and developed random forest models through two machine learning approaches.
Results: First, a log-fold change-derived $TB5_{LF\ change}$-score distinguished disease and treatment stages with high accuracy (AUC=0.89 for T0 vs. HC and 0.92 for T0 vs. Te), whereas performance was suboptimal at an early stage of therapy owing to its variability in T1. Its five populations exhibiting the greatest differences between T0 and Te included PD-L1$^+$CD80$^-$, PD-L1$^+$HLA-DR$^-$ and PD-L1$^+$ neutrophils, PD-L1$^+$CD80$^-$ monocytes, and PD-L1$^+$HLA-DR$^+$ CD4$^+$ lymphocytes.
Second, a LASSO-derived $TB5_{Lasso}$ score demonstrated superior diagnostic performance (AUC=0.91 and 0.93, respectively) and increased progressively with therapy. Two of five cell populations were identical in both scores:

PD-L1^{+}CD80^{-} neutrophils and PD-L1^{+}HLADR^{+} CD4^{+} lymphocytes. Additional $TB5_{Lasso}$-score populations included CCR4^{-}CXCR3^{+} CD4^{+} T cells, CD56^{+} Vd2^{+} gd T cells and CD56^{+} bright NK cells.

The $TB5_{Lasso}$-score correlated with clinical disease severity (r=–0.43, p=0.002), which was defined using seven clinical predictors selected based on effect size (alcohol abuse, active smoking, baseline smear grade, the presence of cavities, baseline fever, leukocytosis, and anemia) each associated with time to sputum culture positivity and conversion.



Conclusions: These findings suggest that cell populations associated with PD-L1-mediated immune exhaustion (neutrophils, CD4^{+} lymphocytes), early cytotoxic mycobacterial control (CD56^{+} Vd2^{+} gd T cells, CD56^{+} bright NK cells), and a Th1 immune response (CCR4^{-}CXCR3^{+}) define a comprehensive immunological signature varying with disease and treatment stages. This integrated signature represents a promising diagnostic and monitoring tool, warranting validation in larger and more diverse cohorts.

EP24-934-19 Influence of single nucleotide polymorphism of IL-10 (rs.1800896, -1082 A/G) On the risk of tuberculosis and drug resistance in Kaduna State, Nigeria

S. Madaki,[1] Y. Mohammed,[2] L. Rogo,[3] M. Yusuf,[4]
[1]Bayero University, Department of Medical Microbiology and Parasitology, Kano, Nigeria, [2]Bayero University, Department of Medical Microbiology and Parasitology, Faculty of Basic Clinical Sciences, Kano, Nigeria, [3]Bayero University, Department of Medical Laboratory Science, Faculty of Clinical Sciences, College of Health Sciences, Kano, Nigeria, [4]Bayero University, Department of Medical Microbiology and Parasitology, Faculty of Basic Clinical Sciences, College of Health Sciences, Kano, Nigeria

Background: Comprehensive research to understand genetic factors influencing tuberculosis (TB) susceptibility and drug resistance is crucial to overcoming TB as a global health challenge. Single Nucleotide Polymorphisms (SNPs) could help identify genetic variations that influence susceptibility to TB and its treatment. Our study, to the best of our knowledge, investigated for the first time, the association between IL-10 (-1082 A/G) SNP and susceptibility to TB and TB drug resistance in Kaduna State, Nigeria. We aimed to determine the presence of IL-10 (rs.1800896, -1082 A/G) SNPs and their associations with age, sex and TB and drug resistance risk among TB patients in Kaduna state.

Design/Methods: A total of 140 participants, comprising drug-resistant TB (DR-TB) patients, drug-susceptible TB (DS-TB) patients, and Apparently Healthy controls (AHCs), were enrolled. Data collection involved medical records, structured questionnaire and genetic analysis. Genomic DNA was extracted, and SNPs were genotyped using PCR-based techniques. Associations between genotypes, alleles, age, and sex were analyzed. Odd ratios and Hardy-Weinberg equilibrium were employed for demographic and genetic analyses.

Results: Although overall, the AA genotype was the most expressed, in DR-TB, GG genotype and G allele were prevalent, with significant difference in genotypic and allelic frequencies of IL-10 (A/G) in DR-TB and AHCs [OR, 16.25; 95% CI (3.63–72.67); p = 0.0001] and [OR, 4.89; 95% CI (2.27–10.52); p = 0.0001], indicating potential associations with DR-TB risk. In DS-TB, similar trends were observed with GG genotype and the G allele posing a risk of almost 10 times and 3 times for TB respectively, highlighting potential genetic influences on susceptibility. Hardy-Weinberg equilibrium analysis revealed significant deviations in some groups, suggesting genetic variations.

Conclusions: Prevalence of specific genotypes and alleles indicates potential genetic markers for TB risk assessment. Findings underscore the importance of genetic factors in TB outcomes and advocate for tailored interventions for different populations.

EP25 Community wide systematic screening: Programmatic considerations

EP25-935-19 21st century challenges in scaling communityTB active case finding: Abnormal X-ray and negative mWRD?

B. Datta,[1] A. Story,[2] P. Goyal,[1] A. Hayward,[3] E. Rogers,[3]
[1]Medanta The Medicity, Respiratory, New Delhi, India, [2]Medanta The Medicity, Respiratory, London, United Kingdom of Great Britain and Northern Ireland, [3]University College London, Epidemiology, London, United Kingdom of Great Britain and Northern Ireland
e-mail: bornalidatta@gmail.com

Background: Scaling community active case finding (ACF)for TB is a priority in high burden settings internationally. New tools havetransformed the landscape of ACF through ultra-portable x-ray, computer aided detection(CAD) and highly accurate molecular diagnostics. A challenge internationallyremains how to manage people with abnormal radiological presentation, with orwithout symptoms, who have a negative WHO-recommended rapid diagnostic test(mWRD). Studies demonstrate that this population have a high risk ofprogression and mortality, but the current evidence base to inform managementis limited and guidelines are arguably inadequate. Current guidance recommends exploringalternative diagnoses, repeat sampling or empirical treatment of severely illpatients.
Design/Methods: We prospectively followed-up a cohort of 302 patients identified during community ACF in Haryana, India with abnormal radiology and negative mWRD and undertook two further sequential mWRD specimensand repeat radiology (CAD) at 3 and 12 months on all patients.
Results: There was no statistically significantchange in mean CAD scores irrespective of microbiological outcome at either 3or 12 months post first negative mWRD. Second mWRD at 3 months yielded 4%positivity (12/302) and third mWRD at 12 months yielded an additional 4% positivity(11/290).
Conclusions: In total, 8% of the initially mWRD negative cohort tested positive on two further sequential molecular tests, representing a significant yield of active cases. This evidence supports the recommendation for sequential testing of patients with radiological abnormalities suggestive of TB who have an initial mWRD negative test result irrespective of symptoms. Our results also call into question the value of repeat imaging CAD score. Further studies are required to improve the management of ACF patients with an initial negative mWRD, including optimal frequency and duration of repeat testing for specific populations. These patients highlight the need for improved diagnostic tools relevant to early disease stages.

EP25-936-19 Bacterial and host determinants of cough aerosol culture-positivity in minimally symptomatic or asymptomatic patients with tuberculosis diagnosed during community-based active case finding

S. Jaumdally,[1] A. Kotze,[1] T. Perumal,[1] A. Scott,[1] C. van der Merwe,[1] A. Esmail,[1] B. Reyneke,[1] S. Meier,[1] R. Warren,[2] M. Folkerts,[3] D. Engelthaler,[3] K. Dheda,[1]
[1]University of Cape Town Lung Institute, Medicine, Cape Town, South Africa, [2]University of Stellenbosch, Molecular Biology and Human Genetics, Cape Town, South Africa, [3]The Translational Genomics Research Institute (TGen), Immunology and Microbial Genomics, Flagstaff, United States of America
e-mail: shameem.jaumdally@uct.ac.za

Background: Preventing the spread of TB is critical to reducing the burden of TB disease. There is potentially a large reservoir of TB 'super-spreaders' present in the community that perpetuates amplification of the epidemic. Thus, transmission within the community will remain a problem unless these undiagnosed infectious cases are identified and treated. The overarching aim of this study was to identify alternative tools to detect TB infectiousness.
Design/Methods: We enumerated colony forming units (CFU) in aerosols (≤10μm) from 175 individuals diagnosed with tuberculosis (during community-based active case finding) and sampled using the cough aerosol sampling system (CASS; Andersen cascade impactor). Individuals with TB were either symptomatic or asymptomatic.
We compared microbiological, clinical, and radiological characteristics, performed sputum LAM (PATHFAST, PHC), 16S rRNA (TB-MBLA, StAndrewsUniversity), and blood transcriptomic profiling.
Results: 13.1% (n=23/175) with microbiologically-proven TB (Xpert and/or culture) were CASS+ve (probably infectious). 39.1% (n=9/23) of the CASS+ve individuals were smear-negative, contrasting with CASS+ve individuals passively diagnosed (7%; n=10/142 in a previous study). Symptomatic individuals (OR=7.6; p=0.03) and smokers (OR=6.0; p=0.0006) presented with greater odds of being CASS+ve.
Mycobacterial sputum smear-positivity (OR=24.5; p<0.0001), 16S rRNA level (OR=19.5; p<0.0001) and sputum LAM concentration (cut-off set at 200pg/mL; OR=35.3; p<0.0001), were strongly predictors of cough aerosol culture-positivity.
Sputum LAM had a sensitivity of 85% and specificity of 85% for CASS-positivity (cut-off 200pg/mL); for a sensitivity of 90%, corresponding specificity was 90% (400 pg/mL cut-off); and for a specificity of 95% corresponding sensitivity was of 65% (7700pg/mL cut-off).
Preliminary blood transcriptomic data revealed differential gene expression patterns observed between the groups (CASS positive versus negative).

Conclusions: Collectively, these data indicate that a significant proportion of community-based undetected individuals with TB are probably infectious with a high likelihood. Moreover, sputum LAM, sputum 16s RNA, and blood transcriptomic signatures are promising transmission-limiting tools to detect infectious TB in the community.

EP25-937-19 Repeated community-wide screening for tuberculosis: Impact on burden

G. Amanya,[1] H. Luzze,[2] E. Tweyongyere,[2] A. Mulindwa,[2]
[1]Makerere University, Infectious Diseases Institute, Kampala, Uganda, [2]National TB and Leprosy Programe, Communicable Disease Prevention and Control, Kampala, Uganda
e-mail: geofrey.amanya@health.go.ug

Background: Uganda has consistently implemented a community wide active case-finding screening and Testing(CAST) intervention, However the scale of implementation varied in some regions, in the country, some had a consistent full-scale implementation CAST since 2022, while other not, we explore the impact of CASTon TB burden.
Design/Methods: A generalized linear mixed model (GLMM), with negative binomial regression model using routine surveillance data, to estimate the prevalence ratio, adjusting for clustering by sub counties. To evaluate the effectiveness of active community wide screening we compared CAST (Intervention) with standard passive case detection (Control) alone to monitor for any changes in burden of tuberculosis. For intervention sub-counties were screened for pulmonary tuberculosis, regardless of symptoms, annually for 3 years from 2022, active community screening and Testing screening (CAST) was not performed in the 60 control sub counties in the first 3 years. The outcome, measured in the fourth year, was the Case notification rate of microbiologically confirmed pulmonary tuberculosis.
Results: We analyzed TB case notification rates (CNR) per 100,000 across 84 sub counties The CNR was (528 per 100,000 population) for Sub counties in the intervention group, and control group (245 per 100,000 from 2022 to 2024. The annual change in CNR for controls was not significant (rate ratio [RR] = 1.0069, 95%CI: 0.9448–1.0730, p=0.833). The intervention (more visits) did not significantly alter the trend in CNR decline between cases and controls (RR for interaction = 0.9353, 95% CI: 0.8558–1.0222, p=0.140). Baseline differences in CNR between cases and controls were also non-significant (p=0.137).
Conclusions: These findings indicate no substantial reduction in TB burden over the study period, nor a differential impact of the intervention, suggesting limited effectiveness of increased visits in reducing TB burden. Longer period for study or bigger studies may provide clues to this evidence.

EP25-938-19 Optimizing digital chest X-ray for TB screening: A process evaluation across South Africa

F. Sathar,[1] T. Thobejane,[2] E. Ramarumo,[3] K. Velen,[4] S. Allen,[5] M. Dube,[1] J. Boffa,[1] P. Subrayen,[1] L. Lebina,[6]
[1]TB Think Tank, Implementation Research Division, Johannesburg, South Africa, [2]Lean Institute Africa, ., Johannesburg, South Africa, [3]National Department of Health, TB Program, Pretoria, South Africa, [4]FIND, ., Geneva, Switzerland, [5]Lean Institute Africa, N/A, Johannesburg, South Africa, [6]Africa Health Research Institute, KwaZulu Natal, South Africa

Background: The World Health Organization recommends digital chest x-ray (dCXR) for tuberculosis (TB) screening. We evaluated current dCXR processes to identify bottlenecks and provide recommendations for more efficient deployment.
Design/Methods: A process evaluation of the screening procedures with dCXR were conducted at eight purposefully selected sites across five South African provinces between September–October 2024. The identified sites varied based on throughput (high and low), mode of operation (fixed and mobile) and on province. Data collection included staff interviews, observation, and historic data review. Observers documented process times, client numbers, queue lengths, and turnaround times. Journey time refers to the time between arrival and departure.
Results: Processes varied depending on team size and composition, highlighting the importance of optimising team structure for improved efficiency. Total journey time varied between 7-45 minutes.
Dual data capture on paper and digital tools resulted in the longest patient wait time (2-37 minutes) at the first step of the process while taking the dCXR had the shortest wait time (1-2 minutes). Teams with dedicated community engagement support staff performed better at processing and recruiting clients.
Key opportunities for improvement in process flow included:
1. A recommended team structure consisting of 2 people for registration, 1 person collecting sputum and 1 radiographer,
2. Improving data collection efficiency by simplifying screening tools (fewer data fields) and eliminating paper-based systems,
3. Investing in intranet solutions to address connectivity gaps,
4. Strengthen community mobilisation for demand planning, hotspot mapping and appropriate targeting, and;
5. Implement queue management systems.
Background and challenges to implementation: The World Health Organization recommends digital chest x-ray (dCXR) for tuberculosis (TB) screening. We evaluated current dCXR processes to identify bottlenecks and provide recommendations for more efficient deployment.

Conclusions: dCXR throughput is hindered by inefficient data capture and variable team support. Further research is required to assess if these key improvements in data collection, connectivity, community engagement, and queue management are recommended to enhance efficiency, reduce processing times and ultimately optimize TB yield.

EP25-939-19 Scaling TB elimination: High-yield community screening and detection strategies from South Africa's ACCELERATE program

P. Subrayen,[1] D. Moonsamy,[2] M. Mphahlele,[2] V. Chihota,[3] M. Dube,[2] J. Boffa,[4] S. Charalambous,[3] [1]The Aurum Institute, Implementation Research Division, Durban, South Africa, [2]The Aurum Institute, Implementation Research Division, Johannesburg, South Africa, [3]The Aurum Institute, Executive Office, Johannesburg, South Africa, [4]The Aurum Institute, Implementation Research Division, Edmonton, Canada
e-mail: psubrayen@auruminstitute.org

Background: South Africa bears one of the world's highest TB burdens, and facility-based TB detection is insufficient for elimination. To accelerate progress, the USAID-funded ACCELERATE (ACC1) program implemented three community-based active TB screening and detection strategies across seven high-burden districts in South Africa:
1. Mobile outreach,
2. Household contact tracing, and;
3. Digital chest X-ray (dCXR) screening.
These approaches were designed to enhance early detection, expand access, and strengthen TB prevention.
Design/Methods: We conducted a retrospective analysis of routinely collected programmatic data from March to December 2024. TB screening and sputum specimen collection were conducted by community healthcare workers.
Outreach and contact tracing data were recorded in real time using the Department of Health Information System 2 (DHIS2) application on tablets. dCXR screening data were input into the Lynx data system, with qXR used for image interpretation.
We calculated testing rate, test positivity, number of people diagnosed with TB, TB preventive treatment (TPT) initiation, and numbers needed to screen/treat (NNS/NNT).
Results: Across all strategies, over 200,000 people were screened, 2,875 were diagnosed, and 7789 people were initiated on TPT (see Table).
No individuals screened via dCXR were initiated on TPT, as system limitations prevented monitoring and documentation—a recognized implementation gap. Limited ability to produce sputum may have affected diagnostic testing across strategies.

Strategy	Screened	Tested	Testing Rate	Test Positivity	TB Detected	NNS	NNT	TPT Initiated
Outreach	170,709	43,098	25%	5.0%	2,172	79	20	1,198
Contact Tracing	13,86	11,074	80%	4.6%	510	27	21	6,591
dCXR	16,805	1,219/1,916 TB suggestive	64%	15.8%	193	87	6	—

Abbreviations: dCXR = digital chest x-ray, NNS = number needed to screen, NNT = number needed to treat, TPT = TB preventive treatment

Table. Outcomes by Community-Based Screening Strategy

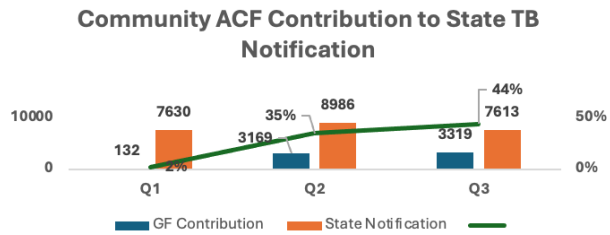
Conclusions: Differentiated community-based TB screening and detection contributed to diagnosis and TPT initiation, highlighting the value of outreach beyond facilities. dCXR showed the highest test positivity (15.8%) and efficiency (NNT=6%). Contact tracing strengthened TPT uptake, while outreach expanded access. Findings demonstrate the value of integrated models. Scale-up should prioritize dCXR where feasible, alongside outreach and contact tracing. However, limited TPT initiation after dCXR and sputum collection challenges highlight the need for stronger systems and enhanced sputum collection strategies.

EP25-940-19 Strengthening health systems: The role of community health workers (CHWs) in improving access to TB and HIV services in Kano State, Nigeria

H. Baffa,[1] A. Okoh,[2] M. Sheshi,[2] T. Adetiba,[1] B. Odume,[2] M. Tukur,[2] [1]KNCV Nigeria, Program, Kano, Nigeria, [2]KNCV Nigeria, Program, Abuja, Nigeria, [3]IHVN, Program, Abuja, Nigeria
e-mail: hbaffa@kncvnigeria.org

Background and challenges to implementation: Health systems are undergoing rapid and often unpredictable transformations**.** Community health workers (CHWs) have re-emerged as significant cadres in low-middle income countries and are now seen as an integral part of achieving the goal of universal health coverage. The deployment of CHWs has been advocated by WHO as a key strategy for reaching the most marginalized populations and reducing health inequities. We present results showcasing role of CHWs in improving access to TB and HIV services in Kano State.
Intervention or response: In April 2024, 760 CHWs were trained to conduct screening for TB, HIV, and syphilis, through house-to-house visits, outreach activities targeting underserved populations in slums, and IDP camps to identify presumptive TB cases for further evaluation and enrolment on treatment. Additionally, pregnant women in the community who are not attending antenatal care, are being screened and tested for HIV and syphilis ensuring complete referrals for positive pregnancies and provided with follow-up care until 18 months postpartum. Data from Jan-Sep 2024 was collated and analyzed.

Results/Impact: In Q1 2024, 7,630 TB cases were notified, with community contributing 132 cases, accounting for only 2% of the total TB case notification. After deployment of CHWs in April, 3,169 cases were diagnosed in Q2 from the community translating to a 35% contribution. Subsequently, in Q3 community contribution increased to 3,319 (44% contribution). Additionally, 8157 pregnant women were tested for HIV & Syphilis, with 10 testing positives for HIV and 151 tested positives for syphilis.



Conclusions: Results bespeak a consistent rise across quarters underscoring the crucial role of CHWs in strengthening community-based TB/HIV systems. This integrated approach has shown the possibility of providing multiple services in a one stop shop manner giving the clients increased accessibility to healthcare services within their communities. We recommend a multisectoral approach across different disease entities at community level for broader health Impact.

EP25-941-19 Detecting missed tuberculosis cases at health facilities in Ethiopia Using WRD test

K. Damete,[1] A. Moges,[2] T. Letta,[2] G. Asnake,[2] [1]Kassahun Damete, Disease prevention and control Lead Executive Office, Ministry of Health Ethiopia, Addis Ababa, Ethiopia, [2]Ministry of Health Ethiopia, Disease prevention and control Lead Executive Office, Ministry of Health Ethiopia, Addis Ababa, Ethiopia
e-mail: dkassahun2023@gmail.com

Background and challenges to implementation: Ethiopia's National Strategic Plan (2023–2030) aims to achieve the SDG set for tuberculosis (TB) by addressing the gaps in patient pathway, preventing infection, and integrating equitable healthcare. Integrating TB case finding in all service outlets is one of the initiatives in the plan. This study aims to detect missed tuberculosis cases through intensified case finding at health facilities using the WRD test.
Intervention or response: A facility-based prospective cross-sectional study conducted in 90 high-loaded health facilities across all regions of the country from July 1, 2024 to December 31, 2024, Data collection tools were developed to track the cascade of care, from case finding to treatment initiation, and health workers received training at service outlets. The Kobo tool was used for monthly data collection.

Results/Impact: During the six-month cross-sectional period, approximately 87% of outpatient clients were assessed and screened for tuberculosis (TB) using mWRD, resulting in the detection of 1,297 TB cases—equivalent to a case notification rate of 345 per 100,000 populations. Notably, certain outpatient departments (OPDs) were disproportionately affected, such as the chronic care OPD, with a notification rate of 448 per 100,000 population, and newly enrolled people living with HIV, with a rate of 2,917 per 100,000 populations.
Additionally, among contacts of bacteriologically confirmed pulmonary TB (BCPTB) cases, 30 new TB cases were detected, with a notification rate of 1,634 per 100,000 populations

Type of OPD	Total population	Number screened (#/%)	Presumptive TB (#/%)	TB diagnosed (#/%)	Case notification rate CNR/100K
Adult OPD	356,280	312,537 (88)	14,316	1,065	341
chronic OPD	23,513	19,196 (82)	828	86	448
under 5 years OPD	49,063	40,770 (83)	3,035	70	172
PLHIV newly enrolled in Care	1,599	1,577 (99)	122	46	2,917
Contacts of BCPTB case	1.877	1,836	200	30	1,634
Summary	432,332	375,916 (87)	18,501	1,297	345

Table 1: Number & proportion of TB cases detected among different categories of OPDs, July 1, 2024 to December 31, 2024.

Conclusions: Intensified case finding using mWRD effectively identified missed TB cases, especially among high-risk groups. Targeted screening and contact tracing are key to improving early TB detection and control.

EP25-942-19 Fostering sustainable facility-based active TB screening through human resource for health strengthening: TB LON project experience in three southern states of Nigeria

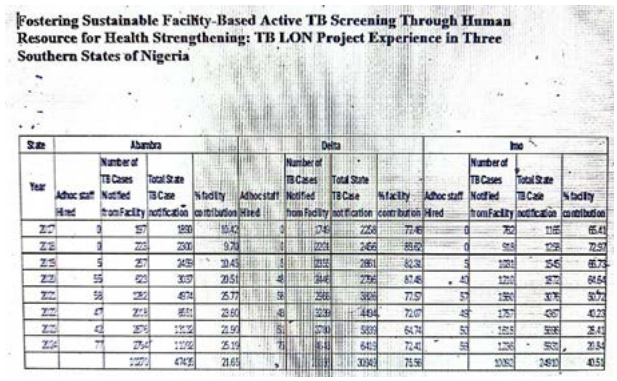
C. Oke,[1] O. Chukwuogo,[2] B. Odume,[2] I. Onochie,[3] [1]KNCV Nigeria, Program and Technical, Awka, Nigeria, [2]KNCV Nigeria, Program and Technical, Abuja, Nigeria, [3]KNCV Nigeria, Administration and Finance, Awka, Nigeria
e-mail: rchokey2@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a significant public health concern in Nigeria, requiring innovative and sustainable strategies for detection and management. Efficient Human Resources for Health (HRH) is a critical determinant to effective TB screening, to enhance TB case finding. However, the shortage and workload of the frontline health-

care workers (HCWs) pose challenges to the coverage and quality of active TB screening in health facilities. The TB Surge intervention under the USAID-funded LON 2 project aimed to engage, train, supervise and monitor personnel to expand facility coverage and improve knowledge and skills to promote TB case findings in both public and private health facilities. This study examines the outcome of HRH interventions on TB case notifications from 2017 to 2024 in the 3 southern states

Intervention or response: A retrospective analysis of TB notification data from Anambra, Delta, and Imo was conducted. Key indicators analyzed included the number of ad hoc staff hired, TB cases notified from facilities, total state TB notifications, and the percentage contribution of facilities

Results/Impact: A significant increase in TB case notifications from 197 cases in 2017 to 2,794 cases in 2024 was observed in Anambra , and the facility contribution rose from 10.42% to 25.19%. Delta consistently recorded the highest facility contribution, and the TB notifications increased from 1,749 in 2017 to 4,648 cases in 2024, with a stable facility contribution above 70%. Imo showed a decline in facility contribution from 65.41% in 2017 to 20.84% in 2024, despite an increase in absolute cases notified. Overall, the number of facility-notified TB cases in all states increased significantly.



Fostering Sustainable Facility-Based Active TB Screening Through Human Resource for Health Strengthening: TB LON Project Experience in Three Southern States of Nigeria

State	Anambra				Delta				Imo			
Year	Adhoc staff Hired	Number of TB Cases Notified from Facility	Total State TB Case notification	% facility contribution	Adhoc staff Hired	Number of TB Cases Notified from Facility	Total State TB Case notification	% facility contribution	Adhoc staff Hired	Number of TB Cases Notified from Facility	Total State TB Case notification	% facility contribution
2017	0	197	1890	10.42	0	1749	2258	77.46	0	762	1165	65.41
2018	0	203	2300	9.78	0	2201	2466	89.62	0	918	1259	72.97
2019	5	357	2459	20.43	0	2332	2861	82.38	5	1201	1545	85.73
2020	55	625	3057	20.51	48	3946	2756	87.48	43	1220	1572	84.64
2021	58	1262	4974	25.77	58	2566	3656	77.57	57	1561	3078	50.72
2022	47	2018	8651	23.66	48	3239	4494	72.07	48	1757	4367	40.23
2023	42	2575	11232	21.99	51	3740	5699	64.74	53	1818	5696	26.42
2024	77	2794	11092	25.19	73	4648	6449	72.42	58	1726	5521	20.84
			47423	21.65			30342	75.56		10382	24913	40.53

Conclusions: The findings highlight the positive impact of HRH strengthening on TB case notification. However, Imo state experienced a decline in facility contributions despite an increase in absolute cases notified. This suggests that additional contextual factors, such as infrastructure and social security, may influence outcomes.

EP25-943-19 Interim findings from community-wide screening to treat TB disease and infection in a high prevalence MDR-TB setting in Papua New Guinea

T. Marukutira,[1] N. Pank,[1] A. Aung,[1] I. Krangaie,[1] G. Kama,[2] A. Maha,[3] G. Chan,[4] W. Pomat,[5] M. Kal,[6] K.L. Huang,[4] S. Graham,[7] S. Majumdar,[4] SWEEP-TB Study Group

[1]Burnet Institute, International Development, Daru, Papua New Guinea, [2]Western Provincial Health Authority, Public Health, Daru, Papua New Guinea, [3]National Department of Health, Medical Standards Division, Port Moresby, Papua New Guinea, [4]Burnet Institute, International Development, Melbourne, Australia, [5]Papua New Guinea Institute of Medical Research, Medical Research, Port Moresby, Papua New Guinea, [6]National Department of Health, National Tuberculosis Program, Port Moresby, Papua New Guinea, [7]University of Melbourne, International Child Health, Melbourne, Australia

e-mail: tafireyi.marukutira@burnet.edu.au

Background: Daru island in PNG has a very high incidence of tuberculosis (TB) and multidrug-resistant (MDR/RR) TB that has persisted despite high treatment success rates. A comprehensive community-wide TB detection initiative (SWEEP-TB) was implemented from 2023 aiming to reduce incidence.

Design/Methods: Following engagement and partnership with the community in Daru (population 22,548) and public health program, a community-wide house-to-house approach utilized symptom screening and mobile CXR/AI (CAD4TB) for all resident adults and adolescents ≥10 years with Xpert Ultra to detect TB disease and link to treatment. People aged 5-34 years without TB disease (confirmed or clinical) were offered a tuberculin skin test (TST) and if positive, a novel TB preventive therapy regimen of daily isoniazid and levofloxacin for six months (6HLfx). Treatment support for disease and infection with monitoring for adverse events was provided in the community.

Results: By end of March 2025, 12,204 (54.1%) Daru residents had been screened, of whom 1,540 (12.6%) had presumptive TB with symptoms and/or CAD4TB score ≥40. Of these, 171 (11.1%) were diagnosed (135; 79% bacteriologically confirmed TB and 36 clinically diagnosed); resulting in a screening yield of 1.4%. Of 171 (including 35 MDR/RR TB) diagnosed, 150 (87.7%) initiated treatment. Of 7,172 people 5-34 years without TB, TST was performed in 6,277 (87.5%), 2,367 (37.7%) were positive, 2,327 (98.3%) were eligible for TPT and 1,750 (75.2%) were initiated on TPT. Interim analysis has found that 6LfxH has been well tolerated overall with 330 individuals report grade 1/2 side effects. Whilst the intervention had good uptake, multiple operational and health system challenges hindered the pace of screening.

Conclusions: Community-based screening and prevention in a remote setting in PNG was acceptable and feasible with high case detection yield and uptake of novel

TPT. This was due to strong community engagement and quality improvement approaches that incorporated learning to overcome barriers.

EP25-944-19 A retrospective analysis of screening activities from 2019 to 2023 in Pakistan: What more needs to be done!

A. Mahfooz,[1] A. Latif,[2] A. Tahir,[2] M. Wasim,[1] F. Emmanuel,[3]
[1]Center for Global Public Health, Pakistan, TB, Islamabad, Pakistan, [2]Mercy Corps, Pakistan, TB, Islamabad, Pakistan, [3]University of Manitoba, Canada, Institute of global public health, Winnipeg, Canada
e-mail: amna.mahfooz1@gmail.com

Background: Although resource and labor intensive, Active case finding (ACF) is crucial for identifying TB cases missed by routine surveillance in Pakistan. We conducted a retrospective analysis of ACF data from 2019-23 to look at its effectiveness and impact in reducing the TB burden in Pakistan.
Design/Methods: Systematic screening for TB through community chest camps is being implemented by Mercy Corps along with the National TB Program in Pakistan. A fleet of 40 vans conduct mobile chest X-ray units using CAD software and Xpert MTB/RIF for accurate TB diagnosis. Each camp operation (screening activity) is supported by a doctor, a medical imaging technician and a laboratory technician supported by District Field Supervisors (DFS) and community volunteers. All data collected is entered in a database in real time.
Results: A total of 485,237 individuals were screened in 7,789 camps from 2019 – 2023 conducted in 93 districts across Pakistan. With an overall TB+ yield of 37 per 1000 screened, we identified 18,100 individuals with TB (42.3% B+ vs 57.7% clinically diagnosed). Nearly 44.5% camps did not detect any B+, whereas 31.7% of camps identified only one B+ case. Of the 149,500 missing cases in 2023, chest camps were able to find 8,319 TB cases and reduced the missing gap only by 5.6%.
Conclusions: This study provides the largest dataset on mobile X-ray-based ACF. Significant variability in detection rates was observed, driven largely by geographic factors. Given limited resources, ACF strategies should be assessed for their incremental yield in detection and cost-effectiveness. Without a targeted approach using localized prevalence data, general ACF efforts yield low TB detection rates and are impractical in resource-poor countries. Improved screening and diagnostic methods are essential to reduce empirical treatment rates and ensure more accurate care.

EP26 Finding the missing millions: A focus on key populations

EP26-946-19 An experience from Pakistan under a multi-country TB grant; TB and MDR-TB interventions among Afghan refugees, returnees, and mobile populations in Afghanistan, Iran, and Pakistan

M. Ul Haq,[1] F. Siraj,[1] A. Ismail,[1] A. Nasrat,[2] Q. Abbass,[3]
[1]National TB Control Program, Pakistan, TB, Islamabad, Pakistan, [2]UNDP, TB, Kabul, Afghanistan, [3]Common Management Unit (TB, Malaria and HIV), TB, Malaria and HIV, Islamabad, Pakistan
e-mail: mahboob0345@yahoo.com

Background and challenges to implementation: Afghanistan has one of the highest numbers of refugees in South East-Asia. Pakistan is hosting one of the largest populations of Afghan refugees since 1979, around 4 million are living in Pakistan in the refugee camps. The burden of Tuberculosis (TB) is presumed to be higher in the refugee camps with a significant number of undetected cases. To address this, The UNDP Afghanistan, as Principal-recipient of the Global Fund implemented the Project of Multi-Country Grant (MCG) in Iran, Afghanistan and Pakistan with the aim of finding and treating TB cases among Afghan refugees. In Pakistan, NTP, Pakistan implemented the MCG as a sub-recipient of UNDP Afghanistan during 2019-24.
Intervention or response: This study evaluates the Active Case Finding (ACF) intervention implemented by NTP Pakistan under the MCG, including treatment outcomes. ACF being implemented in 45 refugee camps in Khyber Pakhtunkhwa and Baluchistan Provinces, Pakistan, by trained Field staff, through symptom screenings and contact tracing. Presumptive TB cases identified were referred to the nearest TB facility for diagnosis, and confirmed cases were registered for treatment with regular follow-up.
Results/Impact: Out of 560,000 individuals screened, 53,995 (10%) identified as presumptive TB cases, with 4,860 (9%) confirmed TB cases. Among them, 52% were female, 76% pulmonary and among pulmonary, 62% were bacteriologically confirmed. The Number Needed to Screen to identify to one TB patients among presumptive cases was 11.
Unfavorable treatment outcomes were lower in ACF cases (3%) compared to routine cases (6%) ($P < 0.05$). Among bacteriologically confirmed cases, there was a higher contribution of cure to treatment success in the ACF group (86.5%) compared to routine cases (69%).
Conclusions: The ACF strategy is useful and have additional benefits such as contribution to early case finding and detection of patients from the refugee camps, with an extended benefit for reducing secondary cases in the community.

EP26-947-19 A strategic active case finding approach to maximize coverage among working men population, Madurai, Tamil Nadu-India

A. Frederick,[1] R. Veluchamy,[1] R. Kubendiran,[1] T. Neelakantan,[1] K.K. Shankar,[1] GOI-WHO NTEP Technical support network Tamil Nadu [1]Department of Health and Family Welfare, Chennai, India
e-mail: stotn@rntcp.org

Background and challenges to implementation: Globally, Tuberculosis (TB) is more common in men than women. In 2023, an estimated 6.0 million men fell ill with TB, compared to 3.6 million women. Considering the fact that 70% of TB is diagnosed among men in Madurai district of Tamil Nadu (TN) and 80% of these men were in the working age group (25-65 years). Reaching this population during routine daytime Active Case Finding (ACF) camps was difficult, therefore a time-adaptive evening camp approach was considered.
Intervention or response: In the State of TN, India, for 'ACF Camp' Mobile Vans fitted with Digital X-Rays are used for Community screening. Plans were drawn to conduct screening between 17:00 and 21:00 hours to cover the working male population among daily wage laborers living in urban slums and evening markets through community mobilization and advocacy. 12 health care workers per camp were involved and incentivized for working extra hours during the evenings.
Results/Impact: A total of 65 Moonlight TB Camps were conducted from December 2024 to February 2025, where 2,141 chest x-rays offered after screening, 266 sputum samples were transported for upfront rapid molecular tests and 22 (17 men & 5 women) were diagnosed with TB, of which 13 PwTB were bacteriologically confirmed. Whereas, the daytime routine ACF during the same period had 61 Camps, 2958 chest x-rays taken after screening, 296 sputum samples transported for upfront rapid molecular tests and 12 (10 men & 2 women) diagnosed with TB, of which 10 PwTB were bacteriologically confirmed.
Conclusions: The evening camps helped to screen the working male population who would otherwise be missed during daytime ACF camps. This innovative time adaptive method demonstrates the importance of tailoring healthcare delivery to the schedules and needs of specific populations, and has also yielded higher case finding as compared to conventional ACF screening camps.

EP26-948-19 Enhancing tuberculosis detection in elderly general population using Rapid qPCR tongue swabs for active case finding during routine physical examinations in low burden city

T. Li,[1] F. Sun,[2] J. Chen,[2] J. Li,[3] X. Xiao,[1] G. Sui,[4] Y. Li,[2] Y. Miao,[5] S. Ge,[2] X. Shen,[6] W. Zhang,[2] [1]Shanghai Public Health Clinical Center, Infectious Diseases, Shanghai, China, [2]Huashan Hospital, Shanghai Medical College, Fudan University, Infectious Diseases, Shanghai, China, [3]Guizhou Center for Disease Control and prevention, Infectious Diseases, Guiyang, China, [4]National Medical Center for Infectious Diseases, Infectious Diseases, Shanghai, China, [5]National Medical Center for Infectious Diseases, Medical Research, Shanghai, China, [6]Shanghai Center for Disease Control and Prevention, Infectious Diseases, Shanghai, China
e-mail: yang.li@nmcid.org.cn

Background: Tuberculosis (TB) remains a major cause of infectious disease mortality worldwide, and diagnosis remains challenging. The utilization of Rapid quantitative PCR (qPCR) on tongue swab presents a convenient approach for TB active case finding.
This study aimed to estimate the cost-effectiveness of tongue swab testing in combination with routine chest radiograph (CXR) physical examination among elder general population in six districts of Shanghai, a low-burden city of TB in China, to optimize TB case detection.
Design/Methods: This prospective study enrolled 42,731 elderly participants undergoing routine CXR l examinations across six Shanghai districts. Tongue swab specimens were collected, and the individuals with positive tongue swab results were conducted systematic evaluations by composite microbiological reference standard (MRS), which included sputum smear, culture and Xpert MTB/RIF.
Results: Among 42,731 participants, the median age was 71.0 years. Positive tongue swab testing was observed in 9 and was asymptomatic in 4/9 (44.4%). Microbiologically diagnosed TB occurred in 7 (7/9, 77.8%) with 57.1% (4/7) being asymptomatic. The additional cost of tongue swab screening per TB case detected was $24,958.06, which is slightly lower than Shanghai's per capita gross domestic product (GDP) of $25,896.5.
Conclusions: Approximately half of microbiologically diagnosed TB cases in the elderly population were asymptomatic, underscoring the critical need for active case finding. Tongue swab screening detected 77.8% of TB cases at a cost of $24,958.06 per case, given its cost-effectiveness relative to the local GDP.
Extrapolating our findings, we observed five and two microbiologically diagnosed TB cases in two specific districts, corresponding to incidence rates of 29.15 (95%CI 10.7–72.3) and 14.99 (95%CI 2.6–60.5) per 100,000 population, suggesting that the true burden of TB in these areas may be underestimated.

The potential of tongue swab screening in economically developed, low-burden settings, particularly among asymptomatic elderly populations, remains to be further explored for broader implementation.

EP26-949-19 Active tuberculosis screening and case finding within informal drinking establishments and drug abuse dens in Githurai, Nairobi County, Kenya

E. Mueni,[1] P. Makena,[1] R. Wangusi,[2] C. Macharia,[3] C. Ngunu,[1] S. Macharia,[4] [1]County Government of Nairobi, Health, Nairobi, Kenya, [2]CIHEB, Health, Nairobi, Kenya, [3]Center for Health Solutions, Health, Nairobi, Kenya, [4]National TB Program, Health, Nairobi, Kenya
e-mail: mlitswa03@gmail.com

Background and challenges to implementation: Alcohol use disorder is the 3rd risk factor attributed to TB cases in Kenya (WHO Report 2024) after HIV and undernutrition. The use of drugs and excessive consumption of alcohol damage a person's organs and weaken their immune system increasing susceptibility to tuberculosis. Furthermore, they may not access adequate food and mostly spend time in crowded or poorly ventilated homes or social venues (NACADA/CHS Report 2022). In 2024, Nairobi notified 929 cases among this key population, contributing to 6.7% of the total TB cases. This was an increase from 5.6% (751) notified in 2023.
Intervention or response: In March 2025, Nairobi County conducted a five-day TB screening in drinking and substance abuse dens in Githurai. Community health promoters sensitized the population living within the dens on TB and mobilized them to visit designated TB screening center. Health education and counseling were provided, those who provided consent underwent an initial digital chest X-ray. Individuals with abnormal chest X-ray results were subsequently evaluated by clinicians and referred for GeneXpert testing.
Results/Impact: A total of 218 were reached with tuberculosis messages, consisting of 85% (151) males and 15% (67) females. About 86% (188) of clients were screened using digital X-ray of which 72% (132/188) were males. Of those screened, 13% (24/188) had abnormal x-ray findings with a score of ≥ 50 and were subjected to GeneXpert test. Additionally, 83% (180) had respiratory symptoms and were further evaluated for TB by the clinicians. In total, 23 TB cases were diagnosed (14 bacteriologically and 9 clinically diagnosed). The burden was higher in males (17 cases) than females (6).
Conclusions: This study emphasizes the importance of developing TB case-finding strategies specifically designed for individuals who engage in alcohol and substance use. This group, often stigmatized and hard to reach, faces significant barriers to accessing care, linkage to care, and treatment adherence.

EP26-950-19 Yield of targeted universal TB testing strategy among people living with HIV in Zimbabwe

J. Ershova,[1] T. Maphosa,[2] O. Diura-Vere,[3] B. Mushangwe,[3] R. Dhliwayo,[3] M. Charles,[1] G. Gonese,[3] F. Kavenga,[4] L. Babiker,[1] W. Coggin,[1] H. Cham,[2] [1]US Centers for Disease Control and Prevention, Division of Global HIV and TB, Atlanta, United States of America, [2]US Centers for Disease Control and Prevention, Division of Global HIV and TB, Harare, Zimbabwe, [3]Zimbabwe Technical Assistance, Training and Education Center for Health (Zim-TTECH), HIV Treatment and Care, Harare, Zimbabwe, [4]Ministry of Health and Child Care, National TB Control, Harare, Zimbabwe
e-mail: bmushangwe@zimttech.org

Background: The use of symptom-based TB screening misses almost 15% of TB clients with untreated HIV and up to 50% of TB clients among those on antiretroviral therapy. Targeted universal TB testing (TUTT) strategy adds chest X-ray (CXR), lateral flow urine lipoarabinomannan assay (LF-LAM), and rapid molecular tests to the screening algorithm among high-risk populations at least once per year. We assessed the increase in TB case finding following the implementation of the TUTT strategy among people living with HIV (PLHIV) in Zimbabwe.
Background and challenges to implementation: The use of symptom-based TB screening misses almost 15% of TB clients with untreated HIV and up to 50% of TB clients among those on antiretroviral therapy. Targeted universal TB testing (TUTT) strategy adds chest X-ray (CXR), lateral flow urine lipoarabinomannan assay (LF-LAM), and rapid molecular tests to the screening algorithm among high-risk populations at least once per year. We assessed the increase in TB case finding following the implementation of the TUTT strategy among people living with HIV (PLHIV) in Zimbabwe.
Intervention or response: TUTT was implemented in district- and primary-level facilities. During March-September 2024, all PLHIV seeking care at selected facilities were screened for symptoms and referred for CXR, Xpert® MTB/RIF assay (Xpert), and LF-LAM, regardless of symptoms. We used descriptive statistics to report the number of symptomatic and asymptomatic clients among all TB diagnoses.
Results/Impact: Among 14,960 clients who visited selected facilities at least once during the implementation period, 13,688 received the TUTT strategy; 199 (1.3%) were diagnosed with TB. Among them 73 (36.7%) did not report TB symptoms. Majority (64, 87.7%) of asymptomatic client were diagnosed using Xpert and 4 (5.5%) by LF-LAM; 5 (6.8%) were clinically diagnosed according to TB-suggestive CXR. Among 126 (63.3%) symptomatic TB clients, 82 (65.1%) were bacteriologically confirmed by Xpert and 21 (16.7%) by LF-LAM; 23 (18.3%) were clinically diagnosed based on TB symptoms and CXR results. Of 199 TB clients, 196 (98.5%) started TB treatment, 3 (1.5%) were lost to follow-up or transferred out.

