Background: Tuberculosis (TB) remains a major global health challenge, particularly in low- and middle-income countries, where access to rapid and accurate diagnostic tools is often limited. Point-of-care tests (POCTs) that are rapid, reliable, and affordable are essential for improving TB detection.

PortNAT TB is a novel, portable nucleic acid test designed to detect Mycobacterium tuberculosis DNA from tongue swabs, offering potential as a non-invasive diagnostic tool. However, its diagnostic accuracy must be assessed before clinical use.

Design/Methods: We conducted a prospective multicentre cross-sectional study enrolling 49 adults with bacteriologically confirmed pulmonary TB based on Xpert MTB/RIF Ultra from sputum. Each participant provided two tongue swab samples, tested using PortNAT TB and Xpert Ultra. The primary outcome was the sensitivity of the PortNAT TB tongue swab.

Results: Among 49 participants with confirmed TB, PortNAT TB detected TB in 22 (44.9%) compared to Xpert Ultra from sputum. Sensitivity was higher in smear-positive individuals (73.3%, 11/15) than in smear-negative individuals (32.4%, 11/34). Xpert Ultra from tongue swabs had a sensitivity of 46.9% (23/49) against Xpert Ultra from sputum. Compared to Xpert Ultra from tongue swabs, PortNAT TB had a sensitivity of 82.6% (95% CI: 61.2–95.0%), increasing to 91.7% (95% CI: 61.5–99.8%) in smear-positive participants and 72.7% (95% CI: 39.0–94.0%) in smear-negative participants.

Group	Total	PortNAT Tongue Swab (vs Xpert sputum)	Xpert Tongue Swab (vs Xpert sputum)	PortNAT Tongue Swab (vs Xpert Tongue swab)
All Participants	49	22 (44.9%)	23 (46.9%)	19 (82.6%)
Sputum smear Positive	15	11 (73.3%)	12 (80.0%)	11 (91.7%)
Sputum smear Negative	34	11 (32.4%)	11 (32.4%)	8 (72.7%)

Conclusions: PortNAT TB demonstrated moderate sensitivity (44.9%) for TB detection from tongue swabs, with higher sensitivity in sputum smear-positive individuals (73.3%) compared to those who were smear-negative (32.4%). While its sensitivity was slightly lower than Xpert Ultra from tongue swabs (46.9%), PortNAT TB showed high concordance with Xpert Ultra, particularly in smear-positive individuals. These findings suggest that PortNAT TB may have the potential as a complementary tool for TB diagnosis. Further studies are needed to assess its feasibility and utility in diverse populations and clinical settings.

SOA08-586-20 Evaluation of clinical performances of the PATHFAST TB LAM Ag assay, a new diagnostic test for tuberculosis

T. Fouchet,[1,2] M. Nait Chabane,[2] F. Mougari,[2] Z. Awad,[2] C. Allam,[2,3] A. Hartmann,[1] E. Cambau,[2,3] M. Rochelet,[1]
[1]INRAE-UBE-IAD, Agroecologie, UMR 1347, Dijon, France, [2]APHP Bichat GHU Nord, Service de Mycobactériologie Spécialisée et de Référence, Laboratoire Associé du Centre National de Référence des Mycobactéries et Résistance des Mycobactéries aux Antituberculeux (CNR-MyRMA), Paris, France, [3]Université de Paris, Inserm UMR 1137 IAME, Paris, France
e-mail: theo.fouchet@aphp.fr

Background: Tuberculosis (TB) remains a global health burden, with 10.8 million new cases and 1.25 million deaths in 2023 (WHO). Current diagnostic tools—microscopy, PCR, and culture—suffer from various limitations, including low sensitivity, long time-to-result, and high cost. The PATHFAST TB LAM Ag assay (PHC Corporation), a chemiluminescent immunoassay, quantifies lipoarabinomannan (LAM) in sputum within 1 hour and may offer a rapid alternative for TB diagnosis and monitoring.

Design/Methods: We retrospectively evaluated the performance of PATHFAST using 100 decontaminated and frozen sputum samples at the French National Center for Mycobacteria. Of these, 40 samples were positive for *M. tuberculosis* (20 smear+/culture+, 20 smear-/culture+), 20 were negative controls, and 40 were positive for non-tuberculous mycobacteria (NTM).

Additionally, longitudinal samples from 8 patients with pulmonary TB were tested to assess treatment monitoring.

Results: The PATHFAST assay showed an overall sensitivity of 75% and specificity of 55% for MTB detection, with cross-reactivity observed in 23/40 NTM-positive samples, consistent with prior studies. A strong correlation was observed between LAM concentration and time to culture positivity (Spearman r = 0.873).

Importantly, in the 8 follow-up patients, LAM levels significantly decreased after one month of treatment ($p = 0.002$), indicating potential for treatment monitoring.

Conclusions: In conclusion, the PATHFAST TB LAM Ag assay offers a rapid, easy to handle approach for detecting MTB in sputum. While low specificity was attributed to NTM cross-reactivity, this could be a potential for diagnosing NTM infections.

The results in monitoring early treatment response are very promising since no tests are provided today in this indication. Further studies with more longitudinal data are warranted to confirm these findings.

SOA08-587-20 Lipoarabinomannan (LAM) as a biomarker for the diagnosis of tuberculosis

S. Pichlo,[1] P. Sanchez Carballo,[1,2,3] K.I. Gaede,[4,5,6] Y.A. Shuaib,[7,8] M. Reimann,[1,2,3] N. Zielinski,[1,2,3] N. Köhler,[1,2,3,9] T.T. Brehm,[1,2,9] D. Wölk,[1,2] D. Chesov,[1,10,11] C. Lange,[1,2,3,12] DZIF-TB cohort study group [1]Research Center Borstel, Leibniz Lung Center, Clinical Infectious Diseases, Borstel, Germany, [2]German Center for Infection Research (DZIF), Tuberculosis Unit, Partner Site Hamburg-Lübeck-Borstel-Riems, Germany, [3]Respiratory Medicine & International Health, University of Lübeck, Lübeck, Germany, [4]Biomaterial Bank Nord, Research Center Borstel Leibniz Lung Center, Borstel, Germany, [5]German Centre for Lung Research (DZL), Airway Research Centre North (ARCN), Großhansdorf, Germany, [6]PopGen 2.0 Biobanking Network (P2N), Kiel University, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany, [7]College of Veterinary Medicine, Sudan University of Science and Technology, Hilat Kuku, Khartoum North, Sudan, [8]PHC Europe B.V., ., Breda, Netherlands, [9]Division of Infectious Diseases, I. Department of Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, [10]Chiril Draganiuc Phthisiopneumology Institute, Department of Pulmonology and Allergology, Chisinau, Republic of Moldova, [11]Discipline of Pneumology and Allergology, Nicolae Testemitanu State University of Medicine and Pharmacy, Chisinau, Republic of Moldova, [12]The Global Tuberculosis Program, Texas Children's Hospital, Immigrant and Global Health, Department of Pediatrics, Baylor College of Medicine, Houston, United States of America
e-mail: spichlo@fz-borstel.de

Background: Routine diagnostic methods for tuberculosis (TB) rely on detecting pathogen-specific DNA or bacterial growth in culture. Lipoarabinomannan (LAM), a component of the mycobacterial cell wall, has emerged as a promising biomarker for TB diagnosis.
Currently, only LAM detection in urine is endorsed as diagnostic point-of-care test by the WHO for TB, restricted to people living with HIV.
This study aims to independently evaluate the PATHFAST LAM Ag assay for pulmonary TB diagnosis, assess its reproducibility and optimize sputum-based testing, and explore its utility in non-sputum matrices (serum, plasma, urine, and exhaled breath).
Design/Methods: The PATHFAST TB LAM Ag Test is an in-vitro diagnostic test that quantitatively measures LAM concentration in sputum. Based on chemiluminescence enzyme immunoassay in just 17 minutes. PATHFAST LAM Ag assay was evaluated for diagnostic accuracy on sputum specimens from confirmed culture patients and healthy controls recruited at the Research Center Borstel in Germany.
Moreover, assay reproducibility was evaluated in sputum samples.
Additionally, diagnostic accuracy was also evaluated on serum, plasma, urine and on collectors of exhaled breath.
Results: With the manufacturer's declared cut-off, the assay was 85.2 % sensitive and 100 % specific on sputum samples. Reproducibility analysis of duplicate sputum samples had a mean coefficient of variation (CV) of 54.5 % (SD = 31.8) for non-homogenised samples which could be reduced to CV of 16.0 % (SD = 27.3) by homogenisation with 2.5 % NALC-NaOH solution.
The assay's diagnostic accuracy of PATHFAST LAM applied to non-sputum matrices was insufficient (results not shown).
Conclusions: The PATHFAST LAM Ag assay is meeting the WHOs TTP benchmark for a near point-of-care-test for the diagnosis of TB on sputum samples. Reproducibility is greatly enhanced by homogenising sputum samples prior to analysis. For non-sputum biological matrices, like urine, serum, plasma or exhaled breath the assay is not suitable for TB diagnosis.

SOA08-588-20 Performance of Fujifilm SILVAMP TB LAM for detection of pulmonary tuberculosis across different healthcare facilities and urban-slum communities in Bangladesh

S.M.M. Rahman,[1] N.N. Ruhee,[1] S. Choudhury,[1] T. Rahman,[1] S. Miah,[1] S. Ahmed,[1] S. Kabir,[1] M.K.M. Uddin,[1] R. Byrne,[2] V. Iem,[2] T. Wingfield,[2] S. Banu,[1] [1]International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Infectious Diseases Division, Dhaka, Bangladesh, [2]Liverpool School of Tropical Medicine, Centre for Tuberculosis Research, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: smmazidur@icddrb.org

Background: The Fujifilm SILVAMP TB LAM (FujiLAM) assay, a urine-based point-of-care test, has shown promise for detecting pulmonary tuberculosis (PTB) in HIV-positive patients. However, its performance in HIV-negative populations remains unclear.
This study evaluates the performance of FujiLAM for PTB detection among adults in Bangladesh, across primary and district healthcare facilities and urban-slum communities.
Design/Methods: As part of the 'Start4All' project, urine samples were collected from presumptive PTB patients (aged ≥15 years) between July 2024 and February 2025. Participants were enrolled through passive case finding at healthcare facilities and active case finding in urban slums. Sputum samples were tested using Xpert MTB/RIF Ultra (Ultra) and cultured on MGIT 960. FujiLAM results were compared to sputum Ultra and culture to assess sensitivity and specificity.
Results: A total of 2165 participants with available sputum culture results were included. The overall FujiLAM positivity rate was 3.3% (71/2165), highest in urban slum (5.8%, 45/781), followed by district (2.6%, 16/622) and

primary (1.3%, 10/762) healthcare facilities. Against the microbiological reference standard (sputum Ultra and/or culture), FujiLAM showed an overall sensitivity and specificity of 28.5% (49/172) and 98.9% (1971/1993), respectively. At the district level, sensitivity and specificity were 37.2% (16/43) and 100% (579/579), respectively. At the primary level, they were 20.5% (9/44) and 99.9% (717/718), respectively. In urban slum populations, FujiLAM demonstrated 28.2% (24/85) sensitivity and 97.0% (675/696) specificity.

Conclusions: FujiLAM demonstrated high specificity but suboptimal and variable sensitivity across settings in adults in Bangladesh. These findings underscore the need for further refinement of the assay to improve its utility as a non-sputum-based diagnostic tool for detection of PTB in HIV-negative populations at low-resource contexts.

SOA08-589-20 Diagnostic accuracy and reproducibility of the FujiLAM II point-of-care assay to detect TB in stored urine specimens

N. Biatu,[1] N. Kontogianni,[2] C. Mbuli,[1] C. Vuchas,[1] R. Nsamenang,[1] N. Ndi,[3] C. Nadege Bonkar,[1] A. Etiendem,[1] D. Kolieghu Tcheumeni,[1] N. Ndze Mbuh,[1] M. Sander,[1] A.I. Cubas Atienza,[2] [1]Center for Health Promotion and Research, Research, Bamenda, Cameroon, [2]Liverpool School of Tropical Medicine, Centre for Drugs and Diagnostics, Liverpool, United Kingdom of Great Britain and Northern Ireland, [3]Baptist Convention Health Services and Baptist Institute of Health Sciences, Health Services, Bamenda, Cameroon
e-mail: nbiatu@gmail.com

Background: Currently the only WHO-recommended urine-based, point-of-care test to detect TB is the AlereLAM, with limited sensitivity. Earlier versions of the FujiLAM test showed lot-to-lot variability. The new FujiLAM II assay (Fujifilm, Japan) has been designed to address these limitations, and clinical and analytical evaluations are needed.

Design/Methods: We tested bio-banked urine specimens collected from people living with HIV in two prospective cohort studies. Urine samples were tested on the FujiLAM II and read by two readers blinded to other results. Sensitivity and specificity were assessed against a microbiological reference standard including two sputum cultures, sputum Ultra, blood Ultra, and other results, with AlereLAM as comparator. Sensitivity was evaluated across four lots with graded intensity levels. In addition, the limit of detection (LoD) and lot-to-lot reproducibility were assessed across 10 lots using cultured LAM and 87 clinical specimens with quantified LAM concentrations (EclLAM, MesoScale Diagnostics, USA).

Results: Urine from 810 people was tested, including 119(15%) with bacteriologically-confirmed TB and complete results. Preliminary estimated sensitivity of FujiLAM II was 50% (59/119, 95%CI:40-59) and specificity was 96% (638/667, 95%CI:94-97). Sensitivity in hospitalized participants (median CD4 count 77 cells/mm3, IQR: 51-186 cells/mm3) was 55% (37/67, CI:42-67) as compared to 42% (22/52, 95%CI:29-57) in ambulatory participants. In comparison, AlereLAM sensitivity was 36% (43/119, 95% CI:28-46, difference +14%). Sensitivity was similar across three additional lots (49% (58/119), 52% (62/119), 49%(58/119)). Further analyses confirmed reproducible results across 10 additional lots in contrived and clinical specimens.

Conclusions: Sensitivity of the FujiLAM II assay was 50%, as compared to 36% for AlereLAM, in people living with HIV in this study, which is lower than WHO target product profile of 65% for non-sputum point-of-care tests. The assay had reproducible results across multiple lots in both analytical and clinical testing.

SOA08-590-20 Effect of sputum quality on performance of tuberculosis molecular bacterial load assay for tuberculosis diagnosis and treatment monitoring among adults in Uganda

A. Sessolo,[1] W. Worodria,[1] W. Sabiiti,[2] K. Byanova,[3] E. Musisi,[1] R. Abelman,[4] I. Sanyu,[1] J. Zawedde,[1] P. Byanyima,[1] S. Kasinga,[1] L. Huang,[5] N. Chang,[6] [1]Infectious Diseases Research Collaboration (IDRC), Lung heath research, Kampala, Uganda, [2]University of St Andrews, Microbiology, Glasgow, United Kingdom of Great Britain and Northern Ireland, [3]University of California San Francisco (UCSF), Division of Pulmonary, Critical Care, Allergy and Sleep Medicine, San Francisco, United States of America, [4]University of California San Francisco (UCSF), Division of HIV, Infectious Diseases, and Global Medicine, San Francisco, United States of America, [5]University of California San Francisco (UCSF), Division of Pulmonary, Critical Care Medicine & Division of HIV, Infectious Diseases and Global Medicine, San Francisco, United States of America, [6]University of California San Francisco (UCSF), UCSF Department of HIV, Infectious Diseases, and Global Medicine, San Francisco, United States of America
e-mail: asabdses@gmail.com

Background: WHO has identified Tuberculosis Molecular Bacterial Load Assay (TB-MBLA) as a potential replacement for sputum smear microscopy to monitor TB treatment due to its high accuracy. This study evaluated the effect of sputum quality on performance of TB-MBLA.

Design/Methods: Tuberculosis presumptive adult patients were prospectively enrolled for a longitudinal follow up study at Naguru Hospital Kampala, Uganda. Participant sputum was collected at enrolment, its macroscopic quality was documented and tested using Xpert MTB/RIF Ultra and TB-MBLA. All Xpert MTB/RIF Ultra positive

patients at enrolment received 6 months of anti TB treatment and their sputum quality documented and tested at 2, 8, 17, and 26 weeks post-treatment initiation. Using Mycobacteria Growth Indicator Tube (MGIT) culture as a reference test, we compared difference in diagnostic yield, sensitivity and specificity of TB-MBLA among sputum quality categories using 2 sample tests of proportions.

Results: We included 637 (198 at diagnosis) samples in our analysis. The majority of samples were salivary (349, 55%), while blood-stained (16,3%) were the least common. Compared to a combined positive TBMBLA proportion for other sample types, salivary samples had the lowest (-0.4; 95% CI -0.44, -0.30) while purulent had the highest (+0.5; 95% CI 0.30- 0.44) proportions. Overall, salivary samples had a lower sensitivity by 19% (95% CI 13-25), 27% (95% CI 20-34), and 30% (95% CI 25-35) compared to mucoid, purulent, and blood-stained samples, respectively. Sensitivity didn't vary significantly by sputum types at diagnosis. At follow up only, salivary samples still showed significantly lower sensitivity by 22% and 33% when compared to Mucoid and purulent samples respectively. Specificity for mucoid and purulent samples was lower than salivary samples by 8% and 37% respectively (Table1).

	per sample type at follow-up only			
Sample type (n)*	Sensitivity(95%CI)[1]	Comparison of sample types	diff[2] (95% CI)	P value
Salivary (n=289)	58.5% (42.1- 73.7)	Mucoid - Salivary	22% (13-30)	0.0001
mucoid (n=132)	80.4% (66.9-90.2)	Purulent - Salivary	33% (19-48)	0.003
Purulent (n=17)	91.7% (61.5- 99.8)	Purulent - Mucoid	8% (-7- 22)	0.2
Sample type	Specificity(95%CI)	Comparison of sample types	diff (95% CI)	P value
Salivary (n=289)	96.8% (93.7- 98.6)	Salivary - Mucoid	8% (2.2-13)	0.0006
mucoid (n=132)	88.9% (80-94.8)	Salivary - Purulent	37% (13-60)	0.0001
Purulent (n=17)	60% (14.7-94.7)	Mucoid - Purulent	29% (50-53)	0,0007
(n)*=total samples analysed per sample type	(95%CI)[1]=95% Confidence intervals		diff[2]=Difference of sensitivity or specificity between sample types	

Table1: Performance of TBMBLA

Conclusions: Quality of sputum samples should be emphasized when using TB-MBLA for treatment monitoring. Studies with bigger sample sizes are required to confirm our findings.

SOA08-592-20 Xpert MTB/XDR external quality assurance rollout by NTP Bangladesh: A milestone unveiled

U.T. Maliha,[1] S. Bhargava,[2] T. Huda,[1] I. Ara,[1] M. Hasan,[1] T. Begum,[1] S. Asma,[1] P. Barua,[1] T. Haque,[2] S.K. Shanmugam,[3] Z. Kabir,[1] Z. Nasreen,[1] [1]National Tuberculosis Control Program, NTP, DGHS, Dhaka, Bangladesh, [2]Foundation for Innovative New Diagnostics, FIND, New Delhi, India, [3]National Institute for Research in Tuberculosis, NIRT, Chennai, India
e-mail: tuli37micro@gmail.com

Background: The National Tuberculosis Control Program (NTP) of Bangladesh has introduced the Xpert MTB/XDR assay as a reflex test primarily focusing to diagnose resistance to Isoniazid and Fluoroquinolones. This implementation allowed expanded access to Drug Susceptibility Testing (DST) and ensured early treatment with appropriate regimen. External Quality Assessment (EQA) Proficiency Testing (PT) is essential to maintain quality across pre-analytical, analytical, and post-analytical stages of the assay. In 2024, NTP Bangladesh launched EQA PT program for Xpert MTB/XDR assay, in collaboration with the ICMR - National Institute for Research in Tuberculosis (NIRT), Chennai with technical support from FIND.

Design/Methods: Dried Tube Specimen (DTS) panels were manufactured at NIRT Chennai using CDC's DTS technology and dispatched to NTP Bangladesh. EQA portal was adapted for data collection, monitoring and analysis. Reference lab staffs were oriented to monitor and implement EQA PT round. Panels were further shipped to Regional Reference Labs. They oriented site staffs regarding EQA protocol, data submission and handed over panels (5 panels/sites, set of 5 tubes/panel) for testing. Sites submitted their results through EQA portal. Scoring criteria were predefined by NIRT. Data was analyzed, shared with NTP and reports released to sites. Post EQA desk reviews were conducted for unsatisfactory and false reporting sites by reference labs, followed by repeat panel testing.

Results: A total of 81 sites participated, reflecting full national engagement. While 80 sites (98.8%) had satisfactory results (scored 80 or above out of 100), 1 site (1.2%) scored below 80. False resistance not detected results were reported by two sites. Post EQA assessments and corrective actions were carried out for both sites and on repeat PT both achieved 100 score.

EQA PT ROUND RESULTS	
No. of sites enrolled and participated (each having one machine)	**81**
Analysis of Results (through EQA portal)	
Sites with satisfactory results i.e. score of 80 & above (No. and %)	**80 (98.8%)**
Sites with unsatisfactory results i.e. <80 score (No. and %)	**1 (1.2%)**
➢ One site reported unsatisfactory results, i.e. False Resistance Not Detected to FLQ and Error-5007. ➢ Out of 80 machines with satisfactory results, 67 (83.75%) machines scored 100 and 13 (16.25%) machines scored 80-90. Among these 13 sites, 1 site (7.7%) reported False Resistance Not Detected, 11 sites (84.6%) reported errors (maximum 5007) and 1 site (7.7%) gave invalid result.	
Turn Around Time (TAT: Time between panel receipt and result submission)	
2 Days (No. and %)	**62 (76.5%)**
3-4 Days (No. and %)	**18 (22.2%)**
5-7 Days (No. and %)	**1 (1.3%)**

Conclusions: The implementation and operational performance of Xpert MTB/XDR EQA indicates quality testing capacity across the lab network with reliable diagnostic services.

SOA08-593-20 Incorporating differential test attributes into population-level models of new TB diagnostics

M. Bekker-Nielsen Dunbar,[1] H. Ngyuen,[1,2] L. Koeppel,[1] M. Gaeddert,[1,3] S. Arif,[4] K. Thielemann,[1] A. Gupta-Wright,[3,5,6] C.M. Denkinger,[1,3] F.M. Marx,[1,7] [1]Heidelberg University Hospital, Department of Infectious Diseases and Tropical Medicine, Heidelberg, Germany, [2]Heidelberg University Hospital, Heidelberg Institute of Global Health, Heidelberg, Germany, [3]German Center for Infection Research, Partner site Heidelberg, Heidelberg, Germany, [4]University of Manchester, Division of Population Health, Manchester, United Kingdom of Great Britain and Northern Ireland, [5]NHS Trust, North Bristol, Bristol, United Kingdom of Great Britain and Northern Ireland, [6]Imperial College London, Department of Infectious Disease, London, United Kingdom of Great Britain and Northern Ireland, [7]Stellenbosch University, South African Centre for Epidemiological Modelling and Analysis, Stellenbosch, South Africa
e-mail: bl328@uni-heidelberg.de

Background: Mathematical models of tuberculosis (TB) provide valuable estimates of the population-level health impact of novel diagnostic tests. Test accuracy—sensitivity and specificity—as well as turn-around time (time to actionable test result, TAT), sample accessibility (ease of sample collection), and deployability (feasibility of test implementation across different settings) are important test attributes. We aimed to assess how these five key attributes are included in population-level transmission-dynamic modelling studies of TB diagnostic tests.
Design/Methods: We performed a scoping review of population-level transmission-dynamic modelling studies published between 2010 and 2023 that evaluated the impact of TB diagnostic tests. Publications were eligible for inclusion if current or novel TB diagnostic tests were modelled and at least one of either TB incidence, prevalence or mortality was considered as the outcome. We extracted data on the test investigated, inclusion of key test attributes (sensitivity, specificity, TAT, sample accessibility, and deployability), and how these attributes and their effects were modelled.
Results: We included 21 modelling studies. Nine (43%) investigated hypothetical future tests, nine (43%) modelled the implementation of Xpert MTB/RIF or Xpert Ultra, and three (14%) considered other tests. Population-level outcomes modelled were: TB incidence (16 studies, 76%), mortality (15 studies, 71%), and prevalence (11 studies, 52%). Of the 21 studies, 20 (95%) considered test sensitivity, eight (38%) considered TAT, seven (33%) considered specificity, eight (38%) considered deployability, and two (9.5%) considered sample accessibility.
Conclusions: Population-level models of novel TB diagnostics have primarily focused on improved sensitivity, with limited inclusion of other important test attributes. Current research and development is focused on non-sputum-based, easily deployable diagnostic tests with shorter TAT which current model formulations may not capture well. Future population-level models of TB diagnostics should incorporate a broader set of the key attributes to better estimate real-world impact in high-burden settings.

SOA09 Communities at the centre: Driving TB awareness, support, and science

SOA09-594-20 "Make sure you involve us": Experiences and care needs among youth with TB in East Africa

L. Enane,[1,2] L. Diero,[3,4] W. Muyindike,[5,6] K. Prabhudas-Strycker,[1,7] J. Omondi,[4] S. Kitur,[4] B. Ssekyanzi,[8] M. Waugh,[9] H. Byakwaga,[5] A. Semeere,[10] N. Navuluri,[11,12] K. Wools-Kaloustian,[2,7,4] East Africa International epidemiology Databases to Evaluate AIDS (EA-IeDEA) Consortium [1]Indiana University School of Medicine, Department of Pediatrics, Indianapolis, United States of America, [2]Indiana University, Center for Global Health Equity, Indianapolis, United States of America, [3]Moi University College of Health Sciences, Department of Medicine, Eldoret, Kenya, [4]Academic Model Providing Access to Healthcare, AMPATH, Eldoret, Kenya, [5]Mbarara University of Science and Technology, Department of Medicine, Mbarara, Uganda, [6]Mbarara Regional Referral Hospital, Immune Suppression Syndrome Clinic, Mbarara, Uganda, [7]Indiana University School of Medicine, Department of Medicine, Indianapolis, United States of America, [8]Mbarara Regional Referral Hospital, Department of Clinical Research, Mbarara, Uganda, [9]Indiana University Indianapolis, Honors College, Indianapolis, United States of America, [10]Infectious Diseases Institute, Makerere University, Research Department, Kampala, Uganda, [11]Duke University School of Medicine, Department of Medicine, Durham, United States of America, [12]Duke University, Duke Global Health Institute, Durham, United States of America

Background: Tuberculosis (TB) is the leading infectious cause of death for youth (ages 15-24) globally. Data are needed on TB care needs among youth to inform youth-focused interventions.

Design/Methods: The TB Sentinel Research Network of the International epidemiology Databases to Evaluate AIDS is a global prospective study of people aged ≥15 with pulmonary TB. At sites in Eldoret, Kenya, and Mbarara, Uganda, in-depth interviews were conducted with a purposive sample of youth treated for TB and with healthcare workers (HCWs) providing TB care, following a semi-structured guide investigating youth experiences and care needs. A reflexive thematic analysis was conducted. A youth advisory board supported study implementation.

Results: We analyzed 28 interviews, with HCWs (n=15) and with youth with TB (n=13), among whom median age was 23, 7 (54%) were male, and one was living with HIV. Youth and HCW narratives described delays in youth TB diagnoses, with youth having multiple contacts with the healthcare system before accessing chest X-ray or TB testing (Table). Barriers to youth TB treatment adherence included pill burden and side effects, increased hunger coupled with food insecurity, and difficulties taking treatment at school. Stigma and depression particularly impacted youth, complicating TB diagnosis, contact tracing, and adherence. While some youth experienced persistent symptoms after treatment completion, they had limited access to care. Youth and HCWs expressed needs for increased TB awareness and access to testing, nutritional and economic support, stigma and mental health interventions, and post-TB care. They favored youth-friendly interventions, noting youth survivors may best promote TB awareness and treatment adherence, including through peer support and community-based interventions.