Conclusions: More than a third of PLHIV diagnosed with TB during the project did not have TB symptoms and were only found through the TUTT strategy. The use of additional tools for routine TB screening and testing among PLHIV can help increase TB case finding and reduce TB transmission in the country.

EP26-951-19 Point-of-care C-reactive protein testing for tuberculosis screening among people living with HIV: A feasibility study in Uganda

P. Namuwenge,[1] D. Tugumisirize,[2] V. Kasone,[3] J. Kyokushaba,[1] H. Luzze,[4] S. Nabadda,[3] S. Turyahabwe,[5] [1]Ministry of Health, Aids Control Program, Kampala, Uganda, [2]Ministry Of Health Uganda, Supra National Reference Laboratory, Kampala, Uganda, [3]Ministry of Health, Uganda National Health Laboratory Services, Kampala, Uganda, [4]Ministry of Health, Tuberculosis and Leprosy Program, Kampala, Uganda, [5]Ministry of Health, Communicable Disease Control, Kampala, Uganda
e-mail: vkasone@gmail.com

Background: Tuberculosis (TB) remains a leading cause of mortality among people living with HIV (PLHIV). The World Health Organization four-symptom screen (WHO 4SS) has low sensitivity, which can lead to missed opportunities for early detection of TB. To address this gap, the WHO recommends using a C-reactive protein (CRP) test as a screening tool for TB in PLHIV.
This study evaluated the feasibility of implementing CRP testing in Uganda.
Design/Methods: A cross-sectional study was conducted from April to June 2023 at 50 health facilities, during which healthcare workers screened for TB among PLHIV above 10 years using POC CRP, and the WHO 4SS. Focus group interviews were held with healthcare workers at all facilities to ascertain key feasibility indicators such as acceptability, usability, the costs , equipment and data management.
Results: Out of 50 facilities, 32 had 100% access to CRP testing for eligible people with PLHIV. However, the remaining facilities faced challenges due to intermittent equipment breakdowns, adoption challenges, and knowledge gaps in new TB screening policies and guidelines. Among healthcare workers, 98% reported that they found the POC CRP test procedures easy to use and felt comfortable recommending the test to other facilities. The turnaround time for results and the cost of the tests were three times lower than those of conventional CRP equipment. Connectivity was a significant challenge, with 16 facilities reporting internet-related barriers that affected CRP data interoperability.
Conclusions: The study showed that POC CRP testing is a feasible method of TB screening among PLHIV in Uganda. However, to ensure the successful implementation of CRP testing, it is essential to invest adequately in CRP commodities, equipment management, data connectivity, continuous training, mentorships, and technical support supervision activities.

EP26-952-19 Field performance evaluation of the point of care afinion C-reactive protein for TB screening in people living with HIV in Uganda

D. Tugumisirize,[1] P. Namuwenge,[2] J. Kyokushaba,[3] V. Kasone,[4] H. Luzze,[3] S. Nabadda,[4] S. Turyahabwe,[5] [1]Ministry of Health, Supra National Reference Laboratory, Kampala, Uganda, [2]Ministry of Health, Aids Control Program, Kampala, Uganda, [3]Ministry of Health, Tuberculosis and Leprosy Program, Kampala, Uganda, [4]Ministry of Health, Uganda National Health Laboratory Services, Kampala, Uganda, [5]Ministry of Health, Communicable Disease Control, Kampala, Uganda
e-mail: namuwengep@yahoo.com

Background: Tuberculosis (TB) remains a leading cause of mortality among people living with HIV (PLHIV), yet current screening tools such as the WHO 4-symptom screen (WHO 4SS) have suboptimal sensitivity. C-reactive protein (CRP) is emerging as a potential biomarker for TB screening. This study evaluated the performance of CRP for TB screening among people living with HIV (PLHIV) in programmatic settings in Uganda.
Design/Methods: A cross-sectional study was conducted across 50 health facilities in Uganda, enrolling 12,449 PLHIV above 10 years. CRP levels were measured using a cut-off of >5 mg/L. We compared the performance of CRP to WHO 4SS using sensitivity, specificity, receiver operating characteristic (ROC) analysis, and the number of PLHIV needed to screen (NNS) using each tool in order to yield one TB case. PLHIV with a CRP 5mg/L and or a positive WHO 4SS were subjected to a sputum GeneXpert test which was used as a gold standard for TB diagnosis.
Results: Out of 12,449 eligible participants, 66.8% were female, 83.1% were aged 30 years and above, and about 20% had CD4 counts <200 cells/mm^3. CRP demonstrated higher sensitivity (50.4%) and specificity (71.8%) compared to WHO 4SS (38.3% sensitivity, 68.9% specificity) and had a better area under the curve (0.61 vs. 0.54). The number of PLHIV needed to screen (NNS) to identify one TB case using CRP >5 mg/L was 8.8 Vs. 7.8 (WHO 4SS). CRP performed better among males (63.4% Sensitivity, 70.3% specificity) and in PLHIV with CD4 <200 cells/mm^3 (SE = 49.5%, SP = 71.8%). Thirty-two additional TB cases were identified using CRP that WHO 4SS would have missed.
Conclusions: CRP-based TB screening demonstrates improved sensitivity and specificity over WHO 4SS, particularly among high-risk subpopulations. Integrating CRP into routine TB screening for PLHIV may enhance early TB detection and contribute to reduced mortality.

EP26-953-19 Peak tuberculosis transmission at 24 weeks post-exposure with BCG-driven risk reduction in household contacts

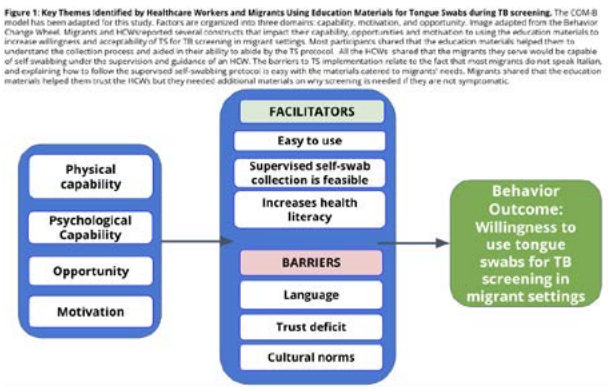
F. Mi,[1] H. Li,[1] Y. Pang,[1] [1]Capital Medical University, Beijing Chest Hospital, Beijing, China
e-mail: mfl667@163.com

Background: Household contacts of active tuberculosis (TB) patients face elevated infection risks, yet optimal screening intervals remain undefined. This study aimed to characterize TB infection dynamics and identify key risk factors among close contacts using interferon-γ release assays (IGRA).
Design/Methods: We conducted a 12-month prospective cohort study of 229 household contacts from 107 culture-confirmed pulmonary TB cases. Participants underwent serial IGRA testing at enrollment and regular intervals. Multivariate logistic regression analyzed demographic, clinical, and exposure-related risk factors for IGRA conversion.
Results: The cumulative IGRA conversion rate was 52.0% (119/229), with 99.2% (118/119) of conversions occurring within 24 weeks post-exposure. Significant independent risk factors included: age (aOR=1.8 per decade, p<0.01), comorbidities (OR=2.3, p=0.003), shared residence (OR=2.1, p=0.02), and index case bacterial load (OR=3.5, p<0.001). BCG vaccination demonstrated 40% protection against infection (OR=0.6, p=0.04).
Conclusions: TB transmission predominantly occurs within 24 weeks of exposure, suggesting this as the critical window for detection. Our findings support: (1) targeted IGRA retesting at 24 weeks for exposed contacts, particularly those with identified risk factors; and (2) continued BCG vaccination in TB control programs. This approach offers an efficient strategy for early detection and prevention in high-burden settings.

EP26-954-19 Acceptability of education materials for training and collection of tongue swabs for tuberculosis screening in migrant settings: A qualitative study

R. Codsi,[1] [1]University of Washington School of Public Health, Environmental Health and Occupational Sciences, Seattle, United States of America
e-mail: codsi@uw.edu

Background: TB screening is challenging among migrant populations because of a reliance on sputum-based testing and the migrants' hesitation to seek healthcare. This study evaluates the feasibility and acceptability of targeted educational materials to guide migrants and healthcare workers (HCWs) in a non-sputum option, supervised tongue swabs (SSS) for TB screening. TS is up to 95% sensitive when swab-specific laboratory analytical methods are used. To scale TS for screening and population health, users should be able to swab themselves effectively. This is the first study to evaluate targeted educational materials for SSS.
Design/Methods: This user experience study uses in-depth interviews and purposive sampling of migrants and HCWs experiencing and conducting TB screening in Milan, Italy. Recruitment began in March 2024 and will continue until saturation among themes is reached. Hamilton's Rapid Qualitative Analysis Method was adapted to summarize key findings.
Results: Results reveal participants' perceptions of illustrations and videos to teach how to collect a valid provider- or self-collected sample. All the participants reported that the video was the best option, but it needed audio narration in the migrants' primary language. All HCWs shared that the videos and illustrations guided the migrants to swab effectively. HCWs shared the need for accessibility of the illustrations to be shared on their websites and social media. Many migrants shared that they want videos to explain the impacts of TB and why screening is important. The majority of the migrants shared that this was the first time that anyone had asked them what they thought and what would make it easier, and that made them feel seen and increased their willingness to participate.



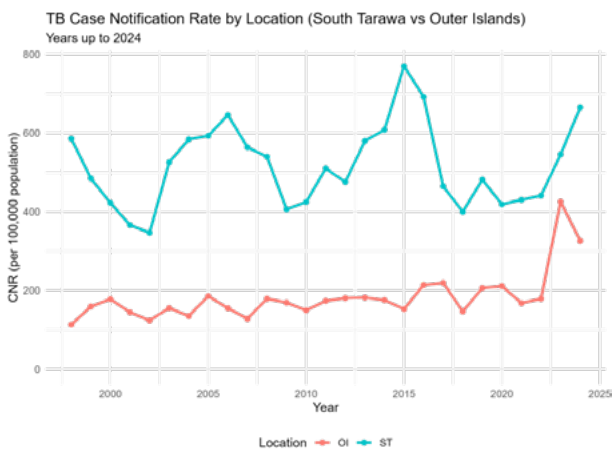
Conclusions: Illustrations and videos are acceptable to both migrants and HCWs. There is a need for TS educational materials and health promotion campaigns that HCWs can use to tailor care to migrants' needs.

EP27 Cracking the code on TB surveillance

EP27-955-19 Long-term sub-national trends in tuberculosis case notification in Kiribati

J. Hill,[1] B. Marais,[1] W. Britton,[2] A. Tonganibeia,[3] M. Tikataake,[3] [1]University of Sydney, Sydney Institute for Infectious Diseases, Sydney, Australia, [2]Centenary Institute, TB Research, Sydney, Australia, [3]Ministry of Health and Medical Services, Department of Public Health, South Tarawa, Kiribati
e-mail: jeremy.hill@sydney.edu.au

Background and challenges to implementation: Kiribati continues to face one of the highest tuberculosis (TB) burdens globally. National data often obscure geographic variation, particularly between the densely populated capital, South Tarawa, and the remote outer islands. To date, no subnational analysis of TB epidemiology from Kiribati has been published or presented internationally.
Intervention or response: We reviewed routinely collected TB programme data over a 26-year period (1998 to 2024). Annual case notification rates (CNRs) were compared between South Tarawa and the outer islands. We analysed long-term trends in TB notifications and disaggregated data by age, sex, and TB disease type.
Results/Impact:
TB CNRs in South Tarawa were consistently 2–3 times higher than in the outer islands, with a peak of 770 per 100,000 in 2015 and rate of 665 per 100,000 in 2024. It is notable that South Tarawa experienced notification peaks during periods of intensified active TB case finding. The male:female gender ratio was 53:47 (similar in South Tarawa and outer islands), with the greatest proportion of cases (38%) detected in the 10-29 years age categories. Children aged 0-9 years comprised an increasing proportion of notified cases, particularly in South Tarawa (26% in 2024), indicative of uncontrolled community transmission and an increased focus on paediatric TB. The proportion of pulmonary TB notifications rose sharply in 2018, following the introduction of first-line sputum Xpert testing.



Conclusions: This is the first longitudinal subnational assessment of TB epidemiology in Kiribati. The findings emphasise the importance of geographically disaggregated surveillance to guide targeted responses. Reducing TB transmission in South Tarawa, while maintaining equity and access in remote outer islands, is essential to achieve national TB control goals. Key lessons also apply to other small island states with dispersed populations.

EP27-956-19 Digitization of tuberculosis data through a quality improvement approach: Electronic case-based TB surveillance system at 155 health facilities in Uganda

D. Cherotin,[1] C. Joshua Brianwong,[2] D. Kiragga,[3] [1]Baylor Foundation Uganda, Strategic Development, Monitoring and Evaluation, Mbale, Uganda, [2]Baylor Foundation Uganda, Medical and Psychosocial, Mbale, Uganda, [3]Baylor Foundation Uganda, Medical and Psychosocial, Kampala, Uganda
e-mail: dianacherotin@gmail.com

Background and challenges to implementation: In 2020, the Ugandan Ministry of Health, supported by partners, introduced the Electronic Case-Based TB Surveillance System (eCBSS) to improve TB and leprosy patient management, reporting, and surveillance. By December 2023, eCBSS was implemented in 155 health facilities in the Bugisu and Bukedi regions, but only 23% of facilities reported TB cases in real-time. To address this gap, quality improvement (QI) strategies were employed.
Intervention or response: A root cause analysis in January 2024 identified barriers including undefined roles for data teams, limited internet access, poor data triangulation with Health Management Information System (HMIS) reports, and data backlogs. The Quality Improvement (QI) strategies implemented included:
- Defining data team roles and setting daily entry targets.
- Providing 7.5GB internet bundles per facility.
- Creating a communication directory of trained personnel.
- Sending weekly reminders via SMS, email, and WhatsApp.
- Assigning two eCBSS mentors per district for support and follow-up.
- Deploying extra human resources to clear backlogs in high-burden facilities.

Results/Impact: By June 2024, 96% of TB cases from weekly HMIS reports were entered into eCBSS in real-time. This improved the system's ability to notify drug-susceptible TB patients, with 1,124 patients notified in real-time.
Conclusions: QI innovations improved real-time TB reporting across 155 health facilities. These digital enhancements, coupled with a quality improvement approach, strengthened TB control efforts and decision-making.

EP27-957-19 Addressing the missing millions: A digital health and community-led approach to TB detection in India

B. Pandian,[1] S. Raj,[2] Rainbow TB Forum & Blossom Trust [1]Dure Technologies, MEL, Chennai, India, [2]Rainbow TB Forum, Management, Virudhunagar, India

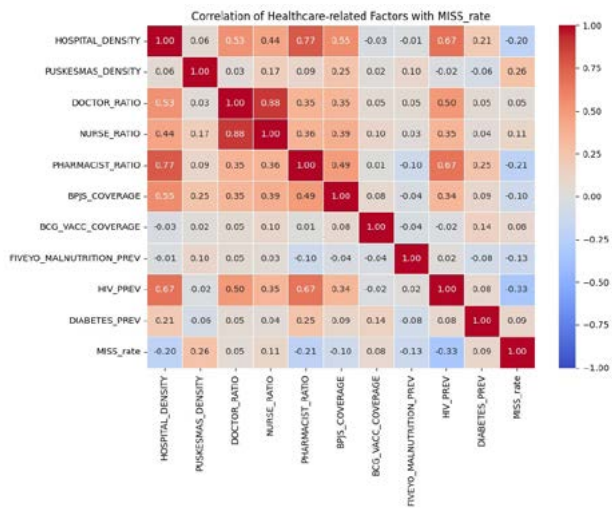
Background and challenges to implementation: India's vast population, diverse geography, and persistent TB-related stigma hinder effective TB control. The "Missing Millions" refers to undiagnosed or unreported cases, especially in rural areas, where stigma and exclusion prevent individuals from seeking care. Despite progress under the National TB Elimination Program (NTEP), detection remains challenging in rural Tamil Nadu due to stigma, exclusion, and geographic barriers.
Intervention or response: To address these challenges, Blossom Trust implemented OneImpact India, a digital health platform developed with STOP TB and Dure Technologies. Based on Community-Led Monitoring (CLM) and the Availability, Accessibility, Acceptability, and Quality (AAAQ) framework, the app provides a confidential, stigma-free space for individuals to access TB-related information, report symptoms or side effects, and raise care and treatment challenges. Tailored to rural Tamil Nadu's needs, the app addresses local barriers such as geographic isolation and fear of discrimination. From January to June 2024, it was rolled out across four districts: Madurai, Virudhunagar, Thoothukudi, and Theni.
Results/Impact: The app engaged 2,189 users who reported 2,078 TB-related challenges, including fear of testing and difficulty accessing services; 102 of these were resolved. A user survey (n=655) revealed the following:
- 66.2% gained improved knowledge of TB
- 54.5% learned about local treatment centres
- 33.9% discovered testing locations
- 34.6% identified medicine access points
- 39.1% understood treatment follow-up
- 95.5% found the app easy for reporting symptoms or side effects

The evidence shows that the app not only improves patient engagement but also enhances treatment adherence, a critical factor in reducing TB transmission.
Conclusions: OneImpact India demonstrates how digital tools can bridge gaps in TB care by empowering communities, improving awareness, and strengthening healthcare connections. While challenges remain, including digital literacy and technical stability, continued optimisation and integration of the app can offer a scalable, sustainable solution with the potential to ensure no one is left behind in eliminating TB.

EP27-958-19 Healthcare-related factors associated with the rate of missing tuberculosis cases: A subregional ecological analysis in Indonesia

M.P. Wardoyo,[1] A.P. Aulia,[2] N.N. Pamadi,[2] E. Burhan,[3,4] [1]Respiratory Programmatic Implementation and Research Institute, Department of Medical and Scientific Writing, Jakarta Timur, Indonesia, [2]Respiratory Programmatic Implementation and Research Institute, Department of Clinical Operation and Research, Jakarta Timur, Indonesia, [3]Faculty of Medicine Universitas Indonesia - Persahabatan Hospital, Department of Pulmonology and Respiratory Medicine, Jakarta Timur, Indonesia, [4]Respiratory Programmatic Implementation and Research Institute, Directorate, Jakarta Timur, Indonesia

Background: Healthcare-related factors may significantly influence efforts to identify individuals with tuberculosis (TB), as reflected in the rate of missing cases. These diagnostic gaps contribute to delays in treatment initiation and ongoing transmission. This study analyzes the relationship between healthcare-related factors and the rate of missing TB cases across eight provinces with the highest TB burden in Indonesia.
Design/Methods: This ecological analysis utilized secondary data from the Indonesian National TB Programme, provincial health profiles, and the Central Statistical Bureau. Multiple linear regression and spatial analysis across Java, North Sumatra, South Sumatra, and South Sulawesi were employed to evaluate associations between healthcare-related indicators and the rate of missing TB cases at the subregional level.



Results: The prevalence of HIV (r=–0.33) showed the strongest correlation with the missing case rate, followed by the primary health center (PHC) ratio per population (r=0.26), pharmacist ratio (r=–0.21), and hospital ratio (r=–0.20). HIV prevalence (coefficient=–636.67; 95%CI: –974.67 to –298.69; p<0.001), PHC ratio (0.0512; 95%CI: 0.029 to 0.074; p<0.001), malnutrition prevalence (–8.25;

95%CI: –14.78 to –1.71; p=0.014), and diabetes prevalence (2.88; 95%CI: 0.25 to 5.51; p=0.032) were independently associated with the missing case rate. Spatially, several factors were regionally-specifically correlated with missing case rate, such as HIV and diabetes prevalence in North Sumatra (p<0.001) and PHC ratio, malnutrition and HIV prevalence in Java (p<0.05).
Conclusions: Healthcare system indicators—including PHC facility density and prevalence of HIV, malnutrition, and diabetes—were significantly associated with the rate of missing TB cases at the subregional level. These findings highlight the need for context-specific healthcare strategies to improve TB identification and reduce diagnostic gaps.

EP27-959-19 Characteristics of TB cases and clustering of TB risk factors: An analysis in the ERASE-TB study

E.T. Marambire,[1,2] C. Calderwood,[3,4] K. Madziva,[1] C. Khosa,[5] L. Minja,[6] G. Kallenius,[7] C. Sundling,[7] K. Held,[8,9,10] F. Kavenga,[11] J. Mutsvangwa,[3] N. Heinrich,[8,9,10] K. Kranzer,[4,3,8] ERASE-TB team [1]Biomedical Research and Training Institute, The Health Research Unit, Harare, Zimbabwe, [2]University Hospital, LMU Munich, CIHLMU Center for International Health, Munich, Germany, [3]Biomedical Research and Training Institute, The Health Research Unit Zimbabwe, Harare, Zimbabwe, [4]London School of Hygiene & Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom of Great Britain and Northern Ireland, [5]Instituto Nacional de Saúde, Instituto Nacional de Saúde, Marracuene, Mozambique, [6]National Institute for Medical Research, Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, [7]Karolinska Institutet, Division of Infectious Diseases, Department of Medicine Solna, Center for Molecular Medicine, Stockholm, Sweden, [8]LMU University Hospital, LMU Munich, Institute of Infectious Diseases and Tropical Medicine, Munich, Germany, [9]German Center for Infection Research (DZIF), Partner Site Munich, Munich, Germany, [10]Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Immunology, Infection and Pandemic Research, Munich, Germany, [11]Ministry of Health and Child Care, National TB programme, Harare, Zimbabwe
e-mail: Edson.Marambire@lrz.uni-muenchen.de

Background: Risk factors such as HIV, smoking, alcohol use and malnutrition contribute significantly to TB burden. These risk factors may cluster in individuals and their prevalence differs by gender. We aimed to investigate the prevalence, clustering and population attributable fractions (PAFs) of TB risk factors, stratified by gender, in three high-TB/HIV burden, southern African countries.
Design/Methods: This was a cross-sectional study of adults with highly-infectious pulmonary TB in Harare, Zimbabwe; Maputo, Mozambique; and Mbeya, Tanzania (2021–2022). Risk factors were determined through a self-reported questionnaire. Prevalence and 95% confidence intervals (95%CI) were calculated stratified by gender and country. PAFs were calculated using published risk estimates and observed prevalences.
Results: Of 905 participants, 619 were men (68%). Median age was 28 (interquartile range 25–32) years. Prevalence of HIV, smoking, alcohol use, self-reported known diabetes was 30% (95%CI: 27-33%), 36% (95%CI: 32-39%), 16% (95%CI: 13-19%) and 2.3% (95%CI: 1-4%) respectively and differed by gender (Table). Half (95%CI 47-53%) of participants had more than one risk factor. Clustering of risk factors was more common in men than women (prevalence of >1 risk factor: 57% vs 35%). The most common risk factor combinations were HIV-smoking and alcohol-smoking. Smoking had the highest PAF among men across all countries (20%–36%) followed by HIV (15%–18%). Importantly the estimated PAF for smoking was much higher than the World Health Organisation (WHO) estimates. Among women, HIV had the highest PAF across all countries (16%–25%) while the PAF for smoking was relatively low (2.1%–4.9%).

	Risk factor	RR from literature review	Male TB prevalence (ERASE TB study)	Female TB prevalence (ERASE TB study)	PAF (Pc (RR-1/RR) Male	PAF (Pc (RR-1/RR) Female
Zimbabwe	Smoking	2.32	63.6%	8.6%	36.2%	4.9%
	Alcohol abuse	1.43	41.6%	13.3%	12.5%	4.0%
	HIV	2.49	30.6%	41.0%	18.3%	24.5%
Mozambique	Smoking	2.32	35.9%	3.9%	20.4%	2.2%
	Alcohol abuse	1.49	4.4%	2.0%	1.3%	0.6%
	HIV	2.49	30.4%	31.4%	18.2%	18.8%
Tanzania	Smoking	2.32	48.2%	3.8%	27.4%	2.1%
	Alcohol abuse	1.43	12.4%	6.3%	3.7%	1.9%
	HIV	2.49	25.7%	26.6%	15.4%	15.9%

Table1: Prevalence of risk factors by country and sex

Conclusions: Prevalence and clustering of TB risk factors differ by gender, however WHO PAF estimates do not account for gender differences. Our findings highlight the need for tailored prevention and control strategies which take gender into account.

EP27-960-19 Long-term transmission dynamics and phylogeography of *Mycobacterium tuberculosis* in an emerging city in China: A population-based phylodynamic analysis

X. Zhu,[1] Y. Wang,[2] J. Mei,[2] C. Yang,[1] [1]Sun Yat-sen University, School of Public Health (shenzhen), Shenzhen, China, [2]Bao'an District Hospital for Chronic Diseases Prevention and Cure, Department of Tuberculosis Prevention and Control, Shenzhen, China
e-mail: zhux73@mail2.sysu.edu.cn

Background: Shenzhen, with high population mobility, faces TB control challenges. By integrating whole-genome sequencing and phylodynamics, we explore genomic factors driving sustained MTB transmission and trace its origins and spread.

Design/Methods: Whole-genome sequencing was conducted on MTB strains collected between 2014 and 2022 from Baoan, Shenzhen, China. Bayesian modeling and phylogeographic analysis assessed the evolutionary history and transmission fitness of lineages and sublineages.

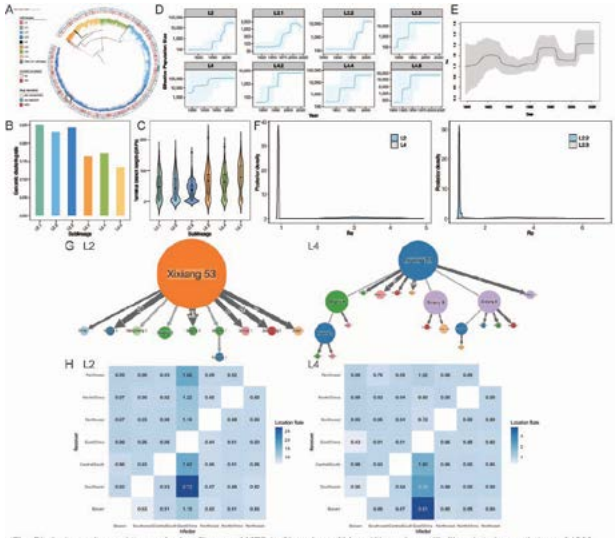


Fig. Phylodynamics and transmission fitness of MTB in Shenzhen, China. (A) maximum-likelihood phylogenetic tree of 4560 MTB isolates. (B) Comparison of genomic cluster rates between clades using 12-SNP thresholds. (C) Comparison of terminal branch length (TBL) across clades. (D) Effective population size estimates by clade. (E) Birth-death skyline plots of the effective reproductive number (*Re*) for all MTB isolates. (F) Relative transmission fitness of MTB by lineage. (G) Spatiotemporal ancestral reconstruction of L2 and L4 strains with inferred geographic spread events. (H) Heatmap of estimated interregional migration rates between L2 and L4 lineages across China.

Results: Among 4,560 MTB strains, L2 was the most prevalent lineage (73.3%), followed by L4 (25.9%). The dominant sublineage was L2.3 (49.5%), followed by L2.2 (22.1%) and L4.4 (10.9%) (Fig. A).

Sublineages L2.1 to L2.3 showed higher clustering rates and shorter TBLs than sublineages L4.2 to L4.5 ($P < 0.001$) (Fig. B, C).

Bayesian Skyline estimated that L4 had a more ancient TMRCA (1538, 95% HPD 1438-1830), with its effective population sizes (N_e) remaining stable since the 1950s, whereas L2 had a younger TMRCA (1837, 95% HPD 1773-1889) and its N_e expanded around the 2000s (Fig. D).

Birth-death Skyline revealed three phases of increase in the effective reproductive number (R_e) of MTB in Baoan, with an ongoing growth from the 2000s to the present (R_e 1.42, 95% HPD 1.23-1.67) (Fig. E).

The multitype birth-death model identified that L2 strains, especially L2.3, had significantly higher R_e than L4 and L2.2 (Fig. F).

Phylogeographic analysis suggested that L2 strains likely originated from Xixiang (CBD), while L4 strains spread from Fuyong (industrial areas) (Fig. G).

Nationwide, L2 and L4 strains from Baoan both showed the strongest connection with the East China region (Fig. H).

Conclusions: Shenzhen's TB epidemic shows sustained growth, driven mainly by L2 strains, especially L2.3. Our results emphasize the urgent need for TB control in Baoan, particularly in CBD and industrial areas.

Routine WGS surveillance will enhance understanding of TB biology and transmission and improve targeted responses.

EP27-961-19 Refining TB molecular surveillance in Taiwan: A cohort study addressing MIRU-VNTR variations with WGS validation

S.-Y. Huang,[1] K.-H. Liu,[1] Y.-X. Xiao,[1] Y.P. Li,[1] J.-J. Mu,[1] [1]Centers for Disease Control, Center for Diagnostics and Vaccine Development, Taoyuan, Taiwan
e-mail: syh@cdc.gov.tw

Background: Compared to whole genome sequencing (WGS), Mycobacterial Interspersed Repetitive Unit-Variable Number Tandem Repeat (MIRU-VNTR) requires less specialized equipment and technical expertise and is more cost-effective. As a result, it remains the primary method for genotyping and phylogenetic analysis in many countries, particularly those with a high TB burden. However, variations in MIRU-VRNT loci can lead to inaccuracies in phylogenetic analysis.

This study systematically analyzed the factors associated with MIRU-VRNT loci variations, providing insights into their impact on strain classification and epidemiological interpretations.

Design/Methods: We performed genotyping and phylogenetic analysis of multidrug-resistant TB (MDR-TB) using MIRU-VNTR and WGS from 2017 to 2024. WGS was conducted via Illumina MiSeq, and UPGMA and MEGA 7 were used for phylogenetic inference. Single nucleotide polymorphism (SNP) thresholds of ≤5 and ≤15 were applied to define definite and probable transmission.

We further examined the relationship between MIRU-VNTR variation and strain lineage, patient characteristics (age, sex, nationality, comorbidities, drug resistance, and treatment).

Results: Of the 604 MDR-TB cases, 447 (74.0%) were male, with a median age of 61 years. Among them, 524 (86.8%) were newly diagnosed, 510 (86.8%) had pulmonary TB, and 176 (29.1%) were acid-fast bacillus (AFB) smear-positive. Based on MIRU-VNTR-defined clusters, 27 cases were reclassified after WGS-based phylogenetic analysis. WGS provided more precise genotyping and phylogenetic information, enhancing tuberculosis surveillance and outbreak tracking. In addition, this study investigated the causes of MIRU-VNTR repeat sequence variation and evaluated the influence of epidemiological factors on these changes.
Conclusions: MIRU-VNTR requires cautious interpretation, especially for transmission tracking. WGS validation is recommended for cluster confirmation. This study supports refining MIRU-VNTR protocols or incorporating additional markers to improve resolution and TB surveillance.

EP27-962-19 Distribution of *Mycobacterium tuberculosis* lineages and clades by drug profile in Ethiopia: Systematic review and meta-analysis

M. Getahun,[1] [1]Ethiopian Public Health Institute, Infectious Disease Research, Addis Abba, Ethiopia

Background: *Mycobacterium tuberculosis* lineages exhibit variability in geographic distribution, transmissibility and disease phenotype. Ethiopia is one of the countries with the highest prevalence of tuberculosis. However, information on the proportion of lineages and clades by drug profile and disease phenotype is limited.
Design/Methods: The results were reported by the PRISRM guidelines. The study protocol was registered with ID CRD42024498336. Studies reporting Mtb lineages and/or clades with drug resistance profiles published between March 2010 and June 2024 were included. I^2 was used to evaluate heterogeneity. A p-value of less than 0.05 and an I^2 value >75% were indicative of significant heterogeneity.
Results: A total of 5554 *Mycobacterium tuberculosis* strains were enrolled from 32 studies. Percentage of East-African-Indian was 26.8% (95% CI: 22.6-30.6), and Euro-American was 64.1% (95% CI: 59.6-68.4). In studies that only included multidrug or rifampicin resistance cases, percentage of East-African-Indian was 31.2% (95% CI: 23.5-38.9), while Euro-American was 47.1% (95% CI: 37.5-56.6). Euro-American followed by East-African-Indian was the predominant lineage across locations and type of TB; however, East-African-Indian was significantly high in the Amhara region for both pulmonary TB and extra-pulmonary TB than it was in Addis Ababa. As defined by spoligotyping, T_3ETH (28.22%), CAS1-Kili (18.13%), and T_1 (11.54%) were the three most common clades among MDR/RR TB cases, while CAS1-Delhi (20.23%), T_1(16.71%), and T_3ETH (13.50%) were the three most common clades among susceptible cases.
Conclusions: This data helps the TB program to address issues unique to a given area.

EP27-963-19 Leveraging the AIM250 ODK Vantage Solution for enhanced performance monitoring and data-driven decision-making in TB and HIV grant implementation by KNCV Nigeria

M. Chukwu,[1] L. Ugochukwu,[1] A. Okoh,[2] M. Sheshi,[2] B. Odume,[3] U.E. Madubuko,[4] O. Adebayo,[5] T. Adetiba,[6] O. Chijioke-akaniro,[7] E. Ubochioma,[8] J. Kimeu,[9] A. Reilly,[10] [1]KNCV Nigeria, Strategic Information, Abuja, Nigeria, [2]KNCV Nigeria, Programs, Abuja, Nigeria, [3]KNCV Nigeria, Executive Director, Abuja, Nigeria, [4]IHVN, Technical, Abuja, Nigeria, [5]IHVN, Programs, Abuja, Nigeria, [6]IHVN, TB, Abuja, Nigeria, [7]NTBLCP, Strategic Information, Abuja, Nigeria, [8]NTBLCP, NTBLCP, Abuja, Nigeria, [9]GFCT, Programs, Switzerland, Switzerland, [10]GFCT, GFCT, Switzerland, Switzerland
e-mail: mchukwu@kncvnigeria.org

Background and challenges to implementation: Under the Global Fund Grant Cycle 7 (GC7), KNCV Nigeria implements TB and HIV project across Akwa Ibom, Anambra, Bauchi, Cross River, Kano, Kaduna, and Katsina States. Prior to the adoption of the AIM250 ODK Vantage Solution, the project faced critical challenges including delayed data reporting, low data completeness, inconsistent performance tracking, and limited accountability at state levels. These gaps hindered timely interventions and reduced project efficiency. Addressing these challenges, KNCV Nigeria deployed the AIM250 ODK Vantage Solution across all GC7 states for effective and real-time state-level monitoring and swift corrective actions.
Intervention or response: In October 2024 7 Public-Private Mix Cluster Coordinator (PPMCC) member and 7 State Technical Officer (STO) were trained across the 7 implementing state on the use of the ODK platform for weekly and monthly reporting. Metrics tracked included compliance with reporting timelines, platform adoption rates, adherence to program protocols, and improvements in data quality (completeness and accuracy).
Results/Impact: A comparison of project performance from Quarter four 2024 to Quarter One 2025 revealed significant improvements. Data completeness increased from 62% to 90%, and reporting timeliness improved from 55% to 88%. Adherence to weekly and monthly reporting rose by 70%, while active platform adoption reached 95% across states. TB case detection improved by 33%, and HIV service linkage rates increased by 28%. These gains underscore the effectiveness of AIM250 in driving data-informed decision-making.

Conclusions: The AIM250 ODK Vantage Solution has strengthened real-time performance monitoring and accountability, enabling data-driven decisions that enhance TB and HIV program outcomes. Its scalability offers potential for nationwide application.

EP27-964-19 Transitioning to a paperless system for tuberculosis data management: Evaluating the eTB Manager in Sherpur District, Bangladesh

FMM. Haque,[1] Z. Nasreen,[2] Y. Hassan,[3] S.B. Bhattacharjee,[4] A.H. Khan,[5] M.S. Alam,[6] S. Anjum,[7] S. Yeasmin,[8] M.A.Rahman [1]National TB Control Program, Monitoring and Evaluation, Dhaka, Bangladesh, [2]Directorate General of Health Services, Health Service Division, Dhaka, Bangladesh, [3]National TB Control Program, Program, Mymensingh, Bangladesh, [4]National TB Control Program, Program, Sherpur, Bangladesh, [5]National TB Control Program, M&E, Dhaka, Bangladesh, [6]Rajshahi University, Population Science and Human Resource Development, Rajshahi, Bangladesh, [7]National Tuberculosis Control Program, Monitoring and Evaluation, Dhaka, Bangladesh, [8]National TB Control Program, Monitoring And Evaluation, Dhaka, Bangladesh
e-mail: tonmoy.ndc@gmail.com

Background and challenges to implementation: Tuberculosis (TB) management in Bangladesh has traditionally relied on paper-based systems for patient data entry, which can be time-consuming, prone to errors, and difficult to scale. In recent years, the eTB-Manager application has been introduced to digitize TB data management, enhancing data accuracy, accessibility, and operational efficiency. Initially, both paper and digital systems were maintained to ensure data validation.

This ongoing pilot study in Sherpur district of Bangladesh aims to evaluate the feasibility and effectiveness of fully transitioning to the eTB-Manager, eliminating paper-based recording entirely.

Intervention or response: In December 2024, devices and training were provided to participants, and piloting began in January 2025. A structured survey was conducted in March 2025 with 26 respondents, including TB Leprosy Control Assistant (TLCA), Field Organizers/Program Officers/ Non Government Organization (NGO) representatives.

The survey assessed device functionality, internet connectivity, software usability, and workload changes as part of the pilot. The objective was to evaluate how well the eTB-Manager performs in real-world conditions.

Results/Impact: Preliminary findings from the ongoing pilot show that 100% of participants had functional devices, though some faced performance issues and Subscriber Identity Module (SIM) card challenges. While 88.5% reported uninterrupted internet connectivity, all respondents found the software easy to use. A significant 96.2% reported a reduction in workload, with some experiencing up to 70% time savings in data entry. Statistical analysis shows a significant correlation between device functionality and workload reduction ($p < 0.05$), while internet connectivity did not significantly affect software usability ($p > 0.05$).

Conclusions: The ongoing pilot in Sherpur district demonstrates the potential of digital tools like the eTB-Manager to improve TB data management. However, challenges related to device performance, SIM card support, and internet connectivity in remote areas remain.

Recommendations include upgrading devices, improving rural connectivity, offline features of the system and ensuring continuous training and support for long-term success.

ABSTRACT PRESENTATIONS THURSDAY 20 NOVEMBER 2025

ORAL ABSTRACT SESSION (OA)

OA16 Reaching the hard-to-reach: Increasing access and uptake

OA16-249-20 Measuring TB stigma and Its impact on accessing TB care: A study of 15 countries

J. Malar,[1] P. Mok,[2] C. Smyth,[1] M. Lunga,[3] A. Subakti,[4] K. Ul Eman,[5] D. Tobaiwa,[6] V. Denysenko,[7]
[1]Stop TB Partnership, Country and Community Support for Impact, Genève, Switzerland, [2]Independent Consultant, Independent Consultant, Kuala Lumper, Malaysia, [3]Club des Amis Damien, Club des Amis Damien, Kinshasa, Democratic Republic of the Congo, [4]Penebulu, TB, Jakarta, Indonesia, [5]Dopasi Foundation, TB, Islamabad, Pakistan, [6]Jointed Hands, TB, Harare, Zimbabwe, [7]100% Life, Advocacy, Kyiv, Ukraine
e-mail: jamesm@stoptb.org

Background and challenges to implementation: TB stigma remains a significant barrier to quality TB care. At the 2023 UNHLM on TB, countries committed to ending TB stigma by 2027. To reach this target, national TB responses must understand how stigma manifests at each stage of the TB journey.
Through the Challenge Facility for Civil Society, the Stop TB Partnership supported 15 countries to implement the TB Stigma Measurement Assessment, helping to identify stigma's impact and inform targeted interventions.
Intervention or response: The assessment used a standardized, civil society-led tool, guided by National TB Programmes (NTPs), to foster multi-stakeholder engagement, raise awareness, and develop stigma reduction strategies.
Oversight was provided by a steering committee composed of CSOs, NTP, people with TB (PWTB), and women. The tool applied qualitative and quantitative methods to assess stigma across the TB journey (from symptom recognition to post-treatment follow-up) in community, health, family, and work settings.
Community and healthcare worker perspectives on stigma were also included. Validated stigma scales (KNCV 2018) measured self-stigma, secondary stigma, and external stigma. A policy and legal workshop assessed rights-related frameworks and media coverage.
Results/Impact: Among 24,453 respondents across 13 countries, community stigma (26%) and self-stigma (25%) were most frequently cited as barriers to accessing TB services, followed by stigma in health facilities (20%), family (19%), and workplace (17%). The most common stigma point was during symptom recognition in the community. Sub-group analysis revealed women and key and vulnerable populations (KVPs) faced greater and differently experienced stigma. While protective laws existed in most countries, enforcement and media coverage were weak.
Conclusions: Community and health facility stigma during symptom recognition and treatment adherence stages most hindered TB care. TB programmes must focus on these areas and stages, and strengthen the implementation of legal protections and media advocacy to meet stigma reduction goals.

OA16-250-20 Content strategies on TikTok to address TB stigma: A quantitative study of the engagement on @TuberculosisTV

M.D. Firdaus,[1] F. Novanra,[1] P.S. Widiarto,[1] A.N. Rahadhi,[1] B.A. Sulaiman,[1] R. Ramadhan,[1] E. Burhan,[1] [1]Respiratory Programmatic Implementation and Research Institute, Clinical Research, Jakarta, Indonesia
e-mail: dea.firdaus@yayasanrpri.org

Background and challenges to implementation: Tuberculosis (TB)-related stigma is a persistent challenge to TB prevention and treatment in high-burden countries such as Indonesia. Stigma can reduce care-seeking behavior, lead to treatment delays, and fuel discrimination. With the rising popularity of TikTok among youth and the general population, social media offers an innovative platform to address stigma. However, there is limited evidence on which content strategies are most effective in engaging audiences and reducing TB-related stigma.
Intervention or response: This study analyzes engagement data from the TikTok account @TuberculosisTV, which produced 643 TB education videos between 5 January 2023 and 12 April 2025. Of these, 52 videos directly addressed TB stigma and were categorized into four content types: entertainment (n = 22), personal identity or lived experience (n = 12), informational (n = 8), and social interaction (n = 10). We collected public engagement metrics including views, likes, comments, shares, and saves. Engagement Rate, defined as the sum of likes, comments, and saves divided by views, was used as the primary outcome metric.
Results/Impact: Personal identity content had the highest average engagement (Mean ER = 3.16%, SD = 1.4) followed by interaction (2.69%), information (1.51%), and entertainment (1.48%). A Welch ANOVA showed significant differences in ER across content types (CI(3, 17.93) = 9.28, $p < 0.001$) and in LTV (like-to-view ratio) (CI(3,

17.65) = 10.23, $p < 0.001$). The Games-Howell post hoc analysis showed significant differences between entertainment-personal identity content and entertainment-interaction content.

Content Type	Number of Videos	Mean Engagement Rate (ER) (%)	Standard Deviation (ER)	Mean LTV	Significant Differences (Games-Howell)
Entertainment	22	1.48	0.54	0.012	Lower ER than Identity (p = .005)
Personal Identity	12	3.16	1.40	0.033	Highest ER, Higher than Entertainment (p = .005)
Information	8	1.51	0.75	0.013	–
Interaction	10	2.69	0.85	0.023	Higher ER than Entertainment (p = .013)

Conclusions: Findings demonstrate practical applications for public health communication efforts, especially for programs seeking to reduce TB stigma through social media engagement. The study highlights lived experiences contents generated the most meaningful engagement to address stigma. These results can inform other digital health campaigns targeting stigma reduction in high-burden settings and support strategic content planning for wider dissemination. Future research should expand the dataset and incorporate qualitative insights.

OA16-251-20 Leveraging social media and television campaigns to raise awareness of tuberculosis during the war in Ukraine

O. Pazynych,[1] Z. Islam,[1] E. Geliukh,[1] [1]Alliance for Public Health, Public health, Kyiv, Ukraine

Background and challenges to implementation: In 2024, Ukraine launched a media campaign to combat persistent stigma and discrimination around tuberculosis (TB), which is a major barrier to healthcare access. The initiative aimed to disseminate accurate TB information amid wartime disruptions to traditional media, necessitating alternative communication channels to ensure population-wide reach.

Intervention or response: The campaign strategically combined television broadcasts with digital platforms, leveraging live YouTube streams and Facebook content to engage audiences. Reaching over 2.1 million people, the effort addressed stigma, gender-specific challenges, diagnostic accessibility, and innovative treatments.

Experts—including civil society representatives, scientists, doctors, and TB survivors—shared insights, while interactive social media Q&A sessions addressed public concerns directly.

Results/Impact: The campaign achieved over 2.1 million views across platforms. The broadcast on innovative TB treatments garnered the highest engagement (480,560 views), reflecting public interest in medical advancements. Workplace stigma discussions received 370,353 views, emphasizing the need for societal support. Topics like fear of stigma, gender dimensions, and diagnostic access each attracted ~400,000 views, demonstrating balanced public engagement. The hybrid television-digital approach proved adaptable and resilient in wartime, ensuring vital health information dissemination despite media disruptions.

№	Topic	Reach (TV + YouTube Live + Facebook)
1	Fear of stigma and discrimination – is a barrier to diagnosis and treatment	402311 views
2	Gender aspect of tuberculosis	426366 views
3	Innovative approaches to overcoming the tuberculosis epidemic in Ukraine	480560 views
4	Stigma and discrimination against people with tuberculosis in the workplace: how to fight it?	370353 views
5	Accessibility of tuberculosis diagnosis: new treatment methods, risk groups	415368 views
Total		2 094 958 views

Conclusions: The campaign highlights the effectiveness of integrating television and digital platforms to raise TB awareness during crises. High engagement with treatment innovations signals public demand for progress in TB care. Addressing stigma, gender disparities, and diagnostic access remains critical.

Future initiatives should prioritize multi-platform strategies and adapt to evolving media landscapes to maximize reach. Interactive formats, such as social media Q&As, enhance audience engagement and understanding by fostering direct dialogue.

This approach underscores the importance of flexible, participatory communication in public health messaging, particularly in conflict-affected settings.

OA16-252-20 The power of friendship: A child-centered comic to overcome tuberculosis stigma during war in Ukraine

Y. Kuvshynova,[1] [1]CONVICTUS UKRAINE, All-Ukrainian Charitable Organization, Convictus Ukraine, Kyiv , Ukraine, Ukraine

Background and challenges to implementation: Stigma is a key barrier to tuberculosis (TB) care, especially for children and adolescents. They often face isolation and discrimination, impacting treatment and mental well-being. The war in Ukraine worsened these challenges by displacing families, disrupting healthcare, and increasing stress.
Traditional awareness campaigns rarely engage children. There was a need for an innovative, child-friendly way to explain that TB is curable and that children deserve empathy, inclusion, and support.
Intervention or response: To address these challenges, an innovative approach was implemented through Ukraine's first child-centered TB comic, "The Power of Friendship: how Zlata overcame tuberculosis". It tells the story of a girl displaced by war and diagnosed with TB, who faces illness and social challenges with support from friends and family. Created with health professionals, educators, psychologists, and artists, the comic simplifies complex information in a supportive format. It is distributed freely and used in schools and outreach efforts to reduce TB stigma.
Results/Impact: By March 2025, over 5,000 children in Ukraine received the comic. Healthcare providers and psychologists observed positive effects in reducing fear, stigma, and isolation among children with TB.

The comic serves as both an educational tool and a source of emotional support. Its visual storytelling helps children relate to characters and understand the disease. Plans are underway to expand its use nationally through education and awareness programs, especially in conflict-affected regions.
Conclusions: The comic is an effective tool for reducing TB stigma and promoting empathy among children. It highlights that TB is curable and recovery depends on social support. Positive feedback from health and education professionals confirms its value. Plans are underway to expand its use in Ukraine. This model may be adapted globally in humanitarian settings.

OA16-253-20 Improving TB case detection among men at community level: A case study from Malawi

P. Mwamlima,[1] E. Lungu,[1] K. Phiri,[1] B. Kadyeremwana,[1] S. Matewere,[1] D. Nkosi,[1] C. Mbalanga,[1] K. Mbendera,[2] L. Kanyenda,[3] S. Phiri,[1,4] J. van Oosterhout,[1,5] G. Talama,[1] [1]Partners in Hope, Program, Lilongwe, Malawi, [2]Ministry of Health, National TB and Leprosy Elimination Program, Lilongwe, Malawi, [3]United States Agency for International Development, Health, Lilongwe, Malawi, [4]School of Global and Public Health, Kamuzu University of Health Sciences, Lilongwe, Malawi, [5]University of California Los Angeles, Department of Medicine, California, United States of America
e-mail: petermwamlima@gmail.com

Background and challenges to implementation: In Malawi, TB is two times more prevalent in men than women and men spend a year longer before being diagnosed with TB. There is paucity of data on interventions to improve early TB detection among men. To address this gap, we implemented a community-based TB screening intervention at community structures where men usually congregate.
Intervention or response: With funding from USAID, Partners in Hope, a Malawian, non–Governmental Organization, collaborated with Ministry of Health (MOH) to conduct intensified TB screening utilizing both mobilized men gatherings and existing male congregation points (workplaces, businesses, hangout spots) across six health facility catchment areas in Nsanje, Chikwawa and Lilongwe districts. A team of one Health Surveillance Assistant, four community volunteers, one HIV Diagnostic Assistant and one clinical staff used WHO 4-symptom screening tool to identify persons with presumed TB, who submitted sputum for laboratory TB testing at the nearest health facility or were further evaluated by a clinician if they failed to produce sputum. Screening sessions were coordinated through local leadership structures to ensure community participation. While focusing on men, females were included if they were willing to participate.
Results/Impact: From June to December, 2024, 6,803 individuals (6,104 males, 669 females) were screened for TB. Of these, 8.7% (593/6,803) had presumptive TB

symptoms, out of which 86.8% (515/593) managed to submit sputum. 7.4% (44/593) were diagnosed with active TB and were initiated on treatment out of which 90.2% (40/44) were men. Of all persons diagnosed with TB, 81.8% (36/44) were bacteriologically confirmed, none had drug resistant TB, and 4.5% (2/44) were persons living with HIV.

Conclusions: The intervention effectively targeted men, demonstrating success in reaching this underserved population. Strong coordination with MOH teams was key to successful implementation. Additional measures, including availability of on-site TB diagnostic equipment, such as mobile X-ray, may further enhance timely screening and diagnosis.

OA16-254-20 Challenges in TB screening among internally displaced persons. a case study of Benue state Nigeria

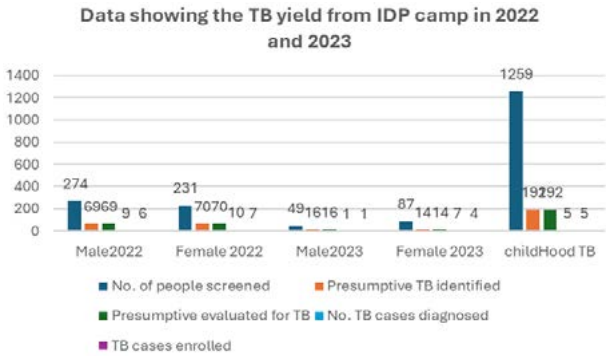
S. Gande,[1] C. Ogbudebe,[2] B. Odume,[3]
[1]KNCV Nigeria, Programs, Abuja, Nigeria, [2]KNCV Nigeria, Strategic Information, Abuja, Nigeria, [3]KNCV Nigeria, Project management, Abuja, Nigeria

Background and challenges to implementation: Tuberculosis (TB) remains a significant public health challenge worldwide, with Nigeria ranking sixth globally, among the countries with the highest TB burdens. KNCV Nigeria, has continued to implement active TB case-finding withing the IDP to curtail the spread and manage appropriately this disease. The prevalence of TB in Benue state is exacerbated by socio-economic factors, HIV co-infection, and limited access to healthcare services, particularly among vulnerable populations such as people living with HIV, internally displaced persons (IDPs), and rural dwellers.

This paper explores the major challenges faced in TB screening within the IDP camp in Benue state.

Intervention or response: KNCV Nigeria through the LON 1&2 project implemented intensive active TB case-finding (ACF)activities such as community outreaches, mass screening of clients with the use of portable digital X-ray (PDX) machine and the presence of the Wellness on wheels (WoW) truck to boost TB cases finding within the IDP camps. Public TB awareness campaigns and educational programs, community workshops, and media campaigns were organized to improve knowledge about TB prevention and treatment and address issues around stigma. To close gaps around the integration of HIV and TB services, coordination of TB screening with HIV services was ensured to enhance early case detection and treatment initiation.

Results/Impact: Within a two-year implementation program (2022-2023), the project was able to screen **1,900** clients of which **361(19%)** of them were presumed to have TB from the community outreaches conducted within the camps. Presumptive identified who were successfully evaluated were **361**(giving a **100%** evaluation rate). Those who were diagnosed to have TB were **32(9%).** Children diagnosed from the total were **(15%)**. Challenges encountered were around cultural barriers and stigma.



Conclusions: Challenges of TB screening among vulnerable populations in Benue State requires a comprehensive approach that integrates community-based strategies, improved healthcare infrastructure, policy support, and educational efforts.

OA16-255-20 Prevalence and associated factors of tuberculosis among tea estate workers in Thyolo and Mulanje districts, Malawi: A cross-sectional study

B. Isake Chiwaka,[1] F. Sinyiza,[2] E. Francisco,[1] P. Ngoma,[1] B. Mbakaya,[3] M. Chisale,[4] H. Kanyerere,[5] K. Mbendera,[5]
[1]Ministry of Health, Malawi, Thyolo District Hospital, Thyolo, Malawi, [2]Ministry of Health, Malawi, Mzuzu Central Hospital, Mzuzu, Malawi, [3]University of Livingstonia, Publich health, Rumphi, Malawi, [4]Mzuzu University, Biomedical Sciences, Mzuzu, Malawi, [5]Ministry of Health, Malawi, Tuberculosis and Leprosy Elimination, Lilongwe, Malawi
e-mail: benchiwaka@gmail.com

Background: Tuberculosis remains one of the major health problems in the tea gardens worldwide. . Early diagnosis of people with TB helps to cut transmission of the disease and also leadss to improved treatment outcomes. The World health organization launched the End TB strategy which aims at identifying all TB patients and putting them on treatment. Thyolo and Mulanje are the tea growing districts which has a high burden of TB and HIV in Malawi. There is paucity of data of TB burden among tea estate workers in Malawi.

This study was conducted to determine the prevalence and associated factors of TB among tea estate workers in Thyolo and Mulanje districts in Malawi.

Design/Methods: A cross section study was conducted in the tea estates of Thyolo and Mulanje targeting 1,068 estate tea workers. Multi stage random sampling was done to obtain a sample size. Socio-demographic, employ-

ment and clinical data was collected using a structured questionnaire. Chest x-ray and gene x-pert machine were used to test the participants for TB. Ethical clearance was obtained from National Health Sciences Research Committee, letter of authorization was obtained from Tea Association of Malawi, and district councils of Thyolo and Mulanje. Data analysis was conducted using SPSS version 25.

Results: A total of 976 participants took part in the study. Prevalence of TB was found to be 1.84% translating to 1840 TB patients per 100,000 population of tea estate workers. Level of education (P=0.012), type of employment (p=0.019), HIV status (p=0.046) and history of TB among household contact (p=<0.001) were factors associated with TB infection.

Conclusions: Prevalence of TB among tea estate workers is high yet not included among high-risk group targeted with TB interventions in Malawi. Therefore, there is need to strengthen TB control and prevention strategies among tea estate workers if we are to end TB by 2030.

OA16-256-20 Using people-centered approach to enhance active TB case finding in internally displaced persons (IDPs) during the war in Ukraine

E. Geliukh,[1] N. Kamenska,[1] T. Bakhmat,[1] Z. Islam,[1]
[1]ICF „Alliance for Public Health", Treatment, Procurement and Supply Management, Kyiv, Ukraine
e-mail: geliukh@aph.org.ua

Background and challenges to implementation: Full-scale war started in February 2022 caused the unprecedent population migration both inside the country and abroad. This migration process is followed by substantial stress, prolonged stays in overcrowded places with inadequate ventilation (bomb shelters, evacuation trains), and irregular, poor meals. All these factors facilitate the spread of TB infection in the population. In 2024, there were about 4.4m IDPs in Ukraine of whom 60.5 thousand live in the places of temporary compact accommodations.

Intervention or response: Alliance has been working on ACF-TB in IDPs since 2018. Starting from 2022, the number of persons screened for TB symptoms as well as the number of diagnosed TB cases has increased. Since 2024, having shortage of finance and being unable to increase the number of IDPs screened for TB, Alliance has changed the approach of reaching the IDPs. Instead of screening those who apply to social services centers for social support, Alliance issued grants to 16 NGOs for identifying IDPs in the places of compact accommodation, therefore making TB screening services more accessible to IDPs. NGOs provide screening for TB symptoms, followed by medical examination in healthcare facilities for those who are screen-positive and enrollment in treatment for those with diagnosed TB.

Results/Impact: In 2024, ACF-TB is provided by 16 NGOs in 19 regions of Ukraine. Among other services, NGOs help IDPs to sign declarations with family doctors and provide payment for TB diagnostics services for those who lost their documents and therefore unable to sign the declaration.

	# of IDPs screened for TB symptoms	# of screening-positive	# and % of IDPs examined for TB in HCF	# of diagnosed TB cases. Total (susceptible/DR-TB)	NNI	# and % of enrolled in treatment	# of signed declarations with PHC Centers	# of IDPs received paid services in HCF
2021	10,149	2,832	2,832 (100)	13 (10/3)	218	13 (100)	2	5
2022	24,578	5,784	5,146 (89)	25 (23/2)	206	25 (100)	1	5
2023	39,830	11,630	10,447 (90)	78 (68/10)	134	78 (100)	2	29
2024	22,009	9,938	9,855 (99)	196 (163/33)	50	196 (100)	23	581

Conclusions: An innovative approach has allowed for the diagnosis of more TB cases without increasing the number of screened IDPs. Among all TB cases within IDPs diagnosed in Ukraine in 2024, 37% (196 out of 523) were diagnosed in projects funded by Alliance. A people-centered approach in service provision enables IDPs to seek TB screening and diagnostics in HCF.

OA16-257-20 Integrating tuberculosis services into mobile clinics in nomadic settings: An evaluation of the TB LON 1&2 Wellness on Wheels innovation in Bauchi State, Nigeria

C. Igwetu,[1] S. Useni,[1] B. Odume,[2] M. Tukur,[1] H. Ma'ab Baffa,[1] L. Ugochukwu,[1] [1]KNCV Nigeria, Technical and Program Department, Federal Capital Territory, Nigeria, [2]KNCV Nigeria, Technical and Program Department, FCT Abuja, Nigeria
e-mail: cigwetu@kncvnigeria.org

Background and challenges to implementation: Tuberculosis case detection and treatment outcomes are suboptimal in nomadic populations where access to health services is minimal. Responding to these challenges, especially among nomadic communities, necessitates innovative approaches to healthcare delivery. KNCV Nigeria's introduction of the Wellness on Wheels (WOW) Truck initiative under the USAID-funded TB LON 1&2 project marks a significant stride towards improving access to TB diagnostic and treatment services in these remote and underserved areas.

This study evaluates the impact of this mobile clinic initiative in Bauchi State, highlighting its potential to enhance TB case finding and treatment in nomadic settings.

Intervention or response: The WOW Truck, a mobile TB diagnostic unit funded by USAID, was launched in Bauchi State in November 2022, targeting nomadic and hard-to-reach communities. The truck provides free TB screening and diagnostic services alongside general healthcare. Equipped with a digital X-ray machine,

CAD4TB (Computer Aided Detection for TB) software, and two four-modular GeneXpert machines, it facilitates timely TB diagnosis in remote areas, including nomadic settlements.

Results/Impact: We analyzed data from the nomadic population screened using the WoW truck between January and October 2023. With a 27% TB yield, the findings highlight a significant outcome in TB case detection within the nomadic population in Bauchi State.

Notably, this increase in cases coincided with the rainy season, when the nomads are more settled, suggesting that the period of increased settlement may contribute to higher case detection.

Reporting Period	Number clients screened for TB	Number of presumptive TB cases identified	Number of presumptive TB cases who completed evaluation	Total number of TB cases diagnosed	Total number of TB cases started on treatment	TB YIELD%
Jan-23	3437	122	122	24	24	20%
Feb-23	3268	162	162	48	48	30%
Mar-23	2966	82	82	8	8	10%
Apr-23	2646	180	180	27	27	15%
May-23	3592	184	184	33	33	18%
Jun-23	1912	55	55	21	21	38%
Jul-23	2908	147	147	59	57	40%
Aug-23	4395	142	142	37	37	26%
Sep-23	3580	162	162	61	61	38%
Oct-23	2947	155	155	63	62	41%
TOTAL	31651	1391	1391	381	378	27%

Conclusions: The WOW Truck initiative in Bauchi state represents a novel model for delivering TB and general healthcare services to nomadic communities. Its success in increasing TB case detection underscores the importance of mobile health interventions in addressing health disparities. While the initial outcomes in Bauchi State are encouraging, sustained funding and strategic expansion are essential to capitalize on its full potential to contribute to the eradication of TB in Nigeria

OA16-258-20 Prevalence of tuberculosis among people with substance abuse disorder: Lessons on collaboration with traditional mental health homes for TB case detection in Southwest Nigeria

A. Alege,[1] S. Odunjo,[2] A. Agbaje,[3] O. Daniel,[4] M. Tijani,[5] J. Anyanti,[6] R. Eneogu,[7] A. Ihesie,[7] O. Chijioke-Akaniro,[8] C. Mensah,[9] P. Dakum,[9] [1]Society for Family Health, TB LON, Lagos, Nigeria, [2]Society for Family Health, TBLON, Abeokuta, Nigeria, [3]Institute of Human Virology, Nigeria, Special projects, Abuja, Nigeria, [4]Institute of Human Virology, Nigeria, Prevention and Care, Lagos, Nigeria, [5]Ogun State Ministry of Health, Public Health, Abeokuta, Nigeria, [6]Society for Family Health, STG, Abuja, Nigeria, [7]USAID, HIV/TB, Abuja, Nigeria, [8]NTBLCP, PMU, Abuja, Nigeria, [9]Institute of Human Virology, Nigeria, Office of CEO, Abuja, Nigeria
e-mail: alege.abiola@yahoo.com

Background and challenges to implementation: Prevalence of Tuberculosis (TB) among people with Substance abuse disorder is notably higher than the general population as they are likely to contract TB due to factors such as weakened immunity and co-occurring health issues. In Nigeria, traditional mental health homes served as the first point of treatment for most with such condition due to cultural belief. USAID Tuberculosis Local Organization Network 3 (TB LON 3) aimed to find the missing TB cases among high risk groups by conducting TB screening activities in traditional mental health homes.

Intervention or response: Between November 2022 and August 2023 four traditional mental health homes were purposively selected. Advocacy and engagement visits were paid to the stakeholders outlining the signs and symptoms of TB and its determinants which include alcohol use disorder, smoking and substance abuse.

TB screening was done using WHO 4 clinical questions checklist and emphasis placed on other risk factors such as history of contact with chronic cough. Sputum samples collected were analyzed using GeneXpert MTB/Rif Assay.

Results/Impact: A total of 741 persons were screened, 264 (35%) presumptive TB cases identified and evaluated with 66 (25%) TB cases (61 DSTB, 5 DRTB) diagnosed and commenced on treatment and notified to the National TB program. Number needed to screen (NNS) and Number needed to test (NNT)was 11 and 4 respectively compared to 54 and 9 among similar high-risk groups on the USAID TBLON 3 Project.

Conclusions: This intervention shows a high prevalence of Tuberculosis among persons who suffer from substance abuse disorder and its implication for public wellbeing. Collaboration and effective engagement with traditional mental health home in TB endemic region shows promise as a replicable model for high-risk population in the End TB strategy especially in communities where cultural beliefs influence the general health seeking behavior of the people.

OA17 TB screening and finding TB in marginalised populations

OA17-259-20 Finding tuberculosis among children in seemingly safe places, lessons from multi-sectoral collaboration on TBLON3 in Ogun State, Nigeria

A. Alege,[1] S. Odunjo,[2] O. Daniel,[3] O. Taiwo,[4] J. Anyanti,[5] O. Chijioke-Akaniro,[6] R. Eneogu,[7] D. Nongo,[7] C. Mensah,[8] P. Dakum,[8] A. Agbaje,[9] [1]Society for Family Health, TB LON, Lagos, Nigeria, [2]Society for Family Health, TB LON, Abeokuta, Nigeria, [3]Institute of Human Virology, Nigeria, Prevention and Care, Lagos, Nigeria, [4]Ogun State Ministry of Health, Public Health, Abeokuta, Nigeria, [5]Society for Family Health, STG, Abuja, Nigeria, [6]NTBLCP, PMU, Abuja, Nigeria, [7]USAID, HIV/TB, Abuja, Nigeria, [8]Institute of Human Virology, Nigeria, Office of CEO, Abuja, Nigeria, [9]Institute of Human Virology, Nigeria, Special Projects, Abuja, Nigeria
e-mail: alege.abiola@yahoo.com

Background and challenges to implementation: Tuberculosis (TB) among children is a public health problem of special significance as it is a marker for recent transmission of TB in the community. The USAID TBLON-3 project aimed to halt ongoing transmission by conducting TB screening in schools, orphanages and other informal schools. This is especially crucial in settings where children are exposed to risk factors that predispose them to TB such as malnutrition and overcrowding.
The aim of the intervention is to increase childhood TB case detection and demonstrate the effectiveness of multisectoral engagement in finding Tuberculosis among children.
Intervention or response: This intervention required collaborative efforts across multiple sectors, the Ministry of Education, Ministry of Women Affairs and Social Development, as well as religious bodies to locate and engage with these children effectively.
Increased resources, including manpower, funding and Social and Behavioural Change communications (SBC) materials, were mobilized to create awareness for TB screening activities**.**
Volunteers were trained on screening using WHO 4 clinical questions with emphasis on other peculiar signs and symptoms of TB in children. 4 public schools,3 orphanages and 7 Qur'anic schools were selected from TB Hotspots mapped using an AI-enabled geospatial mapping platform.
Results/Impact: The screening was done between Oct 2022- Aug 2023 with a total of 2,121 children screened,541 presumptive identified (26% yield) and evaluated using GeneXpert. 53 TB cases were diagnosed, NNS is 40 and NNT is 10 respectively which is more efficient compared to screening in an infant welfare clinic. 51(96%)of the cases identified were enrolled on treatment and notified to the National TB Program.
Conclusions: Multi-sectoral targeted screening for childhood TB cases is a highly effective and efficient way of reaching out to children who may not present in health facilities as they are presumed to be healthy, sustaining this collaboration can help reduce child mortality due to Tuberculosis.

OA17-260-20 Efficiency of different active TB case-finding strategies among coal mine communities in Pakistan

K.U. Eman,[1] U.R. Lodhi,[1] M. Ali,[1] G.N. Kazi,[1] B. Kirubi,[2] J. Creswell,[2] S. Tahseen,[1] [1]Dopasi Foundation, Programs, Islamabad, Pakistan, [2]Stop TB Partnership, TB Reach, Geneva, Switzerland
e-mail: kinza_kz@yahoo.com

Background: Among high-risk groups, coal miners are particularly vulnerable due to their occupational exposure to coal dust, which compromises lung function and increases risk of TB.
Design/Methods: This cross-sectional study was conducted in 2020/21 to detect active tuberculosis among returnee coal-miners (RCM) and their associated-communities (ACM) in six districts of Pakistan with high concentrations of coalminer workforce. Three different active-case-finding (ACF) strategies were employed. Ultra-portable chest X-ray (CXR) machines equipped with AI were used for screening in camps, whereas verbal screening was used in camps and communities. People screened positive were tested using Xpert MTB/RIF. TB prevalence in 100,000, number needed to screen (NNS) and number needed to test (NNT) to find one bacteriologically confirmed TB case were calculated and analysed stratified by screening strategy.
Results: A total of 150,242 individuals including 44% RCM were reached. Of these 8.3% were screened by CXR in camps, 91% by verbal screening in camps (10%) and community outreach (81%). Among individual screened by symptoms, 45% of RCM and 15% of ACM had symptoms whereas proportion with CXR suggestive of TB was similar in both (10-11%). NNS to find one TB case was lowest among RCM group screened by CXR (n=87) and among ACM screened by symptoms(n=134). TB was diagnosed in 226 RCM and 204 ACM. The estimated TB prevalence in RCM was 341 and 243 in ACM. However, the estimates of TB prevalence varied significantly with screening strategy and among RCM population it ranged from 1156/100.000 in group screened by CXR followed by 566/100,000 in group screened by symptom in camps and 177/100K in those screened by verbal screening in community outreach.
Conclusions: With CXR screening, the low NNS and NNT, along with threefold higher estimates of TB prevalence, underscore the efficiency of CXR in detecting TB in a population with a high prevalence of symptoms.

OA17-261-20 Tuberculosis case finding among internally displaced persons: Navigating hard-to-reach underserved communities of Adamawa State, Northeast Nigeria

S. Abdulkarim,[1] S. John,[2] S. Kwaghe,[2] A. Abubakar,[3] T. Garg,[4] J. Creswell,[4] [1]Sufabel Community Development Intiatives, Programme, Gombe, Nigeria, [2]Janna Health Foundation, Programme, Yola, Nigeria, [3]Federal College of Education, Geography, Katsina, Nigeria, [4]Stop TB Partnership, TB REACH, Geneva, Switzerland

Background and challenges to implementation: Since 2016 internal Organisation for Migration (IOM) estimated over 3 million people were displaced in Northeast Nigeria due to insurgent activities. Internally Displaced Persons (IDPs) face significant barriers in accessing timely and quality health services including tuberculosis (TB) due to their remote/hard-to-reach locations, insecurity, and often restricted movement among other factors.
As part of the Uniatid supported Start4All project, we implemented a community-based active case finding (ACF) targeting IDP communities in hard-to-reach areas of Adamawa State. We document the contributions of ACF in IDP communities of Adamawa State.
Intervention or response: From August 2024 to January, 2025, 39 screening sessions in 35 IDP communities of Adamawa State were conducted through mobile outreaches using portable digital CXR with AI-interpretation to screen individuals ≥15. People with qXR AI score of ≥0.3 were considered to have presumptive TB and had their sputum collected, transported and tested with Xpert MTB/RIF Ultra.
Results were actively retrieved, people confirmed with TB were promptly linked to treatment while those found to be Bac- were further reviewed by radiologists/medical officers and managed appropriately.
Results/Impact: 60 volunteers were identified and trained on TB prevention and care from IDP host communities. Overall, 1,208 individuals (including 755 females) were screened with CXR-AI. Of these, 180 individuals (15%) had AI scores ≥0.3 and were tested using GeneXpert MTB/Rif. 67 people were diagnosed with TB including 8 with Bac+ TB; 24 (36%) were females.
All people confirmed with TB were successfully initiated on treatment.
Conclusions: Community-based ACF using CXR-AI is effective in the timely detection and initiation of IDPs on treatment. Such targeted outreaches can bridge the diagnostic gap among IDPs and accelerate progress toward ending TB.

OA17-262-20 Active tuberculosis case finding using digital chest X-ray with artificial intelligence in prisons of Nepal: An initial experience

B. Sharma,[1] S. Tiwari,[2] B. Thapa,[3] A. Shrestha,[4] L.R. Joshi,[5] P.V. Shahi,[6] M. Micklum,[7] M.M. Billah,[8] P. Shrestha,[9] [1]National Tuberculosis Control Centre, Department Of Health Services, Thimi, Nepal, [2]National Tuberculosis Control Centre, Department of Health Services, Kritipur, Nepal, [3]Apara Innovation, NA, Lalitpur, Nepal, [4]Save the Children , TB – Global Fund | Save the Children, NA, Lalitpur, Nepal, [5]Save the Children , TB – Global Fund | Save the Children, NA, Kathmandu, Nepal, [6]National Tuberculosis Control Centre- WHO, NA, Kathmandu, Nepal, [7]National Tuberculosis Control Centre, Department of Health Services, Thimi, Nepal, [8]South Asia Field Epidemiology and Technology Network inc. (SAFETYNET), NA, Dhaka, Bangladesh, [9]Bir Hospital- NAMS, Respiratory - Medicine, Kathmandu, Nepal
e-mail: aryal.basundhara@gmail.com

Background and challenges to implementation: Nepal's National Tuberculosis Program (NTP) estimates 68,000 annual TB cases (229/100,000 population), with 40% remaining undiagnosed. The National TB Prevalence Survey 2018-19 Nepal reported that 72% of TB cases were asymptomatic, highlighting gaps in passive case detection and limitations for screening for TB using only symptoms screening. To address this, the NTP piloted AI-enhanced DELFT light chest radiography (CXR) and Computer-Aided Detection (CAD4TB) to improve TB case detection in prisons. Prioritizing prison settings recognized globally as high-risk TB settings, which often face overcrowding, limited access to health care, poor ventilation and undernutrition thereby amplifying transmission risks.
Intervention or response: Coordination with Department of Prison Management for official permission and chosen the prisons which have > 500 inmates and not doing screening camps regularly. Camps were organized after orientation session to the prison staff and health workers.
All inmates and staff underwent symptomatic screening with questionnaire, digital-CXR analyzed with CAD4TB software (threshold score ≥35). Sputum for presumptive cases were tested using molecular WHO-recommended rapid diagnostic test (GeneXper)t and Pulmonary clinically diagnosis was made based on CXR findings. All diagnosed TB cases were promptly enrolled in treatment.
Results/Impact: Of 1,514 participants (median age 31; 98% male, 2% security staff), 28 (1.8%) had prior TB history, 9% (139/1514) were current smokers. Screening identified 75 (5%) presumptive cases (symptoms or CAD4TB scores ≥35). Twelve (0.8%) were diagnosed with TB: 6 bacteriologically confirmed (MTB -positive),17% (1/6) female and 6 clinically diagnosed made based on chest X-ray findings. The TB prevalence in prisons was 794 per 100,000 which is three times higher than Nepal's national estimates.

Conclusions: Prison TB prevalence far exceeds national estimates, underscoring the urgency of routine AI-enhanced CXR screening in such high-risk settings. Early diagnosis, treatment, and targeted interventions will support in halting the TB transmission and advance global TB elimination goals.

OA17-263-20 Reaching the unreached: Programmatic innovations for identification of tuberculosis (TB) among underserved populations in Bangladesh

F.N. Seheli,[1] S. Islam,[1] M.A. Islam,[1] S. Reja,[1] S. Marjia,[1] I. Begum,[1] [1]BRAC, BRAC Health Program, Dhaka, Bangladesh
e-mail: nishatseheli@gmail.com

Background and challenges to implementation: Bangladesh bears a high tuberculosis (TB) burden, with vulnerable populations facing the greatest barriers to diagnosis and care. Groups such as slum dwellers, industrial and transport workers, children, the elderly, and residents of remote areas often experience delayed diagnosis due to socio-economic challenges, limited awareness, stigma, and poor access to health services. These barriers contribute to ongoing transmission and underscore the need for equitable, people-centered TB service delivery.
Intervention or response: To address these gaps, BRAC, a development organization, implemented targeted interventions to enhance identification of TB among high-risk and underserved populations. Sputum collection centers were set up in factories, garments, and transport terminals, focusing on industrial and transport workers. Special TB campaigns and sputum collection initiatives were carried out in rural remote and hard-to-reach areas. Screening services were also expanded to urban slums, brickfields, tea gardens, and tailored to reach children and elderly individuals. Cough pots were distributed to potential persons with presumed TB, and collected samples were transported to nearby laboratories for molecular testing, ensuring timely diagnosis and treatment initiation.
Results/Impact: A total of 42,336 persons with presumed TB were tested among transport and industrial workers, resulting in 2,994 confirmed TB patients. Among urban dwellers and vulnerable groups like children and elderly people, 29,431 persons with presumed TB were tested, leading to detection of 2,111 TB patients. Furthermore, 94,260 TB persons with presumed TB were tested by special TB campaign and outreach initiatives in rural remote communities, resulting in 7,115 TB patients' identification.
Conclusions: BRAC's innovative, community-based approaches have improved access to TB services for underserved groups, promoting early diagnosis and equitable care. These models demonstrate the effectiveness of tailored, inclusive service delivery in strengthening national TB control efforts. Sustained investment and scale-up of such inclusive, people-centered approaches are vital to achieving Bangladesh's End TB targets and leaving no one behind.

OA17-264-20 Enhanced diagnosis of asymptomatic tuberculosis in vulnerable populations: Impact of the 100 days TB Mukt Bharat Abhiyan compared to previous year

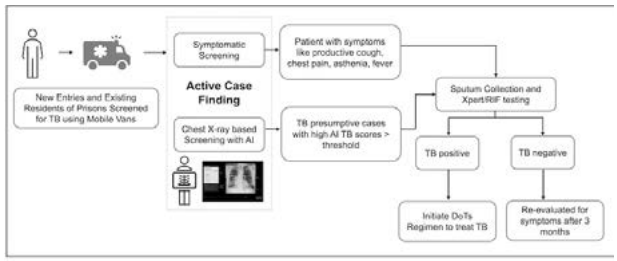
D. Panchal,[1] R. Rao,[2] M. Deka,[1] S. Malviya,[2] U. Singh,[2] [1]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [2]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India
e-mail: panchald@rntcp.org

Background and challenges to implementation: India's tuberculosis (TB) burden remains among the highest globally, with a substantial proportion of cases going undiagnosed—particularly among asymptomatic individuals. As per the National TB Prevalence Survey, 63.6% of symptomatic individuals did not seek care, and many TB cases present without typical symptoms. To address this diagnostic gap, the Government of India launched the 100 Days TB Mukt Bharat Abhiyan on December 7, 2024, with a key focus on screening vulnerable and high-risk populations for early and often asymptomatic TB detection.
Intervention or response: The campaign implemented an aggressive, multi-sectoral approach in 347 high-burden districts, combining mobile diagnostics (Ni-kshay Vahans), handheld X-rays, and NAAT-based molecular testing. High-risk groups—such as undernourished individuals, the elderly, PLHIV, diabetics, and TB contacts—were systematically line-listed and screened through Ayushman Arogya Mandirs and public outreach platforms. Community participation was enabled through Jan Bhagidari, with support from elected representatives, health workers, and civil society actors.
Results/Impact: From December 7, 2024, to March 17, 2025, **2,85,033 asymptomatic TB cases** were diagnosed with a **120% increase** compared to **1,29,464 cases** during the same period in 2023. This significant rise demonstrates the effectiveness of the campaign's targeted screening strategy, advanced diagnostics, and proactive community engagement. The integration of X-ray and NAAT technologies was instrumental in detecting cases that would have gone unnoticed, allowing for earlier intervention and treatment initiation.
Conclusions: The 100 Days TB Campaign markedly improved the detection of asymptomatic TB cases, reaffirming the value of community-based, technology-enabled screening in high-risk groups. These outcomes strengthen the case for sustained, intensified efforts as India strives to eliminate TB.

OA17-265-20 Addressing tuberculosis at the nexus of incarceration and conflict: Computer-aided detection-based mobile active case finding in prisons of Haiti and the Central African Republic

M. Bury,[1] I. Calder,[2] J. May,[2] E. Jean Prophete,[3] K. Duverger,[4]
[1]Health Through Walls, Health Management, Port-au-Prince, Haiti, [2]Health Through Walls, Head Quarters, Miami, United States of America, [3]Health Through Walls, Health Assistance in Prisons, Port-Au-Prince, Haiti, [4]Health Through Walls, Deparment Management, Pap, United States of America
e-mail: mbury@htwinc.org

Background and challenges to implementation: Mobile digital chest X-ray screening with WHO-endorsed computer-aided detection (dCXR+CAD) was used for Tuberculosis (TB) detection in prisons in Haiti and the Central African Republic (CAR). These two low-income countries, facing post-conflict challenges, overcrowded prisons, and a high TB burden (incidence rates of 254 and 540 per 100,000, respectively), were selected for Active Case Finding (ACF) to improve case identification and address inmate vulnerabilities.
Intervention or response: Health through Walls (non-governmental organization) facilitated ACF using dCXR+CAD across 17 and 5 prisons in Haiti and CAR respectively, from March 2023 to December 2024, to systematically screen all newly admitted and existing inmates. Those flagged with a CAD-generated probability score ≥0.5 were classified as TB presumptive and were subsequently confirmed microbiologically using Xpert MTB/RIF and smear microscopy. Treatment was initiated in line with national TB program protocols.



Active case finding workflow implemented at the prisons for early TB triage and treatment.

Results/Impact: In Haiti prisons, 9465 individuals were screened, 547 individuals (5.7%) were flagged by dXR+CAD as TB presumptive, and 236 (TB positivity rate:43.14%; 95% CI: 38.95–47.41%) were microbiologically confirmed. While in CAR prisons, among the 2301 inmates screened, dXR+CAD triaged 281 (12.2%) for TB and 66 cases (TB positivity rate: 23.5%; 95% CI: 18.7–28.9%) were Xpert MTB/RIF confirmed. It was found that the number needed to screen to get one confirmed TB case was 40 in Haiti prisons and slightly lower in CAR (34.8). Notably, a higher proportion of confirmed TB cases had a greater TB score (≥0.90) in CAR (69.1%) than in Haiti (38.13%). The positive predictive value of dXR+CAD for TB detection was 75.2% (95% CI: 70.0–79.8%) in Haiti; this was not estimated for CAR due to unavailable data.
Conclusions: ACF using dCXR+CAD is a feasible and effective strategy to detect TB that is missed by traditional symptomatic screening, particularly in high-risk populations, with dual vulnerabilities like prisons in conflict settings.

OA17-266-20 Facilitators and barriers for the implementation of peer-led tuberculosis active case finding among people who use drugs in Dar es Salaam, Tanzania

L.T. Minja,[1] [1]National Institute for Medical Research, Research Programmes, Mbeya, United Republic of Tanzania
e-mail: liliantinaminja@gmail.com

Background and challenges to implementation: In 2023, an estimated 2.7 million cases of TB were undiagnosed or unreported. To address missing cases, the World Health Organization recommends systematic screening synonymous to TB active case finding (TB-ACF). Despite the high incidence and prevalence of TB among people who use drugs (PWUD), there is a significant gap in data, on their perspectives, regarding the implementation of TB-ACF services. We aimed to explore facilitators and barriers to implementing peer-led TB-ACF, as perceived by both, current and potential service users.
Intervention or response: We conducted in-depth interviews among:
1. Peer PWUD with prior history of illicit drug use and medication-assisted treatment (MAT) (n=10),
2. Current medication-assisted treatment service users receiving clinic-based daily methadone (n=8), and;
3. Community PWUD not on MAT recruited from various community locations (n=4).
All peer PWUD were experienced in TB-ACF. Thematic content analysis was utilized with the support of NVivo12.
Results/Impact: Two categories, individual and structural, with three main themes (1) facilitators, (2) facilitators for targeted improvement and optimization and (3) barriers) were identified. A critical facilitator was the acceptability of peer PWUD in providing TB ACF services. Key facilitators for improvement and optimization included the TB screening tool, mobile TB diagnostic services, integrated methadone/TB services, and monetary incentives to peer PWUD. Barriers included a reluctance to wear face masks due to stigma, misconceptions that prior TB preventive therapy among peers negates their need for protective preventive measures, high mobility of PWUD and the fear of withdrawal symptoms associated with the use of anti-TB medication, leading to non-adherence to TB treatment.
Conclusions: We highlight the crucial role of peer-led approaches in enhancing TB-ACF among PWUD. Peer acceptance as service providers highlights the potential

of community-driven interventions. Future research should explore the feasibility of providing peer-supported TB diagnosis and treatment services at friendly drop-in centers.

OA17-267-20 Integrated NCD and TB screening to improve active case finding in India

T. Chandra,[1] M. Singh,[1] S. Shrivastava,[1] P. Jain,[1]
[1]William J Clinton Foundation, TB, New Delhi, India
e-mail: tchandra@wjcf.in

Background and challenges to implementation: In India, stigma associated with TB leads to delayed diagnosis and treatment. Diabetes, undernourishment, alcohol or tobacco consumption are some of the established key vulnerabilities for tuberculosis in India. However, identification and thereby screening of key & vulnerable populations continues to be a major impediment for ACF interventions due to distance and time, unavailability of sufficient trained health workers, TB stigma and treatment costs.
Intervention or response: Through the Global Fund C19RM grant, William J Clinton Foundation, under the aegis of the Central TB Division (Government of India) has undertaken active case finding for TB in community settings in India through an integrated service delivery-based model, using 41 CAD enabled X-Ray devices. ACF camps, referred to as "Express health camps", involve opportunistic NCD & BMI screening along with TB.
This integrated approach reduces TB stigma, lowers community OOPE, enables targeted mobilization in communities and improves identification of TB-comorbidities such as diabetes and undernourishment.

Category	Availability	Footfall/camp in Presence of	Footfall/camp in Absence of	Difference %
NCD test Availability	Blood Pressure	83	60	+38%
	Random Blood Sugar	83	66	+25%
Health Staff Availability	Accredited Social Health Activist (ASHA)	91	59	+54%
	Auxiliary Nurse Midwives (ANM) or Staff Nurse	87	68	+28%
	Community Health Officer	89	64	+39%

Table.

Results/Impact: Data was analyzed for 10,238 camps held between April 2023 to February 2025. By integrating additional services such as Blood Pressure (BP), Random Blood Sugar (RBS), the camp footfall increased by 38% and 25% respectively.
Additionally, the presence of community level workers improved targeted mobilization of high priority KVPs, that directly resulted in higher case detection rates across all cohorts. 19% of the beneficiaries had BMI<18.5 that contributed to 40% of the total TB confirmations; while tobacco and alcohol consumers formed 33% and 14% of the total cases detected, the KVPs being non-mutually exclusive.
Conclusions: NCD Screening and the involvement of community health workers is crucial for mobilization of targeted populations for community ACF.
Lower footfalls in the absence of NCD indicate that stand alone ACF camps do not adequately serve the community needs - integrated health camp approach targeting the determinants of TB should be the default ACF design.

OA17-268-20 Formative evaluation of community wide screening using ultra-portable handheld X-rays in urban slums of Delhi, India

K. Mukhopadhyaya,[1] R. P.S.,[1] N. Srivastava,[1]
M. E. Mathew,[1] J. Jaju,[1] B. Vadhera,[2] C. Healer,[3] N. Saini,[4]
[1]The International Union Against Tuberculosis and Lung Diseases (The Union), TB, New Delhi, India, [2]USAID, India, TB, New Delhi, India, [3]BJRM Chest clinic, New Delhi, TB, New Delhi, India, [4]State TB Cell, New Delhi, TB, New Delhi, India
e-mail: kamalini.mukhopadhyaya@theunion.org

Background: Delhi is the state with highest burden of TB in India (>700/100000) and studies revealed that 69% did not seek care for their TB symptoms. At least, 14 million individuals live in urban slums of Delhi, with limited access to health care.
A community wide screening using ultra-portable handheld X-rays devices with CAD for TB and testing using rapid molecular test has been implemented in select urban slums since January 2025.
Design/Methods: A multidisciplinary implementation team has been constituted. Logic model, activity plans and standard operating procedures were developed. Formative evaluation has been integrated into the implementation of intervention *to guide the design process.* Project management information system has enabled real-time monitoring of cascade of care data.
Weekly reviews were conducted with the project staff with an intention to optimize operations and document the learnings. Weekly field visits were made and field notes were prepared based on participant observation. Fidelity was assessed using a structured checklist, activity log and administrative data.
Results: A total of 5601 X-rays were taken, 1241 were abnormal. Average number of X-rays taken per day per X-ray unit is 72 (40-123) and is only limited by the number of beneficiaries mobilized from the community.
Number Needed to Test to detect a case of TB was 7 and Number Needed to Screen was 35. Only 70% of presumptive TB could be offered a test. The leaks were minimal in areas where spot collection of specimen and transportation happened.

Major challenges were convincing asymptomatic clients for sputum tests, perceived stigma of the community, unstable internet connection and identifying places to store X-rays on a daily basis.
Conclusions: Project's logic model is plausible, community is responsive. Interventions are being delivered with increasing fidelity and the short-term outcomes are encouraging. Spot collection of specimen and transportation is recommended.