Select Themes	Illustrative Excerpts
Delayed TB diagnosis	"It took about 5 months [to be diagnosed with TB] while taking tablets for cough, not knowing what was in my chest. I would get them from [the] health center. … I was in pain; I was getting worse day by day. When I inquired about X-ray, I was told I could only find it in Mbarara. That is how I came for further medical tests, but I did not know that I had acquired TB. I had only come for check-up and to find out why the chest was paining me so much. When I arrived, I was tested, and it was discovered that TB and it's in advanced stages."
Experiencing TB symptoms at boarding school	"The cough started when I went to school. … I just went to the chemist and asked for a flu tablet which I was given, yes, I took it but then there was no change. So, when I saw no change, I decided to just forget about it because I could not come saying that I bought this and that, I took some time just assuming it, you are there, you go to class, you do whatever."
Financial difficulties	"During the time that I was admitted, for us at our home, family, we only depend on my dad, so that is why I decided that I look for something to do so that I can at least help him because … he is the only one helping everybody. … So that time when I was sick, we did not manage to pay the whole [hospital] bill, though at work they helped me a bit with ten thousand shilling then we paid half of it and there is still a pending bill. That is the problem that I have."
Experiences of stigma	"Even myself I was scared of my neighbors, because the moment they will know [about the TB diagnosis] everyone would close their door, so you will just be like neglected, people are looking at it like as if it is something like an abomination to them, as in they just look at you like as though you are cursed, they don't want to associate with you anymore. That is where you get yourself like...you just feel like these people don't want you anymore."
Post-TB: physical complaints	"After completing treatment, whenever I get flu or cough, they take long to recover, and I don't know why. Even sometimes I get weak. … Flu and cough have disturbed me a lot. Sometimes I get scared and think that I may have acquired TB again because I am not recovering from flu and cough."
Post-TB: difficulties accessing care	"I have had challenges because I got this problem two months ago but because I am at work they can't easily let me leave to come this side. By the time I get the permission it really takes time and even when I come this side and get the treatment, they write for me drugs that am supposed to buy yet I don't have money."
Post-TB: recovering after TB and overcoming stigma	"You know once you have completed your medication is when now your health is returning, but you need to remember that you have been down in those previous years, so maybe you lost your work, or lost something else, a lot of, maybe let's say, the things you had planned in life, you have lost them. Maybe you have lost friends. So, catching up to get all that back is not easy. … For someone who has lost things, they need support. … You know love is one of the supports, you need that love [from friends], so that you come and fit as a normal human being. So that people see you as normal and now you have fit into a similar league as them."
Needs for post-TB follow-up	"Like for my case … I still have some problems so they should at least inquire how the patient is doing even post-treatment because people respond differently."
Youth as "ambassadors" for increasing TB awareness and reducing stigma	"I usually tell people, 'Now I am an ambassador of TB' in some way. So, like TB is something that can be treated. Me, I took my medication and now, like, I'm good. So, I do tell people, like… if you do cough, you need to go take that test, it doesn't cost anything. … Telling that person to take the test you are trying to...you are just trying to make this TB look normal."

Conclusions: Youth experiences of delayed TB diagnosis, stigmatization, adherence barriers, and food insecurity have implications for TB transmission, treatment outcomes, and post-TB health. Multiple opportunities exist to improve youth TB outcomes. Interventions leveraging youth-led supports and meaningful youth involvement are needed.

SOA09-595-20 From research conceptualisation to scientific publication: A community actor's journey with TB research

Y. Kalancha,[1] L. Tonkonoh,[1] A. Daftary,[2] Y.C. Chorna,[3] S. Hasanova,[4] [1]TB Europe Coalition, N/A, Kyiv, Ukraine, [2]York University, Faculty of Health, Toronto, Canada, [3]York University, Department of Anthropology, Toronto, Canada, [4]WHO, Technical Officer, Joint Infectious Diseases Unit, Copenhagen, Denmark
e-mail: Kalancha@tbcoalition.eu

Background and challenges to implementation: Civil society (CS) and communities' engagement, as emphasized in the multisectoral accountability framework for TB (MAF-TB), demands creating opportunities for their meaningful capacitation and leadership in TB research. While they are increasingly engaged in scientific advisory boards to help set the research agenda, inform study design and implementation, their inclusion–much less leadership–within scientific publication endeavors remains poor. Unfamiliarity with theoretical foundations of research, academic writing, journal submission processes, coupled with competing responsibilities in the community, low investment in research capacitation, hinder their contribution to TB scientific discourse.
Intervention or response: We describe key components of successful scientific publication of community-led TB research, using a recent publication on MAF-TB as an example. We delineate publication process stages, including rigorous representation of quantitative and qualitative data, adherence to publication standards, journal selection, peer review navigation, article processing. We showcase how the process was orchestrated by community and CS, ensuring the inclusion of diverse perspectives–TB survivors, government representatives, researchers (clinical and social science), technical agencies, and funders. By integrating these elements, we showcase how a well-coordinated and collaborative approach can enhance the visibility and impact of community-driven research within the scientific community.
Results/Impact: In the result of this collaborative process, a peer-reviewed manuscript led by CS was successfully published. This presentation demonstrates that with appropriate support, CS can effectively navigate academic publishing and contribute rigorous, policy-relevant evidence grounded in lived experience.
Conclusions: Raising visibility and credibility of community-led research is vital for integrating the experiences of those most affected by TB into policy and practice. Peer-reviewed publications are essential to facilitating this process and establishing community-derived knowledge as scientific evidence. We underscore the significance of increasing multi-stakeholder collaboration in TB research as imperative for decolonizing knowledge, scaling impact, and influencing policy.

SOA09-596-20 Aida on WhatsApp: AI-powered support for TB treatment

K. van Kalmthout,[1] J. van Rest,[1] R. Powers,[1]
[1]KNCV TB Plus, TB Elimination & Health System Strengthening, The Hague, Netherlands
e-mail: kristian.vankalmthout@kncvtbc.org

Background and challenges to implementation: Tuberculosis (TB) remains the deadliest infectious disease, claiming over 4,000 lives daily. Despite being curable, treatment requires daily medication for at least six months, and many patients face barriers to adherence.
While Directly Observed Treatment (DOT) is the standard, it is resource-intensive and not always person-centered. Digital Adherence Technologies (DATs), such as smart pillboxes, showed high engagement in the ASCENT project (2019–2023), but the overall impact on treatment outcomes was limited. This recognizes the need for exploring additional digital interventions to support people on TB treatment.
Intervention or response: To address this, KNCV TB Plus developed ***Aida***, a virtual TB treatment supporter powered by OpenAI's GPT-4o and delivered via WhatsApp. Aida offers multilingual, interactive support, providing 24/7 access to personalized treatment information, motivational messages, and answers to common questions. It complements—not replaces—healthcare provider support and was built using insights from individuals and providers engaged in DAT-supported care.

Results/Impact: In November 2024, **Aida** was pilot tested with 70 public health professionals from 26 countries during the Union World Conference on Lung Health. Most participants came from Indonesia, South Africa, Bangladesh, Nigeria, Uganda, and India. Users exchanged over 500 messages with Aida. Common topics included treatment duration, medication details, side effects, symptom management, and emotional support. Feedback from this test helped refine Aida's content, language, and usability, informing the design of a larger feasibility study.

Conclusions: Aida shows early promise as a digital tool to support TB treatment. A field study is currently underway to evaluate its feasibility and acceptability in real-world healthcare settings.
Findings will help determine how AI-powered chat services can be integrated into TB care programs globally to improve support and adherence.

SOA09-597-20 Community radio stations: A powerful, real and relatable, ‚last mile' communications platform, going beyond, resulting in early TB screening and testing

A. Singh,[1] [1]The Union, India, New Delhi, India
e-mail: anisha.singh@theunion.org

Background and challenges to implementation: Community-level demand generation for TB sevices has been identified by India TB Programme as a key pillar for ending TB. This calls for a mass behaviour change drive towards adoption of health-seeking behaviour. But there are still many remote geographies; typically, areas that might host significant populations vulnerable to TB.
Community Radio Stations (CRS), play a pivotal role in reaching these remote, underserved communities to disseminate information on important issues. Can they convert this into a demonstrated impact on programme metrics?
Intervention or response: The Union, supported by the Gates Foundation, implemented a community awareness, engagement and empowerment intervention through the hyper-local medium of community radio stations (CRS). The objective was to understand the role that these CRS could play, beyond standard communications programming, in nudging participation in Active Case Finding (ACF) drives leading to early screening and testing. It was rolled out through SMART NGO, in 27 high TB burden districts (> 316/1,00,000) with a potential broadcast population of 6.3 million.
Results/Impact: Through, broadcast programming and narrowcasts (in-person engagement), the radio jockeys evolved beyond communicators to community influencers.
They energised a 'whole-of-society' movement by engaging multiple stakeholders in this mission, convinced TB survivors to shed inhibitions and share their stories of hope to address stigma, engaged with local officers to complete the loop and raised TB decibel levels on social media and press.
7,468 community members reached in-person, 892 calls received through dial-in for more information, 215 TB survivors engaged leading to 135,436
people screened during ACF. A dipstick survey showed 50%+ decrease is misinformation and almost a 100% increase in awareness about government schemes.
Conclusions: Community Radio Stations, being community owned, can play a transformative role towards ending TB by giving voice to TB community, social acceptance of TB health-seeking behaviour & providing linkages with services being offered, leading to early disgnosis.

SOA09-598-20 Enhancing TB treatment adherence: Evaluation of a digital support tool in Argentina

J. Roberti,[1] A. Aguilar-Vidrio,[2] B. Lutz,[2] F. Rubinstein,[3] S. Iribarren,[2] [1]CONICET, CIESP / IECS, Buenos Aires, Argentina, [2]University of Washington, Biobehavioral Nursing & Health Informatics, Seattle, United States of America, [3]Institute for Clinical Effectiveness and Health Policy, Tuberculosis, Buenos Aires, Argentina
e-mail: sjiribar@uw.edu

Background and challenges to implementation: Digital Adherence Technologies (DATs) are recommended to address TB treatment non-adherence. Our team developed the Tuberculosis Treatment Support Tools (TB-TST) intervention for testing in Argentina, where treatment success rates are low. This study presents findings from exit surveys conducted with individuals with TB randomized to the intervention.
Intervention or response: The application offers TB education, adherence tracking by self-report and a urine metabolite test, side effects monitoring, an anonymous patient forum, and communication with treatment supporters (TSs).
The study was conducted at four public hospitals where patients undergo self-administered treatment. Four hundred participants with confirmed TB were randomized into usual care or TB-TST intervention. Exit surveys assessed user experience, satisfaction, motivation, and recommendations.
Data were analyzed with descriptive statistics and thematic analysis. The study was approved by relevant ethics committees and participants provided written informed consent.
Results/Impact: Eighty participants completed the survey. The application was rated "very easy to use" (4.3/5±0.8) and the metabolite test was considered "easy to use" (3.9/5±1.0). Participants highly recommended the application (4.7/5±0.6), describing it as helpful, efficient, and practical.
The most valued features were medication reminders, access to a TS enabling quick medical assistance and support, while patients initiating treatment found the forum helpful in managing expectations.
Challenges included lack of calendar notifications of appointments, technical issues with uploading reports and test result images, and alarm issues. Key adherence motivators included improving health, preventing disease

transmission, and family support, with encouragement from TSs and other peers reinforcing adherence. Most participants found the metabolite test helpful in reducing hospital visits. Some improvements included adding alarms, appointment alerts, direct communication with doctors, nutritional information, and visual aids showing lung improvement.

Theme	Quotation
Positive experience	"The app was a companion in the early days when I felt so sad and lost because of the disease. Knowing that there were professionals who answered my questions and there were other patients like me made me feel better. I'm not exaggerating. Reading experiences or having patients tell me that everything was going to OK made me feel better. I didn't feel so alone."
Challenges	„I used the app for medication and appointment reminders but prefer my phone's system. On the phone, I can set multiple alarms for different medication times, while the app needs daily individual entries. For appointments, the phone allows alerts a day before or widgets for easy access, which I found more useful for organization."
Motivation	"I wanted to recover my health and physical condition - because I had lost much weight - and return to my daily routine. I was also worried about infecting someone else. It helped me enormously to receive support from my family, who always accompanied me to all my check-ups."
Metabolite test	"The app is very good, and I´m sorry for the delay in sending the images of the test strips as I don't have money, and there were times when I didn't have internet access. It's practical, so you don't always have to go to the hospital for testing."
	The application should ask how the patients are doing from time to time. Sometimes, you feel fear, and feeling accompanied makes you feel better."
Recommendations	"I had a good experience in the use of the test; if I have to give a recommendation, it would be to include the cup with the strips; in my case, we do not consume products in which we can use the container, and we can´t afford to buy sterile containers so often.

Conclusions: This study demonstrates the potential to support treatment adherence by addressing practical and emotional needs. Findings provide insights for refining DATs in TB treatment programs.

SOA09-599-20 Engaging religious leaders to drive active TB case finding at the community level: Implementation outcomes from Enugu State, Nigeria

U. Okoye,[1] J. Ilozumba,[2] C. Okoye,[3] T. Adetiba,[4] A. Adekunle,[5] E. Ubochioma,[6] C. Adesigbin,[7] J. Ssekitooleko,[8] J. Kimeu,[9] [1]Catholic Caritas Foundation, Strategic Information, Enugu, Nigeria, [2]Catholic Caritas Foundation, Implementation and Control, Abuja, Nigeria, [3]Catholic Caritas Foundation, Implementation, Abuja, Nigeria, [4]Institute of Human Virology of Nigeria, TB-HIV, Abuja, Nigeria, [5]Institute of Human Virology of Nigeria, TB, Abuja, Nigeria, [6]National TB and Leprosy and Buruli Ulcer Control Programme Nigeria, Program Unit, Abuja, Nigeria, [7]National TB and Leprocy and Buruli Ulcer Control Programme Nigeria, Program Unit, Abuja, Nigeria, [8]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Global Fund, Geneva, Switzerland, [9]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Program unit, Geneva, Switzerland
e-mail: uchennaokoye22@yahoo.com

Background and challenges to implementation: Nigeria has a high TB burden, with significant gaps in community-level case detection. In Enugu State, religious institutions are highly influential but had been underutilized in active TB case finding. Barriers such as limited engagement, stigma, and low TB literacy among faith leaders hindered progress. In 2024, a structured approach was implemented to engage religious leaders in promoting TB awareness and screening. This abstract presents key outcomes and lessons from this community-centered strategy.

Intervention or response: Under the Global Fund TB project, a stakeholder engagement framework was implemented to target religious leaders in active TB case finding efforts across Enugu State, Nigeria.

The approach included mapping religious institutions to nearby DOTS facilities to strengthen referral linkages, conducting advocacy visits to introduce the outreach team, and documenting worship schedules to guide targeted outreach.

TB education messages were integrated into routine religious activities, and the outreach team coordinated sputum sample collection, transportation of samples to diagnostic facilities and linkage to care. Data from January to December 2024 were analyzed using Microsoft Excel.

Results/Impact: A total of 32,000 individuals were screened at religious worship centers, leading to 6,124 presumptive TB cases and 748 confirmed cases successfully linked to treatment at DOTS centers. The intervention contributed 19% of the state's TB cases and supported a 27% increase in case finding compared to 2023. Religious leaders improved community acceptance, eased treatment uptake, and helped demystify TB, reducing the need for follow-up. Below is the intervention's contribution to state TB case finding.

Conclusions: This intervention underscores the effectiveness of partnering with religious leaders to enhance TB case finding in community settings.
The Enugu experience offers a replicable, culturally appropriate model for other high-burden areas aiming to reduce TB diagnostic gaps through faith-based collaboration.

SOA09-600-20 Improving knowledge and access to health and development information for illiterate women and girls in three urban slums in Southeast Nigeria

F. Iyama,[1] A. Edechiene,[2] D. Egbule,[1] C. Nwafor,[1] J. Chukwu,[3] O. Ezeakile,[1] L. Ugwu,[1] A. Meka,[1] E. Ossai,[4]
[1]RedAid Nigeria, Programmes, Enugu, Nigeria, [2]RedAid Nigeria, Communications, Enugu, Nigeria, [3]DAHW West Africa, Programmes, Enugu, Nigeria, [4]Ebonyi State University, Community Medicine, Abakiliki, Nigeria
e-mail: francis.iyama@redaidnigeria.org

Background: The COVID-19 pandemic revealed the vital need for accessible health information, especially for marginalized populations. Illiterate women and girls in urban slums are faced with significant barriers to accessing vital health messages, as these were often shared through print media, limiting their reach.
This project was conceived during the pandemic to bridge this knowledge gap and improve access to health information by utilizing localized audio formats, providing a more inclusive solution for those most vulnerable.
This project aimed to increase access to essential health information for illiterate women and girls, using audio formats tailored to local contexts.
Design/Methods: A quasi-experimental study design was adopted. The study involved three arms: A control and two intervention arms. Localized health messages (Covid-19, Tuberculosis, Pneumonia as well as other health topics) in audio forms were administered to illiterate and semi illiterate women and girls in intervention groups via WhatsApp platform (Group-1) and memory card (Group-2) from July to September 2021.
Pre and Post test was conducted to ascertain increase in knowledge. Good knowledge of life events was determined by proportion of respondents who correctly answered ≥50% of 34 variables.
Results: A total of 503 illiterate women and girls were enrolled for this intervention across all groups (WhatsApp group- 202, Memory card group-201, Control group-100).
At baseline, the control group had the highest proportion of respondents with good knowledge (69.0%) (WhatsApp group = 47.0% and memory card, 63.2%) ($p<0.001$). At post intervention, the WhatsApp group had the highest increase in proportion of respondents that had good knowledge (51%) followed by the memory card group (36.8%) then the control group (17.2%). ($p<0.001$).
Conclusions: The use of WhatsApp and memory card to disseminate localized audio health messages are effective and should be encouraged especially among the illiterate and semi-illiterate population.

SOA09-601-20 Enhancing the detection of people with TB (PwTB) in Mozambique

B. Jose,[1] R. Machava,[1] B. Macuacua,[1] S. Mukhopadhyay,[2]
[1]Ministry of Health, Mozambique, National TB Control Program (NTP), Maputo, Mozambique, [2]AZUDA Mozambique, Partnership and TB Projects, Maputo, Mozambique

Background and challenges to implementation: Mozambique is one of the high TB, DRTB, and TB/HIV burden countries of the world. Low detection of PwTB with persisting gap between the estimated incident cases and notified cases remained a critical challenge in the country. The gap was higher in cases of DRTB. The country was additionally challenged by suboptimal proportion in the notified bacteriologically confirmed TB.
The key underlying reasons of inadequate TB detection were difficult geographic terrains and scattered population especially in the Northern provinces of Mozambique with poor outreach activities, limited laboratory facilities across the country, difficulties in sample collection and transportation from the peripheral health-facilities, continuing dependence on diagnosis by sputum microscopy, and low coverage of key and vulnerable (KVP) population.
Intervention or response: The National TB Control Program (NTP) of Mozambique adopted following strategies to enhance the detection of PwTB, facilitated by the updated NSP

1. Rapid scaling up of confirmatory tests by CBNAAT and Truenat
2. Well-planned sputum collection and transportation from non-lab health-facilities to lab-facilities in the districts and provinces
3. Active case finding in selected KVP like miners, ex-miner, prisoners, health-workers, and PLHIV
4. Organization of mobile health services in difficult-to-reach areas

5. Engagement of activists, community-radios, and CSO-partners in fast-tracking community awareness, de-stigmatization, gender-equity, and community-led monitoring activities
6. Comprehensive capacity building of health and community-staff

Results/Impact: Between 2019 – 2024, Mozambique showed a steady incline in the notification of all types of TB, and reduced the gap between estimated incident cases and notified cases. There was a rapid rise in proportion of bacteriologically confirmed TB, and increase in notification of RR/MDR TB, due to increase in primary testing by NAAT. Community-level interventions, and better coverage of the underserved areas further improved case notification in Mozambique.

Indicators	2019	2020	2021	2022	2023	2024
# presumptive cases tested primarily by NAAT	137927	167924	243280	307563	656048	413164
# PwTB notified (all types)	97111	97093	98485	110674	116817	107325
# Drug-sensitive PwTB notified	95645	95677	97010	109110	115035	105468
# Drug-resistant PwTB notified	1466	1416	1475	1564	1782	1857
# Bacteriologically confirmed PwTB notified	29419	32159	36205	45948	53505	52400
# Paediatric PwTB notified	12853	11850	11531	13664	13101	12078
# TB-HIV co-infected notified	31897	26354	24313	27916	26919	25072

Conclusions: The NTP of Mozambique documented good lessons to improve TB notification in the low resource-settings, based on strategic planning, enhanced capacities, and optimal resource-utilization.

SOA09-602-20 Finding the forgotten: Community-led TB surveillance in fragile, conflict-affected communities in Borno and Adamawa States of Northern Nigeria

E. Vincent,[1] T. Adetiba,[1] C. Adesigbin,[2] O. Olupitan,[3] M. Zamzu,[4] J. Ssekitooleko,[4] [1]Institute of Human Virology Nigeria, Prevention, Care and Treatment, Abuja, Nigeria, [2]National Tuberculosis, Leprosy and Buruli Ulcer Control Program, Program Coordinating Unit, Abuja, Nigeria, [3]Institute of Human Virology Nigeria, Program Coordinating Unit, Abuja, Nigeria, [4]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Department, Geneva, Switzerland
e-mail: oolupitan@ihvnigeria.org

Background and challenges to implementation: Insecurity, displacement, and deep-rooted stigma have rendered large swathes of Northern Nigeria "invisible" to routine TB surveillance. These neglected geographies, characterized by armed conflict, gender-based restrictions, and fractured health systems, harbor undetected chains of TB transmission, threatening national disease control gains. To address this, the Global Fund-supported N-THRIP project mobilized community-based organizations (CBOs) to lead a locally rooted, trust-based approach to TB case finding in some of the most fragile and security-challenged areas of Borno and Adamawa states.

Intervention or response: Between January and December 2024, CBOs were empowered to co-design and implement TB screening in eight conflict-affected Local Government Areas (LGAs), many of which are inaccessible to formal health actors. With the support of trained community health volunteers (CHVs), survivors of TB, and locally respected influencers, door-to-door outreach was conducted, integrating TB education, symptom screening, sputum collection, and referral.

Gender-sensitive strategies included deploying female-only teams in conservative communities, while stakeholder dialogues with religious and traditional leaders, built trust and safe entry points. Data were aggregated and analyzed to determine screening reach, presumptive identification, bacteriological yield, and linkage to treatment.

Results/Impact: Out of 256,128 individuals screened across both states, 48,857 (19%) were reached in the high security challenged LGAs. These areas demonstrated a presumptive-to-case ratio of 9:1, outperforming the national average of 10:1, and a 10% TB yield. Crucially, all confirmed cases were notified and linked to treatment, achieving a 100% notification rate.

Conclusions: In fragile, underserved regions where traditional TB programs falter, community-led programming offers a resilient and inclusive pathway to finding the missing cases. By leveraging local actors, cultural fluency, and trust-building mechanisms, this approach illuminates hidden epidemics and reestablishes the community's trust in health systems. Scaling such community-first models can catalyze a paradigm shift in TB control across humanitarian and post-conflict settings.

SOA09-603-20 Strengthening accountability in service delivery and commodity availability through community-led monitoring: A collaborative approach in Kenya

C. Kamau,[1] C. Mwamsidu,[2] T. Kiptai,[2] B. Ulo,[2]
[1]Amref Health Africa, Disease Control Prevention and Management, Mombasa, Kenya, [2]Amref Health Africa, Disease Control Prevention and Management, Nairobi, Kenya
e-mail: catherine.kamau@amref.org

Background and challenges to implementation: Some of the challenges in service delivery and commodities in African countries stem from weak healthcare systems, poor leadership, limited access, inefficiencies in procurement and supply chains that lead to frequent shortages of essential health commodities. Amref with the support of Global Fund and in collaboration with stakeholders implemented this intervention to ensure that there is accountability for health commodities at health facilities.

Intervention or response: The project was implemented from July 2023 to Dec 2024 where the project started with training of peer monitors on CLM and the use of Imonitor ATM+ tool across 25 counties. Communities gave their feedback through the Imonitor tool across all thematic areas and a team of duty bearers called Superusers responded to the issues being raised periodically. Also, issues were discussed in various forums allowing feedback and advocacy.
Results/Impact: In 2023 a total of 21,943 commodity and service delivery issues were raised in iMonitor representing 69% of the total issues raised. Commodity issues were 11,710 53% while Service delivery 10,233 47% . 3221 issues were resolved. Some of the feedback shared under commodities were there were no TB drugs, no condoms and no lab reagents. Under service delivery the feedback was on Social Health Authority SHA/NHIF not functioning and long waiting time for patients in health facilities. [CM1] In Busia there were shortages of drugs and due to the advocacy of the citizen advocates the deputy governor fast tracked the distribution of drugs in the health facilities.
[CM1]Period covered in intervention should suffice.
Conclusions: CLM is a powerful accountability mechanism that amplifies community voices, strengthens transparency and drives meaningful improvements in service delivery at the facility level. These successes can also be attributed to the power of collaboration across governments, civil society and communities.

SOA09-604-20 Beyond the pack: Integrating behavioural science to strengthen pictorial health warnings in India

S. Agnihotri,[1] A. Kumari,[1] P. Sinha,[2] [1]Center for Communication and Change - India, None, New Delhi, India, [2]WHO India Office, Tobacco Free Initiative, New Delhi, India
e-mail: sagnihotri@ccci.org.in

Background and challenges to implementation: Pictorial health warnings (PHWs) on tobacco product packaging are a globally recognized, evidence-based strategy to reduce tobacco consumption and deter initiation, particularly among youth and first-time users. In alignment with Article 11 of the WHO Framework Convention on Tobacco Control (FCTC), India has progressively strengthened its PHW policy since 2008, increasing coverage from 40% to 65% in 2014, and to 85% in 2016. The current mandate by the Ministry of Health and Family Welfare requires 60% of the principal display area to depict graphic images of severe health harms, and 25% for textual warnings and a national quit-line number.
Intervention or response: While regulatory design provides the backbone of PHW implementation, integrating behavioural science is critical to ensure these warnings influence perception, motivation, and behaviour. Recognizing this, the Centre for Communication and Change-India, with WHO support, conducted five rounds of pre-tests over a decade using dummy packs. These were evaluated using behaviourally informed parameters: noticeability (grabbing attention in cluttered environments), credibility (linking images with believable health risks), comprehension (across literacy levels), legibility (visual clarity), informativeness (actionable cues like quit-line numbers), and emotional resonance (evoking fear, disgust, or concern to trigger quitting or resistance to initiation).
These parameters draw from behavioural insights such as framing effects, loss aversion, etc. to disrupt habitual use and activate quit intentions. Focus group discussions and in-depth interviews with users, non-users, and retailers across three culturally diverse settings ensured contextual and behavioural relevance.
Results/Impact: Impact data underscore this approach's success. Between GATS 2009-10 and GATS 2016-17, adults considering quitting due to warnings increased by 83.6%. The toll-free quit-line saw a 7.7-fold rise in daily calls (6,064), with a 3.3-fold increase in registrations and a 264.5% increase in quitters.
Conclusions: Behaviourally informed PHWs go beyond visibility to drive real change, making tobacco warnings more salient, credible, and effective in reducing use.

SOA09-605-20 Amplifying TB treatment uptake through strategic engagement of corporate laboratories in UP and Delhi, India

V. Kurne,[1] S. Agarwal,[2] S. Pandey,[3] M. Kumar,[3] N. Joshi,[1] N. Sethi,[1] C. Thakur,[1] V. Abhishek Laxmalla,[1] [1]Hindustan Latex Family Planning Promotion Trust (HLFPPT), Health-TB, Noida, Delhi-NCR, India, [2]Hindustan Latex Family Planning Promotion Trust (HLFPPT), Health, Noida, Delhi-NCR, India, [3]Hindustan Latex Family Planning Promotion Trust (HLFPPT), Health-TB & HIV, Noida, Delhi-NCR, India

Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge in India, with underreporting and delayed treatment common in the private sector. In 2023, 2.5 million PwTB were notified, with 33% (8.4 lakh) reported by private providers. Laboratories accounted for 20% (1.7 lakh) of these, but gaps in timely reporting and linkage to treatment persist. Strengthening collaboration between public health systems and private corporate diagnostic networks is vital to bridge this gap and advance TB elimination goals.
Intervention or response: Under Project SSHAKTI, HLFPPT launched a corporate engagement initiative to accelerate TB elimination by integrating private sector resources through collaboration with corporate hospitals, labs, and online health providers. this intervention en-

hances diagnosis, treatment, and care services in private settings, especially in Corporate hospitals and Corporate Laboratories chains. The intervention promoted the use of Annexure 15A, a standardized the National Tuberculosis Elimination Program (NTEP) Test Request Form, to ensure accurate data capture. Activities included mapping private labs, consultative meetings, conducting national consultations with key stakeholders, and organized 23 capacity-building sessions. In total, 821 lab personnel from 11 major corporate lab chains (covering 437 labs and 10,000 collection centres across 28 states) were trained.
Results/Impact: Before the intervention, 84% of Persons with TB diagnosed in private labs were not enrolled at the first point of contact. By Q1 2025,this dropped to 67%, showing a 33% relative improvement in timely PwTB enrolment at appropriate health facilities. Treatment initiation increased by 49%, indicating stronger linkages and a more effective public health response.
Conclusions: Engaging corporate labs and emphasizing the importance of notifying Persons with TB at the first point of contact—paired with sustained handholding of referral facilities—has significantly improved PwTB enrolment and treatment uptake, reinforcing the national TB elimination strategy.