OA18 Building sustainable systems and workforce

OA18-269-20 Leveraging WHO standards to improve TB diagnostic access for universal health coverage in Zambia

J. Mzyece,[1,2] M. Muvwimi,[1] A. Mubanga,[2] J. Chama,[3,2]
[1]Ministry of Health, Pathology and Laboratory Services Unit, Lusaka, Zambia, [2]Ministry of Health, National TB and Leprosy program, Lusaka, Zambia, [3]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Zambia Country Office, Lusaka, Zambia
e-mail: judithmzyece@gmail.com

Background and challenges to implementation: A major goal of Universal Health Coverage (UHC) for Tuberculosis (TB) is to provide access to rapid, accurate TB diagnostics without creating financial hardship for patients. In 2020, TB case detection rate in Zambia was estimated at less than 70 percent of total incidence. This was largely attributable to limited access to diagnostic services. This study utilized the WHO standard benchmarks to assess national TB diagnostic coverage, identify gaps, and evaluate progress over time.
Intervention or response: We conducted a national-level assessment using the WHO standards checklist comprising 12 benchmarks across the four steps of the diagnostic cascade: identifying presumptive TB, accessing testing, being tested, and receiving a diagnosis. The assessment covered 3000 health facilities across all 10 provinces of Zambia. We analyzed data from the national laboratory information system covering the period from 2022 to 2023 (annually).
Results/Impact: Access to rapid diagnostic tests improved from 68% in 2020 100% in 2023, with 96% of patients having a WRD test as the initial diagnostic test. The average turnaround time decreased from 7+ days in 2020 to 4 days in 2024. Lusaka province had the highest access (100%) and Western province the lowest (92%). Proportion of samples tested onsite increased 2-fold from 25% to 50%. The average distance traveled per sample decreased from 100km to 50km. The percentage of test results delivered within the same day increased from 26% in 2020 to 56.3% in 2023.
Conclusions: The WHO Benchmarks checklist proved effective in assessing both system capacity and programmatic requirements for TB diagnostics in Zambia. Zambia identified specific gaps in the diagnostic cascade and targeted resources to strengthen the TB diagnostic network. Continued application of these standards will be essential for monitoring progress toward ending TB in Zambia.

OA18-270-20 Building resilient health systems: Enhancing tuberculosis control in Ghana's private sector through capacity building

E. Sam,[1] N. Asare,[1] G. Okyere,[1] D. Dornor,[1] F. Ayichuru,[1] A. Koyaara,[1] N.K. Quakyi,[1] E. Asampong,[2] Y. Adusi- Poku,[3]
[1]The Aurum Institute Ghana, International Division, Accra, Ghana, [2]University of Ghana, School of Public Health, Legon, Accra, Ghana, [3]National Tuberculosis Programme, Ghana Health Service, Accra, Ghana
e-mail: ESam@auruminstitute.org

Background and challenges to implementation: The private sector provides approximately 40% of healthcare services in Ghana yet remains underutilized in the screening and management of tuberculosis (TB). Due to this historical under-engagement, the private sector faces limited workforce capacity for effective TB care – including lack of awareness of national guidelines - posing a major barrier to achieving national TB elimination goals.
Intervention or response: To address these gaps, Aurum Institute Ghana launched a capacity-building intervention in 2024 through the Public-Private Mix initiative of the Global Fund Cycle 7 grant. The program trained 375 private sector health providers - including doctors, nurses, pharmacists, laboratory personnel, and data officers - across 90 high-volume private health facilities. The blended learning approach combined in-person workshops on TB screening, diagnosis, treatment protocols, and case notification guidelines with onsite mentorship and supportive supervision. Digital reporting tools were introduced to improve real-time case notifications and enhance linkage to public health systems. Pre-training assessments revealed deficiencies in TB symptom recognition, diagnostic practices, and adherence to treatment guidelines.
Results/Impact: Post-training evaluations demonstrated significant improvements in TB case detection, diagnostic accuracy, and adherence to national treatment guidelines. Pre-training assessments showed a 42% knowledge gap in symptom recognition and a 50% deficiency in diagnostic practices. Post-training assessments indicated a 90% improvement in symptom identification, 85% improvement in diagnostic accuracy, and enhanced adherence to treatment protocols. Evaluations were executed through quizzes, case studies and observational assessments. Key outcomes included the identification of 602 new TB cases within a year, improved treatment initiation, reduced loss to follow-up, and strengthened public-private collaboration.
Conclusions: This intervention highlights the potential of capacity-building initiatives to strengthen TB control in the private sector. By improving provider knowledge and fostering public-private collaboration, this model offers a scalable framework for optimizing TB services, contributing to global TB elimination goals.

OA18-271-20 Capacity building for health workers: Enhancing prevention of mother-to-child transmission (PMTCT) and TB/HIV services in resource-constrained environments – The Katsina experience

A. Galadima,[1] I. Lawrence,[2] R. Abi,[1] P. Shie,[1] M. Sheshi,[3] A. Okoh,[4] B. Odume,[5] O. Adebayo,[6] T. Adetiba,[7] O. Olupitan,[6] E. Ubochioma,[8] A. Reilly,[9] [1]KNCV Nigeria, Technical, Katsina, Nigeria, [2]KNCV Nigeria, Program, Katsina, Nigeria, [3]KNCV Nigeria, Private Sector, Abuja, Nigeria, [4]KNCV Nigeria, Technical, Abuja, Nigeria, [5]KNCV Nigeria, Executive, Abuja, Nigeria, [6]Institute of Human Virology, Nigeria (IHVN), Program, Abuja, Nigeria, [7]Institute of Human Virology, Nigeria (IHVN), Technical, Abuja, Nigeria, [8]National TB and Leprocy and Buruli Ulcer Control Programme Nigeria, Program, Abuja, Nigeria, [9]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Geneva, Switzerland, Program, Switzerland, Switzerland
e-mail: agaladima@kncvnigeria.org

Background and challenges to implementation: Mother-to-child transmission of HIV, alongside TB/HIV co-infection, remains a significant public health challenge in resource-limited settings like Katsina State, Nigeria. Barriers such as inadequate healthcare infrastructure, insufficient skilled personnel, and weak community engagement hinder effective delivery of Prevention of Mother-to-Child Transmission (PMTCT) and TB/HIV services. To address these challenges, KNCV Nigeria, with funding from the Global Fund, is implementing a three-year TB/HIV grant aimed at strengthening healthcare capacity to improve TB/HIV outcomes.
Intervention or response: In September 2024, a structured capacity-building program trained 614 individuals, including community TB/HIV workers, Community volunteers, mentor mothers, and traditional birth attendants. Training covered TB screening, HIV testing, counselling, referral pathways, and linkage to care for TB/HIV-positive pregnant women.
The community TB/HIV workers and Traditional birth attendants facilitate TB/HIV outreaches, while mentor mothers provided continuous support to HIV-positive mothers. A data-driven approach monitored the impact of the intervention, focusing on TB/HIV testing rates and treatment coverage.
Results/Impact: From October to December 2024 a total of 31,704 pregnant women were screened for TB/HIV, with a 2.2% HIV positivity rate. All HIV-positive pregnant women were linked to antiretroviral therapy (ART), significantly reducing the risk of mother-to-child transmission. 1967 presumptive cases were identified and evaluated. 78 pregnant women were diagnosed with TB and enrolled on treatment.
Conclusions: These results demonstrate the effectiveness of capacity-building strategies in strengthening PMTCT and TB/HIV services in resource-constrained settings. Strengthening health worker capacity is key to improving

PMTCT and TB/HIV outcomes. Future efforts should focus on expanding service coverage, strengthening health systems, and fostering strategic partnerships for long-term impact..

OA18-272-20 Sustaining best practices: An iECHO hub model

K. Lockhart,[1] D. Vambe,[2] A. Kay,[2] C. Cazier,[1] T. Steffy,[3] B. O'Brien,[4] A. Munthali,[5] L. Komba,[6] P. Elyanu,[7] A. Mandalakas,[1] [1]Baylor College of Medicine, Global Tuberculosis Program, Houston, United States of America, [2]Baylor College of Medicine, Global Tuberculosis Program, Mbabane, Eswatini, [3]Baylor College of Medicine, BIPAI International, Maseru, Lesotho, [4]Baylor College of Medicine, BIPAI International, Lilongwe, Malawi, [5]Baylor College of Medicine Children's Foundation Malawi, BIPAI International, Lilongwe, Malawi, [6]Baylor College of Medicine Children's Foundation-Tanzania, BIPAI International, Mbeya, United Republic of Tanzania, [7]Baylor College of Medicine Children's Foundation-Uganda, BIPAI International, Kampala, Uganda
e-mail: kai.lockhart@bcm.edu

Background and challenges to implementation: There are over 200 TB/HIV-focused ECHO programs globally but limited multi-country ECHO Hubs. The ECHO platform allows for easy participant management, scheduling sessions, and collecting demographic data such as country, institution, and profession. It is accessible through mobile devices, apps, and web browsers. TB GAPS ECHO Hub launched in September 2023 and supports disseminating evidence-based best practices across multiple high-TB burden countries: Eswatini, Lesotho, Malawi, Tanzania, and Uganda.
Intervention or response: A core team consisting of site leads and partners developed a schedule of monthly sessions and quarterly webinars on pediatric TB prevention, screening, diagnosis, and treatment. A digital flyer supplied participants with detailed registration instructions for the ECHOHub. Participants and partners are engaged with reminder emails directly through the platform for each session. The ECHO Hub houses pediatric and adolescent TB and TB/HIV guideline updates, provider and implementation job aids, and forums for sharing experiences to strengthen clinical, research, and policy competencies.
Results/Impact: Between September 2023 and March 2025, the program hosted 13 sessions with holiday breaks on topics in pediatric and adolescent HIV/TB prevention, care, and treatment. Of the 198 registered participants, 114 were regularly active, with an average attendance of 23 learners per completed session. The geographic reach included 14 countries and 61 learning sites. Participants represented implementing partners, clinicians, and providers. Other audiences included representatives from Ministries of Health, National Tuberculosis, and AIDS control Programs.

Conclusions: The platform's ease of use and ability to collect and analyze participant data make it a valuable tool for expanding the reach of TB best practices globally. Global reach allowed formal collaboration with the Lesotho MOH ECHOHub and presentations from colleagues and partner projects. This collaboration contributes to the ECHO hub's long-term plan for sustainability, integrating into existing regional systems.

OA18-273-20 Utilizing a grading tool to improve performance of reference laboratories in India's National TB Elimination Programme

N. Kumar,[1] J. Kayesth,[2] A. Kamble,[1] P. Desikan,[3] M. Bhalla,[4] S. Shanmugam,[5] M. HG,[6] S. Giri,[7] H. Singh,[8] L. Rajagopalan,[2] U. Singh,[1] [1]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [3]Bhopal Memorial Hospital and Research Centre, Department of Microbiology, Bhopal, India, [4]National Institute of TB and Respiratory Diseases, Department of Microbiology, Bhopal, India, [5]ICMR-NIRT, Department of Bacteriology, Chennai, India, [6]National Tuberculosis Institute, National Reference Laboratory, Bangalore, India, [7]Regional Medical Research Centre (RMRC), National Reference Laboratory, Bhubaneshwar, India, [8]National JALMA Institute for Leprosy and Other Mycobacterial Diseases, National Reference Laboratory, Agra, India
e-mail: kayesthj@rntcp.org

Background and challenges to implementation: The laboratory network under the National TB Elimination Programme (NTEP) of India is one of the world's largest, aiming to provide high-quality TB diagnostic services with a patient-centric approach. The NTEP recognizes TB control efforts in states using a standardized process to identify strong performers, but similar processes to recognize TB laboratories is lacking.
Intervention or response: To identify programmatic areas for improvement and enhance laboratory performance for better diagnostic services, the Central TB Division (CTD) developed a tool to assess the performance on mandated functions of strategic TB laboratories (Interme-

diate Reference Laboratories; IRLs), including diagnostic service quality, supervision, and monitoring. The grading tool is a structured questionnaire in an Excel file, grouped into nine thematic areas. The tool was initially piloted at two National Reference Laboratories (NRLs) and linked IRLs. Subsequently, 31 IRLs self-assessed themselves using the tool.

Results/Impact: The first round of self-assessment by IRLs was completed and scores were analyzed for 28 IRLs with complete information. Most IRLs scored higher in implementing standard operating and technical procedures, and participating in external quality assessment programs, as per NTEP policy. IRLs scored lower in completing the diagnostic testing cascade, supervision and monitoring activities, followed by biosafety and human resource availability and competency (Figure 1).

These findings highlight scope of improvement and the need for targeted capacity building for identified components. Routine self-assessment by IRLs will empower laboratories to identify persistent weaknesses and work with the CTD and NRLs to take corrective actions to improve performance.

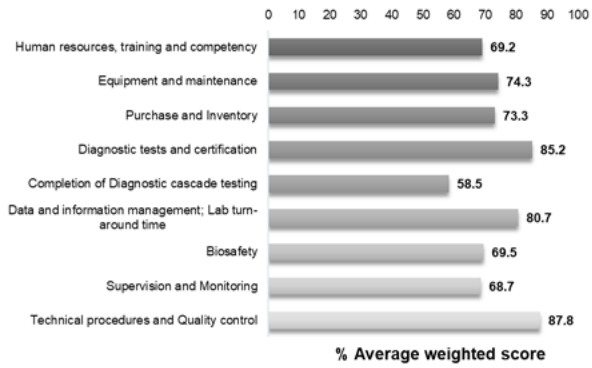


Figure 1. Percentage average scores in the nine thematic areas.

Conclusions: The tool empowers laboratory managers and program managers at state and national levels to understand existing strengths, critical gaps, and underlying challenges. The tool builds NRL and IRL governance capacity for TB diagnostic services, allowing them to institute corrective actions and healthy competition among state-level TB laboratories.

OA18-274-20 Empowered to power machines: GeneXpert superuser model optimizing TB diagnostics in Kenya

J. Ogoro,[1] J. Marcomic,[2] K. Muimi,[3] C. Githinji,[1] [1]National Division of Tuberculosis, Leprosy and Lung Diseases, State Department of Public Health and Professional Standards, Nairobi, Kenya, [2]Amref Health Africa, Amref, Nairobi, Kenya, [3]Centre for Health Solutions Kenya, Laboratory, Nairobi, Kenya
e-mail: jogoro@nltp.co.ke

Background and challenges to implementation: The GeneXpert platform has revolutionized TB diagnostics by enabling rapid and accurate molecular testing. However, challenges such as frequent instrument errors, prolonged equipment downtime, suboptimal utilization, and delays in Service-Level Agreement (SLA) follow-up have hindered its full potential in high tb-burden settings.

To address these gaps, Kenya introduced a GeneXpert Superuser model aimed at decentralizing technical expertise, strengthening diagnostic networks, and enhancing system responsiveness.

Intervention or response: Experienced laboratory professionals were identified and trained as GeneXpert superusers in all 47 counties. The training focused on advanced troubleshooting, error code interpretation, basic module repair, SLA monitoring, and remote support tools. Each superuser was assigned a cluster of facilities within their County to provide real-time technical support, mentorship, and performance monitoring. Superuser quarterly review meetings were conducted to assess the impact on key performance indicators.

Results/Impact: A total of 211 GeneXpert sites supported by GeneXpert superusers demonstrated marked improvements across key operational metrics. Equipment downtime has significantly reduced due to on-site technical troubleshooting and timely escalation of issues. Error rates decreased as users received prompt guidance on pre-analytical and analytical procedures. Utilization rates improved from 2022 (24%) to 2023 (38%) and 2024(49%) in the recent three years, driven by increased user confidence and reduced machine idle time.

Additionally, SLA follow-up became more effective, with all reported issues being resolved within the contracted timeframe. The model also fostered peer learning and boosted regional ownership of diagnostic quality.

Conclusions: The Superuser model is a practical, scalable approach that enhances diagnostic performance, reduces delays, and ensures the continuity of TB testing services. Its success in Kenya highlights its potential for adoption in other countries, aiming to strengthen molecular diagnostic networks.

OA18-275-20 Closing the diagnostic gap: How Nigeria's optimized sample transport networks boosted TB case detection by 105% – A model for scale-up?

A. Joseph,[1] H. Baffa,[1] F. Babayo,[1] A. Okoh,[2] M. Sheshi,[2] A. Adekunle,[3] T. Adetiba,[3] E. Ubochioma,[4] J. Ssekitoleko,[5] J. Kimeu,[5] B. Odume,[6,2] M. Tukur,[1] [1]KNCV Nigeria, Program, Kano, Nigeria, [2]KNCV Nigeria, Program, Abuja, Nigeria, [3]IHVN, Program, Abuja, Nigeria, [4]National TB and Leprocy and Buruli Ulcer Control Programme Nigeria, Program, Abuja, Nigeria, [5]Global Fund, Program, Geneva, Switzerland, [6]KNCV, PROGRAM, Abuja, Nigeria
e-mail: ajoseph@kncvnigeria.org

Background and challenges to implementation: Timely tuberculosis diagnosis remains challenging in low-resource settings like Nigeria, where 2022 case detection was only 50% (WHO). Kano State's high burden and logistical hurdles especially in hard-to-reach areas worsened delays. This Global Fund supported study (2022–2024) assessed an optimized sample referral system using trained riders, monthly incentives, and prioritized inter-LGA transport to improve detection. The intervention aligned with Nigeria's TB Plan, targeting strengthened specimen networks to bridge the diagnostic gap.
Intervention or response: A retrospective analysis (2022-2024) was conducted across all 44 LGAs in Kano state to assess TB case identification and sample movement data. In collaboration with the State TB Program (STBLCP) and Global Fund support, the intervention included; training 786 sample movers from DOTs clinics on biosafety, sample packaging and digital tracking; transitioning to performance-based monthly incentives; and stratifying by intra- and inter-LGA movement. Data were analyzed for trends in presumptive TB evaluations, case yield, and turnaround time.
Results/Impact: Following the intervention, presumptive TB evaluations rose from 326,128 (2022) to 462,696 (2024)—a 42% cumulative increase (annual average: +19.4%). TB case detection surged from 17,939 (2022) to 36,738 (2024) (+105%; p<0.01), with the high yields in LGAs receiving monthly incentives. Turnaround time plummeted from 14 to 3 days (78% reduction), exceeding the WHO target of <7 days for DR-TB diagnostics.

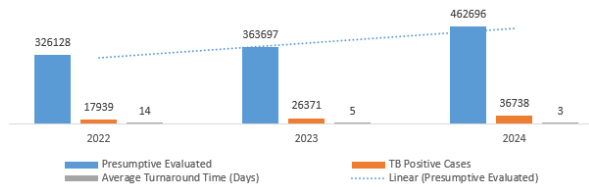

Figure. Three years trend showcasing sample movement and case identification data from 2022 to 2024.

Conclusions: Optimizing sample movement logistics with trained riders and tailored incentives significantly improved TB case detection and reduced diagnostic delays in Kano State, particularly in hard-to-reach areas. This model addresses a critical health system barrier identified in the WHO's 2023–2027 TB Strategy and Nigeria's UHC agenda. To sustain gains, we recommend: scaling the incentive-based transport system nationally, integrating GPS tracking for real-time monitoring, and deploying decentralized molecular platforms in priority LGAs.

OA18-276-20 Scaling-up and optimization of laboratories for diagnosing drug-resistant TB in Uttar Pradesh, India

B.K. Shetty,[1] P. Singh,[1] R. Tripathi,[1] R. Washington,[1] [1]India Health Action Trust, Programs, Lucknow, India
e-mail: bharatesh.shetty@ihat.in

Background and challenges to implementation: While molecular WHO recommended rapid diagnostics (mWRD) detects rifampicin resistance, identifying mono-resistance to isoniazid or second-line fluoroquinolones mandates testing with Line Probe Assays (LPA) and liquid culture and drug sensitivity testing (L-CDST). This aids clinical decision-making for individualising DR-TB treatment, enhances patient outcomes, and helps reduce transmission.
Despite the presence of seven LPA labs in Uttar Pradesh, LPA testing coverage among MTB detected samples and utilization remained suboptimal. This highlighted the need to scale-up the LPA and improve laboratory capacity utilization.
Intervention or response: India Health Action Trust (IHAT) under the Gates Foundation Diagnostic Network Optimization Project collaborated with the State TB Cell, Lucknow and intermediate reference laboratories. IHAT conducted laboratory assessments, identified gaps between testing demand and capacity, standardized quality assurance protocols, optimized sample referral systems, streamlined logistics, and provided on-site training, supervision, and monitoring.
This collaborative approach enabled the operationalization of new LPA labs and enhanced the utilization of existing ones.
Results/Impact: The baseline assessment in 2023 revealed that LPA testing capacity met only one-third of the actual demand. IHAT interventions led to over 107,000 tests conducted in 2024, double the 48,730 tests in 2023.
Similarly, L-CDST testing increased from 33,728 tests in 2023 to 68,861 in 2024. Three new LPA labs became operational in 2024, with two more expected by mid-2025.
Conclusions: This initiative demonstrated that comprehensive assessments, combined with collaborative, multi-pronged strategies to address key gaps, can significantly enhance DR-TB diagnostic capacity and utilization, thereby strengthening overall DR-TB diagnostic services.

OA18-277-20 Transforming primary healthcare services through strategic mentorship approaches in Machakos County, Kenya

E. Atieno Odhiambo,[1] L. Mengo,[1] K. Kioko,[1] H. Ngeso,[1] [1]CMMB, Programs, Machakos, Kenya
e-mail: atienoliz004@gmail.com

Background and challenges to implementation: At the Primary HealthCare (PHC) level, health services depend on accurate, timely, and reliable data to support evidence-based decision-making. However, Community Health Promoters (CHPs) often lack the technical capacity to effectively utilize data for program improvement. To address this gap, in October 2022, the Center for Medical Mobilization Board (CMMB), with support from the Global Fund through Amref, implemented the Kenya Quality Model for Health (KQMH) in Machakos County, Kenya. The initiative aimed to strengthen data understanding and promote its application in generating informed community health solutions.
Intervention or response: Beginning October 2023, ten Community Health Units (CHUs) received structured mentorship to reinforce the KQMH model. The mentorship targeted Work Improvement Teams (WITs), each comprising nine members: one Community Health Assistant, three CHPs, one facility board member, one healthcare provider, and three community representatives—including an adolescent, a person with a disability (PWD), and a community health committee member. Using data from their linked health facilities, WITs assessed performance across key indicators, identified the lowest-performing areas through participatory voting, and implemented targeted interventions using the Plan-Do-Study-Act (PDSA) cycle.
To support effective implementation, CMMB and the county health management teams introduced quarterly mentorship visits. These sessions included one-on-one engagements, review of records, and assessment of usages of tools such as the PDSA cycle and fishbone diagrams—guided by standard mentorship questions. The results were logged online using the Log Alto tool.
While initial implementation in October 2022 showed limited progress, the mentorship sessions introduced in October 2023 triggered steady quarterly improvements in data use and WIT performance.
Results/Impact: Between October 2023 and June 2024, WITs showed consistent improvement, with average performance scores rising gradually from 55% to 75%, and reaching 84% by June 2024.
Conclusions: Mentorship, when combined with community participation and data-driven strategies, is a powerful catalyst for transforming PHC.

OA19 It's all about the money: Optimising TB care

OA19-278-20 TBI tests for contact screening in Brazil: A cost-effectiveness analysis

F. Souza,[1] R. Steffen,[2] M. Pinto,[3] T. Prado,[4] A. Trajman,[5] [1]Federal University of Rio de Janeiro, Internal Medicine, Rio de Janeiro, Brazil, [2]State University of Rio de Janeiro, Institute of Social Medicine, Rio de Janeiro, Brazil, [3]Oswaldo Cruz Foundation, Clinical Research Unit and the Health Technology Assessment (HTA) Center at the Fernandes Figueira Institute (FIOCRUZ), Rio de Janeiro, Brazil, [4]Federal University of Espírito Santo, Nursing Department, Vitória, Brazil, [5]Federal University of Rio de Janeiro, Medical School, Rio de Janeiro, Brazil
e-mail: atrajman@gmail.com

Background: Tuberculosis infection (TBI) testing is recommended in Brazil for household contacts (HHC) of all ages. However, recurring shortages of purified protein derivative and the restricted indication of interferon-gamma release assays (IGRAs)—limited to people living with HIV and children aged 2–10 years—have constrained diagnostic coverage. The World Health Organization recently recommended three new tuberculosis (TB) antigen-based skin tests (TBSTs) - Diaskintest®, C-TST®, Cy-TB® - for TBI diagnosis.
Given the elevated risk of TBI among HHC, we assessed the cost-effectiveness TBSTs and of QuantiFERON-TB Plus® (QFT-Plus®) in comparison to the tuberculin skin test (TST) in Brazil.
Design/Methods: We developed a state-transition Markov model simulating four hypothetical cohorts of 10,000 HIV-negative HHCs across distinct age groups (3 months to 4 years, 5-9 years, 10-14 years, and 15 or older) over five annual cycles. The model evaluated testing and TB preventive treatment from the Brazilian public health system perspective.
Effectiveness estimates were derived from systematic reviews. Cost data were obtained from the Brazilian government (TST and QFT-Plus®) and from manufacturers (TBST). We calculated the incremental cost-effectiveness ratio (ICER) per TB case averted.

Age group	Strategy	Cost	Incremental cost	TB cases avoided	Incremental TB cases avoided	ICER	C/E
3 months to 4 years old	TST	508,976	Reference	151	Reference	Reference	3,375
	QFT-Plus®	615,157	106,182	154	3	35,810	4,001
	Cy-TB®	327,401	-181,575	124	-26	6,854	2,634
5 to 9 years old	TST	677,911	Reference	223	Reference	Reference	3,038
	Cy-TB®	396,791	-281,121	180	-43	6,547	2,202
10 to 14 years old	TST	336,931	Reference	213	Reference	Reference	1,579
	Cy-TB®	235,588	-101,343	175	-38	2,658	1,345
15 years old or more	TST	584,024	Reference	889	Reference	Reference	657
	Diaskintest®	517,481	-66,544	932	43	-1,535	555

Results: TBSTs demonstrated similar accuracy to QFT-Plus® and higher specificity than TST. All TBSTs were less costly and cost-saving across all age groups when compared to both TST and QFT-Plus®. Cy-Tb® was the most cost-saving, followed by Diaskintest® and C-TST®.
Conclusions: The adoption of TBSTs for screening HHCs in the Brazilian public health system would be a cost-saving strategy. Because these tests require the same infrastructure and human resources skills as TST, the tests could be readily implemented.

OA19-279-20 Improving resource allocation for TB programmes: A mechanistic cost function approach for efficient priority setting

A. Madriz,[1] F. Bozzani,[2] [1]London School of Hygiene and Tropical Medicine, Global Health and Development, London, United Kingdom of Great Britain and Northern Ireland, [2]London School of Hygiene and Tropical Medicine, Global Health and Development, Lusaka, Zambia
e-mail: andres.madriz-montero@lshtm.ac.uk

Background: TB services in LMICs are primarily delivered by primary care providers, offering a low-cost, versatile platform that can achieve efficiency gains through task shifting, decentralization, and outreach. However, the costs of these services vary significantly by platform capacity, scale, scope, and implementation efficiency. When integrating or expanding services, these factors are crucial in determining the cost of delivery. Accurate cost estimation for services at scale remains a significant challenge. Current costing models often assume constant marginal costs, a linear approach that fails to capture economies of scale and scope. This limitation hinders decision-making, as traditional models overlook the complexities of varying unit costs, especially when scaling TB interventions in resource-constrained settings.
Design/Methods: This research, part of the CAPTURE project, followed a three-step approach. First, a review and collection of available data from costing initiatives like Integra and South Africa's TB Think Tank were conducted. Second, a context-specific cost function framework was developed based on relevant literature, allowing for the specification of fixed and variable costs and enabling investments to address capacity constraints. In the third step, the cost model was parameterized and tested using the Integra dataset to predict delivery costs across facilities.
Results: The cost function provided more accurate estimates of costs at scale for TB programs compared to traditional methods. By accounting for economies of scale and scope, the model generated improved cost estimates for integrating and expanding TB interventions within primary care platforms. These results were summarized into three use cases, highlighting the model's potential for guiding cost-effective decisions in resource-constrained settings.
Conclusions: This study developed a robust mechanistic cost model for estimating TB service costs at scale, addressing local capacity constraints. The model and data collection tool support allocative efficiency analyses, improving decision-making for scaling interventions and optimizing resource use in primary care systems.

OA19-280-20 Cost-effectiveness of utilising CAD in an active case finding community screening programme to detect TB in Tamil Nadu, India

A. Frederick,[1] R. Kubendiran,[1] T. Neelakantan,[1] K.K. Shankar,[1]
[1]Department of Health and Family Welfare, Chennai, India
e-mail: stotn@rntcp.org

Background: The Global Tuberculosis Report 2024 reveals that 87% of the global TB burden is concentrated in 30 high-TB-burden countries, with India accounting for 26% of estimated cases worldwide. India represents 16% of the global gap between TB incidence and diagnosed cases, highlighting the urgent need to enhance case detection and treatment coverage.
Design/Methods: A cost analysis was conducted for two modes of active TB case finding carried out in 10 districts of Tamil Nadu, India, comparing two TB screening approaches. Five districts implemented AI-aided screening, while the other five used conventional X-ray screening methods.
This study analyzed two components of the program:
a. Patient diagnostic path (PDP), which estimated the cost of finding one patient with sputum-positive TB in both screening methods, and;
b. Clinical care path (CCP), which estimated the Quality Adjusted Life Years (QALY) gained after treatment completion.

Districts	Population Screened	Patient Diagnostic Path Cost	Clinical Care Path Cost	Total Cost	Screening Cost per Patient	Screening Cost per 1000 Patients	Cost to find one patient sputum-positive-TB
AI-aided Screening							
Tirunelveli	15129	$ 64,852.16	$ 3,880.88	$ 68,733.04			
Tiruchirapalli	14861	$ 47,820.80	$ 4,376.32	$ 52,197.12			
Salem	12922	$ 44,350.81	$ 7,514.05	$ 51,864.87	$ 4.13	$ 4,131.36	$ 709.77
Vellore	11634	$ 47,289.36	$ 2,312.02	$ 49,601.38			
Kanchipuram	9536	$ 60,432.52	$ 2,146.87	$ 62,579.40			
Total	64082	$ 264,745.66	$ 20,230.14	$ 284,975.80			
Conventional Screening							
Viluppuram	12938	$ 47,740.83	$ 825.72	$ 48,566.55			
Coimbatore	5521	$ 48,894.97	$ 743.15	$ 49,638.12			
Madurai	7672	$ 25,820.98	$ 2,642.30	$ 28,463.29	$ 4.69	$ 4,688.41	$ 1,287.88
Cuddalore	9324	$ 37,015.04	$ 825.72	$ 37,840.76			
Tirupur	9320	$ 50,451.91	$ 1,238.58	$ 51,690.49			
Total	44775	$ 209,923.74	$ 6,275.47	$ 216,199.21			

Study Setting	Population Screened	Total TB Cases Detected	Patients Cured	Total QALYs Gained	Cost per QALY gained (₹)	CET for India	ICER
AI-aided Screening	64082	373	245	1445.72	$ 189.28	$495.42	$60.18
Conventional Screening	44775	163	76	432.79	$ 491.43		

Table.

Results: The study screened 108,857 individuals, with 44,775 examined through conventional methods and 64,082 using AI-assisted screening. The AI-assisted approach demonstrated significant improvements in costs, with the cost per patient screened reduced by 11.94% from $ 4.69 to $ 4.13 and the cost to find one patient with sputum-positive TB reduced by 44.88% from $ 1,287.88

to $ 709.77. There was a significant increase in the net QALYs, amounting to 234.05% (1,445.72 versus 432.79). The incremental cost-effectiveness ratio (ICER) was $60.2 per additional QALY gained, which is 87.85% lower than India's cost-effectiveness threshold (CET) of $495.42.
Conclusions: This economic evaluation provides compelling evidence that AI-assisted TB screening is cost-effective for case detection in resource-limited settings. The integration of artificial intelligence into TB screening programs demonstrated significant advantages over conventional methods, offering a promising strategy to address the substantial TB burden in high-prevalence regions.

OA19-281-20 Impact and cost-effectiveness of implementing household contact tracing, including TB preventive treatment in Nepal: A model-based analysis

R. Paudel,[1] A. Thapa,[1] S. Shrestha,[2] K. Dorjee,[3] R. Dhital,[1] D. Dowdy,[4] M. Caws,[1,5] S. Shrestha,[4] [1]Birat Nepal Medical Trust, Department of Research, Kathmandu, Nepal, [2]University of Ottawa, School of Epidemiology and Public Health, Ottawa, Canada, [3]Johns Hopkins School of Medicine, Department of Medicine, Baltimore, United States of America, [4]Johns Hopkins School of Public Health, Department of Epidemiology, Baltimore, United States of America, [5]Liverpool School of Tropical Medicine, Department of Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: paudelrajan111@gmail.com

Background: The burden of tuberculosis (TB) remains unacceptably high globally, and it is increasingly recognized that preventive treatment should be integral in fighting TB, even in high-burden settings like Nepal. To scale up preventive treatment, high-quality, local evidence of feasibility and impact is urgently needed.
Design/Methods: We collected data on the costs and yields of implementing three months of isoniazid and rifapentine (3HP) to treat latent TB infection (LTBI), including ruling out and treating TB disease, among adult household contact persons from a pilot study conducted in two districts of Nepal (Chitwan and Pyuthan) in 2022. We developed and calibrated mathematical models representing each district and estimated the number of TB episodes and deaths averted by the intervention during 2023—2042. By combining net discounted costs and discounted impact, we estimated incremental cost-effectiveness of the intervention (compared to no intervention) from a health system perspective as costs (2022 USD) per disability-adjusted life-year (DALY) averted.
Results: The intervention screened 1711 adult household contact persons for TB and LTBI and treated 500 individuals for LTBI, achieving 98% 3HP acceptance and 95% completion at 150 USD per contact person treated (including drug and test procurement and implementation costs). Including the impact of treating TB disease, the intervention was projected to avert 179 disease episodes and 27 deaths during 2023-2042, or 10.5 episodes and 1.5 deaths averted per 100 contact persons screened. The incremental cost-effectiveness of the intervention was 31 USD (14 – 60) and 71 USD (45 – 112) per DALY averted in Chitwan and Pyuthan, respectively, well below Nepal's per-capita gross domestic product.

	Cost in 2022 figures (95% Uncertainty Interval)			Epidemiological Impact (95% Uncertainty Interval)			Cost-effectiveness (95% Uncertainty Interval)
District	Total Cost of Intervention	Estimated future cost savings (associated with TB treatment)	Net Cost	TB episodes averted	TB deaths averted	Discounted estimated DALYs averted	Cost per DALY averted
Chitwan	$39,441	$25,830 (18586 - 31531)	$13611 (7910 - 20855)	113 (80 – 141)	17 (12 – 25)	447 (326 - 601)	31 (14 - 60)
Pyuthan	$33,013	$15,132 (11249 - 18794)	$17,838 (14219 - 21764)	66 (48 – 82)	10 (7 – 14)	252 (186 - 346)	71 (45 - 112)
Combined	$73,829	$40,962 (23834 - 50325)	$31,2491 (22128 - 42619)	179 (128 – 226)	27 (19 – 39)	700 (511 - 946)	51 (29 - 85)

Conclusions: Screening and treating household contact persons for both TB and LTBI can be successfully implemented in both rural and urban settings in a cost-effective manner and should be prioritized to reduce the TB burden in Nepal and similar high-burden countries.

OA19-282-20 Cost-effectiveness of replacing 6-9H isoniazid monotherapy with 3HP for TB preventive therapy in Brazil: A national and sub-national analysis

K. Villalva-Serra,[1,2,3] B. Barreto-Duarte,[1,2,3] M. Rodrigues,[2,4] A. Queiroz,[1,2,3] J. Croda,[5,6] V. Rolla,[7] A. Kritski,[8] T. Sterling,[9] M. Cordeiro-Santos,[10,11,12] M. Araujo-Pereira,[13,1,14] B. e-mail: klaussvs1@gmail.com

Background: Tuberculosis (TB) remains a major public health challenge in Brazil, with an estimated economic burden of $1.3 billion between 2015-2022. TB preventive therapy (TPT) is essential for reducing transmission and economic burden, yet evidence on the cost-effectiveness of different regimens in Brazil remains limited.

Design/Methods: We conducted a cost-effectiveness analysis comparing the shortened 3HP regimen (three months of weekly isoniazid + rifapentine) to traditional 6–9 months of daily isoniazid (6-9H). Using real-world national and state-level surveillance data from Brazil's TPT notification system, we assessed treatment completion rates from individuals initiating TPT between 2019–2023. Cost and TB-related disability-adjusted life years (DALYs) were modelled using counterfactual historical scenarios (2019–2023) and future coverage scenarios (2024–2030), assuming 75% or 100% 3HP prescription coverage. Probabilistic sensitivity analyses (PSA) assessed robustness of results.

Results: Among 126,802 notified prescriptions, 23% received the 3HP regimen, demonstrating higher completion rates (88.8%) compared to 6-9H (76.6%). Economic modelling with PSA showed scaling up 3HP consistently reduced overall healthcare costs and TB-related DALYs, resulting in negative incremental cost-effectiveness ratios (ICERs) (Figure 1). Under universal (100%) adoption of 3HP, estimated net monetary benefits reached $35.8 million [95% CI: $17.8–$58.8 million] for the counterfactual period and $50.3 million [$16.2–$94.2 million] for future scenarios. Subnational analyses indicated that regions with high TB burden but low current 3HP usage, including the state of São Paulo, would achieve significant economic gains by increasing 3HP coverage.

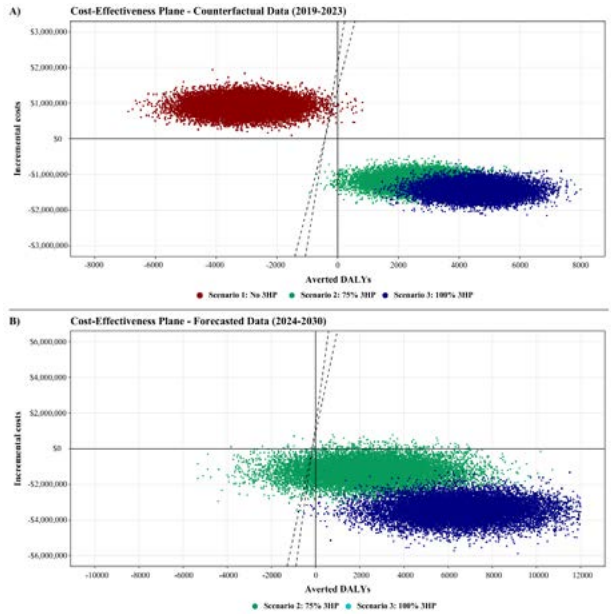

Figure 1. Cost-effectiveness planes comparing scenarios increasing 3HP coverage

Conclusions: Transitioning from traditional isoniazid monotherapy (6-9H) to the shorter 3HP regimen would improve treatment completion rates, while also offering substantial economic savings and reductions in TB-burden across Brazil. This cost-effective strategy presents an impactful opportunity for national and state health policymakers to optimize limited resources, accelerate progress toward TB elimination, and alleviate economic strain on healthcare systems.

OA19-283-20 Cost effectiveness of 1HP vs 3HP in HIV-negative contact persons with latent TB infection in Brazil

C. Baillie,[1] B. Durovni,[2] M. Cordeiro Dos Santos,[3] S. Cavalcante,[4] S. Cohn,[1] B. Kohler,[1] R. Spener,[3] J. Garcia,[2] R. Thompson,[5] D. Dowdy,[6] R. Chaisson,[1] N. Salazar-Austin,[1] [1]Johns Hopkins University, Department of Medicine, Baltimore, United States of America, [2]Secretaria Municipal de Saúde do Rio de Janeiro, Secretaria Municipal de Saúde, Rio de Janeiro, Brazil, [3]Vanderbilt University School of Medicine, Department of Medicine, Nashville, United States of America, [4]Secretaria Municipal de Sáude do Rio de Janeiro, Secretaria Municipal de Saúde, Rio de Janeiro, Brazil, [5]Harvard TH Chan School of Public Health, Department of Global Health and Population, Boston, United States of America, [6]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States of America
e-mail: ddowdy1@jhmi.edu

Background: The World Health Organisation recommends short-course tuberculosis preventive treatment with either 1 month of daily isoniazid and rifapentine (1HP) or 3 months of weekly isoniazid and rifapentine (3HP). The UltraCurto study randomized household contact persons without HIV in Brazil to either 3HP or 1HP and found high adherence to both regimens and more safety events with 1HP than 3HP. Evidence of cost-effectiveness has been limited.
Design/Methods: A Markov model using health state transitions was developed to simulate disease progression and treatment over a 20-year horizon. The model estimated the incremental costs and effects of 1HP vs 3HP in a cohort of 500 simulated patients. The primary outcome was the incremental cost-effectiveness ratio (ICER), measured in 2022 dollars ($) per disability-adjusted life year (DALY) averted. 1HP and 3HP were also compared against six to nine months of isoniazid and a baseline of no treatment. Drug costs were obtained from the GDF 2024 catalogue. Other costs were gathered from a societal perspective incorporating both clinic expenses, time-and-motion data and scientific literature.
Results:

Treatment	Costs ($)	DALYs	Incremental Cost ($)*	Incremental Daly's Averted	ICER	Completion Rate (%)	Dominance Status
No LTBI Treatment	$347,115	3848	$153,371	1492.2	$103	100.0%	1HP Dominant
1HP	$193,744	2355	n/a	n/a	n/a	89.6%	n/a
3HP	$207,067	2359	$13,323	3.7	$3,563	84.1%	1HP Dominant
6-9H	$282,641	2474	$88,897	119	$747	69.0%	1HP Dominant

With rifapentine (300mg) tablets priced at $0.34 and isoniazid (300mg) tablets at $0.02, 1HP was estimated to be cost-effective relative to 3HP, with a, incremental cost per DALY averted of $3,563. 1HP costs were lower, largely driven by fewer clinical visits for patients versus 3HP. The initial cost per patient for 1HP was $67.45 lower than 3HP, at $98.75 for 1HP compared to $166.19 for 3HP.
Conclusions: Due to its shorter regimen duration and similar safety events, 1HP presents a more cost-effective alternative to 3HP for adults exposed to TB in their homes. Combined with the UltraCurto safety results, these findings support the wider adoption of 1HP for TB prevention in the adult population. Future research should explore safety and cost-effectiveness of 1HP in other populations including children and pregnant and lactating persons.

OA19-284-20 Cost and impact of decentralising TB testing: Price thresholds for molecular instruments in high-TB-burden settings

T. Ockhuisen,[1] A. de Nooy,[1] S. Girdwood,[2] M. Hansen,[1] M. Kohli,[3] M. Ruhwald,[4] N. Ismail,[5] B. Nichols,[6,1] [1]Amsterdam University Medical Center, Department of Global Health, Amsterdam, Netherlands, [2]FIND, Impact Department, Cape Town, South Africa, [3]FIND, Medical Affairs, Geneva, Canada, [4]FIND, Medical Affairs, Geneva, Switzerland, [5]University of the Witwatersrand, Clinical Microbiology and Infectious Diseases, Johannesburg, South Africa, [6]Boston University School of Public Health, Department of Global Health, Boston, Netherlands
e-mail: brooken@bu.edu

Background: Despite progress in reducing global tuberculosis incidence, ongoing funding disruptions threaten to reverse gains. Timely, accurate diagnosis integrated with rapid treatment is critical to reducing morbidity, mortality, and transmission—but remains costly and logistically challenging, particularly for decentralized approaches. As global health budgets tighten, identifying the instrument price at which TB diagnostics can be cost-effectively decentralised is crucial to inform scale-up decisions.
Design/Methods: We developed a probabilistic patient pathway model to assess the cost-effectiveness of decentralising TB testing across primary healthcare facilities in high-burden settings. We modelled a distribution of facilities (testing volumes following a Pareto distribution) and varied average testing density across the system (low, medium, high). We assigned ≥1 molecular instrument per facility, matching instrument size to volume (using GeneXpert instrument pricing for baseline; assuming $8 consumable cost/test). Given the documented increase in testing volume with decentralization, we evaluated three scenarios: no increase, partial (+45% increase), and full (+90%), based on recent literature. We included the effects of instrument downtime and calculated the maximum instrument (including warranty) prices at which fully decentralised testing would be considered cost-effective at a $500 per DALY averted threshold.
Results: Decentralisation with increased testing averted up to 23% more DALYs than centralized testing but was not cost-effective at current instrument prices. For full decentralisation to meet the $500/DALY threshold, maxi-

mum viable instrument prices ranged from $0 (no testing increase) to $106–$1,618 (full testing increase, low- to high-density settings) (**Figure**). These price thresholds increased when no instrument downtime can be assured, reaching $6,219-$9,358/instrument in high-density settings.