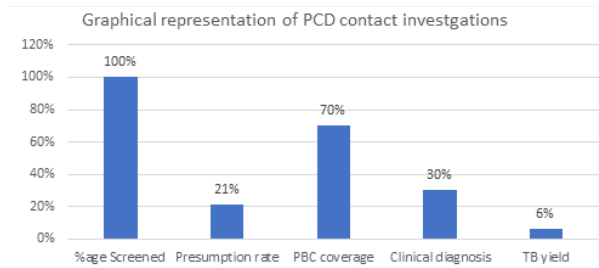
SOA10 Reducing risk for close contacts of people with TB: Find, treat, prevent

SOA10-606-20 Finding TB through community-led interventions: Using clinically diagnosed people with TB to reach their social contacts for TB investigations in Wakiso district, Uganda

L. Namusisi,[1] P. Ajambo,[2] A. Kazibwe,[3] I. Senteza,[4] S. Mukama,[4] S. Zawedde Muyanja,[5] M.G. Nabukenya Mudiope,[6] [1]The AIDS Support Organisation, Programatic Management, Kampala, Uganda, [2]The AIDS support Organisation, Programatic Management, Kampala, Uganda, [3]The AIDS Support Organisation, Programes directorate, Kampala, Uganda, [4]Infectious Diseases Institute, college of health sciences, Makerere University, Health systems strengthening, Kampala, Uganda, [5]Infectious Diseases Institute, college of health sciences, Makerere University, Research, Kampala, Uganda, [6]Infectious Diseases Institute, college of health sciences, Makerere University, Health Systems strengthening, Kampala, Uganda
e-mail: namusisilydia.2022@gmail.com

Background and challenges to implementation: Persons with pulmonary clinically diagnosed TB (PCD TB) disease are generally considered to be less infectious than those with pulmonary bacteriologically confirmed tuberculosis (PBC TB) disease. For this reason, their social contacts are not often prioritized for investigations. However, even when they present as the index patient, a suspicion remains that they may have contracted the disease from an undiagnosed and untreated person with PBC TB. It is upon this background that we investigated to evaluate social contacts of PCD TB patients under four health facilities in wakiso district, Uganda.
Intervention or response: Between July 2024 and March 2025, a team of health workers and community health workers identified newly diagnosed index PCD TB patients. These patients were interviewed and their social contacts enlisted. The team visited these contacts and assessed them for TB disease using symptom screening. Sputum samples were collected from those presumed to have TB and the samples were transported to the laboratories for GeneXpert testing.
Results were returned to patients by the community health workers who also escorted those with positive tests to the health facilities for TB treatment. HIV testing was provided to those eligible as per national guidelines. Contacts who were not diagnosed with TB were provided TB preventive therapy.
Results/Impact: Twenty-five (25) PCD patients were interviewed and 159 contacts were enlisted and screened. Those presumed to have TB were 33 (21%), Bacteriologically confirmed cases were 7 (70%) 3 were clinically diagnosed (30%) and the TB yield was 10 (6%). None

was diagnosed with HIV. All patients were started on TB treatment and all contacts without TB were provided TB preventive therapy.



Conclusions: Pulmonary clinically diagnosed (PCD)TB patients are an important entry point for identification of undiagnosed TB patients in our communities hence their contacts should be prioritized for investigations**.**

SOA10-607-20 Chest radiographic TB screening using human vs. artificial intelligence reads in asymptomatic adult household contacts in South Africa

S. Nyangu,[1] S.C. Mendelsohn,[1] H. Mulenga,[1] M. Tameris,[1] J. Shenje,[1] N. Tredoux,[1] A.K.K. Luabeya,[1] A. Katona,[2] R. Panchia,[3] T. Scriba,[1] M. Hatherill,[1] T.R. Sterling,[2] [1]University of Cape Town, South Africa TB Vaccine Initiative Group (SATVI), Pathology, Cape Town, South Africa, [2]Vanderbilt Tuberculosis Center, Vanderbilt University Medical Center, Tuberculosis center, Nashville, United States of America, [3]University of Witswatersrand, Perinatal HIV Research unit, Johannesburg, South Africa
e-mail: sarah.nyangu@uct.ac.za

Background: Digital chest radiographs (dCXR) are increasingly used for community tuberculosis (TB) screening. We compared dCXR screening by human readers and artificial intelligence among symptomatic and asymptomatic household contacts of TB patients.
Design/Methods: Adults (≥18 years) with recent household TB exposure were enrolled (March 2021-December 2022) in Worcester, South Africa. Baseline procedures included symptom screening, dCXR, and sputum Xpert Ultra and liquid culture. Microbiologically-confirmed TB was defined as positive sputum culture and/or Xpert Ultra.
Asymptomatic TB was defined as microbiologically-confirmed TB in participants who did not have, recognize, or report TB symptoms. dCXR features suggestive of TB (cavity, opacity, miliary pattern, tracheal shift, collapsed lung, or pleural effusion) were reported as compatible with TB. Anonymised dCXR were reviewed by two independent readers (R1 and R2), blinded to symptoms and results. Discordant cases were reviewed by a third reader (R3); majority (2/3) results are reported. dCXR images were read by qTrack (Qure.AI, India), using the manufacturer's TB threshold (50). Human and qTrack reads were evaluated for concordance, sensitivity, and specificity.
Results: 445 participants (mean age 37.6 years; 65% female) enrolled. Of the 445, 42 (9.4%) had microbiologically-confirmed TB, of whom 30/42 (71.4%) were asymptomatic. Human reader sensitivity ranged from 50.0-59.5% for all TB, 50.0-63.3% for asymptomatic, and 50% for symptomatic TB (Table). qTrack detected 27/42 (64.3%, 95%CI 48.0-78.4) of all TB, 20/30 (66.7%, 95%CI 47.2-82.7) of asymptomatic, and 7/12 (58.3%, 95% CI 27.7-84.8) symptomatic TB. Concordance between R1 and R2 was 93.5% (Cohen's kappa 0.71); between human readers (2/3) and qTrack, 93.7% (kappa 0.72).
Conclusions: Among TB-exposed household contacts tested regardless of symptoms, dCXR readings by human and qTrack showed good agreement. qTrack sensitivity was marginally better than human readers, but below the WHO target product profile sensitivity for a screening test (90%), for asymptomatic and symptomatic TB screening.

SOA10-608-20 Role of cadres to increase finding TB through contact investigation based on household and community outreach in Palangkaraya City and Kotim District

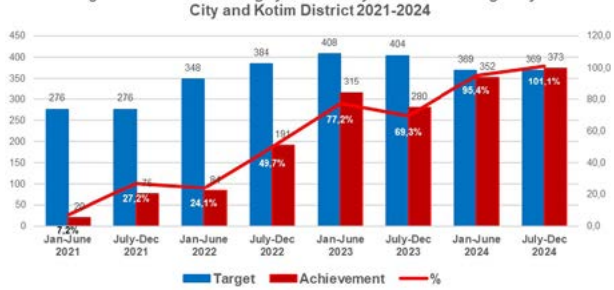
M. Muhammad,[1] The abstract will be presented by Betty Weri Yolanda Nababan (PR Consortium Penabulu-STPI, email: betty.nababan@penabulu-stpi.id) [1]SR Penabulu-STPI Community Central Kalimantan, Non Governmental Organization, Palangkaraya, Indonesia.

Background and challenges to implementation: Two areas with highest TB burden in Central Kalimantan (Borneo) Province are Palangkaraya City and Kotim District, with an estimated number of TB cases 1.299 and 953 respectively. In 2021, only 55% and 33% TB cases were notified. Since 2021, a community-based interventions to increase TB case finding and improve treatment outcomes have been implemented by Penabulu-STPI supported by Global Fund, so starting 2022 there was happened a significant increase in notifications.
The objective of this study is to describe contribution of community health cadres (CHCs) to TB case finding through household contact investigation (CI) and community outreach (CO) between 2021 to 2024 in Palangkaraya City and Kotim District.
Intervention or response: Early 2021, recruitment and training of 60 CHCs was carried out on TB disease and how to conduct CI and CO to find new TB cases. Most CHCs aged 30-45 years (61%), have high education (90%), women (73%)-as housewife (99%). CHCs received incentive from Global Fund for performing CI and CO. CHCs also trace cases index who had changed address. CO activity involves group and individual visits—primar-

ily door-to-door visits in slums, densely populated neighborhoods, and poor communities while carrying sputum containers and encouraging symptomatic individuals to provide samples on-site.

Results/Impact: Figure 1 shows a significant rise in TB case finding from July–December 2022 and peaked until 101% in July–December 2024. According to Central Kalimantan Provincial Health Office, overall TB case detection rate in 2024 has reached 72.5% (targeted 90%), with two area interventions supported by community cadres making significant contributions of 101.1% and 86.3% respectively.

Figure 1: TB Case Finding by Community Cadres at Palangkaraya City and Kotim District 2021-2024



Conclusions: Community cadres play a crucial role in enhancing TB case detection. As grassroots community member, they have easier access to local populations and build stronger trust than government-employed health workers, making them effectively in identifying and referring TB cases.

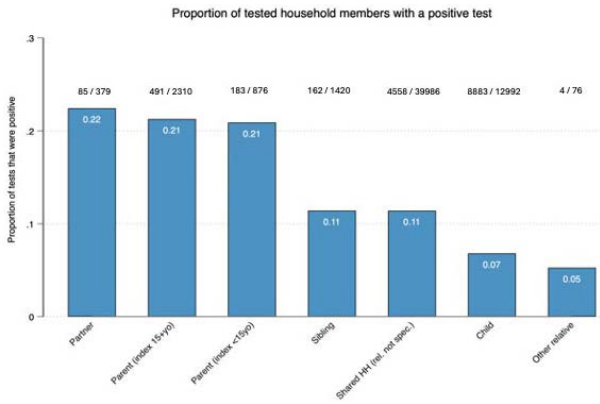
SOA10-609-20 A novel bioinformatics household linkage technique reveals populations at high risk for TB infection within a multi-state US community health network

J. Campbell,[1] M. Brooks,[2] S. Giebultowicz,[3] J. Dankovchik,[3] A. Falkenstein,[4] J. Bressler,[5] H. Angier,[6] R. Epstein,[7] C.R. Horsburgh,[2] H. Jenkins,[8] C. Tschampl,[9] K. Jacobson,[7]
[1]Boston Medical Center, Pediatrics/Pediatric Infectious Diseases, Boston, United States of America, [2]Boston University School of Public Health, Global Health, Boston, United States of America, [3]OCHIN, NA, Portland, United States of America, [4]OCHIN, NA, Los Angeles, United States of America, [5]Boston Medical Center, Pediatrics, Boston, United States of America, [6]Westat, NA, Portland, United States of America, [7]Boston Medical Center, Infectious Diseases, Boston, United States of America, [8]Boston University School of Public Health, Biostatistics, Boston, United States of America, [9]Brandeis University, he Heller School for Social Policy and Management, Waltham, United States of America
e-mail: jeffrey.campbell@bmc.org

Background: Although household testing is a mainstay of tuberculosis (TB) *disease* detection and prevention, few studies leverage households as a locus of TB *infection* clustering in the absence of individuals with known disease. Identifying patterns of household TB infection clustering could enable new, family-centered strategies to diagnose and treat TB infection in low-burden settings.

Design/Methods: We adapted a novel bioinformatics linkage technique to identify household members within OCHIN, a community health center organization serving patients in 40 US states. From OCHIN's research network, we identified all individuals ("index patients") with a positive TB tuberculin skin test (TST) or interferon gamma release assay (IGRA) between 2012-2023, without TB disease. We then linked index patients to "household members" who shared an address with index patients. When multiple individuals in the same household had positive tests, we classified the individual with the first test as the index patient.

Using additional administrative data, we determined the relationships between index patients and household members. We described test positivity by relationship.



Results: We identified 52,378 index patients with a positive TST or IGRA, who were linked to 186,054 unique household members in the OCHIN network. Among household members, 64,460 (35%) had a documented test. Of these, 58,039 (90%) had a valid result, of whom 6,366 (11%) tested positive. We identified high (>20%) test positivity among partners and parents of index patients.

Conclusions: We adapted a novel linkage technique to characterize household TB infection clustering within a multi-state US community health organization network. We found that testing parents and partners of individuals with TB infection may be a high-yield strategy to close TB infection detection gaps in low-burden settings.

SOA10-610-20 Harnessing digital innovations for enhancing contact tracing, early diagnosis and prevention of TB in 15 selected districts of Sindh, Pakistan

N.u. Mian,[1] M. Malik,[1] S.H. Awan,[1] A. Alvi,[1] [1]Contech International, Public Health & Research, Lahore, Pakistan
e-mail: contech@contech.org.pk

Background and challenges to implementation: Despite being preventable and curable, TB remains a leading infectious disease in Pakistan, with Sindh among the high-burden regions. Weak referral-systems, fragmented data-flows, and delays in diagnosis have long hindered efforts. There was a critical need to digitize service delivery and enhance targeted outreach to vulnerable populations.
Intervention or response: Aligned with National TB Guidelines and digital health standards, USAID's IHSS-SD Activity introduced a suite of digital innovations to strengthen TB response in 15 districts.
Key components included TB Management and Analytical Dashboards for real-time data aggregation, performance-tracking, and evidence-based decision-making. The TB Outreach App, is used by trained social mobilisers for automated household contact-tracing, TB screening, and treatment follow-up, while TB HTL App facilitates digital referrals in 30 secondary & tertiary hospitals, using built-in diagnostic algorithms to support TB diagnosis and linkage to care.
To increase detection among hard-to-reach populations, five mobile TB-vans equipped with ultra-portable X-rays, CAD4TB software, and GeneXpert systems were deployed. The approach also integrates hotspot mapping, using cluster analytics from index-case data to target high-risk communities—such as prisons, madrassahs, and urban slums, improving outreach efficiency.
Results/Impact: The initiative screened 56,414 contacts from 9,704 households, including 23,826 children under 15, leading to 785 TB diagnoses. Mobile vans screened 27,233 individuals including 10,148 inmates and 12,242 madrassah students. Hotspot mapping proved pivotal in directing screening resources, reflecting global best-practices for targeting key/vulnerable populations, as recommended by the WHO End TB Strategy. Digital innovations enhanced service transparency, reduced diagnostic delays, and fostered integrated data use at all system levels.
Conclusions: This digitalisation demonstrates a scalable, people-centered, and data-driven approach to TB care, strengthening contact-tracing, diagnosis, and prevention in high-burden settings. Its success in Sindh underscores value of digital tools and hotspot mapping for efficient case-finding and targeted outreach. Wider adoption across provinces and similar contexts can accelerate progress toward TB elimination.

SOA10-611-20 Enhancing finding TB through optimized screening: Lessons from the spot to tent onion model (STOM) of contact investigation

I. Gordon,[1] O. Chukwuogo,[1] M. Sheshi,[1] C. Ogbudebe,[2] O. Nissi,[3] A. Josiah,[3] B. Odume,[1] [1]KNCV Nigeria, Technical/Programs, Abuja, Nigeria, [2]KNCV Nigeria, Strategic Information, Abuja, Nigeria, [3]KNCV Nigeria, Technical/Programs, Uyo, Nigeria
e-mail: igordon@kncvnigeria.org

Background and challenges to implementation: Active Case Finding (ACF) strategies such as contact investigation and house-to-house screening are key elements of TB control in high-burden countries like Nigeria. These strategies are important to reach undiagnosed individuals not presenting to health facilities, which is critical to minimizing community spread.
This study evaluates the effectiveness of Spot to Tent Onion Model (STOM) of TB contact investigation in Akwa Ibom, Nigeria as an optimized approach for TB screening within the community
Intervention or response: Implemented between October 2022 and November 2023 by KNCV Nigeria, the STOM model employed two complimentary approaches. The "spot" involved screening household contacts of confirmed index TB cases from DOT facilities, while the "tent" extended TB screening to households within a 2-kilometer radius of the "spot."
This strategy enabled a more comprehensive reach, facilitating the identification of both missing and newly diagnosed TB cases while addressing the cultural sensitivities associated with household visits, promoting community cooperation, and reducing stigma.
Results/Impact: A total of 22,248 household contacts in the "spot" and 180,483 extended contacts within the "tent" were screened for TB. The model achieved an 8% TB yield from 402 household contacts newly diagnosed for TB and a 5% TB yield from 568 extended contacts newly diagnosed for TB in the "spot" and "tent" interventions, respectively. The dual approach not only increased the reach of TB screening using the same resources, but also contributed an additional 568 newly diagnosed cases which would have been missed, proving the effectiveness of an extended screening radius.

Indicator	SPOT	TENT	STOM
Contacts identified	22,341	180,671	203,012
Number of household/extended contacts screened for TB	22,248	180,483	202,731
Number of household/extended contacts presumed to have TB	5,001	12,541	17,542
Number of presumptive clients evaluated for TB	4,918	12,326	17,244
Number of contacts diagnosed with TB (all forms)	402	568	970
TB cases notified and started on treatment	399	545	944
TB Yield	8%	5%	6%

Conclusions: The "tent" approach contributed nearly 59% of all newly diagnosed TB cases within the period, highlighting the effectiveness of the STOM model's dual strategy in finding missing TB cases. This innovative model is recommended for high-burden settings, especially where stigma and access barriers hinder the effectiveness of traditional screening methods

SOA10-612-20 The value of contact investigation in a human population affected by bacteriological confirmed *M. bovis*

L. de Swart,[1] E. Huisman,[2] T. Guykens,[2] G. Net,[3] M. Broersma,[3] S. Toumanian,[3] [1]Municipal Public Health Service, Gelderland-midden, Regional Expertise Centre North East, The Netherlands, Department of Public Health TB Control, Arnhem, Netherlands, [2]Municipal Public Health Service, Noord- en Oost-Gelderland, Regional Expertise Centre North East, The Netherlands, Department of Public Health TB Control, Warnsveld, Netherlands, [3]Municipal Public Health Service, Twente, Regional Expertise Centre North East, The Netherlands, Department of Public Health TB Control, Twente, The Netherlands

Background and challenges to implementation: Contact investigation is a key part of the tuberculosis (TB) policy in the Netherlands, focusing on early detection, treatment, and prevention of transmission and is conducted using the stone-in-the-pond principle. Risk assessment forms a basic approach to the organization of contact investigation for individuals affected by *Mycobacterium tuberculosis* complex. Two recent cases illustrate the importance of contact investigation in both humans and domestic cats affected by *Mycobacterium bovis (M. bovis)*.
Intervention or response: The first case involves a Dutch adolescent employed in an animal food processing factory, diagnosed with smear-positive pulmonary tuberculosis caused by *M. bovis*. The second case concerns a feline post-mortem diagnosis with bacteriological positive *M. bovis* pulmonary tuberculosis.
Results/Impact: The first case led to the investigation of 11 close contacts, revealing TB infection in four individuals, all colleagues handling raw meat. No TB infections were found among 14 additional colleagues from other departments. Since the index patient had no other *M. bovis* risk factors, the infection likely stemmed from the workplace. Unfortunately, the source was not identified, attributed to incomplete registration by the processing factory.
In the second case, four domestic cats died from *M. bovis* TB. Another cat and dog in the household were diagnosed with possible TB and started treatment. The most likely source being raw cat food. Six human contacts were investigated, revealing one person affected by TB and three TB infections. Among 11 colleagues from a local veterinary clinic, one colleague had a positive IGRA.
Whole genome sequencing (WGS) indicated different *M. bovis* strains in both cases.
Conclusions: These data highlight the importance of contact investigation in both humans and felines affected by *M. bovis*TB, as it enables the identification and treatment of infected individuals, preventing further spread of the disease.

SOA10-613-20 Improving contact tracing and TB diagnosis in children in a drug-resistant TB programme in Punjab province, Pakistan

M. Khalid,[1] K.K. Zaw,[1] H. Fatima,[1] W. Akram,[1] S. Imtiaz,[1] N. Haider,[1] A. Mohammed,[2] S. Khan,[2] F. Hossain,[3] C. Hewison,[4] L. Sannino,[4] [1]Médecins Sans Frontières, Medical, Gujranwala, Pakistan, [2]Médecins Sans Frontières, Medical, Islamabad, Pakistan, [3]Médecins Sans Frontières, Operations, Tokyo, Japan, [4]Médecins Sans Frontières, Medical, Paris, France
e-mail: Laura.Sannino@paris.msf.org

Background and challenges to implementation: Médecins Sans Frontières (MSF) supports the National and Provincial TB Programs of Punjab, Pakistan to provide comprehensive care for patients affected by DR-TB in Gujranwala. Diagnosing children has been a challenge since the outset, with only 8/139 (6%) and 3/136 (2%) patients < 15 year olds enrolled in 2022 and 2023 respectively.
We describe steps taken to increase diagnosis amongst children through improving contact tracing and investigation.
Intervention or response: Due to logistical challenges to perform X-ray, initially contact investigation was done using systematic Xpert testing with sputum or stool samples, according to the age of the contact. As this method did not identify many children with TB, from May 2024, X-ray and clinical examination became the screening methods for contacts <10 years old. As there was only one scheduled pediatric clinic per week, a backlog of children waiting for assessment developed until the number of pediatric clinics increased to 3 times per week.
Results/Impact: From May to December 2024, of 422 contacts <15 years old investigated, 116 (28%) were identified with presumptive TB by clinical and/or radiological signs, 30 (7%) were diagnosed with DR TB and 3 were diagnosed with drug-susceptible TB (DS TB).
Of 143 contacts (34%) with Xpert examination, 12 (8%) had a trace result and 1 had a positive, rifampicin susceptible result. Of patients with a trace result, 3/12 started DR-TB treatment, 2/12 started DS TB treatment, 7/12 (58%) had no clinical or radiological signs of TB and were followed-up without treatment.
Overall, the proportion of <15 year olds enrolled in DR TB treatment increased to 20% (41/209) in 2024.

Conclusions: Investing in clinical evaluation of children who are household contacts of DR TB cases improves diagnosis in this group. Research is needed to understand the significance of trace results in contacts with no clinical or radiological sign of TB.

SOA10-615-20 Optimising TB preventive therapy: A comparative study of completion rates for isoniazid (6H) and isoniazid-rifampicin (3HR) regimens, USAID TB LON 3 project experience

I.G. Ifeanyi-Ukaegbu,[1] B. Kadri,[2] A.O. Okungbure,[2] A. Agbaje,[3] D.O. Sokoya,[4] C. Mensah,[3] P. Dakum,[3] O. Daniel,[2] G. John,[5] R. Eneogu,[6] D. Nongo,[6] R. Nwaulu,[1]
[1]Institute of Human Virology, Strategic Information, Lagos, Nigeria, [2]Institute of Human Virology, Prevention Care and Treatment, Lagos, Nigeria, [3]Institute of Human Virology, Executive Management, Abuja, Nigeria, [4]Lagos State TB Buruli and Leprosy Control Program, TB Unit, Lagos, Nigeria, [5]Loving Gaze, Monitoring and Evaluation, Lagos, Nigeria, [6]United State Agency for Internal Development, Nigeria, HIV/AIDS and Tuberculosis, Abuja, Nigeria
e-mail: iifeanyi-ukaegbu@ihvnigeria.org

Background: Tuberculosis (TB) remains a major public health challenge in Nigeria, necessitating effective preventive strategies, especially among high-risk populations. The USAID TB LON 3 project in Lagos implemented two WHO-recommended TB preventive therapy (TPT) regimens: the traditional six-month isoniazid monotherapy (6H) and the shorter three-month isoniazid and rifampicin combination regimen (3HR). While both regimens are efficacious, evaluating real-world completion rates is crucial to optimize programmatic impact in high-burden, resource-limited settings. This study compared the completion rates of both regimens, stratified by gender, to guide scalable, evidence-informed decisions.
Design/Methods: A retrospective cohort analysis of routine program data was conducted from July to December 2023, involving 2,126 clients initiated on TPT (6H: n=1,727; 3HR: n=399). Treatment completion was defined as finishing the full course within the expected timeframe. Completion rates were calculated for each regimen and stratified by gender. Chi-square tests at a 0.05 significance level assessed statistical differences in completion between regimens and gender groups.
Results: Clients on the shorter regimen had a significantly higher completion rate (90.5%) compared to those on 6H (72.2%). Gender-disaggregated analysis showed marginal differences: females had slightly higher completion on 6H (72.7%) than males (71.7%), while males outperformed females on the shorter regimen (92.5% vs. 88.9%). The difference in regimen completion rates was statistically significant (χ^2=78.4, p<0.001), while gender-based differences were not (χ^2=1.2, p=0.27).

July-Dec., 2023, Uptake	Started on TPT Male	Started on TPT Female	Completed TPT Male	Completed TPT Female	Completion Rate
6H	801	926	574	673	72.2%
3HR	173	226	160	201	90.5%

Conclusions: The shorter regimen demonstrated significantly higher completion rates than 6H, likely due to reduced duration and pill burden, enhancing adherence. No significant gender disparity was observed, indicating equitable uptake. To improve TPT outcomes, scaling up the shorter regimen is recommended. Further research should explore barriers to 6H completion, while sustaining gender-responsive approaches to service delivery. Cost-effectiveness and long-term outcome analyses are also crucial to inform national TB prevention policies and ensure efficient, equitable, and evidence-based scale-up in high-burden settings like Nigeria.

SOA10-616-20 Safety monitoring and completion rates of once-daily isoniazid and rifapentine (1HP) among high-risk populations

P.-C. Chan,[1,2,3] Y.-X. Lin,[1] P.-H. Lee,[1] C.-F. Feng,[1] H.-Y. Lo,[1] C.-C. Lee,[1] [1]Centers for Disease Control, Division of Chronic Infectious Diseases, Taipei city, Taiwan, [2]National Taiwan University, Institute of Epidemiology and Preventive Medicine, College of Public Health, Taipei city, Taiwan, [3]National Taiwan University Hospital, Department of Pediatrics, Taipei city, Taiwan
e-mail: pcanita.tw@cdc.gov.tw

Background: To improve tuberculosis infection (TBI) treatment adherence, Taiwan introduced a 28-day regimen of isoniazid 300 mg plus rifapentine 600 mg (1HP) in 2021 for people living with HIV (PLHIV) and inmates. Domestic trials confirmed its safety and comparable completion rates to the 3-month once-weekly regimen (3HP) among PLHIV and TB contacts in 2020 and 2022, respectively. In 2023, Taiwan CDC expanded 1HP access to all eligible TBI patients. This study compares the safety of 1HP and the 3HP fixed-dose combination (3HP FDC).
Design/Methods: A nationwide pharmacovigilance project was implemented using the TB case management system, Taiwan's National Adverse Drug Reaction Reporting System, and the Taiwan Drug Relief Foundation database. Adverse events (AEs) and severe adverse events (SAEs) leading to permanent discontinuation were analyzed among patients receiving 1HP from 2019 to March 2024 with follow-up until July 2024.
Results: Among 3,320 individuals treated with 1HP, 31.9% were aged 50–64 years. A total of 13.6% discontinued treatment permanently; 11.7% were due to AEs, comparable to the 9.2% in 3HP FDC users (p=0.079). Rash was more common with 1HP (4.8% vs. 2.0%, p=0.031), as were systemic drug reactions (6.9% vs. 3.9%, p=0.047).

SAEs considered highly likely to be drug-related (Naranjo score>=9) occurred in 0.1% of 1HP and 0.2% of 3HP FDC users (p=0.079). Nine patients (0.3%) developed hepatitis with serum alanine aminotransferase (ALT) ≥ 5x upper limit of normal reference (ULN), and 1.1% had jaundice (total bilirubin ≥2 mg/dL) with no different from 3HP-FDC users (0.3% vs. 0.4%, p=0.121; 1.1% vs. 0.6%, p=0.067); all recovered after discontinuing treatment. The treatment completion rate was 86.1%.

Conclusions: This national pharmacovigilance analysis confirms that 1HP has a comparable safety profile to 3HP FDC. These findings support broader clinical adoption of 1HP, helping to expand access to shorter, effective TBI treatment and improve overall adherence.

SOA10-617-20 Risk of progression to incident pulmonary TB among household contacts with abnormal chest X-rays in South Africa

E. Muchiri,[1] H. Mulenga,[1] S.C. Mendelsohn,[1] S.T. Malherbe,[2] M. Tameris,[1] A. Katona,[3] F. Maruri,[3] Y.F. van der Heijden,[4,5] N. Martinson,[6] T.J. Scriba,[1] T. Sterling,[3] M. Hatherill,[1] [1]University of Cape Town, South African Tuberculosis Vaccine Initiative, Institute of Infectious Disease and Molecular Medicine and Department of Pathology, Cape Town, South Africa, [2]Stellenbosch University, Immunology Research Group, Division of Molecular Biology and Human Genetics, Cape Town, South Africa, [3]Vanderbilt University Medical Center (VUMC), Vanderbilt Tuberculosis Center, Nashville, United States of America, [4]Vanderbilt University Medical Center (VUMC), Division of Infectious Diseases, Department of Medicine, Nashville, United States of America, [5]The Aurum Institute, Implementation Research, Johannesburg, South Africa, [6]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa
e-mail: evans.muchiri@uct.ac.za

Background: Close contacts of tuberculosis (TB) patients who have chest X-ray (CXR) abnormalities (CXR+), but negative *Mycobacterium tuberculosis* sputum results (Micro-), are at elevated risk of progressing to incident pulmonary tuberculosis (PTB), with rates estimated to be as high as 10% per annum. We evaluated factors associated with the CXR+ Micro- phenotype and assessed the risk of progression to active PTB.

Design/Methods: Adult (≥18 years) household contacts of index PTB patients were prospectively evaluated at three sites in South Africa. Participants without microbiologically-confirmed (sputum liquid culture and/or Xpert Ultra positive) PTB, regardless of baseline CXR findings, were followed for up to 12 months for incident PTB. Multivariable logistic regression was used to identify factors associated with the CXR+ Micro- phenotype. Risk ratios were used to assess risk of progression to microbiologically-confirmed incident PTB by baseline CXR and interferon-γ release assay (IGRA) results.

Results: Between May 2021 - September 2022, 978 household contacts were enrolled. Of these, 799 were Micro- and had a baseline CXR result, with 159/799 (20%) showing CXR abnormalities. Factors significantly associated with abnormal CXR were increasing age (adjusted odds ratio [aOR] 1.03 per year [95%CI 1.02-1.05], p<0.001) and a prior history of TB (aOR 6.67 [4.33-10.27], p<0.001) after adjusting for study site (*Table 1*).

Demographics clinical characteristics*	Categories	Total (n=799)	CXR abnormal (n=159)	OR (95% CI)	p-values	aOR (95% CI)	p-values
Median Age (years, IQR)		34.8 (25.4 – 45.0)	42.8 (30.4 – 53.2)	1.03 (1.02 – 1.04)	<0.001	1.03 (1.02 – 1.05)	<0.001
Sex, n (%)	Female	513 (64.2)	95 (59.7)	0.79 (0.55 – 1.12)	0.193	0.75 (0.48 – 1.15)	0.190
Ancestry, n (%)	Mixed	412 (51.6)	110 (69.6)	2.55 (1.76 – 3.71)	<0.001	1.39 (0.76 - 2.54)	0.293
History of smoking, n (%)	Current Smoker	418 (52.3)	99 (62.3)	1.90 (1.30 – 2.78)	<0.001	1.47 (0.90 – 2.40)	0.214
	Former Smoker	39 (4.9)	12 (7.6)	2.72 (1.29 – 5.74)		1.76 (0.74 – 4.24)	
Prior TB, n (%)	Yes	148 (18.5)	76 (47.8)	7.22 (4.86 – 10.74)	<0.001	6.67 (4.33 – 10.27)	<0.001
HIV positive, n (%)	Yes	131 (16.9)	24 (15.7)	0.90 (0.55 – 1.45)	0.657		
Study site, n (%)	Worcester	361 (45.2)	82 (51.6)	2.52 (1.61 – 3.93)	<0.001	2.14 (1.07 – 4.26)	0.03
	Ravensmead	141 (17.8)	46 (28.9)	4.15 (2.48 – 6.93)		5.55 (2.63 – 11.73)	

Table 1: Baseline characteristics and risk factors associated with an abnormal chest X-ray among individuals without pulmonary tuberculosis.
Analysis only for TB contacts with available chest X-ray (CXR).
**The ancestry reference is Black/African – Caucasian estimates not reported (2 individuals in the study); History of smoking reference is never smoked; Study sites reference is Klerksdorp site.*

The risk of progression to incident PTB was 4.02 [95%CI: 1.02-15.92] times higher in the CXR+ compared to the CXR- group (p=0.03). The risk of progression to incident PTB was similar between IGRA+ and IGRA- groups (risk ratio = 0.48 [0.12-1.99], p=0.30).

Conclusions: Individuals with CXR abnormalities and negative microbiological tests—who would not routinely be treated for TB disease at baseline had a fourfold increased risk of progression to incident TB. Optimal preventive or curative therapies for this high-risk phenotype should be considered in screening guidelines for TB-exposed household contacts.

SOA11 Bridging gaps in TB care: AI solutions for high-risk populations

SOA11-618-20 How subtle is asymptomatic pulmonary TB? Lessons from using digital chest X-ray with computer aided detection software for TB case finding in communities in Uganda

A. Burua,[1,2] A. Mulindwa,[1] D. Tugumisirize,[1] R. Byaruhanga,[1] M. Mudiope,[2] H. Luzze,[1] S. Turyahabwe,[3]
[1]Ministry of Health, National tuberculosis and leprosy control program, Kampala, Uganda, [2]Infectious Diseases Institute, USAID Local Partner Health services TB Activity, Kampala, Uganda, [3]Ministry of Health, National Disease Prevention and Control, Kampala, Uganda
e-mail: buruaaldo@gmail.com

Background and challenges to implementation: Despite global efforts, the slow decline in tuberculosis (TB) incidence highlights the need for innovative case-finding strategies. Asymptomatic pulmonary tuberculosis remains a significant challenge, as individuals often lack observable symptoms that would prompt diagnostic evaluation.

This study evaluates the potential of community-based active TB case finding through mobile clinics equipped with digital X-ray and computer-aided detection (CAD) software to enhance early detection of TB and treatment initiation.

Intervention or response: The Uganda National Tuberculosis and Leprosy Program deployed two mobile clinics, each fitted with digital X-ray and CAD technology, targeting hotspots and high-risk communities based on TB disease burden. Sputum samples were collected from individuals with abnormal chest X-rays (CAD4TB score ≥50) and/or presence of TB symptoms, for analysis using X-pert MTB/RIF Ultra.

Asymptomatic TB was defined as bacteriologically confirmed TB that does not meet the WHO TB screening criteria for diagnostic evaluation, that is: "no persistent cough for two or more weeks".

Results/Impact: Between February and June 2024, 7243 individuals were screened with digital X-rays, of whom 464 (6.4%) individuals had abnormal X-rays (CAD4TB score > 50).

A total 1,335 sputum samples were collected from those with abnormal imaging and/or TB symptoms, and 99 (7.4%) patients were bacteriologically confirmed. Of these, 48% had asymptomatic TB (cough <2 weeks: 31% and No TB symptom: 17%), underscoring the limitations of relying solely on symptom-based screening. The positivity rate of TB among individuals with abnormal X-ray (CAD score ≥50) was 21% compared to 0.8% among those with normal chest X-ray.

Symptom profile	CAD score	Number screened with CXR and CAD	Number tested with Xpert MTB/RIF	Number bacteriologically confirmed TB	TB positivity rate (%)	Proportion out of all TB cases (%)
Persistent cough for 2 weeks or more	≥ 50	241	237	46	19.4	52
	< 50	1,772	508	5	1.0	
Cough < 2 weeks	≥ 50	173	161	35	21.7	37
	< 50	3,322	356	2	0.6	
No TB symptoms	≥ 50	50	40	11	27.5	11
	< 50	1,685	33	0	0	
Total	≥ 50	464	438	92	21.0	
	< 50	6,779	897	7	0.8	
		7,243	1,335	99	7.4	

Conclusions: Nearly half of the TB patients identified in this community-based screening initiative were asymptomatic. Deployment of digital X-ray and CAD technology enabled detection of cases that might otherwise go unnoticed.

National TB programs and partners are encouraged to prioritize integration of digital X-ray and CAD in TB screening efforts to improve early detection and treatment outcomes.

SOA11-620-20 Enhancing paediatric TB screening: Validation of an enriched artificial intelligence-based computer aided detection model using chest X-rays from children under 15 years

J.A. Chiramal,[1] A. Valsaraj,[2] H. Varatharajan,[3] D. Robert,[4] M. Al Fahim,[5] J. Prabhu,[5] V. Damani,[5] S. Sridhar,[6] A. Kumar Singh,[5] M. Tadepalli,[5] [1]Qure.ai Technologies Inc., Product, Smyrna, United States of America, [2]Qure.ai Technologies Private Limited, R&D, Bangalore, India, [3]Qure.ai Technologies Private Limited, Product, Bangalore, India, [4]Qure.ai Technologies Private Limited, Clinical Research, Bengaluru, India, [5]Qure.ai Technologies Private Limited, R&D, Bengaluru, India, [6]Qure.ai Technologies Private Limited, Product, Bengaluru, India
e-mail: justy.antony@qure.ai

Background: Children account for 12% of the global TB burden and 16% of TB-related deaths, with the majority of deaths occurring in children who were never initiated on treatment. Pediatric TB diagnosis is particularly difficult due to paucibacillary disease, non-specific symptoms, and the challenge of interpreting pediatric chest X-rays (CXRs), especially in resource-limited settings.

Although AI-based computer-aided detection (CAD) tools are WHO-endorsed for adult TB screening, they have shown limited performance in children. We enriched the qXR v4.2 CAD (Qure.ai) with pediatric CXRs and evaluated its performance against the microbiological reference standard (MRS).

Design/Methods: The qXR model was further trained using 23,913 pediatric CXRs (37% GeneXpert-positive) with GeneXpert results as training label and validated the enriched algorithm on 5,845 CXRs from children aged 0–14 years. Area-under-the-receiver-operating-characteristics-curve (AUROC), sensitivity, and specificity were calculated overall and by age bands (0–4, 5–9, 10–14 years) against MRS. Thresholds aligned with WHO Target Product Profile (TPP) were also evaluated.

Table 1. Performance of enriched AI-CAD model with AUROC, sensitivity and specificity at various thresholds and across age bands

	AUROC	Se and Sp at optimal threshold*		Se and Sp at threshold of 0.5		Se and Sp at thresholds yielding WHO TPP	
	AUROC (95% CI)	Se (95% CI)	Sp (95% CI)	Se (95% CI)	Sp (95% CI)	Se at 70% Sp (95% CI)	Sp at 90% Se (95% CI)
Overall n=5845 n_{TB}=1122	0.925 (0.918, 0.932)	88.4 (86.4, 90.2)	81.3 (80.1, 82.4)	82.1 (79.7,84.3)	85.5 (84.5, 86.5)	96.5 (95.3, 97.6)	79.1 (77.1, 81.6)
0-4 n=2572 n_{TB}=212	0.957 (0.948, 0.966)	92.9 (88.6, 96.0)	86.4 (84.9, 87.8)	76.9 (70.6, 82.4)	93.4 (92.3, 94.4)	99.5 (98.6, 1.00)	88.1 (84.6, 90.3)
5-9 n=1725 n_{TB}=437	0.898 (0.882, 0.913)	84.2 (80.4, 87.5)	80.6 (78.3, 82.7)	83.1 (79.2, 86.5)	80.9 (78.6, 83.0)	90.6 (87.2, 93.6)	70.8 (65.5, 77.6)
10-14 n=1548 n_{TB}=473	0.883 (0.867, 0.900)	91.1 (88.2, 93.5)	67.9 (65.0, 70.7)	83.5 (79.9, 86.7)	73.9 (71.1, 76.5)	88.4 (83.9, 92.4)	68.6 (64.2, 72.5)

AUROC: Area under the receiver operating characteristic curve
n: Number of cases
n_{TB}: Number of cases who were bacteriologically confirmed positive for the presence of TB disease
Numbers in parentheses indicate the 95% confidence interval (95% CI)
Se: Sensitivity; Sp: Specificity
* The optimal threshold based on Youden's index for the overall group and for subgroups 0-4, 5-9 and 10-14 were 0.401, 0.245, 0.494 and 0.401, respectively.

Results: Out of 5,845 CXRs, 1,122 (19.2%) CXRs were from children who had GeneXpert confirmed TB, with median age 5 years (IQR:3-10). The enriched model achieved an overall AUROC of 0.925 (95% CI: 0.918–0.932) against MRS. Sensitivity and specificity at optimal threshold were 88.4% (86.4-90.2) and 81.3% (80.1-82.4), respectively.

The model met WHO TPP benchmarks with 96.5% sensitivity and 79.1% specificity, at 70% specificity and 90% sensitivity. Performance was higher in 0–4 years (AUROC: 0.957) than in 10–14 years (AUROC: 0.883). An exploratory analysis using the adult qXR model for older children showed no added improvement.

Conclusions: The enhanced qXR demonstrated strong performance, especially in younger children, and offers a scalable tool for early TB detection in settings with limited pediatric radiology expertise.

Further studies incorporating clinically diagnosed TB (unconfirmed TB) and distinguishing severe from non-severe cases are needed to strengthen screening programs.

SOA11-621-20 Adaptive artificial intelligence for TB screening: Automated age prediction from chest X-rays to improve paediatric TB detection in low-resource settings

J.A. Chiramal,[1] A. Valsaraj,[2] J. Prabhu,[2] P. Jawanjale,[3] H. Varatharajan,[4] M. Tadepalli,[2] S. Vijayan,[5] [1]Qure.ai Technologies Inc., Product, Atlanta, United States of America, [2]Qure.ai Technologies Private Limited, R&D, Bengaluru, India, [3]Qure.ai Technologies Private Limited, Clinical Research, Bengaluru, India, [4]Qure.ai Technologies Private Limited, Product, Bengaluru, India, [5]Qure.ai Technologies Private Limited, Global Health Innovation, Bengaluru, India
e-mail: shibu.vijayan@qure.ai

Background: Pediatric TB causes about 200,000 deaths annually, due to diagnostic challenges such as paucibacillary disease, difficulty obtaining sputum, and subtle clinical presentation. CXR findings vary-hilar lymphadenopathy commoner in children <5 years, while adolescents often present with adult-like patterns. AI tools like qXR used in community-based screening, but unlike in adults, have limited evidence in children. Also, using a single threshold across all age groups would affect sensitivity.

We propose an AI based age regression model to predict age directly from CXR, enabling age-specific thresholds and enabling health workers to use AI without the need for age metadata.

Design/Methods: We developed a ResNet-18-based model to estimate age from CXRs, trained on 677,475 CXRs (51,880 pediatric, 625,595 adult), using 16 years as the classification threshold. The model performance was tested on 110,007 CXRs (8,414 pediatric, 101,593 adult) for age prediction using R^2 (for prediction accuracy) and RMSE (for the average error in years), and precision, recall, and F1 score for classification, with results stratified by age bands.

Table 1: Prediction accuracy of the age adaptive AI model for various age bands

Age Group (yrs)	Samples	Recall/Sensitivity (%)	F1 Score (%)	False Negatives
0–3	2,632	99.5	99.7	14
3–6	1,627	98.9	99.4	18
6–10	1,523	99.5	99.8	7
10–16	2,632	89.4	94.4	280
16–30	26,784	99.3	99.7	178
30–50	34,595	99.8	99.9	59
50–100	40,214	99.93	99.94	30
Pediatric Total	**8,414**	**96.2**	**96.5**	**319**
Adult Total	**101,593**	**99.7**	**99.7**	**267**

Results: The model predicted age with high accuracy- R^2 = 0.932; RMSE = 5.15. For pediatric CXRs, R^2 was 0.58 and RMSE 3.32. At 16-year threshold, binary classification yielded strong pediatric performance: precision 96.8%, recall 96.2%, F1 score 96.5%. Out of the 319 false

negatives & 267 false positives, majority were in the 10–16 age band due to adult-like radiographic features. Age-stratified recall exceeded 98.9% for children aged 0–10 and 89.4% for ages 10–16. Adult classification remained highly accurate (recall/F1 >99.7%).
Conclusions: The model achieved 96.2% accuracy in pediatric classification, enhancing diagnostic precision through age-adaptive thresholds. By automating age estimation from CXRs, it bridges gaps in AI workflows, improving pediatric TB detection and enabling task-shifting to community health workers for more equitable, scalable screening in resource-limited settings.

SOA11-622-20 Predicting the burden of undiagnosed TB cases in India using a machine-learning approach

S.P. Rajaram,[1] A. Sinha,[1] A. Kar,[1] K. Kumarasamy,[2] A. Shah,[3] R. Swamickan,[4] R. Begum,[5] [1]Karnataka Health Promotion Trust, MERL, Bengaluru, India, [2]Karnataka Health Promotion Trust, Tuberculosis Thematic Area, Bengaluru, India, [3]USAID, TB and Infectious Disease, New Delhi, India, [4]USAID, Health Office, New Delhi, India, [5]Karnataka Health Promotion Trust, Tuberculosis Thematic Area, New Delhi, India

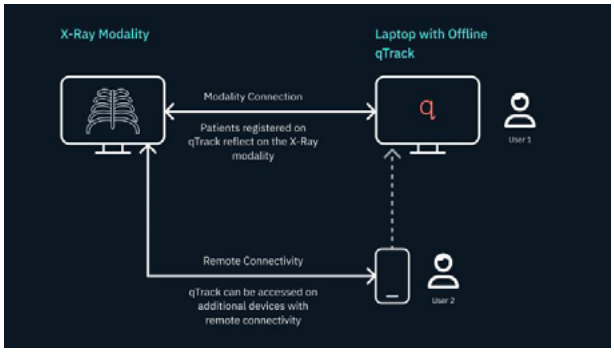
Background: India bears one of the highest tuberculosis (TB) burdens globally, and despite active case-finding (ACF) initiatives, a substantial proportion of individuals with TB symptoms remain untested, contributing to the pool of undiagnosed or 'missing' cases. Estimating this hidden burden is critical for strengthening surveillance and targeting interventions. This study applied machine learning (ML) techniques to predict undiagnosed TB cases among symptomatic individuals who were referred for testing but lacked recorded diagnostic outcomes.
Design/Methods: Data from 212,953 individuals with TB symptoms referred for diagnostic testing across four Indian states under a USAID-supported TB intervention (October 2021 – March 2024) were analyzed. Two ML models—logistic regression and support vector machine (SVM)—were trained on individuals with confirmed test results using features based on reported symptoms and a few demographic variables. The SVM model, optimized through class weighting and hyperparameter tuning, was selected for final predictions based on superior performance. Predictions were then made for symptomatic individuals with missing test results, and the potential burden of undiagnosed TB was estimated under varying assumptions (10–40%) of testing coverage gaps.
Results: Of the referred individuals, 12% lacked documented test results, and 6% (13,203) were diagnosed with TB. The final SVM model achieved an AUC of 0.751 with moderate sensitivity. Based on model outputs, the projected number of undiagnosed TB cases ranged from 210,584 (if 10% of symptomatic individuals were untested) to 1,248,519 (if 40% of symptomatic individuals were untested). These estimates aligned with the prevalence observed in the available dataset, supporting the model's applicability for population-level estimations.
Conclusions: This study highlights the utility of machine learning in enhancing TB surveillance by estimating the burden of undiagnosed cases. While not intended for individual diagnosis, the approach provides valuable insights for programmatic planning, emphasizing the need for improved diagnostic follow-through in TB care pathways.

SOA11-623-20 Improving digital TB screening efficiency in remote rural communities in Nigeria through offline and local intranet-based data synchronisation

C. Okoye,[1] J. Ilozumba,[2] C. Ugwu,[3] [1]Catholic Caritas Foundation of Nigeria, TB/HIV, Abak, Nigeria, [2]Catholic Caritas Foundation of Nigeria, TB/HIV, Abuja, Nigeria, [3]Liverpool School of Tropical Medicine, Global Health, Liverpool, Nigeria
e-mail: cezeobi@ccfng.org

Background and challenges to implementation: AI-enabled digital X-ray technology has enhanced TB screening, but operational challenges persist in remote rural areas. Screening is usually confined to a single laptop, limiting efficiency and output. Expanding to multiple devices typically requires internet access, which is seldom available, hindering data synchronization and team coordination. This study outlines our experience deploying an offline, multi-point digital screening system during community outreaches.
Intervention or response: Caritas Nigeria utilized the traditional single digital laptop for TB screening and chest X-ray exposure from July 2023 to December 2023, then introduced multiple entry digital intervention in January 2024 across communities in Ebonyi State. An on-premise laptop equipped with Qure.ai's offline-compatible qTrack tool was deployed. The laptop served as a local intranet hotspot, allowing multiple smartphones used by outreach staff to connect without internet access. This configuration enabled simultaneous access to the TB screening worklist, synchronized with the central laptop for chest X-ray data capture. Screening data from both pre- and post-intervention periods were analyzed. Below is the post-intervention workflow:
Results/Impact: The implementation of the offline, multi-point screening system in January 2024 led to a 100% increase in TB screening efficiency. In the pre-intervention period (Jan–Dec 2023), only one health worker conducted screenings per community Outreach activity, resulting in 4,734 individuals screened. Post-intervention (Jan–Dec 2024), the use of a local hotspot enabled an average of three health workers to screen simultaneously, increasing

the number screened to 9,475. This multi-user approach significantly improved throughput and optimized the screening process in remote, low-connectivity areas.

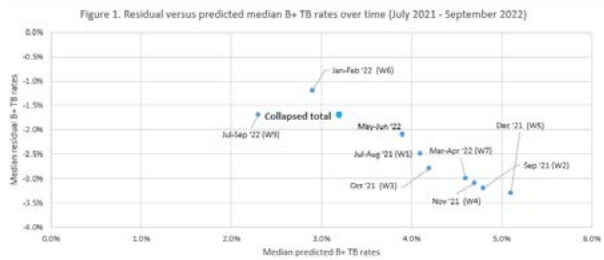


Conclusions: This intervention offers a scalable solution for AI-powered TB screening in remote areas by using a single laptop as a local hotspot. It enables multiple workers to screen simultaneously with mobile devices, improving operational efficiency, extending diagnostic reach, and promoting health equity in underserved, low-connectivity communities.

SOA11-624-20 A retrospective evaluation of the MATCH AI model for prediction of TB positivity rates in active case finding settings of Pakistan

C. Mergenthaler,[1] A. Latif,[2] A. van der Merwe,[3] M. Bakker,[1] M. Potgieter,[3] V. Meurrens,[4] A. Tahir,[5] A. Ismail,[6] D. Brals,[7] F. Cobelens,[8] E. Rood,[1] [1]KIT Institute, Center for Applied Spatial Epidemiology, Amsterdam, Netherlands, [2]Mercy Corps Pakistan, TB Program, Islamabad, Pakistan, [3]EPCON SA Pty (Ltd), NA, Cape Town, South Africa, [4]EPCON, NA, Antwerp, Belgium, [5]Mercy Corps, TB Program, Islamabad, Pakistan, [6]Common Management Unit for AIDS, TB & Malaria, N/A, Islamabad, Pakistan, [7]University of Amsterdam, Global Health, Amsterdam, Netherlands, [8]Amsterdam UMC, University of Amsterdam, Global Health, Amsterdam, Netherlands
e-mail: c.mergenthaler@kit.nl

Background: While subnational TB burden estimation methods have gained traction in recent years, these are not routinely used to geographically target case-finding activities. Program planners are increasingly interested in assessing whether predictive models are useful in prioritizing local areas for TB active case-finding (ACF), especially in settings with substantial gaps in treatment coverage. Public and private sector TB partners in Pakistan are paving the way in use of models to plan ACF efficiently, to help close the gap in treatment coverage, estimated at 66% in 2023.
Design/Methods: We programmed a machine learning engine with variables of the MATCH framework to model bacteriologically positive (B+) TB positivity rates detectable in ACF settings per 10,000 population for all of Pakistan. Our research objectives were to retrospectively evaluate model performance across time (predictions updated over 9 time windows), geographic space, and socio-economic strata, by analyzing model residuals and area under the curve (AUC) scores.

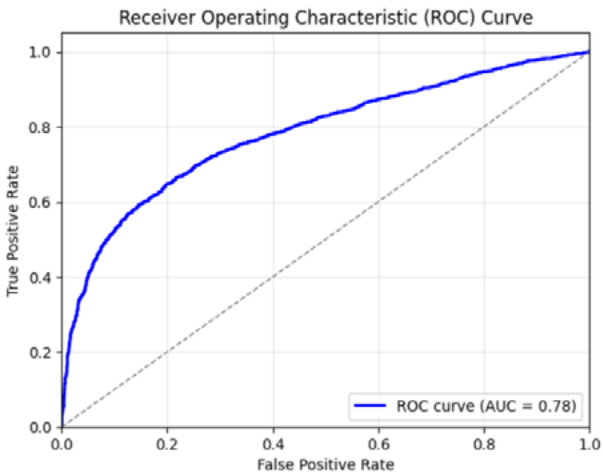


Results: 1,999 ACF events were conducted in 169 tehsils of Punjab, Khyber Pakhtunkhwa, Balochistan and Sindh provinces between July 2021 and September 2022. The median observed B+ TB positivity rate was 1.5%, ranging from 1.2- 2.3% across all windows, while median residuals ranged from -1.2% to -3.3%.
The pooled Spearman's rank correlation coefficient was 0.1621 ($p<0.0001$). ANOVAs and residual analysis showed improved model accuracy in geographic areas that are less densely populated, had lower chest camp attendance, and are farther away from health facilities. Against a cut-off B+TB positivity rate of 0%, the pooled AUC score across nine ROC curves was 0.6325.
Conclusions: While the model's predictive accuracy did not improve over time, results of the stratified analysis of residuals shed light on potential model misspecifications. Results of the analysis contain important learnings about how machine learning models can more accurately prioritize ACF at the local level in resource constrained environments.

SOA11-625-20 Technical validation of Swaasa AI platform for detecting likely presence of pulmonary TB among people presenting with cough in India

R. Kumar,[1] U. Dahiya,[1] P. Chinnakali,[2] A. Kumar Singh,[3] R.S. Rath,[4] M. Kattula,[5] H.V. Reddy,[5] S. Deepti P,[6] H. R Salve,[1] P. Misra,[1] A. Krishnan,[1] [1]All India Institute of Medical Sciences, New Delhi, Centre for Community Medicine, New Delhi, India, [2]Jawaharlal Institute of Postgraduate Medical Education and Research, Preventive and Social Medicine, Puducherry, India, [3]All India Institute of Medical Sciences, Community Medicine and Family Medicine, Bhubaneswar, India, [4]All India Institute of Medical Sciences, Community Medicine and Family Medicine, Gorakhpur, India, [5]Salcit Technologies Private Limited, Research & Development, Hyderabad, India, [6]Salcit Technologies Private Limited, Research & Development, Hyderabad, India
e-mail: dr.rakesh3105@gmail.com

Background: Sub-optimal access to molecular diagnostic tests and chest X- ray hinders the case finding in tuberculosis (TB). Here we present the data on performance of an android mobile-based artificial intelligence platform, Swaasa, which uses cough sounds for diagnosis of pulmonary tuberculosis.
Design/Methods: The study, which started in May 2024, was conducted at five places in India: Ballabgarh, Delhi, Puducherry, Bhubaneswar and Gorakhpur.
The objective of the study was to further refine the AI algorithm by adding cough sounds from 3000 people with tuberculosis and 3000 people without tuberculosis. Four cough sounds were obtained from each person within one week of start of cough.
The diagnosis of tuberculosis was confirmed by positive finding on one of three diagnostic modality: sputum microscopy, any molecular diagnostic test or chest x-ray. Diagnosis of tuberculosis was ruled out if all the three were negative. 70% of the data were used to train the algorithm whereas 30% were used to assess the performance.
In this analysis, we have calculated sensitivity, specificity, and area under curve from first 4027 participants.