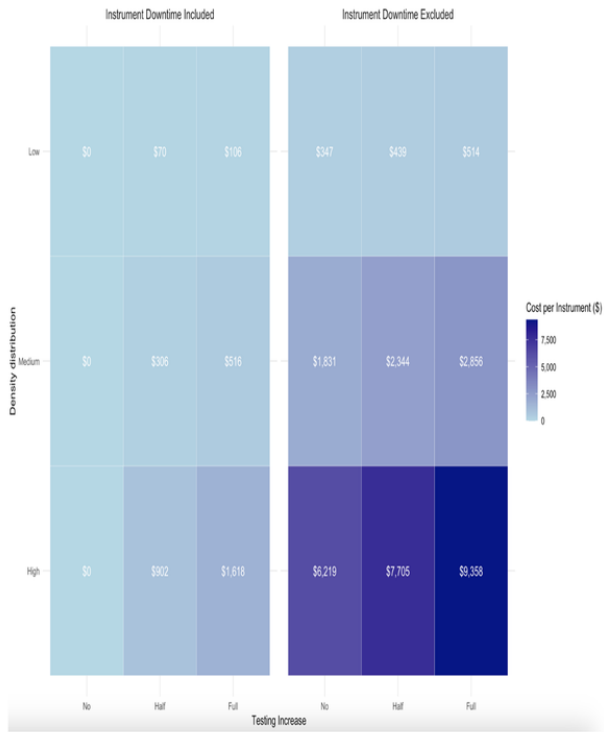

Figure. Instrument and warranty prices to achieve cost-effectiveness at $500 per DALY averted, with and without instrument downtime. The left panel includes 30-day downtime for decentralized testing and the right panel excludes instrument downtime. Results are stratified by the facility density distributions and testing increase (no, partial, and full increase).

Conclusions: At current prices, decentralised molecular TB testing is unlikely to be cost-effective, even with improved uptake. However, meaningful reductions in instrument costs could make decentralisation viable. As countries face tighter budgets, clear price targets for cost-effectiveness can help guide procurement and investment decisions in TB diagnostics.

OA19-285-20 Evaluating the economic impact of low-to mid-throughput multi-disease molecular testing with Cobas MTB and MTB-RIF/INH assays: A case study in the Philippines

T. Tong,[1] R. Calapis,[2] V.G. Ulep,[3] Z. Huynh,[4] S. Salleh,[5] L. R.,[6] T. Srivastava,[7] J. Karichu,[8] [1]ConnectHEOR, Modelling and Analytics, Ha Long city, Viet Nam, [2]San Lazaro Hospital, OPD, Manila, Philippines, [3]Philippine Institute for Development Studies, Philippine Institute for Development Studies, Quezon City, Philippines, [4]Roche Molecular Systems, Clinical Development and Medical Affairs (CDMA), Infection and Immunity, Pleasanton, United States of America, [5]ConnectHEOR, Modelling and Analytics, Selangor, Malaysia, [6]ConnectHEOR, Modelling and Analytics, Calicut, India, [7]ConnectHEOR, HEOR, London, United Kingdom of Great Britain and Northern Ireland, [8]Roche Molecular Systems, Global Access & Policy, Pleasanton, United States of America
e-mail: tushar.srivastava@connectheor.com

Background: Tuberculosis (TB) remains prevalent in the Philippines, posing a significant burden.[1] This study assessed the economic and clinical impact of introducing a low-to mid-throughput multi-disease platform (Cobas® 5800 system) with the Cobas MTB (MTB [*Mycobacterium tuberculosis*]) and Cobas MTB-RIF/INH (MTB-RIF/INH [RIF: rifampicin; INH: isoniazid]) assays to complement the current low-throughput near point-of-care system (Xpert MTB-RIF assay) in the Philippines.
[1] Philippines National Tuberculosis Report, 2022.
Design/Methods: A decision-analytic model was developed to compare a low-to mid-throughput multi-disease testing approach (intervention) to the standard near point-of-care low-throughput TB testing approach (comparator). Key model inputs included: TB incidence and distribution of drug-resistance status, performance of different diagnostic approaches, costs, survival and health-related quality of life. The model population was TB-testing eligible adults. Various scenarios to evaluate cost-effectiveness, return on investment (ROI), and key factors driving the results were conducted. A societal perspective was used. Sensitivity analysis was performed.
Results: From an early investigation of the modelled scenarios (one set of scenarios), introducing a low-to mid-throughput multi-disease testing provides greater clinical benefits, with an increase of 60–371 life years gained, or 54–334 quality-adjusted life years (QALYs) gained, or 120–737 disability-adjusted life years (DALY) averted per 100,000 tested population. The incremental cost per tested person ranged from −$5.10 to +$5.14, with incremental cost-effectiveness ratio between intervention dominant and $4,349/QALY gained, or $1943/DALY averted, meeting the cost-effectiveness threshold for the Philippines. The ROI was between 37% and 262%. Key factors driving the results include test cost, diagnostic performance, proportion of mono-INH resistance and improvement in survival if receiving the optimal treatments.

Conclusions: Optimizing the TB diagnostic network with low-to mid-throughput multi-disease testing in the Philippines has high potential for cost-effectiveness, offering cost efficiency, clinical benefits, and a strong return on investment to improve patient care and outcomes.

OA19-286-20 An extended cost-effectiveness and benefit incidence analysis of decentralised TB diagnostic testing with Molbio Truenat MTB/RIF vs. hub-and-spoke GeneXpert MTB/RIF in Mozambique and Tanzania

S. Arif,[1] L. Fekadu,[2] A. Malhotra,[3] D. Elisio,[4] A. Machiana,[5] A. Lwilla,[6] J. Hella,[7] N. Young,[8] V. Leukes,[9] A. Penn-Nicholson,[10] M. De Allegri,[11] C.M. Denkinger,[12]
[1]University of Manchester, Health Organisation, Policy and Economics (HOPE) Division of Population Health, Health Services Research and Primary Care, Manchester, United Kingdom of Great Britain and Northern Ireland, [2]Ethiopia Ministry of Health, Ethiopia Ministry of Health, Addis Ababa, Ethiopia, [3]University of Washington, Department of Global Health, Seattle, United States of America, [4]Manhiça Health Research Centre, Manhiça Health Research Centre, Maputo, Mozambique, [5]National Health Institute (INS), National Health Institute (INS), Maputo, Mozambique, [6]NIMR, Mbeya Medical Research Center, Mbeya, United Republic of Tanzania, [7]Ifakara Health Institute (IHI), Tuberculosis Research group, Dar es Salaam, United Republic of Tanzania, [8]The Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States of America, [9]FIND, TB Programme, Cape town, South Africa, [10]FIND, TB Programme, Geneva, Switzerland, [11]University of Heidelberg, Institute of Global Health, Heidelberg, Germany, [12]University of Heidelberg, Clinical Tropical Medicine, Heidelberg, Germany
e-mail: saima.arif@manchester.ac.uk

Background: In low- and middle-income countries (LMICs), tuberculosis (TB) remains a leading cause of death. Timely diagnosis is essential, and decentralized testing strategies have shown promise in improving access. While their effectiveness is well-established, national policy decisions also require evidence on affordability and equity impacts.
This study synthesizes economic and equity findings from a multicentre cluster-randomized controlled trial (cRCT) in Mozambique and Tanzania, evaluating a point-of-care (POC) TB diagnostic strategy using the Molbio Truenat MTB/RIF platform compared to the hub-and-spoke Xpert MTB/RIF Ultra model.
Design/Methods: Economic data were collected as part of the TB-CAPT Core cRCT, including implementation costs and participants' out-of-pocket (OOP) expenses. An Extended Cost-Effectiveness Analysis (ECEA) and Distributional Cost-Effectiveness Analysis (DCEA) were conducted to assess incremental costs and TB treatment initiation within seven and sixty days, stratified by socioeconomic status (SES). Benefit incidence analysis was used to estimate public subsidies across SES groups. Equity analysis was based on asset indices developed using Multiple Correspondence Analysis. Concentration curves and indices were used to assess pro-poor distribution.
Results: Average OOP costs were significantly lower in the intervention group (USD 8.82 vs. USD 13.61). Participants in higher SES groups saw greater cost savings, while poorer groups experienced earlier treatment initiation. Treatment initiation within seven days was higher in the poorest quintiles in both countries, and the intervention led to over 1.5 times greater treatment initiation compared to the control.
The societal cost per treatment initiated was higher in the intervention arm, the benefits were more equitably distributed, favouring the poorest groups.
Conclusions: Decentralized POC TB testing using Truenat is both cost-saving for patients and more effective in increasing treatment initiation. The intervention demonstrated a pro-poor distribution of benefits, supporting its potential to improve access and equity in TB care across LMICs.

OA19-287-20 Is universal health coverage the solution to protecting TB-affected households from financial and socio-economic burdens: A cross-sectional cost study in South Korea

J. Seo,[1] K.H. Oh,[2] M. Yang,[3] H. Sohn,[4] Y.A. Kang,[5] D. Jeon,[6] C. Chung,[7] J. Mok,[8] N. Kwak,[9] H. Choi,[1] [1]Korea University, Division of Health Policy and Management, College of Health Science, Seoul, Republic of Korea, [2]World Health Organization, Regional Office for the Western Pacific, Manila, Philippines, [3]Seoul National University, College of Medicine, Seoul, Republic of Korea, [4]Seoul National University, Department of Preventive Medicine, Seoul, Republic of Korea, [5]Yonsei University College of Medicine, Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, Severance Hospital, Seoul, Republic of Korea, [6]Pusan National University School of Medicine, Department of Internal Medicine, Pusan National University Yangsan Hospital, Yangsan, Republic of Korea, [7]University of Ulsan College of Medicine, Department of Pulmonary and Critical Care Medicine, Gangneung Asan Hospital, Gangneung, Republic of Korea, [8]Pusan National University Hospital, Department of Internal Medicine, Busan, Republic of Korea, [9]Seoul National University Hospital, Division of Pulmonary and Critical Care Medicine, Department of Internal Medicine, Seoul, Republic of Korea
e-mail: hongjo@korea.ac.kr

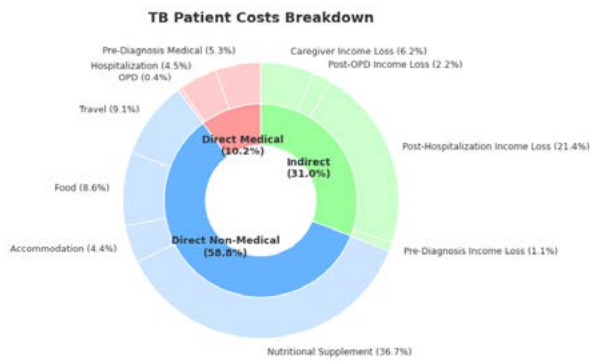
Background: Universal health coverage (UHC) and zero catastrophic costs among tuberculosis (TB)-affected households are core goals of the WHO End TB Strategy, yet evidence from countries with national health insurance systems remains limited. This study aimed to generate the South Korean national estimate of the catastrophic

cost levels in households affected by TB and to identify the patient cost drivers in a high-income setting with a declining TB burden.

Design/Methods: We conducted a cross-sectional study across five public-private (PPM) healthcare institutions in South Korea from August 2024 to February 2025. A total of 133 adult DS-TB patients were recruited using quota sampling based on age and gender distribution from 2023 national TB notification data.

We modified the survey questionnaire based on the WHO TB Patient Cost Survey and the Korea Health Panel Survey to reflect the local healthcare context. Self-reported TB-related costs were categorized as direct medical, non-medical, and indirect costs. Household income-stratified analysis was performed across five groups at 2 million KRW intervals.

Results: The proportion of TB-affected households incurring catastrophic costs was estimated at 41.4% (95% CI 32.4-49.4). Major cost drivers included direct non-medical costs (58.8%) (e.g., nutrition supplements, travel, food), indirect costs (31.0%) (i.e. income loss), followed by direct medical costs (10.2%). Stratified analysis by household income (HHI) revealed a clear gradient in the proportion of catastrophic cost, ranging from 78.9% in the lowest HHI group to 5.0% in the highest, indicating substantial disparities by income.



Conclusions: Despite having high national health insurance coverage, households affected by TB in South Korea continued to face significant financial and socio-economic burdens. These findings reveal critical gaps in TB-sensitive social protection, particularly for non-medical and income-related expenses, and highlight the need to expand personalized protection strategies beyond medical care cost (e.g., paid sick leave and sickness benefits) to further protect TB-affected households.

OA20 Prevalence surveys (TB disease and M. TB infection) and transmission studies

OA20-288-20 TB infection by age groups in Mongolia

E. Narmandakh,[1] G. Sharkhuu,[1] E. Tumur,[1] Y. Igarashi,[2] G. Ganbaatar,[3] N. Dambaa,[3] N. Batbayar,[3] G. Dorj,[3] M. Baatar,[4] O. Enkhtaivan,[5] B. Burneebaatar,[1] S. Mitarai,[2]
[1]National Center for Communicable Diseases, NTRL, TB Surveillance and Research Department, Ulaanbaatar, Mongolia, [2]Japan Anti-Tuberculosis Association, Department of Mycobacterium Reference and Research, RIT, Tokyo, Japan, [3]National Center for Communicable Diseases, TB Surveillance and Research Department, Ulaanbaatar, Mongolia, [4]National Center for Communicable Diseases, TB Clinic, Ulaanbaatar, Mongolia, [5]National Center for Communicable Diseases, Quality Control Department, Ulaanbaatar, Mongolia
e-mail: eegiinee8222@gmail.com

Background: Mongolia is one of the 30 countries with a high TB burden an estimated incidence rate of 491 per 100,000 population. This study aimed to determine the prevalence of tuberculosis infection among relatively healthy individuals residing in crowded metropolitan settings.

Design/Methods: A cross-sectional study was conducted between June 2024 and March 2025 at the National Center for Communicable Diseases in Ulaanbaatar, Mongolia. Eligibility criteria included being relatively healthy, asymptomatic for TB, with no history of TB treatment or known contact with TB cases. Participants completed questionnaires, and tested QuantiFERON-TB Gold Plus (QFT-Plus) assay in whole blood. Python (3.8.8) and other libraries were utilized to analyze the dataset.

Results: A total of 766 individuals were included in the analysis. The mean age was 38.2 years (SD=15.7), and the median age was 36 years, with an age range from 10 to 87 year. Of the participants, 47.1% (n=361) were female and 52.9% (n=405) were male. The weighted prevalence of TB infection was estimated at 33.4% (95% CI: 30.1%–36.8%). The QFT-plus positivity rates were 10-19 (7.9%, 95% CI: 2.3%- 13.6%), 20-29 (27.5%), 30-39 (37.9%), 40-49 (42.1%), 50-59 (36.7%), 60< (46.1%, 95% CI: 35.7%-56.4%) respectively, by age group. The QFT-plus positivity rates increase with age across both genders, peaking in the 60< group (p-0.000). Females in age groups 40–59 show slightly higher positive rates than males, whereas the 30–39 male group has the highest observed rate (41.6%, 95% CI: 30.6 to 52.6%) among males. However, gender was not significantly associated with positivity (p = 0.652).

Conclusions: This study identified a TB infection prevalence of 33.4%. Age was significantly associated with higher TB infection rates, whereas gender was not a determining factor, indicating the decrease of active transmission in young ages and shift to a situation where TB from TB infection is predominant.

OA20-289-20 Prevalence and risk factors for tuberculin skin test positivity in Rwanda: A nationwide cross-sectional study

P. Migambi,[1] B. Rusisiro,[1] D. Runyambo,[2] F. Rwabukera,[1] Y. Habimana Mucyo,[1] E. Nisingizwe,[3] P. Rukundo,[1] F. Hakizayezu,[4] C. Mambo Muvunyi,[5] [1]Rwanda Biomedical Center, HIV/AIDS Disease Prevention and Control / Division of TB and Other Respiratory Disease, Kigali, Rwanda, [2]IOM UN Migration, Migration Health Department, Kigali, Rwanda, [3]University of Rwanda, College of Medicine and Health Sciences, Research and Innovation, Kigali, Rwanda, [4]Rwanda Biomedical Center, Biomedical Services/ National Reference Laboratory, Kigali, Rwanda, [5]Rwanda Biomedical Center, General Directorate, Kigali, Rwanda
e-mail: patrick.migambi@rbc.gov.rw

Background: Latent tuberculosis infection (LTBI) affects nearly a quarter of the global population and represents a key obstacle to TB elimination. In Rwanda, while the burden of active TB has decreased significantly, the prevalence and risk factors for LTBI remain poorly characterized. The Tuberculin Skin Test (TST) is commonly used for LTBI diagnosis in Rwanda, yet data on its positivity TST associated factors are scarce.
This study aimed to estimate the prevalence of TST positivity and identify its associated risk factors nationwide.
Design/Methods: A population-based cross-sectional survey was conducted across 90 randomly selected villages in Rwanda, enrolling individuals aged five years and older through systematic random sampling. Data were collected electronically using REDCap and included demographic, clinical, and behavioral characteristics. TST positivity was defined as an induration ≥10 mm.
Descriptive statistics were used to describe the study population, and logistic regression analyses were performed to identify factors associated with TST positivity. Ethical approval was obtained from the Rwanda National Ethics Committee.
Results: Among 1,350 participants, the overall TST positivity rate was 22%. TST positivity was significantly associated with male gender (AOR: 2.11, 95% CI: 1.58–2.83), increasing age (AOR for 55+: 8.9, 95% CI: 2.70–29.40), larger household size (AOR: 1.44, 95% CI: 1.07–1.95), previous smoking (AOR: 1.81, 95% CI: 1.11–2.97), history of TB (AOR: 8.8, 95% CI: 2.19–35.45), chronic disease (AOR: 2.17, 95% CI: 1.27–3.74), and past imprisonment (AOR: 2.83, 95% CI: 1.46–5.51).
Conclusions: This study provides the first national estimate of TST positivity in Rwanda and highlights key demographic, behavioral, and clinical risk factors. These findings are critical for informing LTBI screening strategies and optimizing tuberculosis preventive therapy (TPT) to support Rwanda's End TB goals by 2035.

OA20-290-20 Early results of the first subnational TB prevalence survey in Ho Chi Minh City, Viet Nam

L.N.Q. Vo,[1,2] N.T.T. Nguyen,[3] A.J. Codlin,[4,2] Q.T. Lam,[3] D.T.N. Nguyen,[3] K.H. Le,[3] R. Forse,[3,2] T.M.H. Dang,[5] L.H. Nguyen,[5] H.B. Nguyen,[6] L.V. Dinh,[6] J. Creswell,[7] [1]Friends for International TB Relief (FIT), Management, Ha Noi, Viet Nam, [2]Karolinska Institutet, Department of Global Public Health, Solna, Sweden, [3]Friends for International TB Relief (FIT), Program, Ho Chi Minh City, Viet Nam, [4]Friends for International TB Relief (FIT), Management, Ho Chi Minh City, Viet Nam, [5]Pham Ngoc Thach Hospital, Management, Ho Chi Minh City, Viet Nam, [6]Viet Nam National Lung Hospital, Management, Ha Noi, Viet Nam, [7]Stop TB Partnership, Innovations & Grants, Geneva, Switzerland
e-mail: luan.vo@tbhelp.org

Background: Tuberculosis prevalence surveys (TBPS) are critical epidemiological surveillance tools which National TB Programs (NTP) use to inform national strategies. However, they are costly and complex to implement, resulting in only 43 national TBPS being conducted globally over the past 23 years. With support from TB REACH, the NTP, IRDVN and Friends for International TB Relief conducted a TBPS in Ho Chi Minh City, Vietnam's highest TB burden province, accounting for 20% of national treatment notifications.
Design/Methods: The survey was planned between 11/2023-05/2024 and implemented from 06-08/2024. The sample size was 25,131 in 74 clusters based on Probability-Proportional-to-Size sampling, a between-cluster variation of 1.19, and a relative precision of 25%. Cluster residents aged 15+ years were mapped and mobilized to present for verbal and chest X-ray screening. Persons with symptoms per WHO 4-symptom screen, TB in the last 2 years, or exhibiting radiographic abnormalities provided two spot sputum specimens 30-minutes apart for testing with the Xpert MTB/RIF Ultra assay (Ultra). A third specimen was obtained post-hoc for confirmatory liquid culture for Ultra-positive participants.
Results: We screened 23,986 participants, with 2,239 (9.3%) undergoing double-Ultra testing. The weighted prevalence rate was 474/100,000 or 1.64x-2.02x of the latest national (235/100,000) and southern regional (289/100,000) prevalence rates when using only the Xpert MTB/RIF assay (Xpert). When Trace results are re-classified as negative and 2nd Ultra tests are dropped to approximate single Xpert testing, the weighted prevalence rate was 284/100,000 or 0.98x-1.2x the last national TBPS. The total subnational TBPS costed USD 288,206.
Conclusions: It is feasible to conduct a subnational TBPS that produces robust TB burden estimates within acceptable timeframes and costs. TBPS in subnational hotspots can be valuable surveillance tools to monitor progress towards ending TB. This methodology may also be considered to optimize the timelines and costs for national TBPS.

OA20-291-20 National TB Prevalence Survey in Nepal (2018–2019)

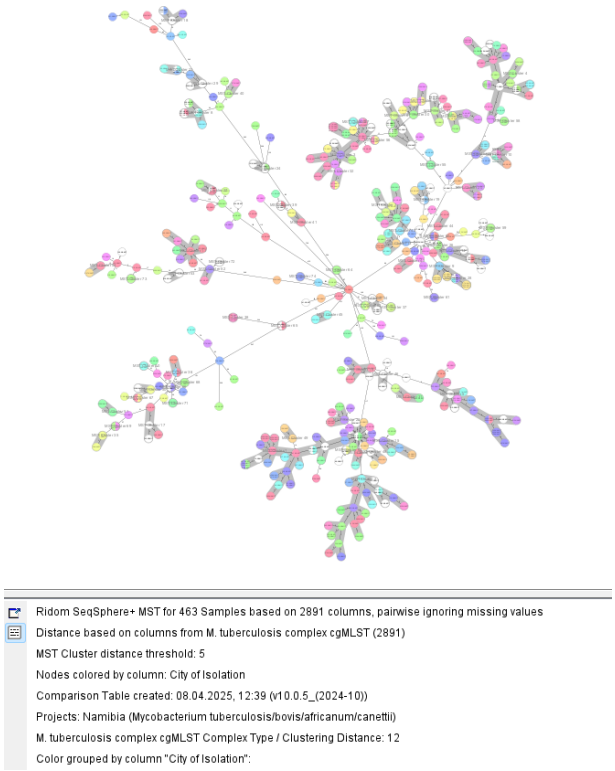
A. Shrestha,[1] S.R. Tiwari,[2] M.N. Khanal,[3] N. Yamada,[4]
[1]Save the Children, Nepal, Global Fund Programs, Bhaktapur, Nepal, [2]National Tuberculosis Control Center, Program Management, Bhaktapur, Nepal, [3]National Tuberculosis Control Center, Planning, Monitoring, Evaluation, Surveillance and Research Section, Bhaktapur, Nepal, [4]Research Institute of Tuberculosis, Training, Tokyo, Japan
e-mail: drshrestha.ashish@gmail.com

Background: Tuberculosis (TB) remains a major public health challenge in Nepal, contributing significantly to morbidity and mortality despite longstanding control efforts. To address gaps in case detection and reporting, Nepal conducted its first national TB prevalence survey (2018–2019) among individuals aged ≥15 years.
This cross-sectional study aimed to estimate bacteriologically confirmed pulmonary TB prevalence, assess healthcare-seeking behaviors.
Design/Methods: Employing a multistage cluster sampling design stratified by terrain and urbanization, 99 clusters were selected via probability proportional to size. Participants underwent symptom screening and chest X-ray (CXR), with sputum samples analyzed using Xpert MTB/RIF and culture.
Data were analyzed using WHO-recommended methods, incorporating inverse probability weighting and multiple imputation for missing data.
Results: Of 93 085 enumerated individuals, 54 200 (92% of eligible participants) were surveyed. The prevalence of bacteriologically confirmed pulmonary TB among those aged 15 and above was 374.5 per 100 000. Prevalence was higher among males, older age groups, and in hill and terai regions. The P/N (prevalence-to-notification) ratio was 3.5, indicating underreporting.
Over 70% of TB cases were identified through CXR screening without symptoms, highlighting the importance of CXR as a screening tool. Health-seeking behavior analysis revealed that 39% of symptomatic individuals did not seek care, with barriers including financial constraints and lack of access.
Conclusions: The survey revealed a higher TB burden in Nepal than previously estimated, with significant underreporting and disparities in access to care.
The findings underscore the need for expanded use of sensitive diagnostic tools like CXR and Xpert MTB/RIF, improved health service accessibility, and targeted interventions for high-risk groups, including the elderly and those in hard-to-reach areas. Strengthening cross-border collaboration, engaging the private sector, and increasing investments in TB control are critical to achieving Nepal's End TB goals.

OA20-292-20 Cross-regional transmission of drug-resistant TB in Namibia: Insights from genomic surveillance

O. Shavuka,[1] L. Mhuulu,[1] V. Dreyer,[2] H. Ekandjo,[1] P. Absai,[3] N. Ruswa,[4] T. Niemann,[1,2] E. Nepolo,[1] M. Claassens,[1] G. Günther,[1,5] S. Niemann,[1,2] [1]University of Namibia School of Medicine, Department of Human, Biological & Translational Medical Sciences, Windhoek, Namibia, [2]Research Center Borstel, Molecular and Experimental Mycobacteriology, Borstel, Germany, [3]Namibia Institute of Pathology, TB- Windhoek Central Referral Laboratory, Windhoek, Namibia, [4]Ministry of Health and Social Services, National Tuberculosis and Leprosy Program, Windhoek, Namibia, [5]Bern University Hospital, Department of Pulmonology and Allergology, Bern, Switzerland
e-mail: oalina715@gmail.com

Background: Drug-resistant tuberculosis (DR-TB) poses a major public health challenge to ongoing efforts to control and eradicate tuberculosis (TB) in Namibia, a country with a high TB burden. Identifying and understanding the factors contributing to DR-TB transmission is crucial.
This study examines DR-TB transmission patterns across Namibia, highlighting the role of regional mobility and interconnected outbreaks.
Design/Methods: Whole Genome Sequencing (WGS) was performed to characterize 463 *Mycobacterium tuberculosis* complex (Mtbc) clinical strains collected between 2016 to 2023 from patients who had documented rifampicin resistance based on Xpert MTB/RIF in all regions of Namibia.
Phylogenetic strain classifications, genomic resistance predictions, and core-genome multi-locus sequence typing analysis were conducted using SeqSphere (Ridom GmbH, Münster, Germany).
Cluster analysis was done using a threshold of 05 alleles, and the region of isolation was also examined to assess cross-regional transmission patterns.
Results: The MTBC population structure had the majority of the isolates classified as belonging to lineage 4 (L4; n=450), while 12 isolates belonged to lineage 2 (L2, Beijing), and the remaining one belonged to lineage 1 (L1).
The cluster rates were high, with 359 out of 463 isolates grouped into 74 clusters, ranging from 2 to 33 isolates. Of the MDR isolates/patients, 316/405 (78.0%) were clustered, 23/27 (85.2%) pre-XDR isolates, 8/9 (88.9%) XDR isolates, and 12/21 (57.14%) non-MDR Mtbc isolates were also clustered.
Eighteen out of the 74 clusters contained isolates from different regions. The largest cluster, consisting of 33 isolates, included isolates from 7/14 regions in Namibia, while the region with highest clustering rate was Otjozondjupa (87.5% (49/56)).



Conclusions: The high clustering rate and the presence of isolates from different regions within the same clusters suggest ongoing cross-regional transmission of DR-TB in Namibia, driven by human mobility. Further investigations are needed to understand the factors contributing to this transmission pattern and guide targeted interventions.

OA20-293-20 The role of prisons in the spread of TB over time in Lima, Peru

C.-C. Huang,[1,2] M.C. Becerra,[2] R.I. Calderon,[3] C.C. Contreras,[4] J. Jimenez,[4] L.W. Lecca,[4,2] M. Mendoza,[4] N.B. Ponce,[4] K. Tintaya,[4] X. Tovar,[2] R.M. Yataco,[4] M.B. Murray,[2,5,1] [1]Brigham and Women's Hospital, Division of Global Health Equity, Boston, United States of America, [2]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States of America, [3]Advanced Research and Health, Advanced Research and Health, Lima, Peru, [4]Socios En Salud, Socios En Salud, Lima, Peru, [5]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States of America
e-mail: chuang17@bwh.harvard.edu

Background: Prisons are recognized as high-risk environments for tuberculosis (TB) transmission, but their long-term impact on community transmission remains unclear. While previous studies show that TB strains are often shared between people with and without a history of incarceration—suggesting spillover from prisons into the community—no studies have quantified how widely these prison-related strains spread over time.

Design/Methods: We analyzed whole-genome sequencing data from two population-based TB cohorts conducted ten years apart in the same area of Lima, Peru. The first study (2009–2012) enrolled 4,500 newly diagnosed TB patients; the second (2020–2022) enrolled 2,000. We obtained Mycobacteria tuberculosis (Mtb) sequences from 3,567 (79%) patients in the earlier cohort and 1,765 (88%) in the later one. For each Mtb strain identified in the earlier cohort, we calculated how many genetically similar strains (≤5 single nucleotide polymorphisms) appeared in the later cohort. This "strain expansion indicator" reflects how widely each strain had spread over the decade.
We then used a Poisson generalized estimating equation to assess whether strains linked to incarceration—defined as those from individuals in the earlier cohort who had spent at least one day in prison within five years before their TB diagnosis—were more likely to expand, accounting for genetic relatedness between strains.
Results: Mtb strains from individuals with recent incarceration had a 1.45-fold increase (95% CI: 1.25–1.67) in genetically similar strains in the later cohort compared to strains from individuals without such a history.
Conclusions: Our findings suggest that prison-related TB strains contribute disproportionately to long-term community transmission. This underscores the need for targeted TB control strategies that address both transmission within prisons and the continued risk posed after release.

OA20-294-20 Population-wide TB screening in Kiribati: Preliminary results

J. Hill,[1] B. Marais,[1] W. Britton,[2] A. Tonganibeia,[3] M. Tikataake,[3] M. Hauma,[3] K. Shaw,[2] [1]University of Sydney, Sydney Institute for Infectious Diseases, Sydney, Australia, [2]Centenary Institute, TB Research, Sydney, Australia, [3]Ministry of Health and Medical Services, Department of Public Health, South Tarawa, Kiribati
e-mail: jeremy.hill@sydney.edu.au

Background and challenges to implementation: Mass TB screening programmes are resource-intensive, but essential in high-burden settings to reduce transmission and support timely care. Evidence comparing different screening modalities in real-world contexts remains limited. Symptom-based screening misses many people, especially older adults and those with subclinical disease. Chest X-ray improves sensitivity but specificity is a concern, especially in people with previous TB.
Intervention or response: The PEARL protocol combined symptom screening, chest X-ray, and sputum Xpert testing in everyone older than 10 years of age, in South Tarawa, Kiribati. We evaluated screening yield and number needed to screen (NNS) by age group, comparing the full PEARL screening protocol (combined symptoms, chest X-ray and sputum testing) with hypothetical scenarios where only symptoms or X-ray formed the initial screening test.

Results/Impact: Screening and diagnostic outcomes for more than 10,000 participants in a high-transmission urban area were available for analysis. In total, 95 people with TB (888/100,000 population) were identified. Across all age groups, the full PEARL protocol achieved the highest overall yield (0.89%) and lowest NNS (113), compared to symptoms-only (0.21%; NNS = 482) and X-ray-only (0.76%; NNS = 132) screening scenarios. Yield increased markedly with age. Among adults ≥50 years, yield from X-ray alone was comparable to the full protocol. In younger age groups, the addition of mass sputum screening with GeneXpert improved detection over symptoms or X-ray alone.

		Symptom Only		X-ray (10+)		PEARL	
Age Group	N	Yield (%)	NNS	Yield (%)	NNS	Yield (%)	NNS
0-9	2,201	0.46	215.1	0.00	–	0.50	200.1
10-19	2,194	0.05	2,177.0	0.33	303.3	0.59	168.8
20-29	2,031	0.10	1,008.5	0.61	163.1	0.69	145.1
30-39	1,666	0.18	553.0	0.62	161.6	1.02	98.0
40-49	1,124	0.09	1,118.0	0.82	122.1	1.07	93.7
50-59	771	0.39	255.3	1.47	68.0	1.69	59.3
60-69	500	0.20	494.0	1.68	59.6	1.60	62.5
70-79	181	0.00	–	2.89	34.6	2.76	36.2
80+	34	2.94	34.0	6.06	16.5	5.88	17.0
Ages 10+	8,501	0.14	703.8	0.78	128.5	0.99	101.2
All	10,702	0.21	481.6	0.76	132.2	0.89	112.7

Conclusions: Comprehensive screening using digital X-ray and sputum Xpert can identify more people with TB earlier, in comparison to symptom-only approaches. Higher screening yield in older age cohorts with X-ray reflects a higher burden of disease and sputum collection difficulties. In younger age cohorts, there was an additional benefit from sputum screening. These real-world findings may guide future mass TB screening programmes.

OA20-295-20 Quantifying undetected TB in Ethiopia using a novel geospatial modelling approach

H.F. Wolde,[1] A.C. Clements,[2] A.K. Erena,[3] S.K. Gelaw,[4] S.W. Lamma,[5] K. Alene,[1] [1]Curtin University, School of Population Health, Perth, Australia, [2]Queen's University, Belfast, School of Biological Sciences, Belfast, United Kingdom of Great Britain and Northern Ireland, [3]Ministry of Health Ethiopia, National TB, Leprosy and Lung Diseases Control, Addis Ababa, Ethiopia, [4]Ministry of Health Ethiopia, Strategic Affairs Executive Office, Addis Ababa, Ethiopia, [5]Ethiopian Public Health Institute, National Data Management Center, Addis Ababa, Ethiopia
e-mail: haileabfekadu@gmail.com

Background: Tuberculosis (TB) is the leading infectious cause of death globally, with approximately three million cases remaining undetected, thereby contributing to community transmission. Understanding the spatial distribution of undetected TB in high-burden settings is critical for designing and implementing geographically targeted interventions for early detection and control. This study presents the first estimates of numbers of undetected TB cases in Ethiopia at national and local levels.

Design/Methods: We employed a Bayesian geostatistical modelling framework, incorporating national TB prevalence survey and TB notification data together with climatic and environmental variables, to estimate the number of undetected TB cases at district and national levels. Spatial clustering of undetected TB cases was assessed using Moran's Index statistic and Local Indicator of Spatial Autocorrelation (LISA). A Bayesian Poisson regression model with conditional autoregressive (CAR) prior structure was developed to identify drivers of the clustering.

Results: We estimated a total of 51,041 undetected TB cases (95% CI: 50,599, 51,486) in Ethiopia, with the majority of these cases predicted in the Oromia region (20,440), Amhara region (9,614), and South Ethiopia region (6,061). Spatial clustering of undetected TB cases was observed in districts near international borders, including the Ethiopia-Somalia and Ethiopia-Kenya border regions, as well as in several districts of Southern Ethiopia. The number of undetected TB cases was negatively associated with the proportion of the population with good mass media exposure (Incidence rate ratio (IRR): 0.67 95% CI: 0.56, 0.80) and the proportion of the population with high wealth index (IRR: 0.73, 95% CI: 0.60, 0.90).

Conclusions: Our findings revealed a high burden of undetected TB in Ethiopia, with spatial clustering in border regions and areas with limited healthcare access. Targeted TB screening interventions to communities with low socioeconomic status along with improving mass media exposure in these regions, could significantly reduce the burden of undetected TB in Ethiopia.

OA20-296-20 Heterogeneity in *M. TB* immunoreactivity in a community-based survey of young children in Blantyre, Malawi

H.M. Rickman,[1,2] M.D. Phiri,[2,3] E. Nightingale,[4] H. Mbale,[5] H.R. Feasey,[6] M. Nliwasa,[5] K.C. Horton,[4] M.Y. Henrion,[7,3] T. Mwenyenkulu,[8] K. Mbendera,[8] E.C. Corbett,[1,2] P. MacPherson,[9,2] [1]London School of Hygiene & Tropical Medicine, Clinical Research Department, London, United Kingdom of Great Britain and Northern Ireland, [2]Malawi Liverpool Wellcome Clinical Research Programme, Population Health Group, Blantyre, Malawi, [3]Liverpool School of Tropical Medicine, Department of CLinical Sciences, Liverpool, Malawi, [4]London School of Hygiene & Tropical Medicine, Infectious Diseases Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [5]Kamuzu University of Health Sciences, Helse Nord Tuberculosis Initiative, Blantyre, Malawi, [6]University of St Andrews, School of Medicine, St Andrews, United Kingdom of Great Britain and Northern Ireland, [7]Malawi Liverpool Wellcome Clinical Research Programme, Statistical Support Unit, Blantyre, Malawi, [8]Malawi Ministry of Health, National Tuberculosis and Leprosy Elimination Programme, Lilongwe, Malawi, [9]University of Glasgow, School of Health and Wellbeing, Glasgow, United Kingdom of Great Britain and Northern Ireland
e-mail: hannah.rickman@lshtm.ac.uk

Background: Tuberculosis (TB) has declined substantially over the past decades in many high-burden settings in sub-Saharan Africa, with transmission increasingly concentrating in vulnerable populations and spatial hotspots. Consequently, repeated disease prevalence surveys have become more expensive and less informative. Passive surveillance methodologies such as case notification rates (CNRs) have known bias due to healthcare access disparities. *Mycobacterium tuberculosis* (Mtb) immunoreactivity surveys may give insights into undiagnosed infectious TB burden, allowing monitoring of transmission and spatial targeting of interventions.

Design/Methods: We performed a community-based interferon gamma release assay (IGRA) survey in children aged 1-4 years in Blantyre, Malawi. Community-representative participants were recruited using novel convenience sampling in primary health clinics, alongside random household sampling guided by satellite imagery, and tested for Mtb immunoreactivity using QFT-Plus. We constructed hierarchical Bayesian logistic regression models for an outcome of positive QFT-Plus, with neighbourhood-level random effects.

Results: We recruited 1,545 children aged 1-4 years. Characteristics were broadly similar between participants recruited through clinic-based convenience sampling and conventional household sampling.

Overall, 102 (6.6%) had Mtb immunoreactivity, corresponding to an annual risk of TB infection (ARTI) of 2.7% (2.2-3.2%). Children in the poorest third of households were more likely to have Mtb immunoreactivity (8.7% vs 5.5%; AOR 1.60, 1.06-2.45). Mtb immunoreactivity was not associated with HIV exposure, malnutrition, household contact, neighbourhood HIV prevalence or population density.

There was substantial between-neighbourhood heterogeneity, with predicted neighbourhood ARTI ranging from 1.1% (0.3-2.4%) to 4.1% (1.7-8.3%)(Figure 1A). There was no association between neighbourhood CNR and ARTI(Figure 1B), suggesting that CNRs may not accurately reflect prevalence of undiagnosed infectious TB.

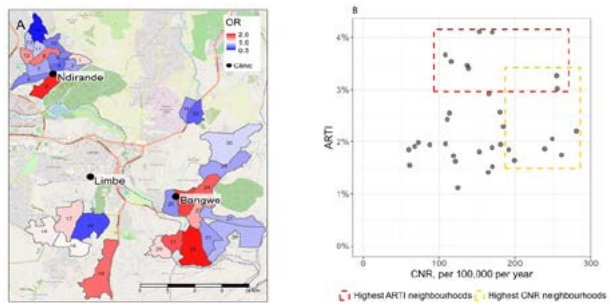


Figure 1
A. Neighbourhood-level odds ratios (OR) of Mtb immunoreactivity.
B. Relationship between neighbourhood-level annual risk of TB infection (ARTI) and case-notification rate (CNR). The highest quartile by each metric are highlighted, indicating those which might theoretically be prioritised for public health intervention.

Conclusions: Immunoreactivity surveillance in 1-4-year-olds using clinic-based convenience sampling provided valuable epidemiological insights in this Southern African urban setting. It has potential to identify children who may benefit from TB preventive therapy, and to allow prioritisation of groups and neighbourhoods for targeted public health intervention.

OA21 Breaking the TB poverty cycle: Tackling inequality, financial burden and policy gaps for people-powered solutions

OA21-297-20 Does TB research presented at The Union World Conference on Lung Health engage with the conditions of poverty, inequality and undernutrition experienced by TB-affected communities? An abstract review

M. Coleman,[1,2] A. Beyersdorff,[1,3] K. Kranzer,[1,4,5] M. Bhargava,[6]
[1]LMU Munich, University Hospital, Division of Infectious Diseases and Tropical Medicine, Munich, Germany, [2]University of Sydney, Sydney Infectious Diseases Institute (Sydney ID), Sydney, Australia, [3]Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Immunology, Infection and Pandemic Research, Munich, Germany, [4]Biomedical Research and Training Institute, The Health Research Unit Zimbabwe (THRU ZIM), Harare, Zimbabwe, [5]London School of Hygiene & Tropical Medicine, Clinical Research Department, London, United Kingdom of Great Britain and Northern Ireland, [6]Yenepoya Medical College (Deemed to be University), Department of Community Medicine, Yenepoya, India
e-mail: mikaela.coleman@sydney.edu.au

Background: Tuberculosis is fundamentally a disease of poverty, driven by and exacerbating financial hardship, inequality, and undernutrition. Despite their clear role in tuberculosis risk, these factors have not received proportional attention in modern tuberculosis research. Given the availability of effective, tuberculosis-protective poverty-focused interventions (e.g. social protection, nutritional support etc), we examined current trends in tuberculosis research engagement with poverty through a review of abstracts accepted at the 2024 UNION World Conference on Tuberculosis and Lung Disease (UNIONconf24).
Design/Methods: Abstracts were extracted using a Python script and those mentioning 'tuberculosis' and cognates were analysed in R. Word frequency analysis and the expert opinion of 3 reviewers assessing 40 randomly selected abstracts identified a list of 37 key poverty-related terms (e.g., inequality, income, undernutrition) which were used to mine abstract and titles for poverty-related abstracts. The proportions of abstracts using poverty and non-poverty-related language were further stratified by presentation type (oral, poster, late-breaker, etc) and geographical location of the first authors.
Results: Of the 1254 extracted abstracts, 95.9% of abstracts/titles (1204/1254) were tuberculosis-related, of which 819 (68.0%) contained no poverty-related terms. Amongst abstracts containing at least one poverty-related term (n=385), 167 (43.4%) included only a single usage, with the most frequent single-use terms being "nutrition" n=95; "stigma" n=81; "financ-" n=57 and "income" n=47. Differential terms between poverty and non-poverty abstracts not included in our initial word-mine were "LGBTQAI" n=23, "Self-help groups" n=18 and "Person-centred care" n=16. Poverty-related abstracts containing ≥2 unique poverty terms (n=131) were most common amongst poster presentations (13% (44/346)) and least common amongst TB-science (0% (0/14)) and late-breaker (3% (1/30)) sessions.

Figure 1. Wordclouds showing relative frequencies of distinctive terms that were most differential between poverty-related (right) and non-poverty related abstracts (left)

Conclusions: Research presented at UNIONconf24 acknowledges the relevance of poverty to tuberculosis, but the representation of studies that engage with poverty appears suboptimal. Future qualitative analyses could give deeper insights into the engagement of UNION research with poverty, equality, and undernutrition.

OA21-298-20 People with TB challenged with catastrophic healthcare expenses before diagnosis and during treatment in Cambodia

K.L. Khieu,[1] C. Huot,[2] K.E. Khun,[2] M. Srey,[3] [1]National Institute of Public Health (NIPH), School of Public Health, Phnom Penh, Cambodia, [2]National Center for Tuberculosis and Leprosy (CENAT), National Tuberculosis Program, Phnom Penh, Cambodia, [3]Abt Global, Local Health System Strengthening (LHSS), Phnom Penh, Cambodia
e-mail: kimleekh@gmail.com

Background: Tuberculosis (TB) is one of the oldest infectious diseases and requires long-term treatment. Although the treatment is provided free of charge in Cambodia, patients must undergo treatment more than 6 months. Only public health facilities are authorized to diagnose and determine treatment outcomes. Despite community-based care availability, TB patients often travel and spend time accessing services , incurring out-of-pocket expenses before diagnosis and during treatment. The study aimed to identify the magnitudes of catastrophic costs borne by TB-affected households.
Design/Methods: A total of 788 patients were randomly selected from 40 health centers and referral hospitals across Cambodia. Face-to-face interviews were conducted in August 2023. Descriptive analysis examined cost variations of TB drug sensitivity (DS-TB) and drug resistance (DR-TB), sociodemographic characteristics, and care-seeking behaviors. Catastrophic cost was calculated using the output approach: (HH_income_before TB

– HH_income_during_treatment + Total_direct_costs) / HH_income_before TB comparing with 20% threshold.
Results: Of 788 TB patients, 91.4% and 8.6% were DS-TB and DR-TB patients respectively.
Approximately 57.6% of them were males and 40.4% were females. The mean age of DS-TB patients was significantly lower (40.2 ± 23.0 years) than DR-TB patients (47.6 ± 18.6 years), p<0.01. The mean HH income before TB diagnosis was US$ 504.4±453.6 and HH income during treatment was US$ 420.8 ± 434.5. The mean direct costs for all TB forms were US$ 538.9 ± 1,252.6 and indirect costs (time loss) were US$ 489.2 ± 1,475.1. Overall, 34.1% of patients experienced catastrophic costs [CI: 30.8%-37.5%], within DS-TB patients 33.5% [CI: 28.8%-38.5%] and DR-TB patients 39.3% [CI: 19.1%-63.9%].
Conclusions: About one-third of TB patients faced catastrophic healthcare costs and other underlying costs. The Ministry of Health (MoH) and National TB Program (NTP) should strengthen implementation of the free treatment policy and expand the preventive efforts to improve public awareness and early case detection through community engagement and media outreach.