Results: Out of the total 4027 persons, data from 2747 were used to train the algorithm and data from 1280 were used to assess the performance. Out of 1280, 688 had tuberculosis and 592 did not have tuberculosis. 64% were males, and 32% were in the age group 30-49 years. The Swaasa AI platform achieved an area under curve of 0.78 with overall sensitivity of 72.2% (95% CI-70.4-74) and specificity of 71% (95% CI-69-72.8). Sensitivity and specificity was similar across gender. Sensitivity was 83% in those ≤29 years, and declined with age, falling to 53% in individuals ≥70 years.
Conclusions: The Swaasa AI platform exhibited good overall performance with better sensitivity in younger patients. The algorithm needs more training, especially using cough sounds from older people, for improvement in performance.

SOA11-626-20 Understanding asymptomatic TB: Insights from community-level screening using AI-enabled portable digital X-ray technology in remote rural Nigeria

C. Okoye,[1] T. Rahman,[2] C. Ugwu,[3] J. Ilozumba,[4] E. Ubochioma,[5] J. Creswell,[2] [1]Catholic Caritas Foundation of Nigeria, TB/HIV, Abak, Nigeria, [2]STOP TB Partnership Geneva, TB/HIV, Geneva, Switzerland, [3]Liverpool school of tropical Medicine, Global Health, Liverpool, Nigeria, [4]Catholic Caritas Foundation of Nigeria, TB/HIV, Abuja, Nigeria, [5]National TB and Leprosy control program, Program Unit, Abuja, Nigeria
e-mail: cezeobi@ccfng.org

Background and challenges to implementation: Asymptomatic tuberculosis (TB) is an emerging public health concern that often goes undetected in routine TB screening, which typically relies on the presence of symptoms. This gap contributes to ongoing transmission, delayed care, and underreporting. AI-enabled chest X-ray technology offers a novel approach to bridge this gap by flagging potential TB cases, including those without symptoms, for further evaluation. This abstract presents the results from a community level TB screening using Ai-enabled X-ray in remote rural communities.
Intervention or response: Between January 2023 and December 2024, our TB REACH Wave 10 project implemented AI-enabled mobile chest X-ray screening in rural communities of Ebonyi and Nasarawa States, Nigeria. The screening followed a parallel algorithm: WHO symptom screening and AI-generated X-ray (QXR) scores. Individuals were classified as presumptive TB cases if they had TB symptoms or a QXR AI score ≥ 0.30. Sputum samples were collected for genexpert testing. All clients were encouraged to produce sputum samples, regardless of quantity.
Those unable to do so, or with negative GeneXpert results but flagged by AI, their X-ray films were sent to radiologist for further review.

Results/Impact: Of the 14,201 individuals screened, 1,553 were identified as presumptive TB cases; 213 were asymptomatic but flagged as TB presumptive by AI. Of these, 132 (62%) provided sputum samples, 4 tested positive via GeneXpert, and 12 more were clinically diagnosed after radiologist review—totaling 17 TB cases. Interestingly, 11 (64%) of the TB cases diagnosed were aged between 16–25.

Conclusions: These findings reveal that asymptomatic TB exists more among adolescents and young adults and may be missed without AI-assisted screening. This emphasizes the importance of enhancing TB screening approaches with advanced tools to detect early disease, particularly in younger, at-risk populations.

SOA11-627-20 Development of artificial intelligence lung sound algorithm using pulmonary physician-expert analysis to improve the accuracy of diagnosing paediatric pneumonia in low- and middle-income countries

S. Kapoor,[1] L.-M. Laubscher,[2] N. Hoekstra,[3,1] A. Gie,[4] A. Gaudio,[5] H. Hahn,[5] P. Barach,[6] C. King,[7] A. Redfern,[4] M. Elhilali,[5] M. van der Zalm,[2] E. McCollum,[8,2] [1]Johns Hopkins University School of Medicine, Global Program in Pediatric Respiratory Sciences, Baltimore, United States of America, [2]Stellenbosch University, Health Sciences and Medicine, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Tygerberg, South Africa, [3]University of North Carolina School of Medicine, Department of Pediatrics, Chapel Hill, United States of America, [4]Stellenbosch University Health Sciences and Medicine, Department of Paediatrics and Child Health, Tygerberg, South Africa, [5]Johns Hopkins University Whiting School of Engineering, Department of Electrical and Computer Engineering, Baltimore, United States of America, [6]Thomas Jefferson University School of Medicine, Jefferson College of Population Health, Philadelphia, United States of America, [7]Karolinska Institute, Department of Global Public Health, Solna, Sweden, [8]Johns Hopkins University School of Medicine, Global Program in Pediatric Respiratory Sciences, Tygerberg, South Africa
e-mail: skapoor@jhmi.edu

Background: Digital stethoscopes embedded with artificial intelligence (AI) can be powerful diagnostic tools for pneumonia, especially in low-resource settings where conventional stethoscope implementation has notable challenges. We aim to improve the diagnostic accuracy of these devices through novel use of real-time reference classifications by pediatric pulmonary physicians (experts) to train an AI algorithm.

Design/Methods: We are prospectively enrolling ≤10-year-olds at Tygerberg Hospital (South Africa) and Johns Hopkins Hospital (USA). We plan to enroll 400 children (1,600 total chest positions) with 100 children enrolled by experts (expert-subset). At enrollment, an expert auscultates using a conventional stethoscope (reference) and classifies lung sounds (normal, crackle (C), wheeze (W), or uninterpretable(U)) at two posterior and two anterior chest positions, while simultaneously recording with a digital stethoscope for 15 seconds. De-identified, unfiltered recordings are randomized to an expert listening panel for detailed breath-to-breath interpretations to generate overall chest position classifications. We assessed raw percentage agreement between real-time reference and panel classifications of enrolled participants.

Results: To date, we enrolled 133/400 (33%) study participants and recorded 698 chest positions. Among 47 expert-subset participants analyzed, the median age was 23 months (IQR 30), 25 (53%) were male, and 29 (61%) presented with respiratory illness. The panel interpreted 63 expert-subset chest position recordings with 45% agreement with the reference. Of 47 (75%) reference positions categorized as "normal", 23 (48%) were categorized as abnormal by the panel (Table).

By Conventional Stethoscope, n (Reference)	By Listening Panel Classification, n					
	Normal	C	W	CW	U	Total
No Adventitious Lung Sounds (Normal)	24	9	2	1	11	47 (75%)
Crackle (C)	2	1	0	0	0	3 (5%)
Wheeze (W)	4	2	1	0	1	8 (13%)
Crackle and Wheeze (CW)	2	0	1	2	0	5 (8%)
Uninterpretable (U)	0	0	0	0	0	0 (0%)
Total	32 (50%)	12 (19%)	4 (7%)	3 (5%)	12 (19%)	63
Agreement Between Reference and Listening Panel Classification (n = 63 total chest positions)						28 (45%)

Table. Expert-Subset Conventional Stethoscope (Reference) and Listening Panel Chest Position Level Classification (n = 63 total chest positions from 28 expert subset participants)

Conclusions: We developed an expert-annotated dataset utilizing simultaneous conventional stethoscope expert auscultation as the reference for AI algorithm training. Higher than anticipated misclassification of normal reference lung sounds as abnormal by the panel suggests digital stethoscope artifact and environmental noise are contributing to classification disagreement. To address this limitation, we are applying a noise-reduction filter to recordings before panel interpretation. This expert-annotated dataset will then train the AI algorithm before testing with non-expert recordings.

SOA11-628-20 Scaling up digital X-ray with CAD for TB screening: Implementation challenges, procurement, and regulatory insights from a market access analysis focused on sub-Saharan Africa

V. Iem,[1,2] C. Mbuli,[3] S. Wandiga,[4] C. Kwanjo Banda,[5] J. Bimba,[6] S. John,[7] T. Matiza,[8] R.L. Byrne,[2,1] T. Wingfield,[9,2,10,11] A.I. Cubas Atienzar,[12] [1]Liverpool School of Tropical Medicine, Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland, [2]Liverpool School of Tropical Medicine, Centre for Tuberculosis Research, Liverpool, United Kingdom of Great Britain and Northern Ireland, [3]Center for Health Promotion and Research, Bamenda, Cameroon, [4]Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, [5]Malawi Liverpool Wellcome Program, Public Health, Blantyre, Malawi, [6]Zankli Research Center, Bingham University, Department of Community Medicine and Primary Health Care, Abuja, Nigeria, [7]Janna Health Foundation, Health, Yola, Nigeria, [8]Market Access Africa, Commercial Life Sciences, Harare, Zimbabwe, [9]Liverpool School of Tropical Medicine, Clinical Sciences and International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland, [10]Karolinska Institutet, Department of Global Public Health, Stockholm, United Kingdom of Great Britain and Northern Ireland, [11]Liverpool University Hospitals NHS Foundation Trust, Tropical and Infectious Diseases Unit, Liverpool, United Kingdom of Great Britain and Northern Ireland, [12]Liverpool School of Tropical Medicine, Tropical Disease Biology, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: vibol.iem@lstmed.ac.uk

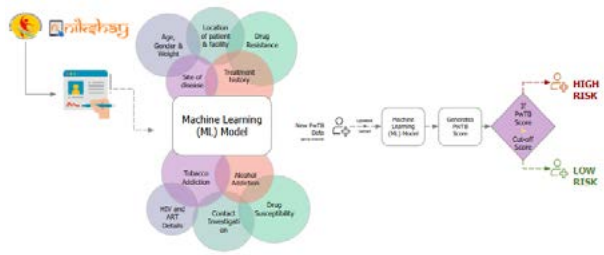
Background: Digital chest X-ray with computer-aided detection (CAD) offers a promising tool for TB screening, especially in settings with limited access to human reads by radiologists. As part of the Unitaid-funded Start4All initiative, a regional assessment was conducted to better understand the logistical, infrastructural, regulatory, and workforce-related barriers to CAD implementation in sub-Saharan Africa.
Design/Methods: A market access assessment was conducted in seven sub-Saharan Africa countries, with in-depth analysis in Cameroon, Kenya, Malawi and Nigeria (Start4All countries), and lighter-touch assessments in Botswana, Côte d'Ivoire, and Zimbabwe. The study combined a literature review, structured stakeholder interviews, and internally validated questionnaires, focused on six core domains: human resources, system integration, product support, diagnostic performance, pricing and contracting, and regulation. Stakeholders included CAD suppliers, National TB Programmes, donors, regulatory agencies, and implementing partners.
Results: CAD uptake is growing in sub-Saharan Africa but remains highly donor-dependent. In Kenya, lack of regulatory guidance limits integration. Malawi faces internet and data governance challenges. Nigeria experiences high import costs and regulatory delays. Cameroon lacks procurement experience and technical capacity. Botswana has limited radiography workforce. Côte d'Ivoire faces unclear import procedures. Zimbabwe struggles with fragmented procurement and limited technical support. Common challenges include limited local support, unclear procurement pathways, insufficient training, and difficulties adapting CAD thresholds to local populations. A few CAD providers (mostly CAD4TB and Qure.ai) dominate the market, with varying pricing and interoperability. Regulatory oversight is minimal in most countries, with CAD systems typically introduced via donor-supported waivers.
Conclusions: To move CAD from pilot to national scale in sub-Saharan Africa, national TB programmes, government regulators, and procurement agencies need clear roadmaps, country-specific procurement strategies, and harmonised policies guided by existing evidence. Investment in local capacity, data governance, and infrastructure, alongside stronger coordination with donors and suppliers, is key to sustainable integration into TB care.

SOA11-629-20 Utilising AI-based risk stratification of TB recurrence for improving post-treatment outcomes

U. Singh,[1] R. Rao,[1] A. Chaudhary,[2] V. Yadav,[3] S.D. Chaudhari,[3] M. Mishra,[5] P. Mahajan,[5] P. Soni,[4] P. Balraj,[3] M. Kulkarni,[5] N. Agrawal,[6] [1]Ministry of Health and Family Welfare, Government of India, Central TB Division, New Delhi, India, [2]Wadhwani Institute for Artificial Intelligence, Central TB Division - AI Unit, Ministry of Health and Family Welfare, Govt. of India, New Delhi, India, [3]Wadhwani Institute for Artificial Intelligence, Solutions, New Delhi, India, [4]Wadhwani Institute for Artificial Intelligence, Machine Learning, New Delhi, India, [5]Wadhwani Institute for Artificial Intelligence, Engineering, New Delhi, India, [6]Wadhwani Institute for Artificial Intelligence, Deployment, New Delhi, India
e-mail: aparna@wadhwaniai.org

Background and challenges to implementation: Tuberculosis (TB) elimination is critically undermined by disease recurrence, which indirectly increases risk of drug resistance and disease transmission. In India, about 5-10% of individuals completing the treatment experience recurrence of TB. National Tuberculosis Elimination Programme (NTEP) mandates a post-treatment completion follow-up at 6-monthly intervals for two years. However, these follow-ups are marred due to several patient-related challenges.
Moreover, individuals with recurrent TB frequently face higher mortality and lower treatment completion rates. Thus highlighting a critical need to identify those at higher risk for timely interventions proactively.
Intervention or response: Wadhwani AI developed an innovative AI-powered tool to predict TB recurrence risk among individuals who have completed treatment. Us-

ing over 20 individual-level indicators for Persons with TB (PwTB) - such as health indicators, sociodemographic factors, comorbidities, and diagnostics from NTEP's case-based real-time surveillance digital platform, the Nikshay portal, the tool generates an individual risk score for all patients who have completed treatment for a TB episode. This score helps prioritise individuals most susceptible to recurrence within the first 24 months of treatment completion, allowing for targeted, intensive interventions alongside routine follow-ups.



Results/Impact: Internal evaluation was done using the dataset of more than 7.2 million PwTB notified on Nikshay portal who experience TB recurrence, splitting into training (5.3 million) and test (1.9 million) datasets. The evaluation demonstrated that by targeting the top 35% of high-risk individuals (ranked in descending order of risk score), the model correctly identified 60% of individuals diagnosed with recurrence of TB within the first 24 months of successful treatment completion. This compares favorably to the best rules-based baselines that achieve 43% sensitivity.

Conclusions: The AI tool shows promising results for effectively stratifying recurrence risk and prioritizing patients for enhanced post-treatment care. This tool could significantly aid NTEPs' follow-up strategies and contribute towards reducing the burden of recurrent TB in India.

SOA12 Making it work for us: Community-led programme design

SOA12-630-20 Campus Leaders Program: Fostering youth participation in TB elimination and SDGs implementation in Indonesia through a collaborative hexa-helix stakeholder engagement model

J.M. Rifai Gani,[1] M.D. Zahran Widodo,[2] S. Rahmadhanie,[3]
[1]Universitas Indonesia, Public Administration, Jakarta, Indonesia, [2]Universitas Negeri Jakarta, Sociology, Bogor, Indonesia, [3]Universitas Indonesia, Social Welfare, Jakarta, Indonesia
e-mail: jimmymgani@yahoo.com

Background and challenges to implementation: With a youth population of over 65 million aged 16–30, Indonesia holds significant potential in the fight against tuberculosis (TB). In response, the Bakrie Center Foundation launched the Campus Leaders Program (CLP), a youth-led initiative focusing on leadership, digital advocacy, education, and grassroots action. Implemented across 13 provinces — West Nusa Tenggara, North Sumatra, West Sumatra, Riau, South Sumatra, Lampung, Banten, DKI Jakarta, West Java, Central Java, East Java, the Special Region of Yogyakarta (DIY), and South Sulawesi — the program empowers young leaders to raise TB awareness and support prevention efforts at the community level.

Intervention or response: The implementation of the Campus Leaders Program is guided by the Hexa-Helix model—a collaborative framework that integrates six strategic sectors: government, academia, the private sector, media, civil society, and non-governmental organizations (NGOs).

Each stakeholder contributes distinct yet complementary roles, ranging from policy support and scientific expertise to financial resources, media outreach, community engagement, and field-level implementation. This multi-sectoral integration strengthens the program's effectiveness, scalability, and long-term sustainability in addressing TB at the grassroots level.

Results/Impact: The following are the outputs of the Campus Leaders Program from 2023 to 2024

General Output	Specific Output	Quantitative Data
Campus Leaders Program	The number of internship students during the 2023–2024 period	737 Students
	The number of individuals who participated in screening activities conducted by community health workers and internship students.	56,869 Individuals
	The number of individuals who received TB counseling and education provided by community health workers and internship students	39.498 Individuals
	The number of TB survivor patients/families who participated in empowerment activities organized by community health workers and internship students	472 Activities
	Capacity Building Activities for CLP Students	179 Activities

Conclusions: The Campus Leaders Program exemplifies how youth can serve as strategic actors in public health through inclusive, community-based approaches. By engaging students as trained advocates and facilitators, the program has contributed to reducing stigma, expanding public awareness, and strengthening cross-sector collaboration.
The Hexa-Helix model has proven essential in anchoring interventions at the local level while enabling scalability at the national level. More than just a series of activities, Campus Leaders Program cultivates long-term leadership, civic engagement, and a replicable model for advancing health equity in alignment with the Sustainable Development Goals (SDGs).

SOA12-631-20 From data to impact: Reducing TB stigma through digital community-led monitoring in Mozambique

N.H. Hallstrom,[1] J. Tomás,[2] K. Tyrell,[3] A. Versfeld,[4]
[1]ADPP Mozambique, Partnership, Maputo, Mozambique, [2]ADPP Mozambique, Project Implementation, Maputo, Mozambique, [3]Humana People to People, International Health Program, Madrid, Spain, [4]Stop TB Partnership, Country and Community support for social impact team, Cape Town, South Africa
e-mail: helen@adpp-mozambique.org

Background and challenges to implementation: Mozambique has a TB prevalence rate of 361 per 100,000 people. Although TB mortality has declined by 50% since 2015, late diagnosis and poor treatment adherence persist, driven by high HIV prevalence (12.5%), malnutrition, and stigma. Stigma, fuelled by myths and misconceptions, undermines timely care-seeking and contributes to preventable TB-related deaths. To address this, ADPP Mozambique implemented the OneImpact digital solution for Community-Led Monitoring (CLM), allowing people with TB (PWTB) to report barriers to care. Between 2022 and 2024, 20,828 people across Zambezia, Maputo, and Gaza provinces engaged with the platform. Stigma was the most reported barrier 38% (3,803 of 9,751 total barriers), with self-stigma at (40%), followed by family stigma (30%), community stigma (24%), workplace stigma (4%), and health facility stigma (2%). These insights guided targeted interventions to improve treatment initiation, adherence, and TB outcomes.
Intervention or response: OneImpact data revealed that 70% of stigma-related reports were linked to self-stigma and family stigma. In response, ADPP implemented targeted psychosocial support interventions for PWTB who reported self-stigma and engaged community leaders to address myths and misconceptions—aiming for increased confidence, safety, and support for PWTB and their families. These interventions were integrated into regular household visits across nine districts in 3 provinces.
Results/Impact: Community interventions informed by CLM data led to the resolution of 72% of reported stigma-related barriers. Resolution rates were highest for family stigma (82%) and community stigma (79%), with notable improvements in self-stigma (63%), supporting better treatment access and health outcomes.
Conclusions: The OneImpact CLM data revealed the magnitude of stigma—particularly self- and family stigma—as a serious barrier to TB control. This insight allowed community actors and health systems to prioritize resources in high-impact areas.
Integrating stigma-reduction efforts into household visits made interventions cost-effective, scalable, and sustainable, strengthening the overall TB response and the journey for people with TB.

SOA12-632-20 Leadership matters: Assessing TB stigma among industrial managers in Telangana's high-burden districts

V. Panibatla,[1] R. Dasari,[2] A. Versfeld,[3] J. Malar,[3]
[1]TB Alert India, Program Implementation and Research, Hyderabad, India, [2]TB Alert India, Programs, Hyderabad, India, [3]Stop TB Partnership, Country and Community Support for Impact, Geneva, Switzerland

Background: TB-related stigma in workplaces negatively affects disclosure, timely testing, treatment adherence, and employee reintegration. Industrial managers influence workplace culture and policies, making their perceptions critical to effective TB response.
This study assessed TB stigma among key management of high TB risk industries like manufacturing, construction, and stone crushing personnel in Telangana's to guide workplace interventions aligned with national TB elimination goals.
Design/Methods: A cross-sectional study was conducted in four industrial districts—Sangareddy, Rangareddy, Medchal-Malkajgiri and Mahabubnagar. 102 purposefully sampled key management staff (human resource leads, factory managers, and health officers) participated in a structured interview adapted from the Stop TB Partnership Stigma Assessment Tool. Translated into Telugu, this and assessed personal attitudes, workplace norms, and policy awareness related to TB. A composite stigma score was generated from Likert scale responses and categorised as low (<15), medium (15–29), and high (≥30). Quantitative data were analysed using STATA.
Results: 17% of participants exhibited high stigma (≥30) and 42% medium stigma (15–29) towards people with TB. While willingness to hire TB survivors was high (95%), TB- training was available (90%) and TB-specific policies were largely in place (76%), 65% admitted that workplace culture discouraged disclosure of TB status.

Over half the participants associated TB with reduced productivity (51%) and reported task-related discrimination of people affected (53%). Other stigmatising attitudes included avoidance of food sharing (49%) and physical contact (47%).

Conclusions: Our findings reveal a range of contradictions and tensions in attitudes and practices towards people with TB, suggesting the need for multifaceted approach to stigma reduction that addresses underlying perceptions, translates awareness into changed behaviour, and holds industry leadership accountable for workplace responses to TB. Reducing stigma at the managerial level is particularly critical for fostering supportive work environments and advancing India's TB response.

SOA12-633-20 Beyond the narrative: Shifting power to communities in driving health research through community led-research strategy in Kenya

C. Mwamsidu,[1] P. Maleya,[2] J. Odhiambo,[3] V. Abuga,[1] P. Nyakwana,[4] J. Ongango,[5] T. Kiptai,[1] A. Rono,[6] B. Ulo,[1]
[1]Amref Health Africa in Kenya, Global Fund TB Project, Nairobi, Kenya, [2]Amref Health Africa in Kenya, Monitoring Evaluation and Research, Nairobi, Kenya, [3]Amref Health Africa in Kenya, Global Fund Grant, Nairobi, Kenya, [4]Kenya Coordinating Mechanism, TB Contituency, Nairobi, Kenya, [5]Kenya Medical Research Institute, KEMRI, Nairobi, Kenya, [6]National TB Program, Global Fund TB Project, Nairobi, Kenya

Background and challenges to implementation: Traditionally, community engagement in health programs has focused on human stories and donor reporting, with limited involvement in generating evidence to inform programming. Community-led research shifts this dynamic by empowering communities to use their own knowledge and experiences to identify challenges and co-create solutions.

With support from the Global Fund, Amref implemented this initiative in partnership with key stakeholders to build community-led organizations' research capacity and promote evidence-based advocacy in Kenya.

Intervention or response: Between August 2022 and December 2024, an open call led to the submission of 67 research concepts from community organizations. Twenty-five (25) were selected, covering 11 out of 47 counties. They were supported with funding, mentorship, and capacity-building workshops on protocol development, data collection, analysis, and report writing. All studies obtained ethical approvals and used a range of research methodologies.

Results/Impact: Of the 25 studies, 23 were completed covering HIV (15), TB (3), malaria (3), governance (1), and COVID-19 (1), with 21 utilizing primary data. Ethical review revealed 16 protocols needed minor revisions and 7 major ones. On lung health, TB studies explored factors influencing treatment adherence, the role of community health promoters in reducing loss to follow-up, and barriers to treatment uptake, while the COVID-19 study analyzed community response mechanisms.

HIV-related studies investigated gaps and determinants affecting prevention, testing, and treatment among key and vulnerable populations, and the governance study examined youth public participation in health policy.

Disseminations have been conducted across all counties, and findings are informing implementation, with the Ministry of Health leading development of national guidelines to institutionalize community-led research.

Conclusions: This initiative marks a paradigm shift positioning communities not just as beneficiaries but as producers of knowledge.

National health systems should formally recognize and integrate community led research to ensure programs are evidence driven, inclusive, and responsive to the needs of the most affected populations.

SOA12-634-20 Building resilient TB interventions: Strengthening community-led monitoring through supervision and mentorship

I. Okekearu,[1] J. Anyanti,[1] J. Adizue,[1] I. Aliyu,[2] O. Idogho,[3] A. Yola,[4] [1]Society for Family Health (SFH), Nigeria, TB, WASH and Corporate Philanthropy Practice Area, Abuja, Nigeria, [2]Kano State MOH, Dept of Public Health, Kano, Nigeria, [3]Society for Family Health (SFH),Nigeria, Office of Managing Director, Abuja, Nigeria, [4]Society for Family Health (SFH), Nigeria,TB, WASH and Corporate Philanthropy Practice Area, Kano, Nigeria
e-mail: iokekearu@sfhnigeria.org

Background and challenges to implementation: Securing adequate funding for Tuberculosis (TB) interventions remains a persistent challenge, particularly in low- and middle-income countries like Nigeria. This funding gap threatens the global target of ending TB by 2030, as outlined in the WHO End TB Strategy. Nigeria, ranking among the top 10 high-TB-burden countries, contributes approximately 4.4% of global TB cases.

Despite these challenges, local resource mobilization remains limited, emphasizing the need to optimize available resources and enhance project efficiency. Supervision and mentoring have emerged as critical mechanisms for improving project implementation, accountability, and community ownership.

Intervention or response: The Challenge Facility for Civil Society (CFCS), a Stop TB Partnership initiative, has demonstrated success in several countries through structured supervision and mentoring frameworks. In Kano

State, Nigeria, two CFCS project cycles have prioritized Community-Led Monitoring (CLM) using innovative strategies, including:
- The OneImpact digital app for real-time tracking.
- Standardized monitoring checklists to ensure project quality.
- Strengthened grantee collaboration and structured mentoring across local, national, and international levels.
- A co-created work plan, mentorship schedule, and participatory data collection, supported by experts from public, private, and civil society sectors.

Results/Impact: Since 2022, the CFCS project in Kano has led to:
- A consistent and sustained increase in TB case notifications.
- Improved community engagement and advocacy.
- Increased participation of key community stakeholders (traditional leaders, religious groups, women and youth associations, teachers, and private healthcare providers) from less than 8% in 2017 to over 45% by 2024.

Conclusions: Amid dwindling donor funding and rising accountability demands, integrating supervision and mentoring into TB interventions is strategic and imperative. This approach optimizes resources, promotes trust and confidence of donors, builds local capacity, fosters innovation (especially in areas of local resource mobilisation), and ensures the sustainability of TB response efforts in Nigeria and other high-burden settings.

SOA12-635-20 Community-led monitoring using real-time data through OneImpact applications in Cambodia

L. Molina,[1] V. Lida,[2] C. Putheara,[3] P. Chanthorn,[3] C. Sok Chamreun,[4] T. Sovannary,[5] [1]KHANA Cambodia, KHANA Center for Population Health Research, Phnom Penh, Cambodia, [2]TBpeople Cambodia, National Network, Phnom Penh, Cambodia, [3]KHANA Cambodia, KHANA Policy and Advocacy Team, Phnom Penh, Cambodia, [4]KHANA Cambodia, KHANA Executive Office, Phnom Penh, Cambodia, [5]The University of Tokyo, Department of Community and Global Health, Tokyo, Japan
e-mail: lmolina@khana.org.kh

Background and challenges to implementation: Tuberculosis (TB) remains a pressing public health challenge in Cambodia, disproportionately affecting vulnerable and marginalized populations. Structural barriers such as financial instability, stigma, and limited access to healthcare continue to delay timely TB diagnosis and treatment. In response, the Challenge Facility for Civil Society (CFCS-R12) project, supported by the Stop TB Partnership, was launched in 2024 to shift the TB response to the community level, empowering affected populations to lead transformative change.

Intervention or response: The project focused on supporting Cambodia's national commitments under the UNHLM-TB declaration by strengthening leadership, accountability, and community ownership. A key intervention was the implementation of Community-Led Monitoring (CLM) through the OneImpactplatform across 17 operational districts. This tool enabled affected individuals to report TB-related issues and access support in real time. CFCS-R12 also prioritized gender-sensitive programming, empowered women and girls affected by TB, and conducted TB stigma assessments and size estimations of key and vulnerable populations across multiple provinces.

Results/Impact: The TBpeople Cambodia network was expanded to over 4,100 members across three provinces, becoming the frontline of the TB response. Through the OneImpact app, 6,972 users reported 206 TB-related issues, 189 of which were resolved through community coordination. More than 400 TB-affected individuals were linked to social protection services, including NSSF cards, Equity Fund cards, and poverty certification. Additionally, 1,797 at-risk individuals received materials on the prevention of sexual exploitation, abuse, and harassment (PSEAH), while a national communication strategy co-developed with the community strengthened outreach and advocacy.

Conclusions: CFCS-R12 tells a powerful story: "When communities are trusted, trained, and empowered, they do not just participate they lead." The project serves as a model for meaningful community engagement and has empowered affected individuals to take leadership in addressing persistent public health challenges in Cambodia, contributing to the national goal of ending TB by 2030.

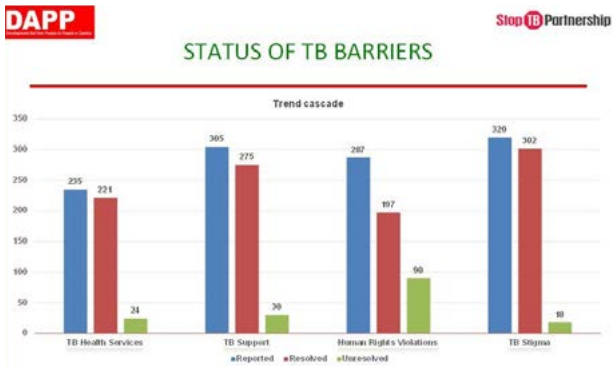
SOA12-636-20 Community-led monitoring for TB: A human rights based approach using OneImpact

A. Hoejrup,[1] F. Mabele,[2] C. Phiri,[1] A. Mwale,[2] K. Tyrrell,[3] [1]Development Aid from People to People, Partnerhip team, Lusaka, Zambia, [2]Development Aid from People to People in Zambia, Programs, Lusaka, Zambia, [3]Humana People to People Spain, Partnerships, Madrid, Spain
e-mail: annedorte@dappzambia.org

Background and challenges to implementation: In Zambia, a critical barrier to effective TB care is the lack of community engagement and real-time feedback from people with TB (PWTB) about their treatment experiences. In addition, service delivery challenges, such as long waiting times, medicine shortages, poor communication, and stigma, often hinder timely diagnosis and treatment adherence. These issues highlight the need for improved patient empowerment and stronger community accountability to enhance TB care and overcome these systemic barriers.

Intervention or response: DAPP Zambia (national NGO) implemented the OneImpact Community-Led Monitoring (CLM) platform from Stop TB Partnership in selected high-burden urban townships in Lusaka (evaluation areas). Individuals affected by TB reported service challenges in real time, accessed essential TB-related information, and engaged directly with Field Officers (FOs) and health providers. The OneImpact collected data from 867 respondents frequenting public health facilities (47% aged 18-25, 53% aged 26-35), with 35.51% male and 64.49% female.

Results/Impact:



Key issues reported include long waiting times **n=126** (10.94%), TB medicine shortages (18.14%), and poor communication with health workers **209** (24.74%), community stigma n=**285** (24.74%) and transport issues n=**247** (21.44%). Of the 1147 reported barriers, community TB stigma (n=320) was the highest reported category (Figure 1), with the overall resolution rate across all categories 86.8%.

OneImpact-enabled areas had faster issue resolution, improved communication, and better adherence to treatment than control sites. In-person interviews revealed unreported concerns, such as health worker rudeness, negligence, and lack of privacy during consultations.

First responders who are HF nurse quickly flagged issues to TB Treatment Supporters, who engaged the Person with TB (PWTB) and health facility staff, facilitated medication delivery, improved communication channels, and escalated unresolved cases.

These interventions hugely strengthened trust and improved service responsiveness.

Conclusions: OneImpact CLM app presents a scalable, rights-based model for improving TB service delivery and improve patient-centered care, recommending its adoption across Zambia National TB Control Program.

SOA12-637-20 415 youth-led actions in 2 months: A rapid movement to transform TB awareness and policy in Indonesia

I.M.P. Zein,[1] [1]Stop TB Partnership Indonesia, Communications, Jakarta, Indonesia
e-mail: iman.m@stoptbindonesia.org

Background and challenges to implementation: Tuberculosis (TB) remains a complex and persistent challenge in Indonesia, characterized by limited public awareness, inadequate social protection, and insufficient political commitment—as evidenced by the omission of TB from the revised Health Law.

Furthermore, youth engagement in the TB response considered minimal. This is a missed opportunity, as young people bring unique strengths to public health efforts, including digital fluency, creativity, and strong grassroots connections. Indonesia, with a large youth population, empowering youth as agents of change is a strategic investment to accelerate TB elimination.

Intervention or response: Stop TB Partnership Indonesia (STPI) launched the Caraka TB Institute, a youth-led initiative positioning young as central actors in TB education, campaigning, and advocacy. Twenty youth from 19 cities were selected and trained to design and implement context-specific awareness and advocacy campaigns. Selection prioritized youth that already active in local movements, with strong community ties and social media reach, ensuring their efforts were embedded within broader youth networks.

Implementation followed a structured model, including mini-surveys to gauge public understanding of TB, social media campaigns and production of a documentary film to boost awareness, and community-based actions engaging policymakers, influencers, and local residents.

See more: *Caraka TB Institute Video*

Results/Impact: In just two months, this movement carried out 415 advocacy actions, generated 98 media coverages, and sparked 1.8 million social media interactions on TB. Over 9,500 youth were mobilized at the grassroots level. Their efforts prompted several local governments to commit regional budgets for TB programs and contributed to TB being formally recognized as a national development priority.

See more: *Caraka TB Magazine*

Conclusions: This initiative demonstrates that youth engagement is not only feasible but transformative. Youth-led, community-rooted strategies can revitalize national conversations on TB, reduce stigma, and influence policy. Youth movements offer a powerful, scalable model to accelerate progress toward TB elimination in Indonesia.

SOA12-638-20 Empowerment of local self-governing bodies to accelerate TB elimination efforts in Kashmir, India

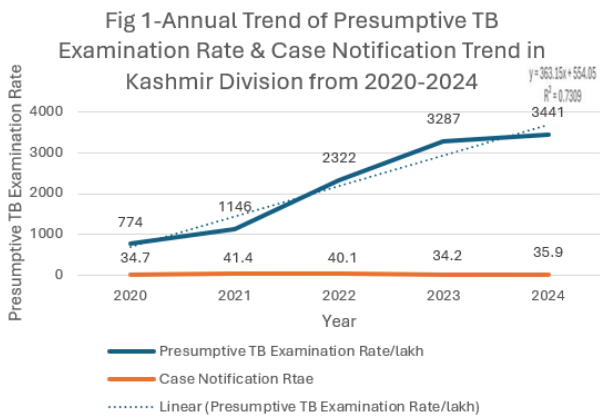
A.Y. Qadri,[1] K. Venkatesan,[2] S. Chandra,[3] P.K. Yadav,[3] A. Nair,[3] U.B. Singh,[4] N. Kumar,[4] A. Bharadwaj,[5] S.S. Tomar,[3]
[1]Directorate of Health Services , Kashmir, Department of Health and Family Welfare , J&K, Srinagar, India, [2]World Health Organisation, Government of India -WHO TSN, Srinagar, India, [3]World Health Organisation, Government of India -WHO TSN, Delhi, India, [4]Ministry of Health And Family Welfare, Department of Health and Family Welfare, Delhi, India, [5]National Task Force, Medical colleges, Delhi, India
e-mail: venkatesank@rntcp.org

Background and challenges to implementation: Panchayati Raj Institutions (PRIs) are rural local elected bodies in India that promote community-led, participatory governance for decision-making in rural areas. In the PRI system, Gram Panchayats (GPs) serve as the governing bodies for each village, overseeing health and development activities. The Kashmir Division undertook the 'Healthy Villages' initiative in 2023 to support Panchayats in meeting the predefined criteria for achieving TB-Free status.

This study aims to assess the impact of this TB Mukt Gram Panchayat initiative on TB program outcomes at the grassroots level in Kashmir, India.

Intervention or response: Since 2024, Jan Aarogya Samiti and Village Health, Sanitation, and Nutrition Committee meetings were held across all GPs, engaging TB survivors, health officials, and PRI members. These meetings shaped the Gram Panchayat Development Plan to monitor and strengthen TB efforts at the grassroots.

Program success was evaluated using six indicators: presumptive TB testing, TB notifications, drug susceptibility testing, social welfare uptake, community nutrition support, and treatment outcomes. The same parameters defined TB-Free GP status. Data was analyzed using SPSS ver. 22 .



Results/Impact: As part of this initiative, PRI representatives across 2,182 GPs were trained and sensitized to strengthen grassroots-level TB response. Notably, 62% of these GPs prioritized the inclusion of TB-affected individuals in welfare programs and related activities, reflecting strong community engagement.

The presumptive TB testing rate in 2024 reached 3,441 per 100,000 population—well above the national average of 1,281 per 100,000,and represented a 344% increase from the 2020 baseline in the state (Fig-1). As a result of these collective efforts, 1,414 GPs successfully met the defined six criteria and were declared TB-Free GPs.

Conclusions: Engaging local self-governing institutions enhances TB elimination efforts by decentralized decision-making, active community participation, and strong sense of ownership, outcomes clearly demonstrated in this initiative. Such approaches warrant greater emphasis in national policy frameworks, especially for hard-to-reach regions.

SOA12-639-20 Using design thinking to translate evidence into strategy: A case study on strengthening community health workers in TB prevention and care in Madagascar

H. Razafimanantsoa,[1] O.G. Ravololohanitra,[1] L. Hecht,[2,3,4] E.H. Andriamasy,[1,2] N. Muller,[2,3,4] [1]Doctors For Madagascar, Research, Antananarivo, Madagascar, [2]Global Digital Last Mile Health Lab at Charité Centre for Global Health, Charité - Universitätsmedizin Berlin, Berlin, Germany, [3]Speciality Network: Infectious Diseases and Respiratory Medicine, Charité – Universitätsmedizin Berlin,, Berlin, Germany, [4]Ärzte für Madagaskar e.V., Project Department, Leipzig, Germany

Background: In Madagascar,community health workers (CHWs) are essential for healthcare access, but only one in five engages in TB response .In 2024, we launched a multisectoral initiative aimed at enhancing CHW engagement in TB and HIV through evidence, strategy design, and evaluation. This abstract presents a case study of how scientific evidence informed the strategy design within this initiative.

Design/Methods: We conducted a three-day, in-person design-thinking workshop with 37 stakeholders, including public health officials (n=19), NGO representatives (n=9), healthcare providers (n=4), and CHWs (n=5). The workshop presented findings from a mixed-methods study on CHW characteristics, conditions, engagement, and motivation across four regions in Madagascar, along with best practices from countries that have strengthened CHW programs. Guided by structured phases of empathy, ideation, and elaboration, participants prioritized challenges and co-developed context-specific, evidence-based solutions-placing CHWs at the centre of the process. Sessions featured presentations, personal testimonials, open plenary discussions, and group work with preformed composition to ensure diverse perspectives and

rich dialogue. For each challenge, participants proposed and refined solutions through iterative discussion and dot voting. Plenary debates helped build consensus on strategic priorities to enhance community-based TB prevention and care.

Results: Seven essential strategy components to strengthen CHW engagement were identified and elaborated in detail, including measures on (1) financial protection, (2) recognition and social support, (3) provision of equipment and materials, (4) training, (5) supervision, (6) security, and (7) improved coordination. The originality and interactivity of the workshop were widely appreciated, with participants emphasizing CHWs' active involvement and calling for even greater representation in future events.

Conclusions: This case study illustrates how design thinking can translate research into public health strategies. The developed strategy will be implemented in a pilot zone, with implementation research guiding its impact evaluation and informing organisational and national policies to sustainably strengthen CHWs' engagement in TB prevention and care.

SOA12-640-20 Uncovering drivers of multi-drug-resistant TB/HIV treatment adherence using natural language processing of routine counselling notes

X. Lu,[1] M. Zhao,[2] B. Seepamore,[3] M. Zulu,[4] H. Nyilana,[4] K. Guzman,[1] K.R. Amico,[5] R. Perumal,[4,6] K. Naidoo,[4,6] A. Daftary,[7,4] J. Zelnick*,[8] M.R. O'Donnell*,[1,4] [1]Columbia University, Department of Medicine, Division of Pulmonary, Allergy, and Critical Care Medicine, New York, United States of America, [2]Lehigh University, Department of Industrial and Systems Engineering, Bethlehem, United States of America, [3]University of KwaZulu-Natal, School of Social Work, Durban, South Africa, [4]Centre for the AIDS Programme of Research in South Africa (CAPRISA), MRC-HIV-TB Pathogenesis and Treatment Research Unit, Durban, South Africa, [5]University of Michigan, Department of Health Behavior Health Equity, Ann Arbor, United States of America, [6]University of KwaZulu-Natal, Nelson R Mandela School of Medicine, Durban, South Africa, [7]York University, School of Global Health, Toronto, Canada, [8]Touro University, Graduate School of Social Work, New York, United States of America
e-mail: xl3214@cumc.columbia.edu

Background: Although multidrug-resistant tuberculosis (MDR-TB) treatment has advanced, adherence remains suboptimal, especially with HIV co-infection. Identifying context-specific strategies to promote adherence is especially challenging in limited-resource settings. We employed novel machine-learning/AI derived methods to identify latent factors related to treatment adherence and inform intervention approaches.

Design/Methods: We analyzed 327 unstructured counseling notes from a prospective study of MDR-TB HIV treatment in KwaZulu-Natal, South Africa using natural language processing (NLP). Preprocessing steps included data preparation, stemming, and tokenization to retain common co-occurrences. We applied BERTopic to identify latent topics influencing adherence by: (1) embedding—transforming texts into numerical representations—with pre-trained Sentence-Transformer model; (2) dimension reduction to simplify embeddings; (3) density-based unsupervised clustering; and (4) keyword extraction to identify keywords that are both frequent within and unique to each cluster. To address data sparsity and validate topic quality, we performed semantic search using a custom corpus built from BERTopic outputs. K-Means clustering was applied to sentence embeddings and semantic search results to evaluate semantic coherence and topic interpretability. We employed human-in-the-loop supervision for results interpretation.

Results: BERTopic generated 20 candidate topics. We selected the six most coherent/representative topics, ranked by number of associated notes ("count"). Noninformative keywords were removed, and topic definitions refined by human-in-the-loop review. Six-group clustering embeddings yielded a C_v coherence—human interpretability score—of 0.671, suggesting that the embeddings captured meaningful semantic variation. Clustering based on semantic search results further improved coherence (C_v = 0.715).

Topics	Keywords	Example from Counseling Notes	Count
Support experiences	home, family, child, grant, partner, support, stay, currently, time, work	"The participant is happy to be at home. They said their family is very supportive; as a result, they were accompanied by their sister, who is their treatment supporter."	42
Medication side effects	vomit, feel, effect, weak, physically, nausea, better, family	"The participant is physically weak. They said that for the past three weeks, they have had vomiting troubles."	29
Impacts of traditional medicines, alcohol and substance use	adherence, substance, use, alcohol, effect, traditional medicine, study	"They want to understand from the nurse regarding the effects of alcohol and traditional medicine, which they view as hindrances to adherence."	25
Barriers to clinic visit attendance	clinic, covid, test, keep clinic appointment, prescribe, importance	"They missed their clinic visit last week because they went home due to the lockdown caused by COVID-19."	16
Barriers to care due to rural residence	device, intake, rural area, problem, poor network, reside, home	"The patient said they did not face any challenges with the devices other than network issues, as they reside in a rural area."	15
Barriers to accessing social grants	grant, sassa, application, letter, disability grant, clinician, adherence	"What is stressing them the most is that they can't apply for a grant because they can't get a letter from the department of labor to prove that they are not working."	14

Note: Keywords are ordered by c-TF-IDF scores and manually screened for interpretability. Low-utility words are put to the end. Pronouns were de-gendered.

Table 1. Top 6 topics generated by BERTopic

Conclusions: Using NLP, we identified topics with high C_v coherence scores derived from embeddings and semantic search clustering, indicating that NLP-extracted topics capture meaningful semantic structures. These topics highlighted common treatment experiences and adherence barriers faced by patients. Incorporating human-in-the-loop supervision further refined keywords within

topic clusters. NLP-assisted analysis of data from routine medical records presents an opportunity to support targeted intervention development.

SOA12-641-20 General and religious coping among people with TB: A systematic enquiry using Brief COPE and Brief RCOPE scales

A. Kadam,[1] P. Kadam,[2] Y. Gao,[3] M. Barthwal,[2] A. Kakrani,[4] S. Kakade,[2] P. Tayde,[2] J. Golub,[5,6] V. Mave,[1,5] A. Gupta,[5,6] A. Gupte,[3] N. Suryavanshi,[1] PTLD Study Team [1]Johns Hopkins Center for Infectious Diseases in India, Medicine, Pune, India, [2]Dr. D. Y. Patil Medical College, Hospital and Research Centre, Pulmonary Medicine, Pune, India, [3]Boston University School of Public Health, Global Health, Boston, United States of America, [4]Dr. D. Y. Patil Medical College, Hospital and Research Centre, Medicine, Pune, India, [5]Johns Hopkins School of Medicine, Division of Infectious Diseases, Baltimore, United States of America, [6]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States of America
e-mail: akadam2@jhmi.edu

Background: Studies have explored general and religious coping using standardized coping scales in ailments like sickle cell anemia to cancer however, literature on coping using coping scales among people with tuberculosis (PWTB) is limited and restricted to financial coping or qualitative enquires. This study explores coping strategies using coping scales among PWTB.

Design/Methods: 30 adults (≥18 years) with drug-sensitive pulmonary tuberculosis (TB) from public TB clinics in Pune, India were administered Centre for Epidemiologic Studies-Depression (CES-D) (20-item), General Anxiety Disorder-7 (GAD-7), Brief Coping Orientation to Problems Experienced (Brief COPE) (28-item) and Brief Religious Coping Scale (Brief RCOPE) (14-item) scales at treatment initiation. Coping scores were summarized using heatmaps, and descriptive statistics were used to compare these scores among PWTB with depression and/or anxiety symptoms versus those without.

Results: Of 30 participants, 13 (43%) reported depression symptoms (DS) and 14 (47%) reported anxiety symptoms (AS) whereas 17 (57%) reported DS and/or AS symptoms. Higher scores indicate more use. Problem-focused coping (higher score indicative of a practical approach to problem-solving) and emotional-focused coping (higher score indicative of regulating emotions associated with stressful situations) were used more whereas avoidant coping (lower score indicative of adaptive coping) was used less by all participants.

However, participants with DS and/or AS (p=0.02), used more avoidant coping compared to those without DS or AS.

Additionally, these participants reported using more denial (p=0.012) and behavioral disengagement (p=0.005) compared to those without DS and/or AS. Positive religious coping (mean18.5, SD5.7) was used more, and negative religious coping (mean10.8, SD4.0) was used less by PWTB but no significant difference between those with DS and/or AS and without (Figure).

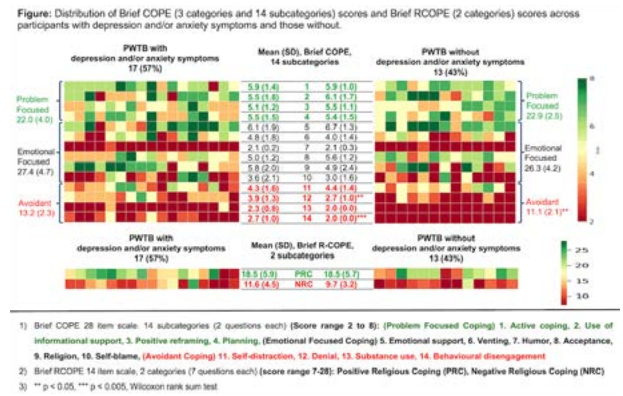


Figure: Distribution of Brief COPE (3 categories and 14 subcategories) scores and Brief RCOPE (2 categories) scores across participants with depression and/or anxiety symptoms and those without.

1) Brief COPE 28 item scale. 14 subcategories (2 questions each) **(Score range 2 to 8): (Problem Focused Coping) 1. Active coping, 2. Use of informational support, 3. Positive reframing, 4. Planning, (Emotional Focused Coping) 5. Emotional support, 6. Venting, 7. Humor, 8. Acceptance, 9. Religion, 10. Self-blame, (Avoidant Coping) 11. Self-distraction, 12. Denial, 13. Substance use, 14. Behavioural disengagement**

2) Brief RCOPE 14 item scale, 2 categories (7 questions each) **(score range 7-28): Positive Religious Coping (PRC), Negative Religious Coping (NRC)**

3) ** p < 0.05, *** p < 0.005, Wilcoxon rank sum test

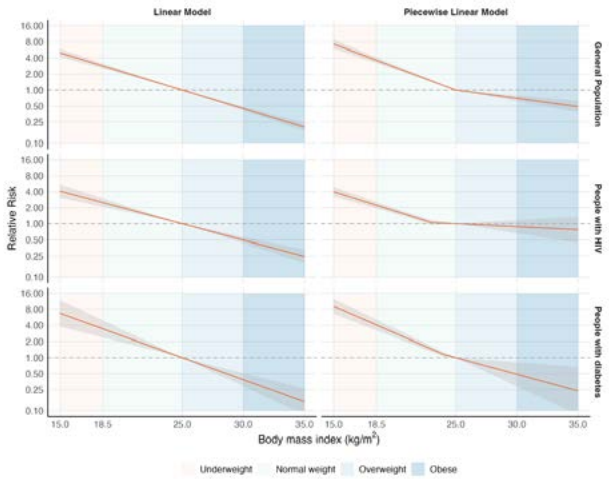
Conclusions: As coping contributes to better health outcomes, TB programs should develop strategies to strengthen coping among PWTB with an additional focus on reducing avoidant coping use and PWTB with depression and/or anxiety symptoms.

SOA13 Feeding recovery, fueling hope: Nutrition's central role in TB elimination

SOA13-642-20 Body mass index and TB risk: An updated systematic literature review and dose-response meta-analysis

M.J. Saunders,[1,2] JP. Cegielski,[3] R. Clark,[4] R.M. Houben,[4] CF. McQuaid,[4] [1]City St George's, University of London, Institute for Infection and Immunity, London, United Kingdom of Great Britain and Northern Ireland, [2]London School of Hygiene and Tropical Medicine, Faculty of Public Health and Policy, London, United Kingdom of Great Britain and Northern Ireland, [3]Rollins School of Public Health, Emory University, Department of Epidemiology, Atlanta, United States of America, [4]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology and Dynamics, London, United Kingdom of Great Britain and Northern Ireland
e-mail: msaunder@sgul.ac.uk

Background: The relationship between nutritional status and tuberculosis is critically important but poorly understood. We extended a 2009 review characterising the relationship between body mass index (BMI) and tuberculosis risk.
Design/Methods: We systematically searched for new studies published between 2009-2024 investigating BMI and tuberculosis risk in adults. We extracted estimates of risk in BMI categories, used resampling to assign a median BMI "dose" within each category, and included these in one-stage dose-response meta-analyses, stratifying results by population group and country tuberculosis burden. We fitted linear models for comparability with the 2009 review, and refined analysis with restricted cubic spline models to investigate non-linear relationships, and piecewise linear models.
Results: We included 43 cohorts – 37 from our searches and six from the previous review. Our analyses showed an inverse, dose-response relationship between BMI and tuberculosis risk across all populations in the full underweight to obese range (15.0-35.0kg/m^2). In the linear models, the reduction in tuberculosis risk per unit increase in BMI was 14.8% (95%CI: 13.3-16.3) in 22 general population cohorts (n=24,921,531); 13.1% (95%CI: 10.6-15.6) in 18 cohorts of people with HIV (n=162,069), and 17.4% (95%CI: 12.5-21.9) in three cohorts of people with diabetes (n=1,118,424) (Figure). The spline and piecewise linear models showed a non-linear relationship – in the general population there was a more steep per-unit reduction in risk for BMI<25.0kg/m^2 (18.0%, 95%CI: 16.4-19.6), which a more gradual reduction for BMI≥25.0kg/m^2 (6.9%, 95%CI 4.6-9.2) (Figure). Based on the global BMI distribution, we estimated an overall relative risk of tuberculosis associated with undernutrition (BMI<18.5kg/m^2 versus BMII≥18.5kg/m^2) of 5.1 (95%CI: 4.3-6.0).



Conclusions: Our results highlight the independent importance of nutritional status as a driver of the global tuberculosis epidemic. Social protection and other interventions to improve nutrition should be urgently scaled up as part of a holistic global tuberculosis response.

SOA13-643-20 Diagnostic accuracy of molecular testing on different respiratory specimens for TB diagnosis in children hospitalised with severe acute malnutrition

E.M. Ngu,[1,2] B. Cuer,[1] C. Chabala,[3] B. Nduna,[4] P. Shankalala,[3] G. Businge,[5] C. Roucher,[6] V. Mulenga,[3] E. Wobudeya,[5] O. Marcy,[6] M. Bonnet,[1] [1]University of Montpellier, IRD, TransVIHMI, INSERM, Montpellier Cedex 5, France, [2]Centre Pasteur du Cameroon, Mycobacteriology, Yaounde, Cameroon, [3]University of Zambia, School of Medicine, Department of Paediatrics and Child Health, Lusaka, Zambia, [4]Arthur Davison Children's Hospital, Department of Paediatrics and Child Health, Ndola, Zambia, [5]Makerere University-John Hopkins University (MU-JHU), Research Collaboration, Kampala, Uganda, [6]University of Bordeaux, Public Health Department, Bordeaux Population Health Research Center (BPH), Inserm (UMR 1219) - IRD (EMR 271), Global Health in the Global South (GHiGS) team, Bordeaux, France
e-mail: edenngu@gmail.com

Background: Childhood tuberculosis (TB) diagnosis challenges are worsened in case of severe acute malnutrition (SAM). We sought to assess the performance of XpertMTB/RIF Ultra(Ultra) assays on stools, Nasopharyngeal Aspirate (NPA) and Gastric Aspirate (GA) for TB diagnosis in children with SAM.
Design/Methods: In the TB-Speed SAM study, children < 5years hospitalized with SAM in 3 tertiary hospitals in Zambia and Uganda were systematically investigated for TB using culture on two GAs, Ultra on 1 GA, 1 NPA and 1 stool sample, clinical examination, chest X-ray abdominal ultra-sound, and followed-up for 6months. We assessed

yield and diagnostic accuracy of Ultra on microbiological samples compared to a Microbiological Reference Standard (MRS) based on 2 GA culture results and NIH-classification-based Composite Reference Standard (CRS).

Results: Of 603 children enrolled - median age 1.2 [IQR 0.9, 1.7]years, 65 (11%) HIV-infected, 16 (2.6%) had culture-confirmed TB, and 51 (8.5%), 57 (9.5%) and 495 (82.0%) were classified as confirmed (culture or Ultra), unconfirmed and unlikely, respectively. Ultra detection yield was 8/603 (1.3%) for NPA, 13/603 (2.2%) for stools and 39/603 (6.5%) for GA.

The sensitivity and specificity of Ultra testing against MRS was 33.3% (95%CI: 11.8 – 61.6) and 99.2 (97.7 - 99.8) for NPA, 56.2 (29.9 - 80.2) and 98.9 (97.2 - 99.7) for stools, and 56.2 (29.9 - 80.2) and 95.8 (93.3 - 97.6) for GA, respectively.

Of 16 children with culture-negative Ultra-positive GA, 11(68.7%) had trace or very low positive Ultra. Combining stool to NPA increased sensitivity to 56.2% but did not improve sensitivity compared to stool alone.

Samples	MRS				CRS			
	n/N	Sensitivity % (CI)	n/N	Specificity % (CI)	n/N	Sensitivity % (CI)	n/N	Specificity % (CI)
NPA	5/15	33.3 (11.8 - 61.6)	372/375	99.2 (97.7 - 99.8)	8/97	8.2 (3.6 - 15.6)	470/470	100 (99.2 - 100)
Stool	9/16	56.2 (29.9 – 80.2)	360/364	98.9 (97.2 - 99.7)	13/102	12.7 (7.0 - 20.8)	452/452	100 (99.2 - 100)
GA	9/16	56.2 (29.9 - 80.2)	366/382	95.8 (93.3 - 97.6)	39/107	36.4 (27.4 - 46.3)	470/470	100 (99.2 - 100)
Combined								
NPA/ Stool	9/16	56.2 (29.9 - 80.2)	381/387	98.4 (96.7 - 99.4)	15/107	14.0 (8.1 - 22.1)	486/486	100 (99.2 - 100)
NPA/GA	9/16	56.2 (29.9 - 80.2)	370/387	95.6 (93.1 - 97.4)	40/108	37.0 (27.9 - 46.9)	481/481	100 (99.2 - 100)
Stool/GA	10/16	62.5 (35.4 - 84.8)	368/387	95.1 (92.4 - 97.0)	43/108	39.8 (30.5 - 49.7)	487/487	100 (99.2 - 100)
NPA/ Stool/GA	10/16	62.5 (35.4 - 84.8)	368/387	95.1 (92.4 - 97.0)	43/108	39.8 (30.5 - 49.7)	487/487	100 (99.2 - 100)

Table1: TB diagnosis on respiratory samples against MRS and CRS.