OA21-299-20 Beyond the cost of free treatment, people with presumptive TB in Cambodia face financial hardship before TB diagnosis

K.L. Khieu,[1] M. Srey,[2] C. Huot,[3] K.E. Khun,[3] [1]National Institute of Public Health (NIPH), School of Public Health, Phnom Penh, Cambodia, [2]Abt Global, Local Health System Strengthening (LHSS), Phnom Penh, Cambodia, [3]National Center for Tuberculosis and Leprosy (CENAT), National Tuberculosis Program, Phnom Penh, Cambodia
e-mail: kimleekh@gmail.com

Background: Tuberculosis (TB) treatment is free of charge in Cambodia. Private clinics or hospitals are permitted to diagnosis or treat TB. However, most patients preferred to seek care from private providers while they had TB suspected TB symptoms. The costs associated with these care-seeking behaviors lead to significant financial hardship on TB-affected households. The study aimed to identify the catastrophic costs borne by TB-affected household prior to TB diagnosis.
Design/Methods: A total of 788 TB patients were randomly selected from 40 clusters, a multistage cluster sampling, which are health centers and referral hospitals. Face-to-face interviews were held in August 2023 across Cambodia. Descriptive analysis was performed to determine the cost variation between drug sensitivity (DS-TB) and drug resistance (DR-TB), sociodemographic characteristics, and care-seeking behaviors. Catastrophic cost was calculated as total out-of-pocket expenditure on medical and non-medical costs divided by total annual household expenditure using 25% threshold.
Results: Among 788 patients, 720 (91.4%) and 68 (8.6%) were DS-TB and DR-TB patients respectively. 470 (57.6%) of them were males and 318 (40.4%) were females. The mean age of DS-TB patients was significantly lower (40.2 ± 23.0 years) than DR-TB patients (47.6 ± 18.6 years), p<0.01. The mean monthly household expenditure did not differ significantly, US$ 503.3 ± 462.4 for DS-TB patients and US$ 516.0 ± 348.3 for DR-TB patients. The mean direct medical cost among DS-TB patients was US$ 102.9 ± 363.1, while and US$ 13.7 ± 41.2 among DR-TB patients. Approximately 79.2% (570) of DS-TB patients and 77.9% (53) of DR-TB patients experienced catastrophic cost.
Conclusions: The findings suggest that a significantly high proportion of TB-affected households incur catastrophic healthcare costs before a TB diagnosis was made. The National TB Program should consider strengthening and expanding the preventive activities to improve public knowledge and healthcare-seeking behavior utilizing media channels and local authorities to raise awareness and case detection efforts.

OA21-300-20 Financial burden of people with TB in Nepal: Assessing catastrophic costs and mitigation strategies

R. Basnet,[1,2] S.R. Tiwari,[3] N.P. Shah,[3] P. Shrestha,[4] M. Khanal,[5] S. Neupane,[6] R.B. Bhattarai,[7] L.R. Joshi,[8] A. Shrestha,[8] [1]National Tuberculosis Program, Global Fund, Kathmandu, Nepal, [2]Maastricht University, Department of Health Services Research, Maastricht, Netherlands, [3]National TB Control Centre, Program, Kathmandu, Nepal, [4]National Academy of Medical Science, Bir Hospital, Pulmonary Medicine, Kathmandu, Nepal, [5]National TB Control Centre, Planning, Monitoring, Evaluation, Research, and Surveillance Section, Kathmandu, Nepal, [6]National TB Program, USAID Technical Assistance, Kathmandu, Nepal, [7]Sydani Group, Nepal, Kathmandu, Nepal, [8]Save The Children, Global Fund TB Program, Kathmandu, Nepal

Background: Tuberculosis remains the seventh leading cause of death in Nepal, presenting a significant public health and socioeconomic challenge. The third goal of the End TB Strategy is to ensure that no household affected by TB incurs catastrophic costs due to the disease. To assess the economic impact of TB and the proportion of households facing financial hardship, Nepal's National TB Program conducted a nationwide TB patient cost survey.
The study assessed the costs associated with TB diagnosis and treatment, determined the proportion of households facing catastrophic costs, and provided evidence-based recommendations to mitigate economic barriers.
Design/Methods: A nationally representative, cross-sectional TB patient cost survey was conducted using a stratified cluster sampling approach. The study included

face-to-face interviews with 600 patients diagnosed with drug-susceptible TB and 400 patients with drug-resistant TB across all seven provinces. All data analysis was performed using Stata/BE 17.0 (Stata Corp LLC).

Results: The survey found that over half (51%) of TB affected households faced catastrophic costs, with DR TB households disproportionately impacted (75%) compared to DS TB households (50%). The primary contributors to these financial hardships were direct non-medical costs, such as transportation and nutritional supplements, which accounted for 44% of total expenses. Indirect costs, including income loss, contributed 39%, while direct medical costs (e.g., hospitalization, consultation, radiography and other imaging, laboratory procedures, medicine) made up 17%.

Notably, nutritional supplements and additional food intake alone comprised 35% of direct non-medical expenses.

Conclusions: To mitigate these economic burdens, we recommend integrating TB care with social protection programs, and implementing measures to reduce catastrophic costs. Additionally, we suggest empowering patients through vocational training, strengthening mental health support, and fostering a multi-sectoral approach by leveraging existing social initiatives.

OA21-301-20 Assessment of social protection for people affected by TB: Development of an indicator matrix for Brazil

M.R.L. Ferreira,[1] V.P. Maurin,[1] P.D. de Abreu,[1] A.B.M. Valença,[1] D.H.M. da Silva,[1] P.A. Bossonario,[2] J.N.d.B. Silva Júnior,[1] R.L.d.P. Andrade-Gonçalves,[1] T. Arakawa,[3] J.G.d.A. Ballestero,[1] I. Fronteira,[4] A.A. Monroe,[1] [1]University of São Paulo, Ribeirão Preto College of Nursing, Ribeirão Preto, Brazil, [2]University of Maringá, Nursing departament, Maringá, Brazil, [3]Ministry of Health, National Tuberculosis Program, Brasília, Brazil, [4]NOVA University, National School of Public Health, Lisbon, Portugal
e-mail: melisane1206@gmail.com

Background: Social protection constitutes a critical intersection between health and broader social policies. In Brazil, however, there remains a notable scarcity of conceptual frameworks and validated indicators capable of capturing the operationalization and implementation of intersectoral strategies to address tuberculosis.

This methodological study, conducted within the Brazilian context, aimed to develop and validate an evaluation matrix to assess the scope and effectiveness of social protection measures directed toward people affected by tuberculosis.

Design/Methods: The study was carried out between March 2023 and May 2024 in two structured phases. The first phase comprised a scoping review and documentary analysis, culminating in the construction of a Logical Model that guided the development of the Evaluation Matrix. The second phase involved content validation through the Delphi technique, engaging subject-matter experts across two iterative rounds to ensure robust consensus, with a target Content Validity Index (CVI) above 0.80.

Results: The systematic construction of the Evaluation Matrix enabled a comprehensive mapping of the existing social protection landscape for people with tuberculosis at the national level. The final matrix was validated with satisfactory CVIs, reflecting substantial expert agreement. It encompasses four dimensions, 11 subdimensions, 20 evaluative categories, and 53 specific indicators (see Table 1), each with clearly defined parameters and data sources. This matrix provides a rigorous framework for evaluating the implementation of social protection policies in the context of tuberculosis.

Table 1 – Quantitative description of evaluative categories and indicators for each subdimension and their respective dimensions in the evaluation matrix.

Dimensions	Subdimensions	Evaluative Categories	Evaluative Indicators
Right to health	Tuberculosis prevention and care actions in the Brazilian Unified Health System (*SUS*)	03	05
	Food and nutritional security	02	03
	Transportation	01	03
	Work	02	05
	Social control	01	02
	Fight against tuberculosis stigma and discrimination	01	04
Right to social assistance	Access to services, programs, projects, and social assistance benefits in the Brazilian Unified Social Assistance System (*SUAS*)	03	17
Right to social security	Access to social security benefits	04	06
Shared responsibility	Coordination between the Brazilian Unified Health System (*SUS*) and the Unified Social Assistance System (*SUAS*)	01	04
	Intersectoral actions	01	03
	Agility of justice	01	01

Source: the authors (2025).

Conclusions: This study introduces a novel, evidence-based evaluation tool designed to support policy-makers, program managers, and other stakeholders in advancing equitable and context-responsive social protection interventions for people affected by tuberculosis. Its application holds potential to strengthen intersectoral collaboration and inform strategic policy development at multiple levels.

OA21-302-20 Evaluating social capital of 2382 people with pulmonary TB: A cross-sectional survey nested within the community-randomised controlled CRESIPT trial, Peru

A. D'Souza,[1] L. Quevedo Cruz,[2] R. Montoya,[2] J. Franco,[2] A. Lozano,[2] R. Sosa,[2] P. Tapia,[2] E. Flores,[2] M. Rivero,[2] T. Wingfield,[3] S. Datta,[2] C. Evans,[4] [1]Liverpool School of Tropical Medicine, International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland, [2]PRISMA, IFHAD, Lima, Peru, [3]Liverpool School of Tropical Medicine, International Public Health and Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland, [4]Imperial College London, Global Health, Lima, Peru
e-mail: amrita.d'souza@nhs.net

Background: Tuberculosis (TB) is a social disease linked with poverty, marginalisation, social isolation and loneliness. These factors lead to low social capital which predicts poor health.
To end TB, National TB Programmes need to tackle social inequalities which perpetuate and exacerbate TB illness, including poor social capital.
Design/Methods: CRESIPT was a non-blinded, community-randomized, controlled trial undertaken between 2012 and 2022 in 32 urban and peri-urban impoverished communities in Lima, Peru. Communities were randomised to either standard of care (SoC) from Peru's NTP or the same SoC plus a socioeconomic intervention consisting of conditional cash transfers and peer-led support. All PTB >= 15-years old completed the World Bank's "Shortened and Adapted Social Capital and Perceived Safety Assessment Tool" questionnaire to quantify their social capital.
Quantitative analyses summarised the perceptions of PTB on their community at recruitment in 2016-19.
Results: 2382 PTB completed the SASCAT with median age 31 (range 15-96) and 1527/2382 (64.1%) of whom were male. Less than one quarter (24.52%) PTB had trust in their community (584/2382), 38.62% felt their community would take advantage of them if able (920/2382), and 65.99% reported other community members were only interested in their own wellbeing (1572/2382).
80.89% PTB reported feeling safe or very safe within their home (1927/2382), 61.67% in their neighbourhood (1473/2525), 56.63% (1349/2382) and 41.15% (980/2382) when walking in their neighbourhood any time or at night, respectively. 26.62% PTB felt crime and violence happened often or all the time (634/2382).
64.44% PTB felt community belonging (1535/2382) and only 50.84% reported meaningful community-based friendships (1211/2382). Only 3.82% had engaged in collective action in the previous 12 months (91/2382).
Conclusions: In urban and peri-urban impoverished communities of Lima, Peru, PTB felt high community mistrust and insecurity. Policies addressing neighbourhood security and trust could improve community-based social capital to improve health outcomes.

Table 1| Characteristics of people with TB (PTB) at CRESIPT recruitment, 2016-2019

Variable	Characteristics	Frequency (n= 2382)	Percentage (%)
Demographic			
Median Age, Years (IQR, Range)	31 (24, 15-96)		
Sex	Male	1527	64.1
	Female	855	35.9

"Do you think there is crime and violence where you live?"		All the time: 285 Often: 349	11.96 14.65

OA21-303-20 People power against TB: Janbhagidari as a transformative force in India's 100-Day TB Elimination campaign

D. Panchal,[1] R. Rao,[2] M. Deka,[1] P. Bordoloi,[1] S. Malviya,[2] U. Singh,[2] [1]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [2]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India
e-mail: bordoloip@rntcp.org

Background and challenges to implementation: India's ambition to eliminate tuberculosis (TB) by 2025 requires more than clinical interventions—it calls for deep community engagement. The 100 Days TB Mukt Bharat Abhiyan, launched in December 2024, gave form to this approach through *Janbhagidari*—a nationwide movement mobilizing people's participation to drive awareness, improve early detection, and reduce stigma in high-burden districts.
Intervention or response: To foster collective ownership of TB elimination, Janbhagidari was integrated across all campaign levels. Citizens, elected representatives, community influencers, and institutions were engaged through structured outreach, public pledges, and targeted IEC efforts. Ministries, schools, corporates, religious organizations, and Panchayati Raj Institutions (PRIs) worked in tandem to create a unified, community-led response.

Results/Impact: From December 7, 2024, to March 17, 2025, over 3.69 crore individuals were screened and 2.16 lakh new TB cases diagnosed, including a 120% increase in asymptomatic case detection compared to the same period in 2023. The campaign saw 41,710 Janbhagidari-related activities across 22 line ministries, and 24,157 additional events by PSUs, trade associations, and voluntary organizations. In schools, 55,774 TB awareness sessions engaged students and educators. High-risk settings were prioritized, reaching 46,344 individuals in prisons, 92,553 in mines, 50,592 in tea gardens, 1,37,369 at construction sites, and 90,898 in other workplaces. Cultural and faith-based outreach extended further through 23,741 activities during festivals and gatherings. Strong political participation was evident, with 162 Members of Parliament, 1,290 MLAs, and 32,286 PRI and ULB representatives contributing actively. This wide-scale engagement enhanced public awareness, encouraged timely care-seeking, and expanded access to essential TB services.
Conclusions: The Janbhagidari-driven campaign redefined TB control in India as a shared societal mission. It demonstrated how community ownership, political will, and intersectoral coordination can collectively advance national disease elimination goals and serve as a model for global health strategies.

OA21-304-20 Breaking the cycle: Integrating economic empowerment into TB care for sustainable outcomes in Indonesia

N. Nurliyanti,[1] H. Diatmo,[2] N. Nuriyanti,[1] [1]Stop TB Partnership Indonesia, Program, Jakarta Selatan, Indonesia, [2]Stop TB Partnership Indonesia, Director, Jakarta Selatan, Indonesia
e-mail: nurliyanti@stoptbindonesia.org

Background and challenges to implementation: Tuberculosis (TB) is both a cause and consequence of poverty. Socio-economic vulnerability—including poor living conditions, malnutrition, stigma, and limited access to care—drives TB transmission and undermines treatment adherence. While biomedical strategies like DOTS have improved case detection and cure rates, evidence shows that addressing socio-economic determinants is critical to achieving long-term impact.
Intervention or response: To complement existing TB interventions, Stop TB Partnership Indonesia piloted an economic empowerment program targeting three TB-affected families identified through financial assessments and catastrophic cost analysis. The intervention began with structured entrepreneurship training over the course of a week, covering business fundamentals, opportunity mapping, production planning, and technical skills in wooden toy manufacturing—selected based on local material availability and artisan potential. What differentiates this initiative from other livelihood programs is that TB-affected individuals were equipped not only with vocational skills but also with essential business management and marketing capabilities. This comprehensive preparation proved to be a key factor in the program's success.
Results/Impact: Each family received start-up capital in the form of tools and raw materials, followed by monthly mentorship and business monitoring. Within several months, families began producing and selling custom wooden toys, generating an average profit of USD 70 per month. Although not a primary income source, this earning supplements treatment-related costs and provides a form of sustainable social protection. Importantly, increased motivation and improved treatment adherence were also observed among participants.
Conclusions: This initiative demonstrates the feasibility and value of integrating socio-economic support into TB care. Economic empowerment can reduce financial hardship, support treatment success, and build long-term resilience. Such approaches should be scaled and embedded within national TB programs to break the poverty-TB cycle and ensure no one is left behind in the effort to end TB.

OA21-305-20 Cost-effectiveness of conditional cash transfers with pre-test and post-test TB counselling in South Africa: A mathematical modelling study

L. Goscé,[1] E. Venero-Garcia,[1] K. Allel,[2] T.O. Prys-Jones,[1] H. Haghparast Bidgoli,[3] S. Madhi,[4] J. Mwansa-Kambafwile,[5] S.V. Omar,[5] N.A. Ismail,[6] R.M. Houben,[1] I. Abubakar,[7] [1]London School of Hygiene and Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [2]University of Oxford, Nuffield Department of Primary Care Health Sciences, Oxford, United Kingdom of Great Britain and Northern Ireland, [3]University College London, Institute for Global Health, London, United Kingdom of Great Britain and Northern Ireland, [4]University of the Witwatersrand, Wits Vaccines and Infectious Diseases Analytics Unit, Faculty of Health Sciences, Johannesburg, South Africa, [5]National Institute for Communicable Diseases (NICD), Centre for Tuberculosis, Johannesburg, South Africa, [6]University of the Witwatersrand, Department of Clinical Microbiology and Infectious Diseases, Faculty of Health Sciences, Johannesburg, South Africa, [7]University College London, Faculty of Population Health Sciences, London, United Kingdom of Great Britain and Northern Ireland
e-mail: Lara.Gosce@lshtm.ac.uk

Background: Tuberculosis (TB) remains a significant global health challenge, disproportionately affecting low-income populations due to socioeconomic barriers, including poverty, malnutrition, and healthcare access constraints. Conditional cash transfer (CCT) interventions have emerged as promising strategies to improve TB treatment adherence, mitigate economic hardship, and enhance health outcomes. However, there is a paucity of

studies exploring the cost-effectiveness of such strategies, particularly when combined with pre-test and post-test tuberculosis counselling.

Design/Methods: This analysis used results from a pragmatic, multicentre, open-label, individual randomised controlled trial conducted between October 2018 and March 2020 in South Africa. Trial results on treatment initiation, treatment completion and on-treatment mortality informed a compartmental model of TB transmission in South Africa where a CCT intervention with pre-test and post-test tuberculosis counselling is offered to all notified adults affected by drug sensitive TB between 2025 and 2050. Epidemiological modelling results were combined with cost data to determine the cost-effectiveness of the intervention from the provider perspective. We estimated the incremental cost-effectiveness ratio (ICER) per disability-adjusted life year (DALYS) averted by comparing our intervention with the standard of care.

Results: Universally applying the CCT intervention would lead to a decrease of 11% TB incidence and 17% TB mortality by 2050 in South Africa, compared to standard of care. The incremental cost of the intervention was estimated at $80.4 USD per patient, leading to a total increase of 7% in TB budget (i.e. ~20 million USD per year) between 2025 and 2050. The intervention was cost effective at ICER of $148.7 per DALY averted compared to a cost-effectiveness threshold (CET) of $3,015-3,314 USD.

Conclusions: CCT interventions with pre-test and post-test counselling appear to be cost-effective in South Africa, leading to a long-term reduction in TB incidence and mortality, and a potential reduction in the risk of catastrophic costs to households.

OA21-306-20 Policy gaps in social protection for people affected by TB: Evidence from high-burden municipalities in Rio de Janeiro, Brazil

Y.M. Alves,[1,2] R.B.V. Tavares,[1,2] V.M.S. Araújo,[2] D.S. Duarte,[2] V.C. Lima,[2] M. Guazzi,[3] M. Martins,[4] C.M. Morgado,[5] R.A. Arcêncio,[1,2] E.L.N. Maciel,[6,2] [1]University of São Paulo at Ribeirão Preto College of Nursing, Maternal-Infant and Public Health, Ribeirão Preto, Brazil, [2]Brazilian Tuberculosis Research Network (REDE-TB), Projects, Rio de Janeiro, Brazil, [3]Rio de Janeiro State Health Department, Social Assistance, Rio de Janeiro, Brazil, [4]Rio de Janeiro State Health Department, Tuberculosis, Rio de Janeiro, Brazil, [5]Pan American Health Organization, Tuberculosis, Rio de Janeiro, Brazil, [6]Federal University of Espírito Santo, Nursing, Vitória, Brazil
e-mail: yan.alves@usp.br

Background: Tuberculosis (TB) remains a major public health concern in Brazil, particularly in socioeconomically vulnerable populations. Although social protection is a key pillar of the End TB Strategy, mechanisms to ensure financial support and food security for people affected by TB remain fragmented. In Brazil, despite national social assistance programs, local-level implementation is inconsistent. This study examines the presence and scope of normative frameworks related to social protection in high-burden TB municipalities in Rio de Janeiro.

Design/Methods: A documentary review was conducted in ten municipalities in Rio de Janeiro state with the highest TB burden. Official websites and public records were systematically screened for laws, decrees, and regulations published since 2020 that address social protection. Documents were categorized by level (municipal or federal), type of benefit (e.g., food support, transport, cash transfer), and explicit inclusion of TB-affected individuals. Data were analyzed descriptively to identify patterns, limitations, and gaps.

Results: A total of 79 normative acts were identified across the selected municipalities. Most documents addressed broad social programs such as food security or poverty reduction. However, none explicitly mentioned individuals undergoing TB treatment as a target group. Only two municipalities offered structured food support linked to health services, but eligibility and implementation criteria were often unclear. The absence of tailored provisions and intersectoral coordination indicates a disconnect between TB care and social protection strategies, particularly in high-burden urban areas.

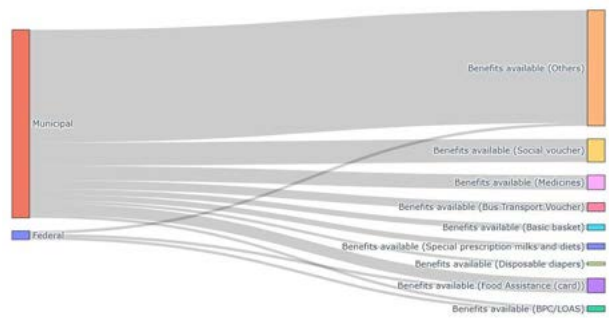

Figure 1 – Flow between normative level and types of social benefits.

Conclusions: Findings reveal critical gaps in the normative landscape of social protection for people affected by TB in Rio de Janeiro. The lack of explicit policies and integration between health and social sectors may hinder treatment adherence and equity. Strengthening local governance and institutionalizing targeted social support are urgent to align municipal policies with global TB control strategies and protect vulnerable populations from avoidable hardship.

OA22 Understanding the impact of case finding modalities: From the facility to the population

OA22-307-20 Stamping out missed TB cases: Evaluating a novel screening strategy on TB presumption and detection from Kunda Nqob'iTB project in Zimbabwe

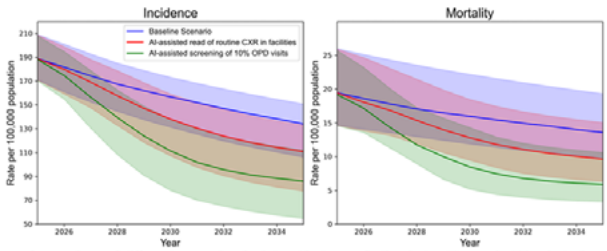
S. Dube,[1] R. Ncube,[1] N. Mlilo,[1] T. Mapuranga,[1] F. Kavenga,[2]
[1]The Union Zimbabwe Trust, Technical, Harare, Zimbabwe, [2]Ministry of Health and Child Care, AIDS and TB Unit, National TB and Leprosy Control Programme, Harare, Zimbabwe
e-mail: sdube@uzt.org.zw

Background and challenges to implementation: Tuberculosis (TB) case finding through systematic screening at healthcare encounters is a strategy to enhance detection within resource-constrained settings. We investigated the potential impact of the Stamp Strategy, using WHO 4-Symptom Screen (4SS) stamped on client booklets, on TB presumptive case identification and yield in Zimbabwe. The Kunda Nqob'iTB (KN-TB) project implemented this strategy to facilitate routine TB screening.
Intervention or response: Healthcare workers across 102 facilities in Insiza, Gwanda, Chirumhanzu and Zvishavane districts received training on the Stamp Strategy in August 2023 and February 2024. Upon arrival, the 4SS was stamped onto client cards, prompting workers to screen clients. Clients screening positive were requested to provide sputum for Xpert MTB/Rif testing. Annual data on presumptive TB cases and yield in 2024 were compared to pre-implementation baseline data from 2023 to evaluate the strategy's impact.
Results/Impact: Overall, the number of presumptive TB cases increased from 11,849 in 2023 to 14,459 in 2024, representing a 22% rise ($p<0.05$, 95% CI). Three of the four districts demonstrated an increase in presumptive TB cases, with Zvishavane exhibiting a surge in monthly cases, peaking at 942 in March 2024 compared to 340 in August 2023. Although modest increase in total TB cases was observed from 1,047 in 2023 to 1,074 in 2024 (2.58% growth, $p=0.78$) the overall yield of TB found reduced (8.8% to 7.4%). Notably, TB cases in the 0–4 years age group showed an increase (82%), rising from 17 to 31 cases.
Conclusions: The Stamp Strategy represents a simple intervention for enhancing TB case finding within facilities in Zimbabwe. Its implementation was associated with an increase in presumptive TB cases and overall TB cases. Reduced yield could be due to added clients presumed having mimickers of TB as well as difficulty in controlling for confounders. Additional assessment of treatment outcomes would be ideal.

OA22-308-20 Modelling the epidemiological impact of strengthening intensified TB case-finding in health facilities in India

Y.A. Raj,[1] R. Parthasarathy,[1] S. Vijayan,[2] S. Pawar,[3] K. Rade,[4] V. Chadha,[5] R. Rao,[6] U.B. Singh,[6] S. Mehra,[7] M.K. Mitra,[8] N. Arinaminpathy,[9] [1]Indian Institute of Technology Bombay, Mathematics, Mumbai, India, [2]Qure.ai, Global Health, Mumbai, India, [3]Qure.ai, Operational Research and Impact Measurement, Mumbai, India, [4]STOP TB Partnership, Public Health, Mumbai, India, [5]National Tuberculosis Institute, Epidemiology, Bengaluru, India, [6]Ministry of Health and Family Welfare, Government of India, Central Tuberculosis Division, Delhi, India, [7]Indian Institute of Technology Bombay, Chemical Engineering, Mumbai, India, [8]Indian Institute of Technology Bombay, Physics, Mumbai, India, [9]World Health Organisation, Global TB Programme, Geneva, Switzerland
e-mail: yashiraj19@gmail.com

Background: In high TB burden settings such as India, it is important to find and treat TB as rapidly as possible, to limit opportunities for transmission. This challenge is further aggravated by the prevalence of asymptomatic TB.
While mass screening in communities can be resource-intensive, growing evidence suggests that intensified case-finding in healthcare facilities may have substantially higher yield. This study aims to quantify the potential impact of facility-based TB screening, on TB incidence and mortality in India.
Design/Methods: We developed a deterministic compartmental TB transmission model for India stratified by health facility and community settings, incorporating the natural history of TB, routine TB services, and presentation to health facilities for other conditions. We calibrated the model to epidemiological data from India and healthcare utilisation.
We modelled the potential impact on incidence and mortality in India, under two screening scenarios:
(i) AI-assisted analysis of all chest X-rays (CXR) routinely being performed irrespective of indication
(ii) pro-active screening with AI-assisted CXR and symptoms, prioritised for patients with known TB risk factors, and overall covering 10% of patients presenting to facilities.
In both scenarios, we assumed that presumptive TB cases would have sputum microbiologically tested with NAAT.
Results: By 2030 AI-assisted reads of routine CXR would avert 6.5% (95% UI 2.7 -14) of cumulative TB incidence and 11% (95% UI 4.4 - 21) of cumulative TB deaths. Proactive screening would avert 18% (95% UI 8.8 - 29) of cumulative TB incidence and 31% (95% UI 14 - 46) of cumulative TB deaths over this period.



Comparison of different scenarios for intensified case-finding in healthcare facilities in India. Shown are scenarios of: (i) AI-assisted reads of routinely conducted CXRs (in red) and (ii) proactive screening, using AI-assisted CXR and symptoms in parallel, prioritised for patients with known TB risk factors, and overall covering 10% of patients presenting to facilities (in green). Being a more proactive strategy, the latter scenario will require greater investment and programmatic effort. While these scenarios emphasise impact, informed programmatic decision-making will require further analysis of cost-effectiveness. The solid lines denote the central estimates and the shaded region denote the uncertainty intervals of each scenario respectively.

Conclusions: These findings highlight the untapped potential of health facilities as key entry points for systematic TB screening in India. Further analysis of cost-effectiveness will facilitate programmatic decision-making. Overall, by reaching individuals who are already seeking care, we can detect cases earlier, and substantially reduce transmission.

OA22-309-20 Modelling 'targeted universal testing for TB' vs symptom-based screening in South Africa

N. McCreesh,[1] P. Khan,[1,2] I. Govender,[1,2] M. Sithole,[2] X. Buthelezi,[2] G. Ording-Jespersen,[2] S. Sweeney,[1] I. Yoon,[1] R.M. Houben,[1] R.G. White,[1] A.D. Grant,[1,2,3]
[1]London School of Hygiene & Tropical Medicine, TB Centre, London, United Kingdom of Great Britain and Northern Ireland, [2]Africa Health Research Institute, Clinical Research Department, Somkhele, South Africa, [3]University of KwaZulu-Natal, School of Laboratory Medicine and Medical Sciences, College of Health Sciences, Durban, South Africa
e-mail: nicky.mccreesh@lshtm.ac.uk

Background: South African guidelines recommend targeted universal testing for TB (TUTT) in primary healthcare clinics, i.e. testing clinic attendees in specified groups (people with HIV [PWH], recent TB, or close contact with a person with TB) with Xpert Ultra, regardless of reported symptoms.
We contrast this with universal symptom-based screening (SBS), assuming all clinic attendees are screened, and tested if symptomatic.
Design/Methods: We developed an individual-based mathematical model of TB in South Africa, incorporating variation in clinic visiting rates by sex, ART status, and TB symptoms, and between individuals; and the high levels of uncertainty in TB natural history with respect to symptoms.
We assume in the baseline scenario that people on ART have a probability of Xpert testing each visit, through annual testing or active symptom-screening, and that people not on ART (PWH or HIV-negative) are only tested if seeking care for TB symptoms. We modelled nationwide TUTT and SBS from 2025–2034, and compared them to the baseline scenario.
Results: SBS and TUTT reduced cumulative TB incidence in 2025–2034 by 38% (95% CI 31–45%) and 23% (20–28%) respectively (Table).
Compared to TUTT, SBS required 23% (3.3%–36%) more Xperts, but increased the proportion of the entire population receiving at least one test in 2025 by 52% (33%–66%), and improved yields per Xpert by 31% (9.2%–66%). SBS resulted in a 51% (95% CI 43–58%) reduction in the proportion of TB episodes that ended in death, compared to 28% (23–33%) for TUTT.

		Baseline (median (95% CI))	Symptom-based screening (median (95% CI))	TUTT (median (95% CI))
Reduction in TB incidence 2025-34 [in 2034]			0.38 (0.31 – 0.45) [0.60 (0.51 – 0.68)]	0.23 (0.20 – 0.28) [0.38 (0.32 – 0.44)]
Reduction in TB mortality 2025-34 [in 2034]			0.51 (0.43 – 0.57) [0.71 (0.62 –0.78)]	0.31 (0.27 – 0.37) [0.47 (0.40 –0.53)]
Xpert tests used in clinic-based active screening/100,000 population in 2025		16012 (14185 – 17914)	63711 (52868 – 72220)	52101 (47278 – 57289)
Proportion of the population receiving an Xpert test as part of clinic-based active screening in 2025		0.030 (0.027 – 0.033)	0.096 (0.083 – 0.11)	0.063 (0.058 – 0.068)
Yield of people with TB per 100 Xpert tests as part of clinic-based active screening in 2025		3.7 (3.0 – 4.5)	4.3 (3.4 – 5.7)	3.2 (2.7 – 3.8)
Number of people with true positive TB starting treatment in 2025/100,000 population	Not on ART (PLH or HIV-)	195 (170 – 225)	431 (361 – 524)	294 (258 – 339)
	On ART	134 (114 – 161)	158 (134 – 188)	179 (151 – 217)
	Overall	330 (295 – 372)	591 (506 – 701)	474 (418 – 540)
Proportion of TB episodes starting in 2025 that end in TB mortality		0.20 (0.16 – 0.24)	0.10 (0.072 – 0.12)	0.15 (0.11 – 0.18)

Conclusions: SBS needed a modest increase in Xpert tests, but improved yields, resulted in greater reductions in TB incidence, and improved TB outcomes by a greater amount than TUTT. The impact of TUTT may be undermined by its focus on PWH, a group in which the coverage of clinic-based testing is already relatively high.

OA22-310-20 Does active case-finding detect people with TB early in programme settings? A national level study from India

H.D. Shewade,[1] S. Kiran Pradeep,[2] P. Ravichandran,[3] A. N. Shah,[4] B. Vadera,[4] V. Roddawar,[5] S. K. Mattoo,[6] K. Kiran Rade,[7] R. Rao,[6] M.V. Murhekar,[8] [1]ICMR National Institute of Epidemiology, Division of Health Systems Research, Chennai, India, [2]Madha Medical College and Research Institute, Community Medicine, Chennai, India, [3]Chettinad Hospital & Research Institute, Community Medicine, Chennai, India, [4]USAID India, Health Systems Research, New Delhi, India, [5]John Snow India Private Limited, Health Systems Research, New Delhi, India, [6]Central TB Division, Ministry of Health and Family Welfare, New Delhi, India, [7]Office of the World Health Organization (WHO), WHO Country Office, New Delhi, India, [8]ICMR National Institute of Epidemiology, Infectious Disease Epidemiology, Chennai, India
e-mail: drkiranpradeep001@gmail.com

Background: India's national tuberculosis program implements active case-finding (ACF) in high-risk populations. In 2023, we determined the differences in extent of severe illness and pre-treatment delay at diagnosis among public-notified ACF- and passive case-finding (PCF)-detected adults (≥15 y) with drug-sensitive pulmonary tuberculosis.
Design/Methods: This was a cross-sectional analytical study involving primary and secondary data from 28 randomly sampled districts (nine states). All ACF-detected and randomly sampled PCF-detected were enrolled. Severe illness was defined as presence of very severe undernutrition or respiratory insufficiency or poor performance status.
Results: Of 790 enrolled, 426 were ACF- and 364 were PCF-detected. When compared to PCF, ACF-detected adults were significantly older, living farther away from a diagnosis facility, less exposed to formal education, poorer and experiencing lower number of healthcare provider visits.

	ACF-detected		PCF-detected		
Type of delay	Total assessed n^	Delay Median (IQR)	Total assessed n^	Delay Median (IQR)	P value*
Patient level (a)	310	30 (10,70)	292	30 (8,67)	0.333
Health system level – diagnosis (b)	335	2 (0, 9)	309	1 (0, 21)	0.165
Health system level – treatment initiation (c)	422	2 (1,5)	360	1 (0,3)	<0.001
Diagnosis delay (a+b)	340	42 (20,92)	292	43 (21,92)	0.811
Health system level (b+c)	333	6 (3,14)	308	4 (2,21)	0.104
Total pre-treatment delay (a+b+c)	338	46 (24,95)	291	46 (22,94)	0.595

TB: tuberculosis; ACF: active case-finding; PCF: passive case-finding; IQR: inter-quartile range; @of 790 enrolled, 672 (85.1%) were interviewed for pre-treatment delays; ^both dates available to calculate the corresponding delay among 672 interviewed; *Mann Whitney U test

Table. Pre-treatment delay among adults (≥15 y) with drug-sensitive pulmonary TB from high-risk populations, notified by public sector, enrolled@ and interviewed@ across 28 randomly selected districts in India, 2023, stratified by ACF- and PCF-detected [N=672]@

Pre-treatment delay from symptom onset to treatment initiation (median 46 days among both, see Table) and extent of severe illness (39% and 34%, p=0.180) were not significantly different in both groups.
Conclusions: This is the first nationally representative assessment of ACF in terms of early detection. Though ACF identified more marginalized people and reduced healthcare provider visits, this did not translate into early diagnosis. High burden of severe illness at diagnosis is a concern.

OA22-311-20 Using geolocation data to inform TB active case finding in the Kulob Zero TB project, Tajikistan

M. Saunders,[1] M. Longley,[1] J. Vyncke,[2] E. Masumbuko Wabulaombe,[3] N. Ali,[3] A. Bayniyazova,[3] B. Tojiddinov,[3] C. Gomez Restrepo,[4] A. Sinha,[1] J.L. Alvarez,[1] [1]Medecins Sans Frontieres/Doctors Without Borders, Manson Unit, London, United Kingdom of Great Britain and Northern Ireland, [2]Medecins Sans Frontieres/Doctors Without Borders, Manson Unit, Brussels, Belgium, [3]Medecins Sans Frontieres/Doctors Without Borders, Tajikistan, Kulob, Tajikistan, [4]Medecins Sans Frontieres/Doctors Without Borders, Tajikistan, Tashkent, Uzbekistan
e-mail: msaunder@citystgeorges.ac.uk

Background: Tajikistan faces a high tuberculosis (TB) burden compounded by low TB awareness among the population and healthcare workers. Médecins Sans Frontières (MSF) initiated the Zero TB project in Kulob to demonstrate the feasibility of active case finding (ACF) using computer-aided chest radiography (CAD4TB) and symptom screening.
Design/Methods: We retrospectively analysed programmatic and geographical data collected between January 2022 and December 2024 from Kulob City and four surrounding Jamoats (sub-districts). People with TB were diagnosed through passive case finding (PCF) after presenting at health centres, or our ACF intervention (between May 2023 and December 2024). Geolocation data for people who started TB treatment were mapped to a lower-level geographical unit (healthcare catchment area) and integrated with population data to calculate annual TB case notification rates (CNR). Spatial maps were developed, and a mixed-effect Poisson model accounting for administrative hierarchy was used to identify factors associated with TB CNRs.
Results: 14,823 people were screened in our ACF intervention (64% female, median age=36 years), of whom 811 (5.5%) were referred for diagnostic evaluation. 22/811 (2.6%) were diagnosed with TB and 21/22 (95%) started TB treatment. Including those diagnosed through PCF, 485 people started TB treatment during the study – an overall CNR of 77/100,000 (95% confidence interval [95%CI]: 71-85). Among 121 geographical units (mean

population size=1,725 people), the TB CNR ranged from 0-575/100,000, with 37/121 (31%) units considered as TB transmission hotspots with CNRs ³100/100,000. Higher TB CNRs were associated with being in an urban versus rural area (adjusted rate ratio [aRR]=1.64, 95%CI: 1.14-2.36), and household size (aRR per additional person per house=1.05, 95%CI:1.00-1.11).

Conclusions: Spatial analysis facilitated the identification of TB transmission hotspots in Kulob Districts. This information will be used to optimise targeted, evidence-based TB screening, prevention, and education interventions as part of the Zero TB project.

OA22-312-20 Modelling the impact of case finding for TB: The role of infection dynamics

T. Ryckman,[1] S. Shrestha,[2] A.T. Fojo,[3] P. Kasaie,[2] D.W. Dowdy,[2] E.A. Kendall,[1] [1]Johns Hopkins School of Medicine, Division of Infectious Diseases, Baltimore, United States of America, [2]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States of America, [3]Johns Hopkins School of Medicine, Department of Medicine, Division of General Internal Medicine, Baltimore, United States of America
e-mail: tryckma1@jh.edu

Background: Population-level case-finding is recommended as a strategy to reduce the global burden of tuberculosis. Mathematical models consistently project that case-finding will yield only modest reductions in incidence, but have tended not to account for the possibility that some *M. tuberculosis* (*Mtb*) infections may be cleared.

We evaluated whether the common assumption of lifelong risk of progression after infection leads models to undervalue the impact of case-finding.

Design/Methods: We constructed two mathematical models of *Mtb* transmission: one assumed lifelong progression risk after infection ("Conventional"), and the other assumed that some individuals eventually clear their infections ("Clearance"). We calibrated these otherwise similar models to the same set of empirical data on tuberculosis burden (in India) and progression after infection (from longitudinal cohorts).

We then projected the impact of biennial community-wide active case-finding campaigns, covering 70% of the population with a screening algorithm having 65% sensitivity, with or without accompanying provision of tuberculosis preventive treatment (TPT).

Results: Relative to the Conventional model, the Clearance model was able to better fit data on disease incidence, *Mtb* infection prevalence, progression to disease over time since infection, and incidence trends.

The Clearance model also projected a greater impact of case-finding on tuberculosis incidence – both in terms of overall magnitude (26% [95% uncertainty interval 15-41%] vs. 11% [7-24%] reduction in incidence after 10 years; *Figure*) and relative to TPT (with case-finding representing 33% [19-50%] vs. 14% [8-30%] of combined case-finding/TPT impact).

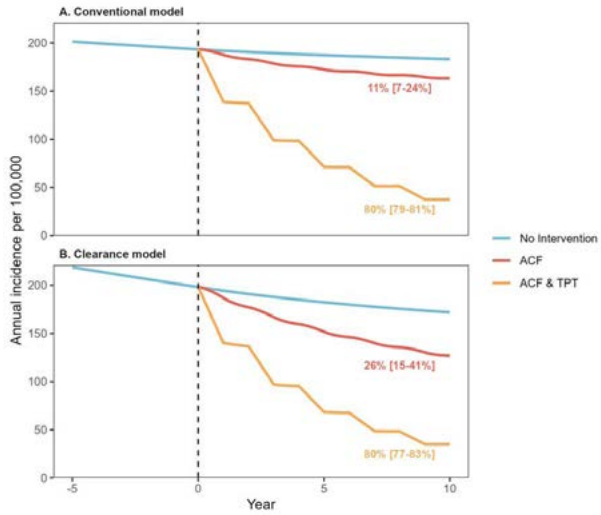


Figure: Effect of considering immune clearance on the impact of mass case-finding & prevention
Figure shows the projected mean annual TB incidence per 100,000 people over ten years of simulated interventions (years 0 through 10), including: no intervention (blue), Active Case-Finding (ACF) waves every 2 years (red-orange), and the same ACF waves with tuberculosis preventive treatment (TPT) added (yellow). Text labels indicate the percent reduction in incidence at year 10 (means and 95% uncertainty intervals), relative to no intervention. Panels differ by whether the model structure allows clearance of some Mtb infections (panel A = conventional model without clearance; panel B = allowing clearance of some infections). Incidence trends in the 5 years preceding the intervention period are also shown in each panel (years -5 through 0).

Conclusions: Given that clearance of a fraction of *Mtb* infections is biologically likely, and that our model incorporating clearance yielded a better fit to empirical data, we conclude that the epidemiological impact of population-level case-finding for tuberculosis may be greater than projected by most previous models, which do not account for clearance.

OA22-313-20 Simulating the ACT3 trial: How TB natural history determines the durability of community screening

D. Gokhale,[1] D. Klein,[1] M. Enriquez,[1] S. Chang,[1] [1]Gates Foundation, Institute for Disease Modeling, Seattle, United States of America
e-mail: stewart.chang@gatesfoundation.org

Background: The ACT3 trial in Vietnam showed a 44% reduction in TB prevalence after three rounds of universal Xpert-based screening. However, concurrent declines in the control arm complicate attribution, and generalizability to higher-burden settings remains uncertain. As TB community screening expands, modeling tools are needed to project long-term impact and separate intervention effects from background trends.

Design/Methods: We developed TBsim, a flexible, open-source agent-based modeling framework for simulating TB natural histories, screening strategies, and long-term outcomes. Using TBsim, we implemented two competing natural history models: (1) a traditional latent reactivation model and (2) a reinfection-dominant undulation model.

Both were calibrated to ACT3 trial data and Vietnam national TB trends. We then simulated post-trial trajectories across lower- and higher-burden settings, with and without secular declines, and quantified prevalence reductions attributable to intervention versus background change.