Conclusions: GA had the highest detection yield despite the low bacterial load characteristic of pediatric patients' samples, explaining the limited sensitivity. Stool has higher sensitivity than NPA with limited advantage of adding NPA to stool in children hospitalized with SAM.

SOA13-644-20 Can we diagnose TB better in nutrition centres? Experience from Maiduguri Nigeria

M.B. Abdullahi,[1] M.M. Gofama,[2] A.M. Gambomi,[1] A.U. Chara,[3] U. Urhioke,[4] J. Armour-Marshall,[5] E. Briskin,[6] C. Hewison,[7] H. Huerga,[8] K. Ogundipe,[9] Z.W. Lassa,[10] O.H. Chinedu,[3] TB ALGO PED study group [1]Medecins Sans Frontiers, Operational Centre Brussels, Maiduguri, Nigeria, Medical, Maiduguri, Nigeria, [2]University of Maiduguri, Paediatrics, Maiduguri, Nigeria, [3]Médecins Sans Frontières, Operational Centre Brussels, Abuja Nigeria, Medical, Abuja, Nigeria, [4]National Tuberculosis and Leprosy Control Programme, Nigeria, Medical, Abuja, Nigeria, [5]Medecins Sans Frontiers, Brussels, Field Epidemiology and Training, England, United Kingdom of Great Britain and Northern Ireland, [6]Medecins Sans Frontiers, Epicenter, Paris, Field Epidemiology and Training, Paris, France, [7]Médecins Sans Frontières, Operational Centre Paris, Medical, Paris, France, [8]Médecins Sans Frontières, Operational Centre Brussels, Belgium, Field Epidemiology and Training, Brussels, Belgium, [9]Médecins Sans Frontières, Operational Centre Brussels, Belgium, Medical, Brussels, Belgium, [10]Leprosy and Tuberculosis Relief Initiative, Nigeria, Program management unit, Maiduguri, Nigeria
e-mail: bashir3987@gmail.com

Background and challenges to implementation: In 2022, WHO introduced treatment decision algorithms (TDAs) to enhance diagnosis and treatment of TB in children. These TDAs were implemented in the inpatient therapeutic feeding center for severely malnourished children supported by Medecins Sans Frontières (MSF), in Maiduguri, Nigeria in June 2023.

Challenges faced in implementation include increased trainings needs, follow-up of the algorithm use, increased human resource needs for follow-up, limited TB medications, and inadequate access to quality chest X-ray.

Intervention or response: Staff training and tools to track outcomes were provided. A focal person was appointed to ensure mentoring and instant feedback to staff. TB medication supply was strengthened in collaboration with the Ministry of Health. Partnerships enhanced access to quality chest X-rays.

Results/Impact: Algorithm use significantly increased TB detection. Proportion of admitted children started on TB treatment increased following algorithm implementation (Figure 1).

However, a reduction in algorithm use and subsequently TB treatments started were observed when less resources were dedicated to support the implementation. To address these decreases, a focal person was appointed to follow TDA usage and mentor clinicians, potentially contributing to a subsequent rebound in the proportion of children initiated on TB treatment.

However, fluctuations over time in the proportions of children started on TB treatment might also be related to the seasonal variations in the number of admissions and the associated workload. Clinicians report improved di-

agnostic capacity and confidence. MSF along with the National TB Program is supporting other centers in adopting the algorithm through training and technical assistance.

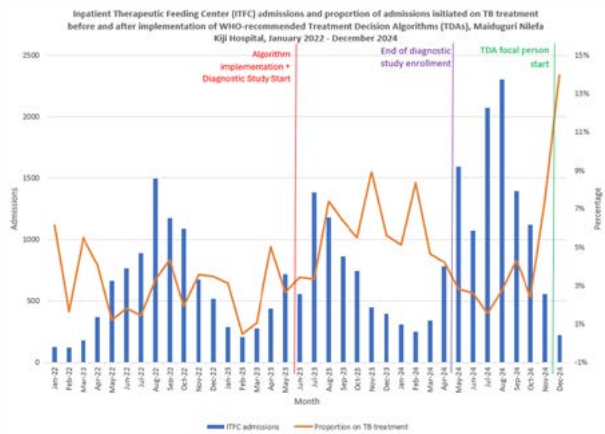


Figure 1.

Conclusions: Integrating the TDAs in a nutritional program has improved TB treatment initiation in malnourished children. Key factors for success included training, resource availability, follow-up of activities, and adaptive strategies.

Future efforts should focus on sustaining progress and ensuring medication supply to enhance TB case care in resource-limited settings and nutrition projects.

SOA13-645-20 Weighing the risk: Severe acute malnutrition determinants in children treated for TB in Papua New Guinea

G. Pukai,[1,2] V. Apis,[2] A. Seeger,[3] C. Ramoni,[4] M. Rapea,[5] A. Vasiliu,[3,6,7] A. Mandalakas,[3] H. Welch,[3,1,4] [1]The University of Papua New Guinea School of Medicine and Health Sciences, Paediatrics, Port Moresby, Papua New Guinea, [2]The Paediatric Society of Papua New Guinea, Child Health, Port Moresby, Papua New Guinea, [3]Baylor College of Medicine, Pediatrics, Houston, United States of America, [4]The Paediatric Society of Papua New Guinea, Pediatrics, Port Moresby, Papua New Guinea, [5]Port Moresby General Hospital, Paediatrics, Port Moresby, Papua New Guinea, [6]Research Center Borstel, Clinical Infectious Diseases, Borstel, Germany, [7]German Center for Infection Research, Infectious Diseases, Borstel, Germany
e-mail: gordonpukai45@gmail.com

Background: Tuberculosis (TB) remains a major public health issue in Papua New Guinea (PNG), particularly among children. Nutritional status is a critical determinant of TB outcomes, yet limited data exist on the drivers of severe acute malnutrition (SAM) in this context. This study describes the clinical and nutritional profile of children treated for TB at Port Moresby General Hospital (PMGH), using mid-upper arm circumference (MUAC) as an indicator of nutritional status.

Design/Methods: We conducted a retrospective analysis of children treated for TB at PMGH from 2016 to 2024. Data included demographics, HIV status, age, bacteriological confirmation, and MUAC. Nutritional status was classified using WHO MUAC thresholds for children under 5, and age-specific MUAC cutoffs for children aged 5–19 years based on reference data from Mramba et al. (2017). Multivariate logistic regression was used to identify predictors of SAM.

Results: A total of 1,162 children with complete data (including MUAC measurement, HIV status, age, and gender) were included in the analysis. Of these, 42% were female, and 2.9% were living with HIV. Xpert testing was performed in 624 children (54%), with 167 (27%) having bacteriologically confirmed TB. Most children (82.5%) were between 6 months and 9 years of age. Nutritional assessments showed that 37.4% had a normal MUAC, 35.5% had moderate malnutrition, and 27.0% were classified with severe acute malnutrition (SAM).

Adolescents (≥10 years) (OR = 2.42; 95% CI: 1.75–3.33) and children living with HIV (OR = 3.39; 95% CI: 1.69–6.88) had significantly higher odds of SAM. Notably, SAM was not associated with increased mortality in this cohort.

Conclusions: SAM is common among children treated for TB at PMGH, particularly in adolescents and those living with HIV. Integrated TB, HIV, and nutritional services are needed to improve pediatric TB outcomes in PNG.

SOA13-646-20 Skip the snakes, ladder up: Let the game do the counselling

S. Bollepogu,[1] R. Adepu,[2] A. Singh,[3] J. Sangawar,[2] A. Pendli,[4] [1]The Union, ACSM NTSU, Hyderabad, India, [2]National TB Elimination Program, Telangana, State TB Cell, Telangana, Hyderabad, India, [3]The Union, ACSM NTSU, New Delhi, India, [4]Veeranari Chakali Ilamma Women's University, Hyderabad, Department of Food and Nutrition, Hyderabad, India
e-mail: bollepogu.suresh@theunion.org

Background and challenges to implementation: Good nutrition and healthy habits are vital during TB treatment—not just for people with TB (PwTB) but also for their families. They support treatment adherence, recovery, and prevention. Effective counselling is essential to promote these behaviours. However, traditional counselling methods face programmatic challenges, such as limited human resources, inadequate skills, and a lack of engaging tools to deliver impactful counselling resulting in poorer adherence.

Intervention or response: The Union and the Telangana State collaborated with the Department of Food and Nutrition, Mahila University, Hyderabad, to develop a Snakes and Ladders-based counselling tool. Professors

and students designed the game by scientifically mapping the nutritional value of healthy foods and the risks of unhealthy habits, using locally available, affordable items. The pictorial gameboard, accompanied by dice and instructions, was distributed to trained frontline workers. Instead of pawns, families used household items like peanuts, cashew, garlic etc. as tokens. Frontline workers facilitated the game by engaging the PwTB and their families, guiding discussions based on game progress. In 2024, 1,500 boards supported over 53,600 counselling sessions across the field.

Results/Impact: In-depth interviews were conducted with medical practitioners (n=7), persons with TB (PwTB) (n=8), family members (n=12), and frontline health workers (n=6). The findings revealed:

Medical Practitioners:

Found the game simplified complex health information, making counselling more efficient and engaging.

Frontline Health Workers:

Reported increased interaction and enthusiasm during sessions. The game sparked conversations and helped reinforce messages about balanced diets and healthy habits.

PwTB and Family Members:

Shared that the game helped them identify affordable, nutritious food options and avoid unhealthy practices. Many reported prioritizing better nutrition, regular exercise, and incorporating indigenous practices like yoga into their routines.

Conclusions: Counselling sessions assisted with the game brought lot of laughs along with the reported behavioral changes which contributed to the treatment adherence and adopted healthy habits.

SOA13-647-20 Enhancing TB treatment outcomes: The role of nutrition education and micronutrient supplementation on immunological markers and quality of life in peri-urban Bangladesh

F. Zaman,[1] [1]National Tuberculosis Control Program, Mychobacterium Disease Control Division, Dhaka, Bangladesh
e-mail: zamanfarzana008@gmail.com

Background: Enhancing Tuberculosis Treatment Outcomes: The Role of Nutrition Education and Micronutrient Supplementation on Immunological Markers and Quality of Life in Peri-Urban Bangladesh.

Design/Methods: Malnutrition and tuberculosis (TB) are closely linked, with undernutrition increasing the risk of TB, while TB exacerbates malnutrition.

This study aimed to evaluate the impact of nutrition education and micronutrient supplementation (Zinc and Vitamin A) on biochemical, immunological markers, and the quality of life (QoL) in pulmonary TB patients receiving DOTS in the peri-urban areas of Bangladesh.

A prospective longitudinal intervention study was conducted involving 216 adult, newly diagnosed sputum-positive TB patients, randomly allocated into three groups: Group A (DOTS only), Group B (DOTS + nutrition education), and Group C (DOTS + nutrition education + micronutrient supplementation). The study assessed nutritional status, biochemical markers (serum Zinc, retinol, leptin), sputum conversion time, and QoL using the SF-36 questionnaire at baseline, 2 months, and 6 months.

Results: Results showed significant improvements in nutritional indicators such as weight and BMI in all groups, with the greatest increase in Group B (16.5%). Group C, which received both micronutrient supplementation and nutrition education, demonstrated the highest increase in serum Zinc (0.85 mcg/mL) and retinol (31.4 mcg/dL) levels. Serum leptin levels, indicative of fat stores, increased in all groups. Although sputum conversion time was shortest in Group B, the overall QoL improved in all groups, reflecting enhanced physical and mental health.

Conclusions: This study highlights that while micronutrient supplementation and nutrition education may not lead to significant outcomes in all parameters, they positively impact the nutritional status, immune function, and QoL of TB patients. Raising awareness about nutrition and integrating it into TB treatment strategies could play a vital role in improving health outcomes and controlling TB in resource-poor settings.

SOA13-648-20 Community-driven nutrition support model to enhance TB outcomes: Insights from Uttarakhand, India

J.S. Negi,[1] B. Bishnu,[2] A.K. Nagarkar,[1] S. Lohakare,[2] Y. Malhotra,[2] A. Akkayasamy,[2] A. Bhardwaj,[3] S. Chandra,[2] N. Kumar,[4] U. Singh,[4] [1]Department of Health and Family Welfare, Government of Uttarakhand, Tuberculosis, Dehradun, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [3]National Task Force, National TB Elimination Program, New Delhi, India, [4]Ministry of Health and Family Welfare, Government of India, Tuberculosis, New Delhi, India
e-mail: bsinha008@gmail.com

Background and challenges to implementation: Recognizing the strong link between undernutrition and adverse TB outcomes, Uttarakhand, a remote mountainous state in India, launched a community-based nutrition kit distribution initiative for people with TB.
This mixed-method study evaluates the effectiveness of this community-driven model versus the conventional health-center-based distribution approach in improving TB treatment outcomes, aiming to assess its impact on treatment adherence, recovery rates, and overall patient well-being.
Intervention or response: In the community-driven model, nutrition kits were sourced from corporate donors, Non-Governmental Organisations (NGO), and individuals and distributed at beneficiaries' homes by TB survivors in contrast with the previous approach where persons with TB collected nutrition kits from health centers. The study analysed treatment outcomes for both groups, notified in 2023, using data from Ni-kshay, India's digital TB surveillance platform. Interviews were conducted with donors, health providers, TB survivors and beneficiaries using an inductive narrative approach to gather insights into the impact of this initiative.

Nutrition Kits Disbursement Approaches	Total Beneficiaries	Favourable outcome rate %	Lost to Follow up rate %	Death rate %
1. Previous Approach				
Persons with TB, who got benefits from Donors directly at health centres	424	88.47	2.82	1.4
2. Community driven approach				
Persons with TB who got benefits at their homes facilitated by TB survivors	1013	92.89	0.79	0.29
X^2 (p value)		0.0115		
Fisher Exact Test (p value)			0.005	0.0229

Table 1: TB treatment outcomes among persons receiving nutrition kits through community driven approach as compared to those receiving nutrition kits at health centers in Uttarakhand, India.

Results/Impact: The study cohort consisted of 1,438 persons with TB (mean age 46 years, 58% male). Of these, 1,013 (70.5%) received kits at home through the community-driven model, while 425 collected their nutrition-kits at health centers. Both groups were similar in sociodemographic characteristics.
The community-based group demonstrated a higher treatment success rate (92.9%) compared to the health-center group (p=0.0115). The former group had 3 deaths and 8 lost to follow-up (LTFU), while the latter had 6 deaths (p=0.0229) and 12 LTFU (p=0.005). Stakeholder interviews revealed satisfaction with streamlined procedures, reduced out-of-pocket costs, improved treatment adherence, and enhanced social inclusion for those receiving home-delivered kits.
Conclusions: The community-based model, facilitated by TB survivors, significantly improved TB treatment outcomes compared to traditional methods. These findings underscore the potential for scaling up such models and integrating corporate, NGO partnerships and engagement of TB survivors, to enhance TB care and achieve TB Elimination goals.

SOA13-649-20 Impact of nutritional support to the person with TB: A comparative study between Nikshay Poshan Yojna and Nikshay Mitra initiative in West Bengal, India

A. Dey,[1] S.K. Roy,[2] U.B. Singh,[3] S. Chandra,[1] T.K. Saha,[2] B. Sengupta,[1] D. Deka,[1] [1]Government of India-WHO Country office for India-Technical Support Network, National TB Elimination Program, New Delhi, India, [2]Government of West Bengal, Department of Health and Family Welfare, Kolkata, India, [3]Government of India, Department of Health and Family Welfare, New Delhi, India
e-mail: drabhijitdey@gmail.com

Background: Tuberculosis (TB) and nutrition have a bi-directional relationship: undernutrition increases the risk of developing TB, and TB can worsen nutritional status, leading to a vicious cycle. The Nikshay Poshan Yojana (NPY) is a Direct Benefit Transfer (DBT) scheme under the National Tuberculosis Elimination Programme (NTEP) in India, launched on 1st April 2018, for nutritional support to the person with TB (PwTB) during their treatment.
The "Pradhan Mantri TB Mukt Bharat Abhiyaan" (PMTBMBA), launched on September 9, 2022, aims to eliminate tuberculosis through community involvement, including the "Nikshay Mitra" initiative, which encourages donor to support TB patients with nutritional, diagnostic, and vocational assistance.
The study aimed to measure the comparative impact of the nutritional support schemes in terms of favourable treatment outcomes.

Design/Methods: This is an observational study. A secondary analysis done on data extracted from the Ni-kshay portal which is the web-based case-based TB surveillance system of India.

Results: 86.9% PwTB received any types of benefits. 75.9% received only NPY , 0.9% received only food basket (NM support), 10.1% participants received both NPY & NM support and 13.1% received none of these two.

Treatment success of the PwTB who received both the benefits vs who received none was 96% vs 66.6%. Lost to follow up rate among PwTB who received both the benefits and who received none was 0.7% and 5.8% respectively. Death rate among these groups was 2.9% & 7.1% respectively (*Fig-1*)

Fig 1: Proportion of different treatment outcomes and correlation with the support of Nikshay Poshan Yojna (NPY) & Nikshay Mitra (NM) in West Bengal in 2024. N=63186, n1= 8271, n2= 47972, n3=581, n4=6362; [N=n1+n2+n3+n4]

Treatment Outcomes		Total N (%*)	No nutritional support n1(%*)	Only NPY (Cash) n2(%*)	Only NM (Food basket) n3(%*)	Both the NPY & NM n4(%*)	p-value
Treatment success	Yes (Cured/Treatment completed)	55,200 (87.4)	5,512 (66.8)	43,091 (89.8)	492 (84.7)	6105 (96.0)	0.000
	No (Unfavourable outcomes)	7,986 (12.6)	2,759 (33.4)	4,881 (10.2)	89 (15.3)	257 (4.0)	
Loss to Follow-up	Yes	1, 379(2.2)	482 (5.8)	843 (1.8)	12 (2.1)	42 (0.7)	0.000
	No	61,807 (97.8)	7,789 (94.2)	47,129 (98.2)	569 (97.9)	6,320 (99.3)	
Treatment failure	Yes	363 (0.6)	48 (0.6)	286 (0.6)	5 (0.9)	24 (0.4)	0.135
	No	62,823 (99.4)	8,223 (99.4)	47,686 (99.4)	576 (99.1)	6,338 (99.6)	
Death	PwTB died before treatment completion	4,459 (7.1)	1,651 (20.0)	2,553 (5.3)	68 (11.7)	187 (2.9)	0.000
	Not died	58,727 (92.9)	6,620 (80.0)	45,419 (94.7)	513 (88.3)	6,175 (97.1)	

Notes: * column percentage (within the category); Proportions & p-Value calculated with Chi square test.

Conclusions: A good proportion of PwTB in West Bengal is receiving the nutritional supports under NPY-DBT or PMTBMBA or through both the schemes. The schemes are impactful in terms of significantly increasing treatment success rate & significantly decreasing LTFU & Death rate. NPY-DBT scheme seems to be more impactful in terms of better coverage, association with higher treatment success rate & lower LTFU & Death rate.

SOA13-650-20
How best to manage TB in households? A modelling analysis of TB preventive therapy and nutritional support in India

S. Mandal,[1] P. Sinha,[2] N. Arinaminpathy,[3] K. Rade,[4] R. Rao,[5] U. Singh,[5] [1]John Snow India, Data Analytics and Modelling Division, New Delhi, India, [2]Boston University, School of Medicine, Boston, United States of America, [3]World Health Organization, TB Monitoring, Evaluation and Strategic Information, Geneva, Switzerland, [4]Stop TB Partnership, Global Health, Geneva, Switzerland, [5]Ministry of Health & Family Welfare, Central TB Division, Delhi, India
e-mail: sandipccmb@gmail.com

Background: Tuberculosis preventive therapy (TPT) is a key strategy for TB prevention, but real-world completion rates consistently fall short of expectations. Emerging evidence suggests that nutritional support can reduce TB incidence among household contacts and improve treatment outcomes. Using a mathematical model, we compared the impact and cost-effectiveness of TPT versus nutritional support in India.

Design/Methods: We built a dynamical model for household cohorts of TB index cases and their contacts. The model incorporated programmatic data for TPT completion rates and subsequent TB incidence. We also used estimated rates of side effects and drug resistance risks from the literature. For nutritional support, we included published estimates of its effect on TB incidence and outcomes. Also incorporating programmatic costs, we estimated incremental cost-effectiveness ratios (ICERs) of two interventions, TB treatment for the index case plus: (i) TPT for all contacts, or (ii) nutritional support for the index case and all contacts.

		TB treatment for index case + TPT in contacts	TB treatment for index case + nutritional support in index case and contacts
Reduction in cumulative TB incidence, per 1,000 index cases	Amongst index cases	None (index cases already incident)	
	Amongst contacts	3.8 (2.4 – 6.9)	5.2 (3.3 – 9.2)
Reduction in cumulative TB mortality, per 1,000 index cases	Amongst index cases	None	25 (20 – 32)
	Amongst contacts	0.27 (0.17 – 0.50)	0.38 (0.25 – 0.68)
ICER: USD per DALY averted		1310 (730 – 2010)	32 (25 – 41)

Table: Summary of modelled outcomes of TPT vs nutritional support in TB-affected households. For both interventions, the comparator is TB treatment for the index case alone, with no uptake of TPT or nutritional support.

Results: Scaling up TPT for all household contacts would avert 41% (95% UI: 38–45) of TB incidence and 0.7% (95% UI: 0.39–1.2) of mortality, at an estimated cost of

USD 1310 (95% UI: 730–2010) per DALY averted. In contrast, nutritional support would avert 56% (95% UI: 52–60) of incidence and 64% (95% UI: 62–66) of mortality, with a much lower ICER of USD 32 (25–41) per DALY averted (See Table). The cost-effectiveness of nutritional support was driven largely by improved survival among index cases. Assuming no mortality benefit increased the ICER to USD 1700, but even mortality reductions of 15% resulted in ICERs comparable to TPT.

Conclusions: Incorporating real-world conditions is essential in planning TB interventions. While TPT remains important, nutritional support may yield greater reductions in TB incidence and mortality among household contacts in India—and do so at lower cost.

SOA13-651-20 Nutritional support for people with or at risk of TB: A systematic review and synthesis of implementation approaches

N. Madden,[1] C. Pell,[1] J. Scholten,[1] I. Spruijt,[1] O. David,[2] D. Jerene,[1] [1]KNCV Tuberculosis Foundation, Division TB Elimination and Health System Innovations, The Hague, Netherlands, [2]University College Limerick, School of Medicine, Limerick, Ireland
e-mail: norma.madden@kncvtbc.org

Background: Undernutrition is one of the five leading risk factors for tuberculosis (TB) disease. Nutritional support is therefore a key focus for TB prevention and care. There is, however, limited understanding of how nutritional interventions are implemented. This review provides a comprehensive overview of the ways in which nutritional support is provided to people with/at risk of TB.

Design/Methods: Using a systematic strategy, we searched four databases, Medline (via OVID), PubMed, Web of Science, and CINAHL for publications in English spanning January 2000 to December 2024. Articles meeting the prespecified inclusion criteria and containing data on the type of nutritional support provided were included. A „best fit" framework synthesis approach, utilizing a published logic model, provided a predefined set of themes against which data were extracted.

Results: We screened 850 publications, of which 29 were included in the framework synthesis. Studies were predominantly conducted in high TB burden countries (*n*=24), mostly in South-East Asia (n=14) or Africa (n=8). We identified seven types of nutritional intervention:
i. Food baskets;
ii. Supplementary nutrition (e.g. „e'Pap", macronutrient powders);
iii. Fortified biscuits;
iv. Food vouchers;
v. Meals consumed at health facilities;
vi. Cash transfers and;
vii. Dietary counselling.

More than half of studies indicate that local food preferences were considered (n=15). All included studies examined the effect of nutritional support within research settings (including 14 randomized controlled trials). The most common endpoint was treatment outcomes (n=10), followed by weight-gain/BMI (n=8). Table 1 summarizes themes per nutritional intervention.

Type of nutritional intervention (# Studies)	Target Population (# Studies)	Frequency of provision (# Studies)	Mode of Access (# Studies)	Cultural differences and food preferences considered (# Studies)
Supplementary Nutrition (10)	Adults newly diagnosed PTB+ (4/10) Adult (18–60 years) and children (3–6 years) (4/10) Adults diagnosed with TB (1/10) Adults 18-60 (2/10) Adults, with or without latent TB infection (1/10)	Daily (9/10) Monthly (1/10)	Distributed in community (1/10) DOTs (4/10) Home delivery (3/10) HF[a] based distribution (2/10)	Yes (8/10) No (2/10)
Food baskets (9)	TB-HIV coinfected adults (1/9) HH contacts of bacteriologically confirmed pulmonary TB patients (2/9) Adults Bac+ confirmed TB (4/9) Adults diagnosed with TB & BMI <18.5 kg/m2 (1/9) Homeless people with TB (1/9)	Daily (1/9) Weekly (2 /9) Monthly (6/9)	Home delivery (2/9) HF based community delivery (1/9) Distributed via TB HF (3/9) DOTs (2/9) NGO program (1/10)	Yes (5/9) No (2/9) Partially (1/9) Not specified (1/9)
High energy enriched biscuit (3)	Adults bac+ pulmonary TB (PTB+) co-infected with HIV (2/3) Adults diagnosed with pulmonary TB both HIV+/- (1/3)	Daily (3/3)	Distributed via TB HF (3/3)	No (3/3)
Voucher (2)	Adults & children diagnosed with pulmonary DS-TB and starting treatment during recruitment period (1/2) Adults (>18) with bac+ or clinically diagnosed with TB (1/1)	Monthly (2/2)	Distributed via TB HF (2/2)	Yes (1/2) Partially (1/2)
Cash transfer (2)	HIV-infected TB patients (1/2) Adults diagnosed with TB (1/2)	1st installment for 2 months, subsequent installments monthly if 2 months of treatment was completed (1/2)	Bank details collected via HF (2/2)	NA
Health facility-based meal (1)	Adults diagnosed with TB (1/1)	Daily (1/1)	Distributed via TB HF (1/1)	Yes (1/1)
Dietary counselling (1)	Adults with TB aged ≥18 years and <66 (1/1)	Counseling was provided at seven visits: Days 15, 30, 60, 90, 120, 150, and 180 of TB treatment (1/1)	Counselling delivered at the HF (1/1)	No (1/1)

Table.
Abbreviations: Bac+, Bacteriologically confirmed; DOT, directly observed treatment; HF, health facility; HH, household; HIV, human immunodeficiency virus; NA, not applicable; NGO, non-governmental organization; PTB+, pulmonary TB; TB, tuberculosis

Conclusions: This synthesis highlights varied approaches to the design and implementation of nutritional support interventions for people with or at risk of TB. Nutritional support has mainly been evaluated in research settings, with varied endpoints.

The financial /operational feasibility and acceptability for programmatic implementation among different target populations require more attention.