Results: Both models reproduced trial-period declines (Intervention: −32%/yr; Control: −17%/yr). However, their long-term projections diverged. In lower-burden settings with flat secular trends, the reinfection model projected a sustained ~25% prevalence reduction a decade after screening, while the latent model rebounded to within ~10% of baseline. The intervention explained ~80% of the decline under the reinfection model, versus ~50% under the latent model. This suggests community screening can have durable impact if recent transmission drives incidence. However, tools like genomic epidemiology remain limited for distinguishing recent from remote infection in high-burden settings.

Conclusions: Our calibrated trial simulation enables causal decomposition of TB trends and highlights the risks of mischaracterizing natural history. When latent infections dominate, short-term screening alone may yield little lasting benefit. Until more direct measurements are available, simulation-based inference provides a practical way to estimate impact and assess whether individual control strategies are sufficient.

OA22-314-20 Potential impact of community-wide screening approaches for TB: A modelling study across the spectrum of disease

K.C. Horton,[1] A.S. Richards,[1] A. Schwalb,[1] R.M.G.J. Houben,[1]
[1]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland
e-mail: katherine.horton@lshtm.ac.uk

Background: Approaches to tuberculosis (TB) prevention and care focus mainly on symptomatic disease but have failed to reduce disease burden at the pace required to meet global targets. Community-wide screening has enabled rapid declines in TB burden in historic and some contemporary settings. However, the potential epidemiological impact of different algorithms and approaches has not been evaluated in the context of the wider spectrum of disease.

Design/Methods: We explored the impact of approaches to community-wide screening, considering diagnostic algorithms (prolonged cough with confirmatory GeneXpert Ultra [Cough+Xpert]; chest X-ray with confirmatory GeneXpert Ultra [CXR+Xpert]; GeneXpert Ultra [Xpert-only]; chest X-ray [CXR-only]) implemented at different levels of population coverage for different durations. We examined these approaches using a model that recognises symptomatic (sTB) and asymptomatic infectious TB (aTB), as well as non-infectious TB (nTB), calibrated to infectious TB (infTB) prevalences of 1,000, 500, and 250 per 100,000 population. We assessed diagnostic performance, diagnostic efficiency, and impact on disease burden.

Results: Symptom-agnostic algorithms led to greater reductions in sTB incidence (13.3% [95% uncertainty interval: 11.3-15.5%] with CXR+Xpert, and 17.5% [15.0-20.1%] with Xpert-only, for 2 rounds with 50% coverage) than symptom-dependent screening (5.6% [4.7-6.7%] with Cough+Xpert, for same approach). Algorithms that detect non-infectious TB are likely to have even greater impact (47.6% [44.7-50.1%] with CXR-only, for same approach), but tools do not currently exist to diagnose this state without large numbers of false positive results (13.5k [10.7k-16.4k] with CXR-only, for 1 round with 100% coverage). We found limited epidemiological impact for single rounds of screening or multiple rounds of screening with low population coverage. Relative performance of algorithms was similar across prevalences.

Median projected reduction in 2035 sTB incidence (%)

	Population coverage									
Rounds	10%	20%	30%	40%	50%	60%	70%	80%	90%	100%
Cough+Xpert										
1	0.6	1.2	1.7	2.3	2.9	3.5	4.1	4.7	5.3	5.9
2	1.2	2.3	3.4	4.5	5.6	6.6	7.6	8.6	9.6	10.5
3	1.7	3.4	5.1	6.6	8.2	9.6	11.0	12.4	13.8	15.0
4	2.3	4.6	6.7	8.8	10.8	12.6	14.4	16.1	17.8	19.4
5	2.9	5.7	8.4	10.9	13.3	15.5	17.7	19.9	21.8	23.7
CXR+Xpert										
1	1.4	2.8	4.1	5.5	7.0	8.4	9.8	11.2	12.7	14.0
2	2.8	5.4	8.1	10.7	13.3	15.9	18.2	20.7	23.0	25.2

CXR only										
1	5.2	10.5	15.9	21.4	26.9	32.7	38.6	44.4	50.6	56.8
2	10.3	20.2	29.7	38.8	47.6	55.6	63.2	70.3	76.8	82.5
3	15.1	29.0	41.7	52.9	62.7	71.4	78.6	84.6	89.4	93.1
4	19.9	37.2	51.8	64.0	73.8	81.7	87.7	92.2	95.3	97.4
5	24.5	44.6	60.4	72.7	81.9	88.5	93.1	96.1	97.9	99.0

Conclusions: Community-wide screening can contribute to rapid reductions in TB burden, with greater impact from approaches that reach larger proportions of the spectrum of disease.

OA22-315-20 Estimating the epidemiological impact of the CAST TB Uganda: A modelling analysis

A. Richards,[1] B. Kirenga,[2] S. Turyahabwe,[3] B. Muzamiru,[4] R. Byaruhanga,[5] S. Dejene Balcha,[6] D. Lukoye,[7] E. Rutta,[8] M. Murungi,[6] P. MacPherson,[1] K. Horton,[9] [1]University of Glasgow, School of Health and Wellbeing, Glasgow, United Kingdom of Great Britain and Northern Ireland, [2]Makerere University, Research and Innovation, Kampala, Uganda, [3]Ministry of Health, Communicable Disease Prevention and Control, Kampala, Uganda, [4]Ministry of Health, National Disease Control, Kampala, Uganda, [5]Ministry of Health, National TB and Leprosy Program, Kampala, Uganda, [6]USAID, NA, Kampala, Uganda, [7]Centre for Disease Control and Prevention, Health Services Branch, Kampala, Uganda, [8]USAID, NA, Washington DC, United States of America, [9]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland
e-mail: alexandra.richards@glasgow.ac.uk

Background: Since 2022, the Community Awareness, Screening, Testing, prevention and treatment to end TB Campaign (CAST) has been implemented in Uganda. During each twice-yearly campaign, 10 to 15% of the total population was screened for symptoms of tuberculosis (TB), with confirmatory testing by GeneXpert Ultra. Case notifications increased over 25% from 2021 to 2022 but impacts on incidence and mortality are unknown.
Design/Methods: We used a deterministic TB transmission model, calibrated to TB prevalence, incidence, mortality, and notifications prior to CAST implementation. We replicated community screening in line with the CAST approach. We also simulated a scenario where symptom screening was replaced with digital chest X-ray screening from 2026. We compared each screening approach against a no-intervention scenario where no community screening had occurred and assessed incidence and mortality in 2025 and 2030.
Results: In 2025, after three years of CAST, the national incidence of TB was estimated to be 4.8% [95% uncertainty interval (UI) 3.3 - 6.6%] lower than if CAST had not been introduced, saving 1,700 [UI 1,400 - 2,000] lives. Continuing CAST TB through to 2030 could achieve a 9.9% [UI 6.7 - 13.8%] incidence reduction relative to no-intervention, saving a further 6,000 [UI 4,700 - 7,700] lives. If CAST shifted from symptom screening to digital chest X-ray screening, incidence in 2030 could be 24.2% [UI 20.4 - 28.6%] lower relative to no intervention, saving an additional 1,600 [UI 1,100 - 2,200] lives compared to symptom screening alone.
Conclusions: Twice-yearly mass TB screening has likely not only increased case notifications, but also led to substantial reductions in incidence and mortality in Uganda over the past three years. Even greater impact could be achieved by shifting from symptom screening to digital chest X-ray screening.

OA22-316-20 Can temporary mass screening campaigns accelerate declines in TB incidence in high-burden TB/HIV countries?

A. de Villiers,[1,2] M. Bekker-Nielsen Dunbar,[1] P. Steimer,[1] P. Naidoo,[3] G. Tanna,[3] F. Marx,[1,2] [1]Heidelberg University Hospital, Department of Infectious Diseases and Tropical Medicine, Heidelberg, Germany, [2]Stellenbosch University, DSI-NRF South African Centre of Excellence in Epidemiological Modelling and Analysis (SACEMA), Stellenbosch, South Africa, [3]Bill and Melinda gates Foundation, South Africa, Johannesburg, South Africa
e-mail: abigail.devilliers@uni-heidelberg.de

Background: Population-level tuberculosis (TB) screening might help close the global TB detection gap. Whether temporary mass screening campaigns could accelerate declines in TB incidence in high-burden countries is currently not well understood. Using mathematical modelling, we aimed to estimate the population-level impact of a screening campaign among high-risk individuals on TB incidence in South Africa and explored the differential impact among people living with HIV (PLWH) and those not living with HIV (PNLWH).
Design/Methods: We used a calibrated, compartmental transmission-dynamic model of TB in South Africa to simulate a temporary, community-based mass screening intervention involving 10 million people annually from 2025 to 2027.
Following initial risk assessment based on TB symptoms, HIV status and other key TB risk factors, high-risk individuals were offered a non-sputum-based rapid molecular TB test. The primary outcomes modelled were reductions in TB incidence and mortality over a 15-year period (2025-2040).

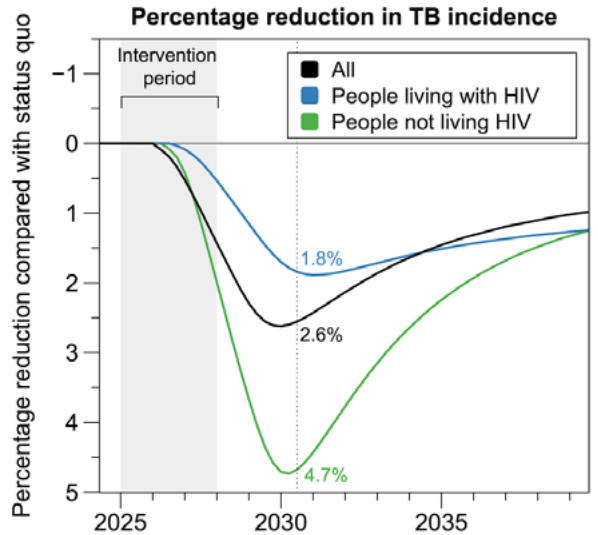

Figure: Projected percentage reductions in tuberculosis (TB) incidence rates under a temporary mass screening campaign among high-risk individuals in South Africa compared to the status quo (no screening) from 2025 to 2040. The figure presents mean estimates from 1,000 simulated model trajectories for the general population (black line), people living with HIV (blue line), and people not living with HIV (green line). Percentage reductions in TB incidence compared to status quo which peaked during 2030 are labelled for each sub-group. The 3-year intervention period is shaded in grey.

Results: In the absence of the intervention, we estimated 3.59million (95% uncertainty interval [UI]: 2.82-4.47million) incident TB cases and 475,000 [358,000–629,000] TB-related deaths between 2025–2040. Of 30million screened during 2025-2028, 9.31million were considered high-risk and tested: 4.36million (90.0% of 4.85million) PLWH, and 4.95million (19.6% of 25.15million) PNLWH. Mass screening reduced incident TB cases by 1.75%(1.06–2.78%) and TB deaths by 4.17%(3.15–5.56%) over 2025-2040. TB incidence reductions peaked ~2.5 years post-intervention, then diminished over time, with greater impact on PNLWH (4.7%) compared to PLWH (1.8%), though effects converged by 2040 (Figure).
Conclusions: A temporary mass screening campaign may reduce TB incidence in the short term in South Africa, particularly among PNLWH, but yields only modest long-term impact. We speculate that persistent delays in care-seeking, a high pool of latent TB infections, and higher reactivation risk especially among PLWH, may limit sustained impact. Combining screening with TB preventive therapy or repeated campaigns might enhance the benefits of screening.

OA23 Prevention, diagnosis, and treatment for people living with HIV

OA23-317-20 Assessing TB vaccine confidence in South African adults with HIV

A. Giovanatti,[1,2] N. Sithole,[3] I. Govender,[3,4] H.J. Larson,[5,6] L. Lebina,[3] P. Drain,[1,2,7] C. Celum,[1,2,7] A.D. Grant,[3,4] A.E. Shapiro,[1,2,7] [1]University of Washington, Department of Medicine, Division of Allergy and Infectious Diseases, Seattle, United States of America, [2]University of Washington, Department of Epidemiology, Seattle, United States of America, [3]Africa Health Research Institute, Department of Clinical Research, Somkhele, South Africa, [4]London School of Hygiene and Tropical Medicine (LSHTM), Department of Clinical Research, London, United Kingdom of Great Britain and Northern Ireland, [5]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Dynamics and Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [6]University of Washington, Department of Health Metrics Sciences, Seattle, United States of America, [7]University of Washington, Department of Global Health, Seattle, United States of America
e-mail: agiovan@uw.edu

Background: Although several TB vaccines are in late-stage clinical trials, there is limited understanding of TB vaccine attitudes among persons likely to be eligible, particularly in the context of rising vaccine hesitancy following the COVID-19 pandemic. We assessed TB vaccine confidence and associated socio-behavioral factors in South Africa to inform strategies for successful TB vaccine implementation.
Design/Methods: We conducted a cross-sectional survey in 2024 at two South African public health clinics serving people with HIV (PWH). Surveys were administered at follow-up visits at least 6 months after undergoing TB screening as part of a study of PWH initiating ART.
Vaccine confidence was defined as willingness to receive a hypothetical, approved TB vaccine and timing of receipt. Kruskall-Wallis analyses examined the relationship between vaccine confidence and socio-behavioral factors.
Results: We surveyed 225 PWH (57% female) with median age 34 years (IQR 27-42), median baseline CD4 count 338 (IQR: 179-514). Of these, 28% had a personal TB history, 96% had ever lived with someone with TB. TB vaccine willingness was 88% "Definitely yes", 12% "Unsure, leaning yes" with nobody "leaning no" or "definitely no." Timewise, 52% would take the vaccine immediately, 48% would wait >=6 months.
Vaccine confidence was significantly higher in participants who perceived TB as an important community health issue, were concerned about contracting TB, or had a history of TB. Vaccine confidence was significantly lower in participants who had lived with someone with TB, used TV/radio for TB information, who relied on friends for general health information, and unexpectedly,

who reported vaccines were compatible with their religion. Age, sex, COVID-19 vaccine status, and safety concerns were not significantly related to vaccine confidence.

	Total Survey N=225	Vaccine Confidence Indicator: 1) Willingness: How willing would you be to take a new TB vaccine if it were approved and 2) Timing: how soon would you receive an approved TB vaccine?					
Clinical/ demographic factors	Response	N (%)	Unsure, Leaning Yes; Wait at least 6 months to over a year	Unsure, Leaning Yes; As soon as available	Definitely Yes; Wait at least 6 months to over a year	Definitely Yes; As soon as available	p-value*
Current or prior diagnosis of TB	Yes (vs. No)	64 (28%)	5 (24%)	1 (17%)	19 (22%)	39 (35%)	p = 0.023
COVID-19 Vaccine Status	Received ≥1 vaccine	52 (23%)	5 (24%)	2 (33%)	16 (19%)	29 (26%)	p = 0.47
Living with a household member who had TB in the past year	No (vs. Yes)	132 (59%)	9 (43%)	3 (50%)	48 (56%)	72 (65%)	p = 0.022
Survey Prompt							
How important do you think tuberculosis is as a health problem for people in your community?	Extremely important (vs. Somewhat / very important)	61 (27%)	4 (19%)	1 (17%)	15 (17%)	41 (37%)	p = 0.0013
Vaccines are compatible with my religious beliefs	Agree (vs. Disagree)	76 (34%)	13 (62%)	5 (83%)	29 (34%)	29 (26%)	p = 0.0006
Personal Concern of Contracting TB	Extremely concerned (vs. Very/ somewhat concerned)	72 (32%)	5 (24%)	1 (17%)	20 (23%)	46 (41%)	p = 0.0026

*Table: Vaccine confidence reported by 225 adults with HIV in South Africa in response to a survey, by clinical and socio-behavioral factors. *p-value from Kruskal-Wallis rank sum test with post-hoc Dunn's test with Bonferroni's correction.*

Conclusions: TB vaccine confidence among South African adult PWH is high. Strategic use of information sources may improve future uptake.

OA23-318-20 Point-of-care biomarker-confirmed adherence to the three-month weekly isoniazid plus rifapentine (3HP) regimen in people with HIV

D. Onyango,[1,2] B. Lutz,[3] J. Mecha,[4] L. Njagi,[4] S. Aoro,[2] J. Kinuthia,[2] H. Yu-Hsuan,[5] A. Kim,[5] D. Leon,[5] N. Panpradist,[5,6] G. John-Stewart,[7,8,9,10] S.M. LaCourse,[7,8,9] [1]Kisumu County Department of Health, Health Services, Kisumu, Kenya, [2]Kenyatta National Hospital, Research and Programs, Nairobi, Kenya, [3]University of Washington, Biomedical Engineering, Seattle, United States of America, [4]Kenya Medical Research Instituite, Center for Respiratory Diseases Research, Nairobi, Kenya, [5]University of Washington, Bioengineering, Seattle, United States of America, [6]The University of Texas at Austin, Biomedical Engineering, Austin, United States of America, [7]University of Washington, Department of Global Health, Seattle, United States of America, [8]University of Washington, Department of Medicine, Seattle, United States of America, [9]University of Washington, Department of Epidemiology, Seattle, United States of America, [10]University of Washington, Department of Pediatrics, Seattle, United States of America
e-mail: macdickens2002@gmail.com

Background: TB preventive therapy significantly reduces TB risk in people with HIV (PWH) but requires consistent adherence for effectiveness. Prior evaluations of a point-of-care (POC) urine dipstick with daily isoniazid (INH) demonstrated color changes in the presence of INH metabolites in urine within 48 hours of self-reported ingestion. The utility of a POC urine dipstick test for INH metabolites in the setting of 3HP is unknown.

Design/Methods: We first assessed the window of detectability of INH metabolites using daily urine dipstick testing for 7 days following a directly-observed 3HP dose in 20 participants. Subsequently, we assessed adherence to self-administered 3HP in a prospective cohort of 200 PWH aged ≥15 years through self-reported adherence and monthly urine dipstick tests.

Consistent biomarker-confirmed adherence was defined as positive tests at all monthly assessments for 3 months. We used generalized estimating equations to evaluate correlates of negative biomarker results.

Results: Dipstick tests were positive in 100% (n=20/20) of PWH within 48-hours of DOT 3HP doses. Among 198 PWH on self-administered 3HP with dipstick results, 68% (n=135/198) were female, median age was 35 years (IQR = 27- 44) and 13% (25/198) were in WHO stage 3/4. Of 552 monthly dipstick assessments 32% (n=175/552) were self-reported to be within 48 hours of a self-administered 3HP dose, and 35% (n=192/552) were positive;89% of tests performed within 48 hours of self-reported 3HP injection (n=156/175) tested positive.

Sixteen percent (n=31/198) of PWH had consistent biomarker-confirmed adherence. Negative biomarker tests were associated with the last dose being >48 hours before testing (adjusted risk ratio [aRR]=8.89; 95% CI 4.74 - 16.68).

Conclusions: The urine dipstick test effectively detected INH metabolites within 48 hours of ingestion. Self-reported intervals >48 hours since last 3HP dose was associated with negative tests. Community-based biomarker assessment could provide objective evidence of adherence to weekly 3HP.

OA23-319-20 Preferred short course TB preventive regimens for adults and adolescents living with HIV

P.A. Bock,[1] E. Vovc,[2] N. Ford,[3,4] H. Cox,[5,6] [1]Stellenbosch University, Paediatrics and Child Health, Cape Town, South Africa, [2]World Health Organization, Department of Human Immunodeficiency Virus, Hepatitis and Sexually Transmitted Infections, Geneva, Switzerland, [3]World Health Organization, Department of Human Immunodeficiency Virus, Hepatitis, and Sexually Transmitted Infections, Geneva, Switzerland, [4]University of Cape Town, Public Health, Cape Town, South Africa, [5]Burnet Institute, TB, Melbourne, Australia, [6]University of Cape Town, Medical Microbiology, Cape Town, Australia
e-mail: helen.cox@burnet.edu.au

Background: Tuberculosis (TB) is the leading cause of death among people living with HIV (PLHIV). While TB Preventive Therapy (TPT) is recommended, the preferred regimen for PLHIV remains unclear. We conducted a systematic review comparing TPT completion, grade 3&4 adverse events (AEs), TB incidence and HIV viral load suppression (VLS) among HIV-positive adults and adolescents (≥13 years) receiving 1HP, 3HP and 6H.
Design/Methods: We searched Pubmed, Embase and the Cochrane register, January 2014 to November 2024, and relevant conference abstracts (2022-2024); randomized control trials (RCTs) and prospective observational studies were included. For TPT completion, toxicity and VLS, single-armed estimates were compared, and meta-analyses were conducted (random-effects models). For TB incidence analysis was limited to comparative studies as data were insufficient for meta-analysis. Evidence certainty was assessed using GRADE.
Results: We screened 2788 studies; 20 studies (13 RCTs) were included.
Overall TPT completion (n=12731) was 80%; highest with 1HP (97%, 95% CI 96-98%) and 3HP (92%, 90-94%), versus 6H (72%, 62-82%). Grade 3&4 AEs (n=6906) were highest with 6H (15%), versus 1HP (7%) and 3H (5%), but differences were not significant. Grade 3&4 hepatoxicity was lowest with 3HP (0.4%). Across 3 RCTs testing either 1HP or 3HP, TB incidence was similar by regimen. VLS (n=830) was similar with 1HP and 3HP combined (93%) versus 6H (92%, one study).
Among 15300 participants, 105 deaths occurred, 3 attributed to 6H, none to 1HP or 3HP. Certainty of evidence was very low (TPT completion) and low (AEs, incidence and VLS).
Conclusions: Rifapentine-containing TPT regimens for PLHIV should continue to be scaled up. As 3HP is associated with high completion and low AEs, it is well-suited for broad implementation across LMIC settings. While 1HP remains promising, there is an overall need for more high-quality data on relative risks and benefits across different TPT regimens.

OA23-320-20 Factors associated with high CAD scores among people living with HIV screened for TB using digital chest X-ray with computer-aided detection software in Kenya

G. Kaluai,[1] I. Kathure,[1] E. Muriithi,[1] I. Umuro Hosea,[1] [1]National Tuberculosis, Leprosy and Lung Disease Program (NTLD-P), Ministry of Health-Department of Public Health, Nairobi, Kenya
e-mail: gmkaluai@gmail.com

Background: Tuberculosis (TB)-HIV co-infection remains a significant global health challenge, with 30% of cases undetected. WHO recommends a chest X-ray (CXR) with optional computer-aided detection software (CAD) as a sensitive tool for TB screening. The National TB program implemented digital CXR with CAD4TB® for individuals aged ≥15 years.
We described characteristics of people living with HIV (PLHIV) screened for TB with digital CXR and factors associated with high CAD scores.
Design/Methods: We conducted a retrospective review of data on the National Digital CXR registry for PLHIV aged ≥ 15 years from 2022 to 2024. An Excel data abstraction tool was used to collect socio-demographic and clinical variables. CAD scores ≥ 60 were considered highly probable for TB. Epi Info® 7.2 was used for analysis with associations assessed by prevalence odds ratio (pOR) and 95% confidence interval (CI).
Results: Among 7,435 PLHIV, 63% were female and mean age 43±12 years. Of these, 7,428 (99%) had symptom screening outcome, with 3880 (52%) TB presumptive. Laboratory testing was performed in 687 (18%) presumptive cases and 286 (8%) asymptomatic individuals. The median CAD score was 7.86 (IQR 3.892-24.8). Laboratory TB positivity for CAD scores above 60 versus below 60 was 11% versus 7% in symptomatic cases and 8% versus 4% in asymptomatic individuals.
High CAD scores were associated with: previous TB history (pOR=5.6, CI:4.7,6.74), male gender (pOR=2.67, CI:2.23,3.18), Symptomatic screening outcome (pOR=2.7, CI:2.22,3.28), smoking (pOR=3.01, CI:2.34,3.88), positive laboratory test (pOR=2.8, CI:1.98,4.01) and TB contact history (pOR=1.58, CI:1.16,2.14).
Conclusions: Digital CXR with CAD effectively identifies high-risk PLHIV for TB, detecting cases even among asymptomatic individuals. Integration of this technology into routine screening could significantly enhance early case detection and improve treatment outcomes.

Our findings support implementation of CAD-assisted digital CXR as a valuable tool in comprehensive TB-HIV management strategies.Future research should focus on evaluating optimal CAD threshold scores for PLHIV.

OA23-321-20 Diagnostic accuracy of Fujifilm SILVAMP TB LAM II for TB in HIV-positive and HIV-negative adults: A multicenter study in Vietnam

H.T. Nguyen,[1,2] L.N.Q. Vo,[3,4] A.J. Codlin,[5,4] R. Forse,[5,4] T.H.N. Ong,[1] T.T. Huynh,[6] N.T.T. Nguyen,[7] H.T. Doan,[8] H.B. Nguyen,[9] L.V. Dinh,[9] J. Creswell,[10] L. Davies Forsman,[2]
[1]FIT RD Ltd., Program, Ha Noi, Viet Nam, [2]Karolinska Institutet, Department of Medicine, Solna, Sweden, [3]Friends for International TB Relief (FIT), Management, Ha Noi, Viet Nam, [4]Karolinska Institutet, Department of Global Public Health, Solna, Sweden, [5]Friends for International TB Relief (FIT), Management, Ho Chi Minh City, Viet Nam, [6]IRD VN Ltd., Program, Ho Chi Minh City, Viet Nam, [7]Friends for International TB Relief (FIT), Program, Ha Noi, Viet Nam, [8]National Lung Hospital, National Reference Lab, Ha Noi, Viet Nam, [9]National Lung Hospital, Steering Department, Ha Noi, Viet Nam, [10]Stop TB Partnership, Innovations & Grants, Geneva, Switzerland
e-mail: han.nguyen@tbhelp.org

Background: Accurate diagnosis of TB, especially in people living with HIV, is hindered by low sputum bacterial loads. Fujifilm SILVAMP TB LAM II (FujiLAM) is a rapid, urine-based assay detecting lipoarabinomannan (LAM) to enhance TB diagnosis. We evaluated the third-generation FujiLAM assay's diagnostic accuracy in HIV-positive and HIV-negative adults in Vietnam.
Design/Methods: A cross-sectional, multicentre study was conducted from June 2024 to April 2025 at the National Lung Hospital, Hanoi Lung Hospital, Pham Ngoc Thach Hospital, and HIV outpatient clinics in Hanoi and Ho Chi Minh City. FujiLAM was performed on fresh urine samples. Xpert (sputum) was the microbiological reference standard. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and 95% confidence intervals (CI) were calculated. We assessed the inter-assay agreement using Cohen's Kappa.
Results: Among 3,549 participants (498 HIV-positive; 3,051 HIV-negative), FujiLAM sensitivity was 41.2% (95% CI: 18.4–67.1%) in HIV-positive individuals and 27.8% (95% CI: 24.0–32.0%) in HIV-negative individuals against Xpert (sputum). Specificity was 99.6% (95% CI: 98.5–99.9%) among people with HIV and 99.6% (95% CI: 99.3–99.8%) in HIV-negative individuals. In HIV-positive cases, PPV was 77.8% (95% CI: 40.0–97.2%) and NPV was 98.0% (95% CI: 96.3–99.0%).
Overall sensitivity was 28.3% (95% CI: 24.5–32.3%), with an area under the receiver operating characteristic curve of 0.64 (95% CI: 0.62–0.66). Agreement with Xpert was fair (Cohen's Kappa = 0.3908, p<0.001).
Conclusions: FujiLAM exhibits high specificity (99.6%) and moderate sensitivity (41.2%) in HIV-positive adults, indicating potential as a non-invasive adjunct to sputum-based tests like Xpert. Its lower sensitivity (27.8%) in HIV-negative individuals limits broader use.
Similar to other urine-based assays, FujiLAM's relevance is most significant for HIV-associated TB, especially for people unable to produce sputum. Further research is needed to optimize its diagnostic role across diverse populations.

OA23-322-20 Diagnostic accuracy of FujiLAM II point-of-care assay for detecting TB in urine among people with and without HIV in Cameroon

C. Mbulli,[1] J.B. Taya Fokou,[1] N. Biatu,[1] R. Nsamenang,[1] G. Nguimfack,[1] G. Tabley,[1] G. Fonyuy,[1] J. Creswell,[2] T. Wingfield,[3] C. Vuchas,[1] N. Ndze Mbuh,[1] M. Sander,[1]
[1]Centre for Health Promotion and Research, Research, Bamenda, Cameroon, [2]Stop TB Partnership, Innovations and Grants, Geneva, Switzerland, [3]Liverpool School of Tropical Medicine, Centre for Tuberculosis Research, Liverpool, United Kingdom of Great Britain and Northern Ireland

Background: Rapid, non-sputum-based point-of-care tests to detect TB are urgently needed. The third-generation urine lateral flow-based test, the SILVAMP TB LAM II assay (FujiLAM II, Fujifilm, Japan) is an updated version of the FujiLAM test that has potential for point-of-care detection of TB. We evaluated the diagnostic accuracy of FujiLAM II as part of the multi-country Start4All project.
Design/Methods: We conducted a prospective, multicenter diagnostic study among hospital and primary care outpatients and people attending community health camps in Cameroon. Eligible participants were ≥15 years with two or more symptoms of TB and/or an abnormal chest X-ray. All participants provided two sputum specimens for Xpert MTB/RIF Ultra (Ultra) testing and urine for FujiLAM II testing.
The reference standard included sputum Ultra and sputum liquid and solid culture to determine sensitivity and specificity of FujiLAM II.
Results: From Dec 2023 to Feb 2025, 2,038 hospital outpatients, including 540 (26%) people living with HIV, 1,498 (74%) HIV-negative participants, and 766 people attending community health camps, were enrolled and had results. In preliminary analyses, TB was confirmed by sputum Xpert MTB/RIF Ultra in 229 (11%) of outpatients and 45 (6%) of people in the community.
As compared to sputum Ultra, FujiLAM II sensitivity in HIV-positive outpatients was 51% (27/53, 95% CI 38-64%), in HIV-negative outpatients 49% (87/176, 95% CI 42-57%), and in community participants 31% (14/45, 95%

CI 20-46%); overall specificity was 98.5% (2,491/2,530, 95% CI 97.9-98.9%). Analyses compared to the full reference standard, including culture, are ongoing.
Conclusions: The similar sensitivity of the FujiLAM II assay in HIV-negative (49%) as compared to HIV-positive (51%) outpatients in this study suggests that these tests have good general promise, although the performance falls below the WHO target product profile of 65% for a non-sputum point-of-care test.

OA23-323-20 Tongue swab based targeted universal TB testing in people living with HIV in KwaZulu-Natal, South Africa

A. Olson,[1] R. Wood,[1] N. Sithole,[2] I. Govender,[2,3] A. Grant,[2,3] T. Smit,[2] A. David,[4] W. Stevens,[4,5] L. Scott,[4] P. Drain,[6,7,8] G. Cangelosi,[1,7,8] A. Shapiro,[6,7,8] [1]University of Washington, Department of Environmental and Occupational Health Sciences, Seattle, United States of America, [2]Africa Health Research Institute, Clinical Research Division, Durban, South Africa, [3]London School of Hygiene & Tropical Medicine (LSHTM), Department of Clinical Research, London, United Kingdom of Great Britain and Northern Ireland, [4]University of Witwatersrand, Wits Diagnostic Innovations Hub, Johannesburg, South Africa, [5]National Priority Programme, National Health Laboratory Services, Johannesburg, South Africa, [6]University of Washington, Department of Medicine (Infectious Diseases), Seattle, United States of America, [7]University of Washington, Department of Epidemiology, Seattle, United States of America, [8]University of Washington, Department of Global Health, Seattle, United States of America
e-mail: olsona8@uw.edu

Background: Targeted Universal Tuberculosis Testing (TUTT) may increase case detection to include asymptomatic people who are at high risk of disease. Tongue swab (TS) testing may facilitate TUTT because swabs are easy to collect and have worked well detecting tuberculosis (TB) in people with TB symptoms. However, there is limited data on TS accuracy for TB detection in people with asymptomatic TB and non-TB-care seekers. We evaluated the diagnostic accuracy of two high-sensitivity TS testing protocols in adults with HIV screened irrespective of symptoms.
Design/Methods: Study staff collected Copan FLOQSwab (N=161) and Medline pint-size foam-swab tongue specimens (N=196), alongside urine (N=249) and sputa, from people with HIV (N=252) presenting for antiretroviral therapy initiation at primary healthcare clinics in KwaZulu-Natal, South Africa. FLOQSwabs were processed and tested by sequence-specific magnetic capture (SSMaC) with qPCR. Foam swabs were processed and tested by centrifuge-sedimentation and high-volume qPCR. Urine lipoarabinomannan was detected by Alere LF-LAM. Sputa were tested by Xpert Ultra and MGIT culture as the microbiological reference standard (MRS).
Results: Participants were enrolled with (67%) or without (33%) self-reported TB symptoms. Participants had a median CD4 count of 346 (IQR 182-551), and 16% (40/252) had prior TB. Foam swabs were 43% (95% CI: 22-66%, 9/21) sensitive and 100% (95% CI: 98-100%, 175/175) specific. FLOQSwabs were 41% (95% CI: 24-59%, 13/32) sensitive and 100% (95% CI: 97-100%, 129/129) specific. When either TS detected TB, overall sensitivity of TS testing was 53% (95% CI: 29-76%, 10/19). Urine LAM detection was 18% (95% CI: 7-35%, 6/34) sensitive and 97% (95% CI: 93-99%, 208/215) specific. Sensitivity increased to 52% (FLOQSwab) and 53% (foam) if MRS Trace Xpert results were categorized as negative.

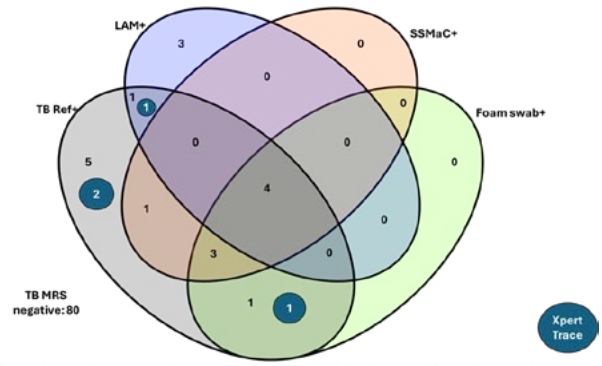

Figure: Venn diagram showing overlap of sample positivity from N=102 participants with urine and both swab types collected.

Conclusions: High-sensitivity laboratory methods enabled the detection of participants with TB using a non-sputum specimen in this active case-finding context. Swab testing outperformed urine LAM testing in this cohort.

OA23-324-20 A randomised-controlled trial comparing C-reactive protein- to symptom-based TB screening of people with HIV in Uganda: Primary 24-month effectiveness results

C. Yoon,[1] L. Chaisson,[2] P. Phillips,[2] S. Makumbi,[3] B. Opira,[4] D. Dowdy,[5] F. Semitala,[6] [1]University of California San Francisco, Department of Medicine, San Francisco, United States of America, [2]University of California San Francisco, Department of Epidemiology & Biostatistics, San Francisco, United States of America, [3]Infectious Diseases Research Collaboration, HIV, Kampala, Uganda, [4]Infectious Diseases Research Collaboration, Pharmacology, Kampala, Uganda, [5]Johns Hopkins University, Epidemiology, Baltimore, United States of America, [6]Makerere University, Medicine, Kampala, Uganda
e-mail: christina.yoon@ucsf.edu

Background: Since 2021, WHO has recommended C-reactive protein (CRP) for TB screening in people with HIV (PWH) due to its demonstrated higher specificity than the WHO 4-part symptom screen (W4SS), the current standard. However, the long-term benefits of CRP relative to W4SS screening remain unknown.

Design/Methods: We enrolled adults initiating antiretroviral therapy (ART) in four clinics in Uganda in a phase 3, partially-blinded, individual randomized trial (NCT04557176). The trial compared point-of-care CRP against W4SS; outcomes included: combined 2-year TB incidence and all-cause mortality (primary), microbiologically-confirmed TB prevalence, and proportions initiating TB preventive therapy (TPT). Screen-positive participants (CRP≥5 mg/L or ≥1 TB symptom, according to randomization arm) underwent confirmatory testing (urine LAM ± sputum Xpert Ultra). Eligible screen-negative participants were referred for 3HP (3-month weekly isoniazid + rifapentine).

Results: Among 1719 participants, the proportion screening positive for TB at enrollment was lower in the CRP arm than the W4SS arm (37.1% [319/861] vs. 64.3% [552/858], p<0.01). However, CRP and W4SS detected a similar proportion of participants with prevalent TB (8.4% [72] vs. 7.7% [66], p=0.61). Consequently, the proportion eligible for (46.7% vs. 24.4%, p<0.01) and initiating 3HP (41.8% vs. 22.5%, p<0.01) was higher in the CRP arm. Overall, 108 (6.3%) participants experienced a primary outcome (incident TB or death) over 3,346 person-years of follow-up, including 50 (5.8%) in the CRP arm and 58 (6.8%) in the W4SS arm (p=0.42). Risk of TB or death was lower in the CRP arm than the W4SS arm (hazard ratio 0.87), although the 95% CI was wide (0.60-1.27, p=0.48).

Table. Baseline clinical characteristics and TB screening outcomes of ART-naïve PWH, by TB screening strategy.

	Total (n=1,719)	CRP (n=861)	W4SS (n=858)	p-value
Female sex	1,076 (62.6%)	536 (62.3%)	540 (62.9%)	
Age, median years (IQR)	30 (25-37)	30 (25-38)	30 (25-37)	
Pre-ART CD4, median cells/mm^3 (IQR)	231 (107-365)	230 (106-372)	233 (109-363)	
TB screen-positive	871 (50.7%)	319 (37.1%)	552 (64.3%)	<0.01
Prevalent TB detected by screening[1]	138 (8.0%)	72 (8.4%)	66 (7.7%)	0.61
TB screen-negative	848 (49.3%)	542 (63.0%)	306 (35.7%)	<0.01
Eligible for 3HP[2, 3]	611 (35.5%)	402 (46.7%)	209 (24.4%)	<0.01
Initiated 3HP[2]	553 (32.2%)	360 (41.8%)	193 (22.5%)	<0.01
Received non-study TPT[4]	280 (16.3%)	106 (12.3%)	174 (20.3%)	<0.01
Time under observation, person-years	3,346	1,668	1,678	
Primary outcome: Incident TB or death	108 (6.3%)	50 (5.8%)	58 (6.8%)	0.42
Incidence rate of TB and death	3.23 (2.67-3.90)	2.98 (2.26-3.93)	3.48 (2.69-4.50)	0.42

Abbreviations: TB (tuberculosis); ART (antiviral therapy); PWH (people with HIV); CRP (C-reactive protein); W4SS (WHO 4-part symptom screen); IQR (interquartile range); 3HP (3 weeks of weekly isoniazid + rifapentine); TPT (TB preventive therapy). *Legend:* [1]Prevalent TB diagnosed by urine lipoarabinomannan (LAM) or sputum Xpert Ultra; [2]Among participants who screened negative; [3]Contraindications to 3HP included liver disease (liver enzymes ≥ 3-times the upper limit of normal, hepatitis, binge or heavy alcohol consumption), pregnancy, <3 months postpartum, planning to become pregnant, breastfeeding, contact with TB patient with known isoniazid or rifamycin resistance, known isoniazid or rifamycin allergy, drug contraindication; [4]Non-study TPT regimen (238 received 6 months of daily isoniazid and 42 received 3HP).

Conclusions: Among ART-naïve PWH, CRP-based TB screening did not reduce 2-year TB incidence and death compared to symptom screening. CRP was, however, able to detect a similar proportion with prevalent TB, while enabling twice as many PWH to initiate 3HP. These results support scale-up of CRP-based screening among ART-naïve PWH.

OA23-325-20 Early adherence trajectories predict six-month outcomes in people living with HIV and multi-drug-resistant TB: Findings from the PRAXIS study

K. Guzman,[1] A. Wolf,[1] R. Perumal,[2,3] B. Seepamore,[2,4] K. Reis,[5] KR. Amico,[6] G. Friedland,[7] J. Zelnick,[8] A. Daftary,[2,9] N. Padayatchi,[2] K. Naidoo,[2] M. O'Donnell,[1,2,10] [1]Columbia University, Department of Medicine, Division of Pulmonary, Allergy, and Critical Care Medicine, New York, United States of America, [2]CAPRISA, MRC-HIV-TB Pathogenesis and Treatment Research Unit, Durban, South Africa, [3]University of KwaZulu-Natal, Department of Pulmonary and Critical Care, DurbanSoS, South Africa, [4]University of KwaZulu-Natal, School of Applied Science, Durban, South Africa, [5]University of Washington, Medicine, Seattle, United States of America, [6]University of Michigan, School of Public Health, Ann Arbor, United States of America, [7]Yale University School of Medicine, Department of Medicine, Division of Infectious Disease, New Haven, United States of America, [8]Touro University, Graduate School of Social Work, New York, United States of America, [9]York University, School of Global Health and Dahdaleh Institute of Global Health Research, Toronto, Canada, [10]Columbia University, Department of Epidemiology, New York, United States of America
e-mail: kg3006@cumc.columbia.edu

Background: Challenges to multidrug-resistant tuberculosis (MDR-TB) treatment remain a major barrier to successful outcomes among people living with HIV, who often face complex regimens and structural barriers to care. Identifying individuals at risk for poor outcomes is essential to guide differentiated service delivery. We used latent class growth analysis (LCGA) to identify early adherence trajectories and assess their association with six-month outcomes in the PRAXIS study.

Design/Methods: This prospective cohort included South African adults with HIV and MDR-TB (NCT03162107) treated with bedaquiline (BDQ)-based regimens and antiretroviral therapy (ART) from 2016 to 2020. Daily BDQ adherence data from the first 6 months of treatment were measured using a cellular-enabled electronic dose monitor (Wisepill RT2000). LCGA was applied on the first 4 weeks of adherence data from 283 individuals to identify distinct adherence patterns. Model selection was based on Bayesian Information Criterion, entropy, and class size ≥10% of the sample. Using Kaplan-Meier curves and log-rank tests, we evaluated associations between adherence class and six-month outcomes, including mortality, favorable MDR-TB treatment response, and total 6-month BDQ/ART adherence.

Results: The three-class model was selected based on fit statistics (lowest BIC and high entropy). Three distinct classes emerged: Class 1 (n=33, 17%) showed steadily declining adherence, Class 2 (n=77, 39%) had stable, moderate adherence, and Class 3 (n=173, 44%) demonstrated consistently high adherence. Class 1 had significantly worse six-month outcomes, including lower ART

and BDQ adherence (p<0.001), higher mortality (36%, p=0.001), and lower rates of favorable treatment outcomes (55%, p=0.023). Kaplan-Meier analysis confirmed significant differences in survival and treatment success across classes.

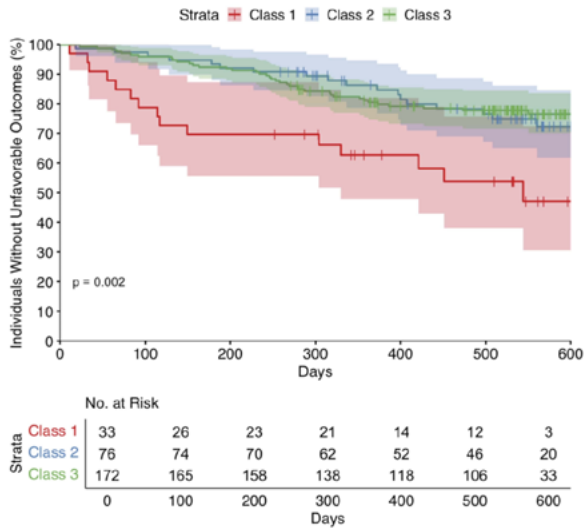

Figure 1: Probability of Favorable Outcome Over Time Stratified by Latent Class Membership

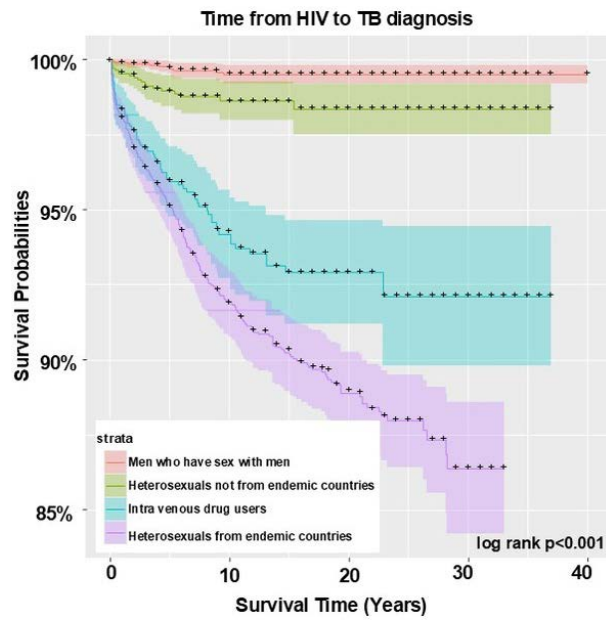
Conclusions: Weekly adherence during the first four weeks of treatment strongly predicted six-month outcomes. Incorporating early adherence data into differential service delivery models may enable the timely identification of high-risk patients, allowing for targeted interventions to improve outcomes for people living with HIV and MDR-TB.

OA23-326-20 HIV incidence among people with TB in Israel: A 42-years follow up study

Z. Mor,[1,2] T. Wagner,[3] Y. Dickstein,[4] S. Perl,[5] [1]Ashkelon Academic College, Program of Public Health, Ashkelon, Israel, [2]Ministry of Health, Jerusalem Department of Health, Jerusalem, Israel, [3]Israeli Ministry of Health, Division of Epidemiology, Jerusalem, Israel, [4]Rambam Health Care Campus, Infectious Disease Unit and HIV Clinics, Haifa, Israel, [5]Ministry of Health, Division of Epidemiology, Jerusalem, Israel
e-mail: zohar.mor@moh.gov.il

Background: HIV/tuberculosis co-infection raises the risk of negative outcomes and death. This 42-years longitudinal study describes tuberculosis incidence in people living with HIV (PLHIV) in Israel, a low tuberculosis incidence country, and identifies populations at high-risk for developing tuberculosis.
Design/Methods: This study includes all tuberculosis cases reported in Israel more than one month following HIV-diagnosis between 1981 and 2023. Cox regression models adjusted for the length of follow-up were divided into three timeframes, in accordance with the availability and quality of anti-retroviral treatment (ART): 1981-1996 (pre-ART), 1997-2016 (ART), 2017-2023 (improved ART). Independent variables that were associated with tuberculosis-incidence were presented by hazard ratio (HR) and 95% confidence interval (CI).
Results: During the study period, 12,004 PLHIV were reported in Israel, of whom 413 (3.4%) developed tuberculosis: 132 (7.4%) developed tuberculosis among 1,782 PLHIV between 1981 and 1996, 263 cases (3.6%) among 7,386 PLHIV between 1997 and 2016, and 18 cases (0.6%) among 2,836 PLHIV between 2017 and 2023 (p<0.001). Tuberculosis cases diagnosed in 1981-1996 and 1997-2016 were more commonly older (p<0.001) and more likely were non-Israeli born (p<0.001) than those diagnosed in 2017-2023. Cox regression model demonstrated that males (HR=1.5, 95% CI: 1.2-1.9, p<0.001) and non-Israeli born PLHIV (HR=2.2, 95% CI: 1.3-3.8, p=0.001) were at higher risk for developing tuberculosis compared to Israeli-born PLHIV (Figure).



The highest risk for tuberculosis was observed among heterosexuals originating in endemic countries (HR=9.0, 95% CI: 2.8-28.6, p<0.001), followed by intravenous drug users (IVDU) (HR=6.9, 95% CI: 2.1-22.0, p=0.001). Interestingly, a decline in HR for developing tuberculosis among PLHIV was observed between the different timeframes: 80% reduction in 2017-2023 and 58% reduction in 1997-2016 compared with 1981-1996.
Conclusions: Tuberculosis incidence among PLHIV was highest among males and migrants from endemic countries, followed by IVDU. Tuberculosis incidence declined after ART was introduced and was further reduced when ART was improved.

OA24 Sustainability in demand: Feasibility, acceptability, cost effectiveness, and TB care approaches

OA24-327-20 Evaluation of a fluorescence immunoassay-based IGRA for latent TB diagnosis: A simplified, cost-effective alternative

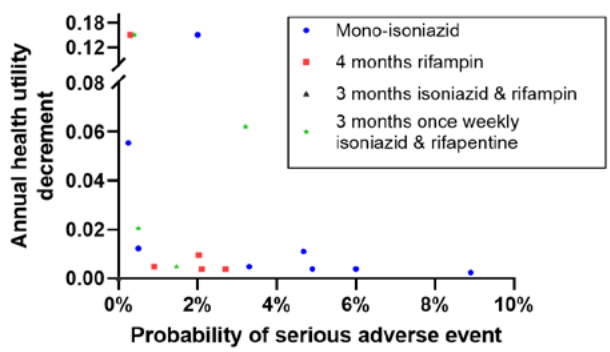
M.K.M. Uddin,[1] A.R. Mahmud,[1] A. Islam,[1] A.A. Rupa,[1] J. Ferdous,[1] R. Nasrin,[1] S.M.M. Rahman,[1] S. Banu,[1]
[1]icddr,b, Infectious Diseases Division, Dhaka, Bangladesh
e-mail: kmuddin@icddrb.org

Background: Approximately one-quarter of the global population is infected with Latent tuberculosis infection (LTBI), with 5–10% of infected individuals at risk of developing active tuberculosis (TB). Interferon-Gamma Release Assays (IGRAs) are effective in diagnosing LTBI, yet the high costs and complexity of ELISA assays restrict their use.
To address this, the study evaluated the performance of a qualitative fluorescence immunoassay (FIA) to detect IFN-γ (Interferon gamma, ichroma IGRA-TB), a cost-effective and simpler alternative method.
Design/Methods: A total of 300 participants from TB Screening and Treatment Centres of icddr,b are being enrolled since December 15, 2024. Participants are categorized into four risk groups: healthy individuals, contacts of TB patients, patients with microbiologically confirmed TB, and individuals with prior TB history. The diagnostic performance ichroma IGRA-TB, will be compared with QuantiFERON-TB Gold Plus (QFT) across these groups. Initial enrollment and test results were available for 160 participants.
Results: The overall agreement between ichroma IGRA-TB and QFT is 85.62% (95% CI: 79.22–90.66%). The highest agreement is observed among TB patient contacts (90.00%, 95% CI: 76.34–97.21%), individuals with prior TB history (90.91%, 95% CI: 58.72–99.77%), and healthy individuals (88.37%, 95% CI: 74.92–96.11%). The lowest agreement is seen in active TB cases (80.30%, 95% CI: 68.68–89.07%). Among contacts of TB patients, who are most likely to have LTBI, ichroma has a sensitivity of 93.33%, specificity of 88.0%, and a kappa value of 0.8.
Conclusions: Ichroma IGRA-TB demonstrates strong agreement with the costlier and more complex QFT. It has excellent performance among TB contacts and individuals with prior TB episodes. However, agreement among active TB cases remains lower, mirroring findings for currently established IGRA assays. With lower infrastructure constraints, minimal training requirements and faster results, ichroma IGRA-TB represents a cost-effective LTBI diagnostic alternative for resource-limited settings.

OA24-328-20 Consideration of risks and consequences of TB and its prevention in cost-utility analyses among immigrants to low incidence countries: A systematic review

S. Robayo,[1] C. Tansey,[2] K. Romanowski,[2] J. Campbell,[2]
[1]McGill University, Experimental Medecine, Montreal, Canada,
[2]McGill University, Medicine, Montreal, Canada
e-mail: sammy.robayobarrios@mail.mcgill.ca

Background: Foreign-born populations bear much of the tuberculosis (TB) burden in many low TB incidence countries, largely because of the progression of TB infection. However, there are divergent conclusions regarding the cost-utility of TB infection treatment programs among immigrants. To investigate why conclusions may differ, we evaluated how cost-utility analyses have considered the risks and consequences of TB disease and tuberculosis preventive treatment (TPT) among immigrants to low-incidence countries.
Design/Methods: A systematic search was conducted in PubMed and Embase from January 1, 2004, to March 25, 2025. Studies were included if they were modeling studies, measured health utility in the form of quality-adjusted life years (QALYs), and evaluated TPT among immigrants to low TB incidence countries. A narrative synthesis was performed, examining how studies considered risks and consequences of TB disease and TPT, and their attendant impacts on health disutility.
Results: The search identified 5,142 records. After title and abstract review, 32 studies were left for full-text review, and 16 were ultimately included. The most commonly considered consequence of TPT was major adverse events (AEs). Thirteen of sixteen studies considered risks of major AE, which ranged from 0.1% to 8.9%; the average health disutility was 0.028 QALYs, but varied substantially, with a coefficient of variation of 1.56 (Figure).
All studies considered health disutility associated with TB disease. Annual disutility ranged from 0.04 to 0.28, with an average impact of 0.13 and a coefficient of variation of 0.5. Four studies considered post-TB consequences in their primary analysis.



Conclusions: There is wide variation in how risks and consequences of both TPT and TB disease are considered in studies evaluating TB infection treatment pro-

grams. This lack of standardization in how risks and consequences are quantified, may be a significant contributor to the inconsistent conclusions surrounding the cost-effectiveness of immigrant TB infection treatment programs.

OA24-329-20 Cost and cost-effectiveness of household contact investigation of pulmonary bacteriologically confirmed people with TB in sub-Saharan Africa

J. Kiendrébéogo,[1] R. Kabore,[2] O. Mbitikon,[3] A. Ouédraogo,[4,5] A. Kuate Kuate,[3,6] A. Soumana,[7,8] M. Dogo,[9] H. Gando,[3,10] A. Yamodo,[3] A. Magassouba,[11,12] G. Badoum,[4,13,14] K.G. e-mail: kgkoura@theunion.org

Background: This study aimed to evaluate the costs and cost-effectiveness of household contact investigation compared to routine passive case-finding in TB clinics across five sub-Saharan African countries: Burkina Faso, Central African Republic, Guinea, Niger, and Togo.

Design/Methods: A comparative approach was used to assess two TB case identification strategies. Household contact investigation through home visits was implemented in 11 intervention sites across the countries. In 11 control sites, routine passive case-finding was practiced, where nurses advised TB index patients to refer their household contacts to the TB clinic for screening.

Costs were collected for six key activities (training, home visits, screening, case follow-up, and supervision) and analyzed using a micro-costing approach. Effectiveness was measured by the number of TB cases treated and pediatric contacts placed on TB preventive treatment. Incremental cost-effectiveness ratios (ICERs) were calculated for each outcome indicator.

Results: The total cost of activities was € 68.129,63 in the intervention sites compared to € 27.541,26 in the control sites (Table 1), with country-specific variations (Table 2). Contact investigation resulted in the treatment of 1,477 TB cases in the intervention sites, versus 565 in the control sites (Table 3).

Additionally, 997 children under five years received TB preventive treatment in intervention sites, compared to 236 children in control sites (Table 3). ICER analysis indicated a cost of €44.50 per TB case treated and €53.34 per child placed on preventive treatment with the active strategy (Tables 4 and 5).

Table 1: Descriptive analysis of costs by component and according to the studied strategies.

Cost per component	Intervention	Control
Initial training	10426,10	0
Data collection and feedback	827,29	827,29
Home visit	1922,89	39,89
Case screening	27447,32	10127,31
Case follow-up	17842,69	6883,42
Supervision	9663,35	9663,35
Total	68129,63	27541,26

Table 2: Differential costs of activities between intervention and control CDTs, and ICER of key indicators for each of the five study countries.

Component	Initial training	Data collection and feedback	Home visit	Case screening	Case follow-up	Supervision	Total
Burkina Faso							
Intervention	3 160,88	142,66	245,87	3 614,92	2 556,89	2 050,51	11 771,73
Control	-	142,66	33,00	2 668,05	1 920,54	2 050,51	6 814,76
CAR							
Intervention	2 321,03	193,43	290,49	5 098,12	3 510,11	183,26	11 596,43
Control		193,43	-	1 050,31	717,79	183,26	2 144,79
Guinea							
Intervention	1 832,00	204,00	329,11	9 760,12	5 933,11	1 676,00	19 734,34
Control	-	204,00	6,89	1 033,79	676,27	1 676,00	3 596,95
Niger							
Intervention	1 551,00	143,50	268,60	6 015,16	3 774,18	2 781,00	14 533,45
Control	-	143,50	-	3 701,57	2 388,71	2 781,00	9 014,78
Togo							
Intervention	1 561,19	143,70	788,82	2 959,00	2 068,40	2 972,58	10 493,68
Control	-	143,70	-	1 673,59	1 180,11	2 972,58	5 969,98

Table 3 : Descriptive analysis of effectiveness results based on the different strategies.

RESULTS	Intervention	Control
Number of TB cases on TB treatment	1477	565
Number of children < 5 years on TB preventive treatment	997	236
Number of PLHIV on TB treatment	6	1
Number of PLHIV TB preventive treatment	0	0

PLHIV = People Living with HIV

Table 4: Differential costs in euros of activities between intervention and control CDTs, and ICER of key indicators.

COST-EFFECTIVENESS		Value
Cost difference (euros)		40588,37
Difference in TB cases identified (N)		912
Difference in children < 5 years on TB preventive treatment (N)		761
Incremental cost (ICER)	TB cases identified through Contact Investigation	44,50
	Children < 5 years on TB preventive treatment	53,34

Table 5: Differential costs in euros of activities between intervention and control sites, and ICER of key indicators by country.

		Country				
		Burkina Faso	**Niger**	**Guinée**	**Togo**	**RCA**
Cost difference (euros)		4956,97	5518,67	16137,39	4523,70	9451,65
TB cases identified through contact investigation	Case difference (N)	149	259	955	154	96
	Cost per index case (ICER, euros)	33,27	21,31	16,90	29,37	98,45
Child < 5 years on TB preventive treatment	Case difference	48	179	443	28	63
	Cost per child under 5 (ICER, euros)	103,27	30,83	36,43	161,56	150,03

Conclusions: Despite higher initial costs, household contact investigation was a cost-effective and efficient strategy for improving TB detection and management, particularly among vulnerable populations. The comparison underscores the limitations of relying solely on passive referral systems. Country-level cost disparities highlight the role of logistical and contextual factors. National TB programs should consider integrating this proactive approach to strengthen TB control in sub-Saharan Africa.

OA24-330-20 Evaluating the effectiveness of the PDX machine in improving sample quality and reducing costs in TB sample processing in Ekiti State

O. Odeyemi,[1] Q.C. Ogbuji,[2] A. Uwajeh,[2] B.C. Nwaogu,[2] O. Onipede-Ojo,[1] H. Raji Bello,[3] A. Adekola,[3] O. Urhioke,[4] R. Iniobong,[4] M. Zamzu,[5] J. Ssekitooleko,[5] A.J. Orojo,[6]
[1]Association for Reproductive and Facily Health, TB/HIV, Ado Ekiti, Nigeria, [2]Association for Reproductive and Facily Health, TB/HIV, Abuja, Nigeria, [3]Global Fund N-THRIP, Institute of Human Virology, Nigeria (IHVN), TB/HIV, Abuja, Nigeria, [4]National TB and Leprosy and Buruli Ulcer Control Programme Nigeria, TB/HIV, Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, TB/HIV, Geneva, Switzerland, [6]Ekiti State TB and Leprosy and Buruli Ulcer Control Programme, ETBLCP, Ado Ekiti, Nigeria
e-mail: odeyemi.o@arfh-ng.org

Background: The portable digital Xray (PDX) machine has emerged as a promising tool for enhancing sample quality and reducing costs. This study aimed to evaluate the effectiveness of the PDX machine in tuberculosis (TB) screening. The specific objectives are to: assess the performance of the PDX machine in detecting TB cases, compare the effectiveness of the PDX machine with conventional TB screening methods of community tuberculosis screening application (COMMTB app) and to evaluate the ability of the PDX machine to detect asymptomatic TB cases. The hypothesis set was that the PDX machine would improve sample quality and reduce costs in sample processing. The challenge addressed was the need for accurate and efficient TB screening methods, particularly in resource-constrained settings.
Design/Methods: The study employed a comparative design, using the PDX machine and CommTB to screen 1455 individuals for tuberculosis in a targeted locations in Ado. Sputum Samples were collected from presumptive individuals and transported in an ice pack into the GeneXpert laboratory. Samples were analyzed for TB, and positive cases were confirmed using Xpert and X-ray. Data were compared to evaluate the performance of the PDX machine and the CommTB. The desired outcome was to demonstrate the effectiveness of the PDX machine in improving sample quality, reducing costs, and detecting asymptomatic TB cases.
Results: The PDX machine detected 105 presumptive TB cases, 12 confirmed positive cases (3 Xpert-confirmed, 9 X-ray suggestive). In contrast, 208 presumptive were detected with CommTB out of which 2 positive cases were confirmed. Notably, the PDX machine identified asymptomatic presumptive cases that were missed by CommTB.
Conclusions: This study demonstrates the effectiveness of the PDX machine in improving sample quality, reducing costs, and detecting asymptomatic TB cases. The findings support the adoption of the PDX machine as a valuable tool in TB prevention programs, particularly in resource-constrained settings.

OA24-331-20 DronEconomics: The cost of implementing drones to facilitate TB sputum sample collection in hard-to-reach areas in Nepal

A. Thapa,[1] K. Dixit,[1] G. Shrestha,[1] R. Dhital,[1] M. Caws,[2,1] N. Teixeira de Siqueira Filha,[3] [1]Birat Nepal Medical Trust (BNMT Nepal), Research Department, Kathmandu, Nepal, [2]Liverpool School of Tropical Medicine, Department of Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland, [3]University of York, Department of Health Sciences, York, United Kingdom of Great Britain and Northern Ireland
e-mail: anchal.thapa@bnmt.org.np

Background: The use of innovative technologies like drones in healthcare is ever-rising. In Nepal, Birat Nepal Medical Trust (BNMT) had piloted the Drone Optimized Therapy System (DrOTS) project which used drones to transport sputum samples for Tuberculosis (TB) diagnosis in a remote district, Pyuthan. Our previous findings suggested that drone transport reduced average travel time from 2.3 hours of walking to just 6.25 minutes. This study aimed to assess the program's financial implications and inform the potential scale up.
Design/Methods: We conducted a cost of implementation study and estimated the financial costs associated with using drone-based transportation. The analysis was performed from the implementer's perspective over the project duration of 13 months. We employed top-down costing approach to calculate cost per flight and cost per sputum sample transported. We conducted sensitivity analysis to assess how variations in key assumptions would affect the outcome.
Results: The total cost of implementation was estimated at $186,215, with a unit cost of $846 per flight and $246 per sputum sample collected. Capital costs (project initiation, training and infrastructure development costs) accounted for 54% of the total costs, while ACF field implementation cost was 30%, drone operation costs (drone equipment, accessories and operator salaries) accounted for 16%.
Based on the sensitivity analysis, including only recurring costs and increasing flight frequency to 2 flights per day, the cost per flight is reduced by over 80%.
Conclusions: The use of drones for sputum transport in remote communities in Pyuthan is feasible but costs are currently highly driven by capital and start-up costs. However, sensitivity analysis demonstrates that significant cost reductions can be achieved by increasing operation intensity and continuing the implementation by prioritizing use of local human resources. There is a need to secure long-term funding to ensure uninterrupted operation and optimize resource allocation to maximise the potential benefits.

OA24-332-20 Testing more for less: Evidence on pooling specimens for molecular testing at healthcare facilities and by active case finding in communities across seven high-burden countries

T. Garg,[1] M.Y.R. Henrion,[2,3] R.L. Byrne,[2] V. Iem,[2] N. Kontogianni,[2] J. Bimba,[4] M. Sander,[5] V. Santos,[6] S.B. Squire,[7] T. Wingfield,[8] J. Creswell,[1] on behalf of the Start4All: Start Taking Action for TB Diagnosis consortium
[1]Stop TB Partnership, Innovations and Grants, Geneva, Switzerland, [2]Liverpool School of Tropical Medicine, Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland, [3]Malawi Liverpool Wellcome Research Programme, Statistical Support Unit, Blantyre, Malawi, [4]Zankli Research Centre, Management, Karu, Nigeria, [5]Center for Health Promotion and Research, Tuberculosis Reference Laboratory, Bamenda, Cameroon, [6]Federal University of Sergipe, Department of Medicine, Lagarto, Brazil, [7]Liverpool School of Tropical Medicine, TB Centre, Liverpool, United Kingdom of Great Britain and Northern Ireland, [8]Liverpool School of Tropical Medicine, Clinical Sciences and International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: tusharg@stoptb.org

Background: In 2023, 48% of people with TB received an initial rapid molecular diagnostic (RMD) test. Specimen pooling can expand access to RMD, combating high costs, supply limitations, and funding constraints. With TB and infectious diseases expertise, pooling is set for WHO guidelines evaluation. We assessed the accuracy of pooling sputum for TB testing by Xpert Ultra.
Design/Methods: Start4All recruited individuals at primary and secondary level facilities, and through active case finding (ACF) in Bangladesh, Brazil, Cameroon, Kenya, Malawi, Nigeria, and Vietnam.
In facilities, sputum was collected and tested in the same facility. ACF samples were transported to the nearest affiliated laboratory. All specimens were tested individually, and in pools of 2-4. Standard procedure was followed for individual testing. For pooling, an equal volume of individual samples was mixed and 2ml of the pool was then tested. Sensitivity and specificity were estimated at the pool level and by screening approach. The number of people with TB missed using pooling was calculated and potential cartridge savings modelled.
Results: Overall, 13,038 specimens were tested individually and in 3,389 pools. 1,069 (8.2%) people had TB on individual testing. Most pools (88.2% n=2,989) contained four samples. About 77% of pools had no individually positive specimens. The sensitivity of pools tested at district labs, primary care, and ACF was 94.3% (95% CI:91.3,96.8), 95.8% (95% CI: 92.7,98.2) and 80.9% (95% CI: 72.5,87.9), respectively. Specificity ranged from 99.1% to 99.9%. Pooled testing missed 52 (4.9%) people with TB and used 48.9% of potential tests if every sample was tested individually.
Conclusions: Pooled testing using Xpert Ultra has high performance and lower cost per person tested, meeting WHO accuracy thresholds in screening test target product profiles. Our results suggest that scale-up of pooling can lead to cost savings and expanded access to RMD in high burden settings.

OA24-333-20 Pooled testing for TB: A cost-saving strategy with trade-offs in detection sensitivity

A.J. Codlin,[1,2] H.T. Nguyen,[3,4] N.T.T. Nguyen,[5] L.N.Q. Vo,[6,2] R. Forse,[1,2] H.T. Pham,[7] H.T. Doan,[8] M.T.H. Dang,[9] H.B. Nguyen,[10] L.V. Dinh,[10] B. Squire,[11] T. Wingfield,[12] [1]Friends for International TB Relief (FIT), Management, Ho Chi Minh City, Viet Nam, [2]Karolinska Institutet, Department of Global Public Health, Solna, Sweden, [3]FIT RD Ltd., Program, Ha Noi, Viet Nam, [4]Karolinska Institutet, Department of Medicine, Solna, Sweden, [5]Friends for International TB Relief (FIT), Program, Ho Chi Minh City, Viet Nam, [6]Friends for International TB Relief (FIT), Management, Ha Noi, Viet Nam, [7]Pham Ngoc Thach Hospital, Microbiology, Ho Chi Minh City, Viet Nam, [8]National Lung Hospital, National Reference Lab, Ha Noi, Viet Nam, [9]Pham Ngoc Thach Hospital, Management, Ho Chi Minh City, Viet Nam, [10]National Lung Hospital, Steering Department, Ha Noi, Viet Nam, [11]Liverpool School of Tropical Medicine, Clinical Tropical Medicine, Liverpool, United Kingdom of Great Britain and Northern Ireland, [12]Liverpool School of Tropical Medicine, Clinical Sciences and International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: andrew.codlin@tbhelp.org

Background: Pooled testing involves combining specimens from multiple individuals and testing the pooled specimen via a two-step process that foregoes individual testing in the event of negative pooled test results. A limited number of studies have assessed the diagnostic accuracy of pooled testing for TB.
Design/Methods: Adult participants were screened and tested across two settings in Vietnam. During community-based screening, people with symptoms and/or an abnormal chest X-ray were indicated for testing, whereas only those with a cough were indicated for testing during facility-based screening. Sputum specimens from eligible people were first individually tested with the Xpert MTB/RIF Ultra assay (Ultra). Remnant specimens were then combined into pools of four and tested for a second time on Ultra. The workload savings and diagnostic accuracy of an upfront pooled testing strategy were modelled.
Results: 2,264 people were individually tested with Ultra, with 119 (5.3%) having a MTB positive result. 566 four-specimen pools were tested on Ultra in parallel, with 83 (14.7%) having a MTB positive result. Ultra testing volumes would have been reduced by -60.3% if pooled testing had been done upfront (-69.1% vs -38.4% for community- vs facility-based screening). However, upfront

pooled testing would have missed 21 (17.6%) individuals who could have been diagnosed via individual testing (20.0% and 16.9% during community- and facility-based screening). The majority of the missed TB diagnoses during upfront pooled testing had a Trace semiquantitative grade (n=15, 71.4%) with no history of TB.

	Community	Facility	Both Settings
Individual Ultra tests performed	1,620	644	2,264
MTB positive results from individual testing	30 (1.9%)	89 (13.8%)	119 (5.3%)
Pooled Ultra tests performed	405	161	566
MTB positive results from pooled testing	24 (5.9%)	59 (36.6%)	83 (14.7%)
Tests required for upfront pooled testing	501	397	898
Savings relative to individual testing	-69.1%	-38.4%	-60.3%
Missed TB diagnoses	6 (20.0%)	15 (16.9%)	21 (17.6%)

Table.

Conclusions: Pooled testing can significantly reduce the workload and costs of diagnostic testing for TB. However, these savings should be reinvested to expand screening and testing coverage to offset the reduction in TB detection associated with this approach. Pooled testing may not be appropriate in settings where early and sensitive detection of all people with TB is vital.

OA24-334-20 Implementation of targeted next-generation sequencing for drug-resistant TB detection in Indonesia

B.W. Lestari,[1] A. Larasmanah,[2] S. Indriani,[2] R.A. Zahra,[2] A.M. Shani,[2] R.W. Rachman,[3] A. Fibriani,[4] R.B. Ristandi,[5] A.Y. Soeroto,[6] [1]Padjadjaran University, Public Health, Bandung, Indonesia, [2]Research Center for Care and Control of Infectious Diseases, Padjadjaran University, Tuberculosis Working Group, Bandung, Indonesia, [3]West Java Provincial Health Laboratory, Department of Biomolecular, Bandung, Indonesia, [4]Bandung Institute of Technology, School of Life Sciences and Technology, Bandung, Indonesia, [5]West Java Provincial Health Laboratory, Department of Clinical Pathology, Bandung, Indonesia, [6]Hasan Sadikin General Hospital, Department of Internal Medicine, Bandung, Indonesia
e-mail: bony.wiem@unpad.ac.id

Background and challenges to implementation: Drug-resistant tuberculosis (DRTB) remains a significant public health concern. In Indonesia, delayed DRTB diagnosis leads to delayed treatment, more severe disease, and a higher risk of mortality. Moreover, current diagnostic tools for DRTB remain limited as they have long turnaround times and minimal drug resistance coverage.
Intervention or response: The World Health Organization (WHO) recommends targeted Next-Generation Sequencing (tNGS) for rapid DRTB detection. To assess its feasibility and potential scalability in DRTB routine diagnostic settings, we conducted a pilot tNGS implementation using the Deeplex MycTB™ in West Java, Indonesia. We also compared the tNGS costs with phenotypic drug susceptibility testing (pDST). Multiple strategic efforts were undertaken to support its adoption, including stakeholder engagement, laboratory training and optimisation, diagnostic network expansion, and continuous monitoring and evaluation.
Results/Impact: 328/402 (82%) clinical samples were successfully sequenced using tNGS from August 2024 to March 2025. It took a median of 8 days (IQR 6-12) from sample receipt by laboratory to the tNGS result, indicating a faster diagnostic turnaround time than conventional methods. Clinicians and laboratory technicians also showed a positive attitude toward tNGS utilisation and recognized its potential to guide treatment decisions.
Although the operational performance of tNGS was considered good, tNGS costs remain a significant barrier. The average cost per sample for PDST was $104.36, while the tNGS cost per sample reached $254.85. Its adoption is further hindered as tNGS has not yet been integrated into national DRTB guidelines. Meanwhile, laboratory technicians highlighted the need for workflow optimisation and improved access to essential laboratory equipment, particularly to address poor-quality samples.
Conclusions: tNGS shows strong potential to be a rapid genomic diagnostic tool in detecting DRTB. However, addressing the identified barriers is critical to ensure its successful integration into routine diagnostic settings.

OA24-335-20 Cost-effectiveness of targeted next-generation sequencing for TB drug-resistance testing as an alternative to the standard of care in South Africa

A. de Nooy,[1] S.V. Omar,[2] A. Zwerling,[3] S. Shrestha,[3] A. Suresh,[4] R.E. Colman,[4,5] T.C. Rodwell,[4,5] S. Uplekar,[4] N. Ismail,[6] S. Khan,[7] S. Girdwood,[7] B.E. Nichols,[1,8,9] [1]Amsterdam UMC, Global Health, Amsterdam, Netherlands, [2]National Institute for Communicable Diseases, a division of the National Health Laboratory Service, Centre for Tuberculosis, National & WHO Supranational TB Reference Laboratory, Johannesburg, South Africa, [3]University of Ottawa, School of Epidemiology and Public Health, Ottawa, Canada, [4]FIND, Genomics and Sequencing, Geneva, Switzerland, [5]University of California San Diego, Division of Pulmonary, Critical Care, Sleep Medicine, and Physiology, San Diego, United States of America, [6]University of the Witwatersrand, Clinical Microbiology and Infectious Diseases, Johannesburg, South Africa, [7]FIND, Impact, Geneva, Switzerland, [8]Boston University, School of Public Health, Global Health, Amsterdam, Netherlands, [9]University of the Witwatersrand, Wits Diagnostic Innovation Hub, Faculty of Health Sciences, Johannesburg, Netherlands
e-mail: a.denooy1@amsterdamumc.nl

Background: South Africa faces emerging resistance to TB drugs like bedaquiline. Phenotypic drug susceptibility testing (DST), the current reference standard for bedaquiline DST, has long turnaround times. Targeted next-generation sequencing (tNGS) offers a comprehensive

alternative, potentially delivering faster results. However, these advantages must be weighed against differences in cost and test accuracy.

Design/Methods: We used a decision tree model to evaluate the cost-effectiveness of tNGS against the standard of care (SOC) in South Africa across different levels of tNGS decentralization (1, 3,4 and 6 sites). Key outcomes included survival rates, time to a correct resistance profile, infectious time, and disability-adjusted life years (DALYs). Sensitivity analyses assessed the impact of drug resistance prevalence, tNGS sensitivity, and improved DST access on overall cost-effectiveness.

Results: tNGS averted 408 DALYs and correctly identified 90.7% of resistance profiles as compared to 87.7% with SOC. Based on model assumptions for South Africa, tNGS had a reduced turnaround time and averted 97 years of infectious time. Centralized tNGS was cost-saving relative to SOC, however decentralization of tNGS resulted in higher costs per DALY averted ($671- $2,454). tNGS outcomes improved at higher bedaquiline resistance and with increased sensitivity relative to the SOC. Any increase in DST access through tNGS improved cost-effectiveness in decentralized scenarios.

DST Algorithm (cost per test)	Total Cost ($) (Range)	Total DALYs (Range)	Incremental cost per DALY averted
Xpert + pDST ($137)	$1.3m ($1,333,883 - $ 1,334,147)	70,893 (70,840 – 71,077)	-
tNGS (1 site, $102)	$1.1m ($1,107,951 – $1,108,319)	70,485 (70,431 – 70,643)	Cost-Saving
tNGS (3 sites, $148)	$1.6m ($ 1,607,618-$ 1,608,106)		$671
tNGS (4 sites, $171)	$1.8m ($1,857,699 - $1,858,282)		$1,283
tNGS (6 sites, $215)	$2.3m ($2,335,511 - $2,336,233)		$2,454

Table 1: Results of cost-effectiveness analysis

Conclusions: tNGS could be cost-saving (centralised) or cost-effective (decentralised) in South Africa and has the potential to improve patient outcomes by returning a greater number of correct results in a shorter time. This analysis should be replicated across other settings to evaluate the broader feasibility of tNGS for DST.

OA24-336-20 Evaluating feasibility and acceptability of TB screening and diagnostic tests: A qualitative study across seven high-burden low- and middle-income countries in the Start4All project

V. Iem,[1,2] S. Banu,[3] V. Santos,[4] C. Mbuli,[5] S. Wandiga,[6] C. Kwanjo Banda,[7] J. Bimba,[8] S. John,[9] L.N.Q. Vo,[10] R.L. Byrne,[2,1] B. Ringwald,[2,1] T. Wingfield,[2,11,12,13]
Start4All: Start Taking Action for TB Diagnosis [1]Liverpool School of Tropical Medicine, Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland, [2]Liverpool School of Tropical Medicine, Centre for Tuberculosis Research, Liverpool, United Kingdom of Great Britain and Northern Ireland, [3]International Centre for Diarrhoeal Disease Research, Bangladesh, Infectious Diseases Division, Dhaka, Bangladesh, [4]Federal University of Sergipe, Department of Medicine, Lagarto, Brazil, [5]Center for Health Promotion and Research, NA, Bamenda, Cameroon, [6]Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, [7]Malawi Liverpool Wellcome Program, Public Health, Blantyre, Malawi, [8]Zankli Research Center, Bingham University, Department of Community Medicine and Primary Health Care, Abuja, Nigeria, [9]Janna Health Foundation, Health, Yola, Nigeria, [10]Friends for International TB Relief, Senior Management, Ha Noi, Viet Nam, [11]Liverpool School of Tropical Medicine, Clinical Sciences and International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland, [12]Karolinska Institutet, Department of Global Public Health, Stockholm, United Kingdom of Great Britain and Northern Ireland, [13]Liverpool University Hospitals NHS Foundation Trust, Tropical and Infectious Diseases Unit, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: vibol.iem@lstmed.ac.uk

Background: Despite advancements in tuberculosis (TB) diagnostics, timely detection remains a challenge in many high-burden, low- and middle-income countries. The Unitaid-funded, seven-country Start4All project aims to evaluate the practicality of implementing novel TB tests and associated sample types in real-world healthcare settings (feasibility) and how they are perceived/experienced by healthcare providers and clients (acceptability).

Design/Methods: Start4All conducted a qualitative study in Bangladesh, Brazil, Cameroon, Kenya, Malawi, Nigeria, and Viet Nam, including 7 focus group discussions (FGDs) with people with TB, 11 FGDs with healthcare providers, and 32 in-country and 6 international key informant interviews with TB diagnosis and care experts. We analyzed data thematically to explore perceived feasibility (using Klaic's, Barker's, and French's feasibility frameworks) and acceptability (using Sekhon's acceptability framework) of TB tests and associated sample types, including molecular diagnostics, chest x-rays (CXR) with and without computer-aided detection (CAD), urine-based tests, blood-based tests (capillary fingerpick and venous) and pooled sputum testing.

Results: Clear testing procedures, adequate infrastructure and staffing facilitated feasibility. Urine-based and finger-prick blood rapid tests were viewed as highly feasible due to quick turnaround, minimal equipment needs, and easy workflow integration. CXR with CAD was considered efficient for screening but limited by rural access. Pooled sputum testing was viewed as cost-effective in high-volume settings, but with operational challenges including additional laboratory processes. Technical demands made machine-based venous blood tests least feasible.
Urine and finger-prick blood were widely accepted for ease and comfort. Sputum remained the standard of care but limited by some people not being able to produce sputum. Overall, healthcare providers and community engagement were perceived as key to acceptability.
Conclusions: Aligning procedures with local service delivery models and resource levels was seen as critical to successful integration of new tests for screening and diagnosis into national TB programs to improve early detection and treatment outcomes.

SHORT ORAL ABSTRACT SESSION (OA)

SOA08 New TB diagnostics in the pipeline

SOA08-582-20 'Sputum is King', but other TB diagnostics are gaining ground: Exploring perceptions of specimens for TB testing in South Africa through the TUTTPlus study

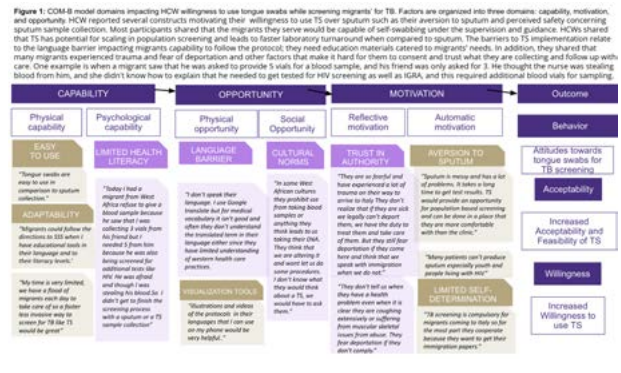
M. Milovanovic,[1] L. Mlambo,[2] L. Genade,[2] A. Kazadi,[2] P. Sebele,[2] M. Mohlamonyane,[2] R. Berhanu,[3] S. Nzama,[4] S.-A. Meehan,[5] H. Myburgh,[5] L. Lebina,[4] N. Martinson,[2]
[1]University of the Witwatersrand, African Potential Collaborative, Johannesburg, South Africa, [2]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa, [3]Vanderbilt University Medical Centre, Department of Medicine, Nashville, South Africa, [4]African Health Research Institute, CTU, Durban, South Africa, [5]Stellenbosch University, Desmond Tutu TB Centre, Cape Town, South Africa

Background: Tongue swabs are a promising, non-invasive alternative for TB testing, as they are potentially simpler and safer to collect than sputum. However, client and provider perceptions for specimen type and diagnostic processes for TB testing have not been widely canvassed. This study explored the acceptability and preferences of tongue swabs compared to other methods TB testing among healthcare providers (HCPs) and clients in South Africa.
Design/Methods: As part of a tongue swab diagnostic yield study (TUTTPlus), six focus group discussions with HCPs and 24 in-depth interviews with clients were conducted across ten primary-care facilities, in three provinces, South Africa. Participants reflected on experiences and preferences related to TB testing specimens and methods. Data were coded and thematically co-analysed using ATLAS.ti.
Results: Many clients preferred blood or chest x-rays for their perceived ability to detect other conditions beyond TB, with some saying, "*blood can show other diseases*" and "*you get to check everything*". The urine LAM test was considered non-invasive by HCPs but sparked doubt among clients about its ability to test for TB, "*normally used to test for pregnancy*". As a novel concept, tongue swabs were generally widely appreciated for being easy, fast, and more private than sputum. However, clients also raised issues of trust and reliability, "*how can you check TB from the tip of the tongue?*".
While both groups described providing and handling sputum as uncomfortable, difficult and stigmatising, it was still considered the gold standard for TB diagnosis because of its established reliability. HCPs believed that how a test was administered and by whom was more important than the specimen itself.
Conclusions: TB specimen preferences were shaped by multiple factors such as convenience, trust, dignity, and perceived reliability. Understanding what makes a test acceptable is important for health messaging to promote and improve uptake.

SOA08-583-20 Healthcare worker acceptance of tongue swabs for tuberculosis screening with migrants in Italy: A qualitative study

R. Codsi,[1] [1]University of Washington School of Public Health, Environmental Health and Occupational Sciences, Seattle, United States of America
e-mail: codsi@uw.edu

Background: HCWs who come into contact with TB patients are at elevated risk of TB infection and disease. The collection and handling of sputum samples pose exposure risks to HCWs. An alternative sample, tongue swabs (TS), was introduced in part to help mitigate some of these risks and challenges.
This study aims to evaluate HCWs' perceived risks, opportunities, and barriers to the use of TS for active TB screening among migrants.
Design/Methods: This study uses in-depth interviews to understand barriers and facilitators to TS use with people migrating to Italy from the Indian Subcontinent and Africa. Purposive sampling was used to enroll HCWs experienced in collecting both sputum and TS samples for TB screening. We adapted Hamilton's Rapid Qualitative Analysis Methods to summarize key findings. Recruitment of HCWs continues until theme saturation is reached.



Results: Emerging themes are shown in Figure 1. All HCWs expressed the need for early TB detection upon migrants' arrival. To support the scaling of TB screening, they indicated a preference for TS over sputum. HCWs shared their perspective that TS was safer to collect, easier to analyze, and provided a possibility of pooling samples. They shared that both symptomatic and asymptomatic migrants could self-swab effectively. They all emphasized the need for solutions to the language barrier and lack of

curated health promotion and educational materials for TB care for migrants. All HCWs reported the need for supervision during swabbing because migrants needed guidance to ensure they were scraping the biofilm off the dorsum of the tongue.

Conclusions: Relative to sputum, HCWs expressed the benefits of TS include the potential for a higher diagnostic yield and a safer tool for TB screening. They also shared the need for tailored educational resources to help mitigate barriers to TS implementation in migrant settings.

SOA08-584-20 Diagnostic accuracy of MultNAT and PortNAT with Swab Sample compared with Xpert MTB/RIF Ultra for *Mycobacterium tuberculosis* (MTB) detection in Nigeria

B. Ajide,[1] T.T. Eliya,[1] Z. Liang,[2] T. Garg,[3] J. Creswell,[4] J.S. Bimba,[1] [1]Bingham University Karu, Nigeria, Zankli Research Center, Karu, Nigeria, [2]Ustar Biotechnologies (Hangzhou) Ltd, Business Development, Hangzhou, Nigeria, [3]Stop TB Partnership, Business Developmet, China, China, [4]Stop TB Partnership, Innovations & Grants, Geneva, Switzerland
e-mail: iliya.taryuta@binghamuni.edu.ng

Background: Accurate screening and diagnostic tests are urgently needed to improve tuberculosis (TB) case finding and advance early detection in high burden settings. This study evaluated the diagnostic accuracy of two new testing tools, MultNAT and PortNAT using swab sample, for detecting MTB, with Xpert MTB/RIF Ultra as the gold standard.

Design/Methods: From January to March 2025, 100 participants aged 12 years and older presenting with cough, or people living with HIV with an elevated C-Reactive protein (CRP) of more than 5mmg were enrolled and tested using MultNAT and PortNAT. Tongue swabs were collected, placed in a tube with its reagents, transported and processed according to manufacturer manual. Diagnostic accuracy of the new tools was assessed against sputum Xpert Ultra results.

Results: The sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of MultNAT and PortNAT in relation to Xpert MTB/RIF Ultra shows significant differences in the performance of the two tests. MultNAT demonstrated a sensitivity of 82.1% and a specificity of 95.8% compared to Xpert, while PortNAT exhibited a sensitivity of 46.4% and a specificity of 95.8%. This indicates that MultNAT was more effective in correctly diagnosing MTB, resulting in fewer false negatives. However, PortNAT exhibited a higher PPV of 100% compared to MultNAT's 95.8%, suggesting that a positive result from PortNAT is more likely to be a true positive. This study provides valuable insights into the comparative performance of MultNAT and PortNAT in detecting MTB using swab.

		Nyanya (46)	Gwagwalada (54)	Overall (100)
Port-NAT	Sensitivity	46.7% (7/15)	46.2% (6/13)	46.4% (13/28)
	Specificity	97.4% (38/39)	93.9% (31/33)	95.8% (69/72)
	Positive Predictive Value	100.0% (7/7)	100.0% (6/6)	100.0% (13/13)
	Negative Predictive Value	84.4% (38/45)	86.1% (31/36)	85.2% (69/81)
Mult-NAT	Sensitivity	73.3% (11/15)	92.3% (12/13)	82.1% (23/28)
	Specificity	94.9% (37/39)	97.0% (32 /33)	95.8% (69/72)
	Positive Predictive Value	91.7% (11/12)	100.0% (12/12)	95.8% (23/24)
	Negative Predictive Value	92.5% (37/40)	97.0% (32/33)	94.5% (69/73)

Table 1. Diagnostic accuracy of MultNAT and PortNAT in relation to Xpert MTB/RIF Ultra across the two clinical sites in Nigeria.

Conclusions: In comparison to Xpert, MultNAT showed better sensitivity in identifying MTB cases, while both MultNAT and PortNAT had high specificity. Although PortNAT had a lower sensitivity, its 100% positive predictive value suggests that a positive result from this test is highly reliable.

SOA08-585-20 Sensitivity of PortNAT TB tongue swabs in adults with confirmed pulmonary TB: Results from a diagnostic study

H.T. Nguyen,[1,2] L.N.Q. Vo,[3,4] A.J. Codlin,[5,4] R. Forse,[5,4] V.C.T. Nguyen,[1] H.T. Tran,[6] H.T. Doan,[7] H.B. Nguyen,[8] L.V. Dinh,[8] J. Creswell,[9] L.