SOA13-652-20 Nutritional support improves treatment success, nutritional status, and functional recovery: Findings from the INSTITUT study

M.F. Dogo,[1] A. Eng,[2] M. Dauphinais,[2] C. Cintron,[3] S. Ate,[4] K. Agossou,[4] B. Ade,[5] A.A. Fiogbe,[6] D. Affolabi,[7] K.S. Adjoh,[8] K. Koura,[9] P. Sinha,[10] [1]The International Union Against Tuberculosis and Lung Disease, Tuberculosis Department, Lomé, Togo, [2]Boston Medical Center, Medicine - Section of Infectious Diseases, Boston, United States of America, [3]Brown University School of Public Health, Epidemiology, Providence, United States of America, [4]National Tuberculosis Programme, Monitoring, Evaluation, and Research Unit, Lomé, Togo, [5]National Tuberculosis Programme, Programme National contre la Tuberculose, Cotonou, Benin, [6]International Union Against Tuberculosis and Lung Disease, Tuberculosis Department, Paris, Benin, [7]National Hospital for Tuberculosis and Pulmonary Diseases, Microbiology, Cotonou, Benin, [8]Sylvanus Olympio University Hospital Center, Pulmonology, Lomé, Benin, [9]International Union Against Tuberculosis and Lung Disease, Tuberculosis Department, Paris, United States of America, [10]Boston University Chobanian and Avedisian School of Medicine, Medicine - Section of Infectious Diseases, Boston, United States of America
e-mail: fall.dogo.consultant@theunion.org

Background: Undernutrition is a leading risk factor for tuberculosis (TB) and is associated with increased mortality. This study evaluated whether nutritional support during TB treatment improves nutritional, functional, and treatment outcomes.
Design/Methods: As part of the INSTITUT Study, adults with bacteriologically confirmed pulmonary TB were prospectively followed for 12 months in Togo and Benin. In Benin, patients routinely receive nutritional support during TB treatment, while in Togo they do not.
The primary outcome was cure.
Secondary outcomes included ≥5% weight gain at month 2 and ≥10% at month 6, adherence to treatment (defined as >90% adherence confirmed with pill counts) and sputum smear conversion after 2 months of treatment. Functional improvement was assessed by the distance gained in six-minute walk test (6MWT) distance at month 6 compared to baseline.
Multivariable models were adjusted for age, sex, baseline body mass index, multidimensional poverty index, alcohol misuse, HIV status, and other covariates significant at p≤0.20.
Results: Among 796 participants (293 in Togo, 503 in Benin), baseline characteristics were comparable. Nutritional support was significantly associated with higher odds of cure (aOR 2.96; 95% CI: 1.35–6.78), better adherence (aOR 3.01; 95% CI: 1.37–6.91), ≥5% weight gain at month 2 (aOR 1.67; 95% CI: 1.16–2.41), and ≥10% weight gain at month 6 (aOR 2.51; 95% CI: 1.65–3.85). Participants receiving nutritional support also showed a greater adjusted 6MWT distance gain of 46.31 meters (95% CI: 30.43–62.17) . No significant difference in sputum smear conversion at month 2 was observed (aOR 1.28; 95% CI: 0.78–2.07).

Outcome	Unadjusted OR (95% CI)	Adjusted OR (95% CI)	p-value
Cure	3.97 (2.05, 7.98)	2.96 (1.35, 6.78)	0.008
Adherence	2.94 (1.82, 4.81)	3.01 (1.37, 6.91)	0.007
≥5% Weight Gain at 2 Months	1.87 (1.35, 2.59)	1.67 (1.16, 2.41)	0.006
≥10% Weight Gain at 6 Months	2.42 (1.68, 3.52)	2.51 (1.65, 3.85)	<0.001
Sputum Smear Conversion	1.78 (1.20, 2.65)	1.28 (0.78, 2.07)	0.322

Table: Impact of Nutritional Support (Benin vs. Togo).

Conclusions: Nutritional support during TB treatment was associated with improved weight gain, physical function, adherence, and cure. These findings support the integration and scale-up of nutritional support into TB programs, particularly in resource-limited settings where undernutrition remains a critical barrier to successful treatment outcomes.

SOA13-653-20 Empowering TB-affected communities: Savings groups as a social protection strategy

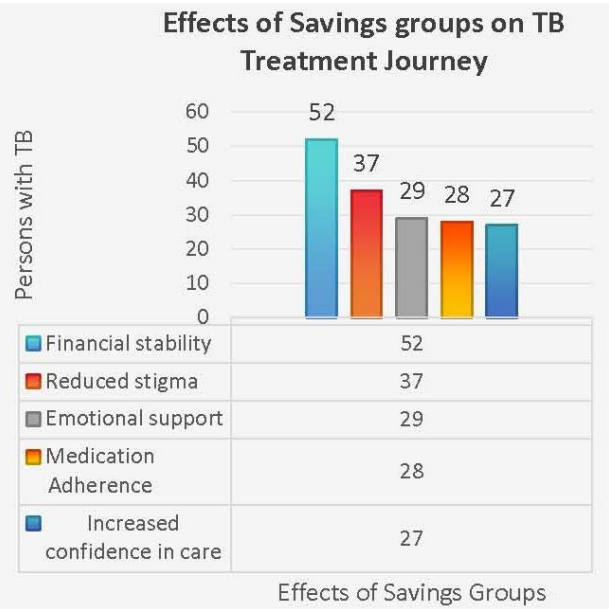
A. Hoejrup,[1] K. Tyrrell,[2] N.E. Maswabi,[3] M. Bwalya,[3] C. Phiri,[1] [1]Development Aid from People to People, Partnerhip team, Lusaka, Zambia, [2]Humana People to People Spain, Partnerships, Madrid, Spain, [3]Development Aid from People to People in Zambia, Programs, Lusaka, Zambia
e-mail: annedorte@dappzambia.org

Background and challenges to implementation: In Zambia, 58% of tuberculosis (TB)-affected households face catastrophic total costs (National TB Cost Survey, 2021). TB disease is associated with economic hardship, social isolation, loss of income, reduced access to nutrition, and difficulty affording transportation to health facilities. In focus group discussions with persons with TB (PWTB), held in Lusaka, Matero township by Development Aid from People to People (national NGO) in April 2024, women reported experiencing partner violence, loss of income due to caregiver responsibilities and extreme poverty.
TB-related myths and misconceptions further affected livelihoods, as customers avoided businesses run by TB survivors or caregivers. To address these challenges, DAPP Zambia examined the effect of savings groups on

the socioeconomic well-being of people affected by TB in evaluation areas Chawama, Mandevu and Matero constituencies in Lusaka.

Intervention or response: In 2024, in the intervention group, people with or affected by TB formed 25 "Savings for Change" model groups (model endorsed by Bank of Zambia). Each group has an average 25 of members (total n=625), consisting of TB survivors, caregivers, community members and community volunteers. DAPP Facilitators provided training in cooperative savings model income generation, and financial literacy, and gave the groups ongoing support.

Results/Impact: Over a nine-month period, 82 members were interviewed for the survey. Majority interviewed, 80% (66/82) had a PWTB in Household (HH) in previous six months, 86.6% (71/82) took loans. The savings were reported being used by 76.7% (56/71) for small business investment and 25.8% (17/66) reported it reduced treatment interruptions. Savings groups became platforms for psychosocial support, foster community solidarity. PWTB reported significant reduction in TB-related stigma. (See Figure 1).



Conclusions: Community based savings groups for those affected with TB provide an opportunity to reduce catastrophic costs due the disease. Policymakers, TB programs and NGO's should consider the integration of community-based savings groups into national TB control strategies.

SOA13-654-20 Assessing the impact of climate change on TB care in Zimbabwe: A mixed-methods evaluation of community and health system needs

C. Christian,[1] R. Mukondwa,[2] C. Avilés-Guamán,[3] M. Hudson,[3] K. Takarinda,[2] N. West,[3] A. Ayer,[3] K. Webb,[2] P. Shete,[3] [1]University of California, San Francisco, Epidemiology and Biostatistics, San Franicsco, United States of America, [2]Organization for Public Health Interventions and Development (OPHID), Implementation Science Research, Harare, Zimbabwe, [3]University of California, San Francisco, Division of Pulmonary and Critical Care Medicine and Center for Tuberculosis, San Francisco, United States of America
e-mail: canice.christian@ucsf.edu

Background: Climate change is increasingly affecting people living with Tuberculosis (TB) in low-resourced settings. The 2023/2024 El Niño-induced drought in Zimbabwe, for example, caused food insecurity and created increased demands on health service delivery.

We sought to assess the impact of climate change on TB services and identify the unmet needs as perceived by affected communities and their healthcare providers (HCWs) due to extreme weather events.

Design/Methods: We conducted a formative evaluation using a convergent parallel mixed-methods approach. We collected survey and clinical data among people living with HIV (PLHIV) at a sample of clinics in Zimbabwe.

We conducted in-depth interviews and focus group discussions (FGDs) with a sample of patients co-infected with TB to understand how climate change has impacted people affected by TB and their HCWs. We mapped the findings to the Consolidated Framework for Implementation Research (CFIR).

Results: Overall, 1363 of 1804 (76%) survey participants reported noticing changes in the typical climate of their communities over the past 5 years. Of those who experienced these changes, 75% reported disruptions to their HIV care due to climate change(n=1024). Three FGDs with TB/HIV co-infected individuals and three HCWs were interviewed regarding TB service delivery.

When mapped to CFIR(Figure 1), individual challenges include food insecurity (887/1024, 86%), leading to challenges in TB treatment adherence by creating competing priorities for patients. Inner setting factors included widespread community-level water and food insecurity and transportation challenges.

Outer setting factors included insufficient social (288/1024, 28%) and economic supports (329/1024, 32%) for those affected by TB. Participants discussed the need for community health outposts for decentralized community-based provision of health services (1086/1804, 60%), water/sanitation services (781/1804, 43%), nutrition support (541/1804, 30%), and transportation support (423/1804, 23%).

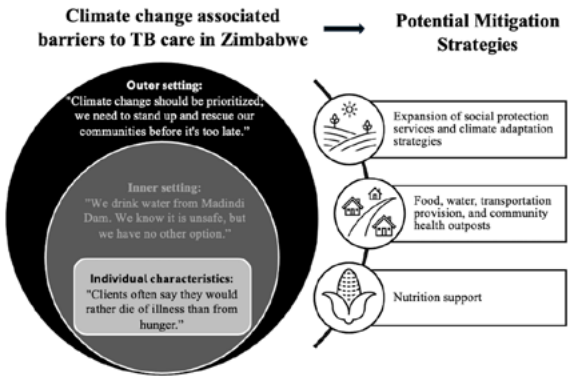


Figure 1. Mapping climate change challenges to TB care and related climate adaptation interventions in Zimbabwe using the Consolidated Framework for Implementation Research (CFIR).

Conclusions: This formative mixed-methods assessment identifies areas where health systems can target interventions to mitigate climate change challenges to TB care in Zimbabwe.

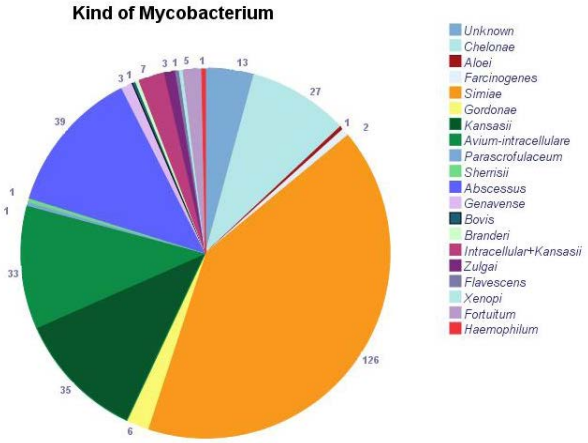
E-POSTER SESSION (EP)

EP28 Advances in diagnosis, epidemiology and management of non-tuberculous mycobacterial disease

EP28-965-20 A cross-sectional survey of people with NTM pulmonary disease

P. Baghaei Shiva,[1] M. Marjani,[1] A. Moniri,[1] P. Tabarsi,[1]
[1]Shahid Beheshti University of Medical Sciences, National Research Institution of Tuberculosis and Lung Diseases, Clinical Tuberculosis and Epidemiology Research Center, Tehran, Iran (Islamic Republic of)
e-mail: pbaghaei@gmail.com

Background: In the recent decades, is increasing the incidence and prevalence of nontuberculous mycobacterial pulmonary disease (NTM-PD). There is still a challenging condition to diagnose and treat the patients effectively. We described the characteristics and outcome of treatment of these patients.
Design/Methods: We analyzed data of all patients with documented NTM (based on ATS criteria), who were admitted and treated at the hospital from Jan 2005 to Dec 2023.



Results: A total of 307 cases with NTM pulmonary disease were diagnosed. Most cases were male (N=168, 55%) and nonsmokers (N=211, 68.7%). Median age was 59 (range, 48-69). 48% of them were more than 60 years old. 11 (3.6%) were HIV positive. The most common symptom was cough (91%), followed by sputum (83%), dyspnea and weight loss (64.5%), loss of appetite (49.5%), fever and night sweat (39.7%), and hemoptysis 30%.
Cavitary lesion, bronchiectasis, and nodularity were reported in 59%, 62%, and 87.5% patients respectively.
Of 307 patients with NTM-PD caused mainly by *M. simiae* (41%), *M. abscessus* (12.7%), *M. kansasii* (11.4%), *MAC* (10.7%) and *M. chelonae* (8.8%). *M. Simiae* and *M. abscessus* patients were older than other groups (more than 60 years, 57% and 54%), but patients with *M. kansasii* and *MAC* were younger.
13 patients (9.2%) died, and NTM therapy failed in 11%.
Conclusions: This study illustrated NTM-PD is more common among male and depend on the species of mycobacterium, can be found more in younger individuals, that it is different from other countries. For better prognosis in NTM-PD patients should consider uniform implementation of the treatment guidelines.

EP28-967-20 Characterisation of NTM isolated in a TB research laboratory using whole genome sequencing, Lusaka, Zambia

B. Shuma,[1] S. Muzazu,[1] S. Silwamba,[1] N. Sanjase,[1] I. Mwape,[2] A. Moono,[1] M. Maimbolwa,[1] C. Luchen,[1] K. Chibesa,[1] K. Mateyo,[3] M. Muyoyeta,[2] [1]Centre for Infectious Disease Research in Zambia (CIDRZ), TB Research Department, Lusaka, Zambia, [2]Centre for Infectious Disease Research in Zambia (CIDRZ), TB Research Department, Lusaka, Zambia, [3]University Teaching Hospital (UTH), Internal Medicine, Lusaka, Zambia
e-mail: brian.shuma@cidrz.org

Background: Nontuberculous Mycobacteria (NTM) are ubiquitous mycobacteria species that may cause opportunistic disease in humans. This study aimed to characterize genomes of culture isolated NTMs using Whole-Genome Sequencing (WGS) and to explore their antimicrobial resistance patterns.
Design/Methods: WGS was performed on NTM isolates recovered during TB culture between November 2021 to February 2023 using an Illumina MiSeq platform. A total of 33 NTM obtained reads were assembled using Unicycler and the obtained assemblies were genotyped with NTM-profiler version 0.6.0 using the GTDB-220 database. Species were determined by achieving an Average Nucleotide Identity (ANI) of over 95% when mapped to reference genomes.
Comprehensive Antibiotic Resistance Database (CARD) was also utilized to evaluate the genomic antibiotic drug class resistance of the isolated NTMs, maintaining a stringent threshold of 90% gene coverage and 80% gene identity. Proportion analysis and visualisations were subsequently performed in R version 4.5.0.
Results: A total of 18 unique species were identified among the 33 sequenced NTM isolates. M. fortuitum was the most dominant species, accounting for 7/33 (21.2%). Other genotypes included M. syngnathidarum 3/33(9.1%), M. szulgai 3/33(9.1%), and M. avium 2/33 (6.1%).
In total, 31/33 (94%) NTM isolates had at least one gene to an antibiotic class present, with the majority of resistomes demonstrating genomic resistance to a combination of macrolides and penams 30/121 (24.7%), followed by rifamycins 28/121 (23.1%).

Furthermore, resistomes to a combination of isoniazid and rifamycin (10.7%) were also observed. The M. fortuitum species exhibited the highest genomic resistance to multiple antibiotic drug classes (penams, tetracyclines, aminoglycosides, macrolides and rifamycins).
Conclusions: Isolated NTMs had high rates of resistance to antibiotics that are recommended for treating NTM disease. The clinical significance of NTMs isolated during culture for mycobacterium tuberculosis should be interpreted with caution and should follow the criteria that is recommended for diagnosis of NTM disease.

EP28-968-20 Molecular subspeciation and antimicrobial resistance prediction in M. avium complex by whole genome sequencing

H. Soualhine,[1] E. Paddock Thiessen,[1] E. Rempel,[1] M. Stobart,[1] M. Sharma,[1] [1]Public Health Agency of Canada, National Microbiology Laboratory, Winnipeg, Canada
e-mail: hafid.soualhine@phac-aspc.gc.ca

Background: Genomic studies using whole genome sequencing (WGS) of *Mycobacterium avium* complex (MAC) is limited, particularly when aiming to identify strains at the subspecies level. Similarly, MAC-specific genetic determinates of antimicrobial resistance are not fully understood.
The aim of this study is to investigate genetic targets for AMR in MAC, with a focus on macrolides, aminoglycosides and fluoroquinolones, and to identify subspeciation targets through WGS analysis.
Design/Methods: Drug susceptibility testing (DST) of MAC isolates (n=450) from Canadian reference laboratory was compared to WGS using Illumina MiSeq. Analyses included SeqReport, Kraken, FastANI, and generation of consensus sequencing mapped to a reference genomes. Geneious Prime 2023.1.2 was used to annotate and extract target regions of the consensus genomes, including *16S, ITS, hsp65/groEL2,* and *rpoB.* Sequences were pooled and compared against a bank of established MAC reference strains using the Classify Sequences tool and compared with WGS analysis using the Average Nucleotide Identity (ANI).
Results: Using the Classify Sequences tool and ANI, we successfully demonstrated the identification ability of these genetic targets in 87% of isolates, with identification of clinically significant MAC isolates *M. avium* subsp. *hominissuis, M. intracellulare*, *M. chimaera* and M. colombiense.
We identified a *23S* mutation in 70% of our isolates with expected high clarithromycin resistance. However, a *gyrA* mutation was identified in less than 20 % of isolates with quinolone resistance, and less concordance between WGS-based prediction and aminoglycoside resistance. Our results also indicate that novel mechanisms, such as efflux-mediated resistance (*efpA_1)*, may contribute to drug resistance in 36 isolates of *M. avium* subsp. *hominissuis* isolates.
Conclusions: Our MAC genomics works has demonstrated potential of WGS for identification and subspeciation of MAC, a concordance between WGS-based AMR prediction and phenotypic DST for macrolide but not for aminoglycosides and quinolones

EP28-969-20 Real-world treatment status of nontuberculous NTM lung disease: Course, restart and regiment switch

C.-C. Shu,[1] [1]National Taiwan University, Graduate Institute of Clinical Medicine, Taipei, Taiwan
e-mail: ccshu@ntu.edu.tw

Background: Nontuberculous mycobacterial lung disease (NTM-LD) is a chronic infection with increasing global prevalence, particularly affecting older adults and those with structural lung conditions. Treatment is complex, prolonged, and frequently modified in clinical practice. However, real-world data on treatment discontinuation, restart, and regimen switching remain limited.
Design/Methods: This retrospective cohort study utilized data from the National Taiwan University Hospital and Taiwan's National Health Insurance Research Database (2006–2020). Adult patients diagnosed with NTM-LD were included if they received anti-NTM therapy ≥28 days. Treatment waves, restart patterns, and regimen changes were analyzed. Multivariable Cox and logistic regressions were used to identify predictors.
Results: Out of 15,589 eligible NTM-LD patients, 3,762 met the treatment criteria. Median therapy duration was 227 days; only 36.2% completed ≥12 months. Treatment discontinuation occurred in 64%, with 20.4% restarting therapy—most (73.7%) within 12 months. Among restarters, 22.4% changed regimens, often from macrolide-based to triple-drug therapy. Regimen switching was associated with prior hospitalization and suboptimal initial regimens.
Conclusions: Early discontinuation, delayed restart, and frequent regimen switching are common in NTM-LD care. These findings highlight the need for improved patient monitoring, support systems, and adherence strategies to optimize long-term outcomes.

EP28-970-20 Multiplex targeted peptidome platform for rapid identification of NTM species

J. Fan,[1] [1]Jia Fan, Biochemistry and Molecular Biology, New Orleans, United States of America
e-mail: jfan5@tulane.edu

Background: Accurate identification of mycobacterial species and subspecies is critical for appropriate antimicrobial therapy, particularly for non-tuberculous mycobacteria (NTM) such as *M. avium*, *M. intracellulare*, *M. kansasii*, and *M. abscessus*. These pathogens often mimic tuberculosis clinically but require distinct treatment regimens. Conventional culture-based diagnostics are time-consuming and lack the resolution needed for precise identification.
Design/Methods: Using species- and subspecies-specific peptide markers discovered through our PEP-TORCH discovery pipeline, we developed a clinically compatible, multiplexed targeted mass spectrometry method for mycobacterial identification. This method uses FDA-approved LC-MS/MS instrumentation and quantifies taxa-specific peptides from MGIT culture filtrates with absolute precision. Stable isotope-labeled standards were used for validation and quantification.
Results: We validated this targeted method across 63 clinical MGIT samples. The assay achieved 100% concordance with PEP-TORCH predictions and accurately distinguished species and subspecies, including *M. avium*, *M. intracellulare*, and *M. abscessus* subspecies. It also quantified mixed infections, providing co-infection ratios with high reproducibility. Compared to culture-based identification, our approach reduces turnaround time from weeks to days while increasing resolution and specificity.
Conclusions: This targeted mass spectrometry platform offers a rapid, accurate, and clinically scalable solution for comprehensive mycobacterial identification. By enabling absolute quantification of species-specific peptides using widely available instrumentation, it bridges the gap between advanced proteomics and real-world diagnostic implementation.

EP28-971-20 Burden of disease in persons with NTM in three west African countries: A prospective cohort study

E.T. Abbew,[1,2,3] M.B. Souleymane,[4,2,3] I. Ahmadu,[5] Y. Adusi-Poku,[6] D. Obiri-Yeboah,[7] T. Decroo,[2] N. Lorent,[8] L. Lynen,[2] L. Rigouts,[3,9] [1]Cape Coast Teaching Hospital, Internal Medicine, Cape Coast, Ghana, [2]Institute of Tropical Medicine, Clinical Sciences (TB/HIV Unit), Antwerp, Belgium, [3]University of Antwerp, Biomedical Sciences, Antwerp, Belgium, [4]Damien Action Foundation, NA, Niamey, Niger, [5]National Tuberculosis Reference Laboratory, NA, Saye, Zaria, Nigeria, [6]National Tuberculosis Control Program, NA, Accra, Ghana, [7]University of Cape Coast, Microbiology, Cape Coast, Ghana, [8]University Hospital Leuven, Respiratory Diseases, Leuven, Belgium, [9]Institute of Tropical Medicine, Mycobacteriology, Antwerp, Belgium

Background: Non-tuberculous mycobacterial pulmonary disease (NTM-PD) is increasing globally, with previous tuberculosis (TB) a key risk factor in sub-Saharan Africa (SSA). Management depends on species, disease type, and patient factors, yet limited awareness and diagnostics may hinder detection.
This study investigates NTM prevalence, species distribution, clinical features, and drug resistance among presumptive TB patients in West Africa
Design/Methods: This prospective cohort study (2022–2024) involved adults with presumed TB in Ghana, Nigeria, and Niger. Diagnostic tests included sputum smear microscopy, Xpert MTB/RIF (in Ghana and Niger), and mycobacterial culture. NTM species were identified using Genotype CM/AS (Bruker, Germany) and/or rrs/rpoB Sanger sequencing. Drug susceptibility testing was molecular (NTM-DR, Bruker, Germany) and phenotypic. Participants with baseline NTM were enrolled. Demographic, clinical, radiological, and laboratory data were collected. Two-year follow-up evaluated clinical outcomes including survival, loss to follow-up, and species relevance to human disease based on previously described pathogenic classifications.
Results: Of 9,975 people with presumed TB screened, 112 (1.1%) had at least one positive NTM isolate at baseline (Ghana 31, Nigeria 42, Niger 39); 100/112(89.3%) were potentially pathogenic species. Most were male (65.2%), with a mean age of 50 years and weight of 51.2kg (SD12.3). Previous TB was reported in 53.6%. Common symptoms included cough (84.8%), fever (49.1%), dyspnoea (33.0%), and haemoptysis (15.2%). Smear positivity (87.5%) and cavitation (50.9%) were frequent. MAC (34.0%), *M. fortuitum* (13.4%), and *M. abscessus* (8.9%) were most common.
Most isolates were macrolide- and amikacin-susceptible. Two-year mortality was 14.3%. Cough and smear-positivity correlated with potentially pathogenic species. No other covariates were significantly associated with smear-positivity or potentially pathogenic NTM.

Table 1: NTM species per country

Runyon Classification	NTM species	Ghana	Niger	Nigeria	Total (n)	(%)	Clinically relevant according to literature
Group I - Photochromogens	*M. kansasii*	0	1	3	4	(3.6)	Yes
	M. simiae	0	1	1	2	(1.8)	Yes
	M. asiaticum	0	5	0	5	(4.5)	Yes
Group II - Scotochromogens	*M. scrofulaceum*	0	0	2	2	(1.8)	Yes
	M. gordonae	0	0	2	2	(1.8)	No
Group III - Nonchromogens	*M. avium*	1	2	1	4	(3.6)	Yes
	M. Intracellulare	11	8	15	34	(30.4)	Yes
	M. xenopi	0	0	1	1	(0.9)	Yes
	M. malmoense	1	0	4	5	(4.5)	Yes
	M. chimaera	0	2	0	2	(1.8)	Yes
	M. interjectum	1	0	1	2	(1.8)	Yes
	M. palustre	0	9	0	9	(8.0)	Yes
	M. sherrisii	0	2	0	2	(1.8)	Yes
Group IV – rapid growers	*M. abscessus* complex	3	0	7	10	(8.9)	Yes
	M. fortuitum	12	0	3	15	(13.4)	Yes
	M. chelonae complex	0	3	0	3	(2.7)	No
	M. goodie	0	0	1	1	(0.9)	No
	M.peregrinum	0	1	0	1	(0.9)	No
Unclassified	*M. bouchedurhonense*	0	1	0	1	(0.9)	No
	M. celatum	1	0	0	1	(0.9)	Yes
	M. chitae	0	0	1	1	(0.9)	No
	M. duvalii	0	1	0	1	(0.9)	No
	M. fluoranthenivorans	0	1	0	1	(0.9)	No
	M. magaritense	1	0	0	1	(0.9)	No
	M. paraense	0	2	0	2	(1.8)	Yes
	Total	**31**	**39**	**42**	**112**		

Conclusions: This study reveals the burden of NTM in West Africa, emphasising the need for improved diagnostics, tailored management, and clinical awareness to avoid unnecessary TB treatment. Understanding the clinical burden and species distribution of NTM in TB-endemic countries will increase awareness.

EP28-972-20 Geographic distribution of most prevalent NTM disease in Brazil

G. Unis,[1] D.M. Pelissari,[1] D. Arakaki-Sanchez,[1] K. dos Santos Casado,[1] F. Dockhorn Costa,[1]
[1]Ministry of Health, Health and Environment Surveillance Secretariat, Brasilia, Brazil
e-mail: giselaunis@gmail.com

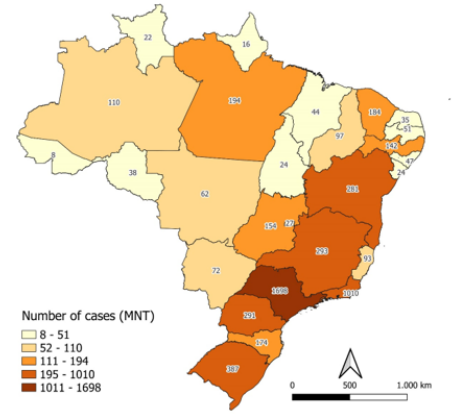
Background: Records of Nontuberculosus Mycobacteria (NTM) disease have increased over the years in Brazil and around the world. The clinical features of diseases caused by NTM often overlap with tuberculosis and other chronic lung diseases. This clinical convergence requires diagnostic differentiation to allow the definition of appropriate care and treatment and, thus, improve clinical practice.

Design/Methods: The study shows the disease occurrence by state in Brazil, based on notifications made in the Special Tuberculosis Treatment System (SITE-TB). To date, NTMs are not compulsorily notified and the cases registered, in general, were identified from the diagnostic evaluation for tuberculosis.

Results: All records from 2013 to 2024 were analyzed, totaling 5579 cases. Considering the most prevalent states, São Paulo, Rio de Janeiro and Rio Grande do Sul presented 1698, 1010 and 387 cases respectively. Analyzing the more recent period from 2020 to 2024, *M.avium* complex was the most prevalent species, followed by *M.kansasii* and *M.abscessus* group.

Regarding the three most commonly found species, the findings respectively showed female gender (55.8%, 36.9%, 58.8%), pulmonary form (86.6%, 96.7%, 85.7%), record of structural lung disease in 24.8%, 30.9% and 28.6%, immunosuppressive condition (mainly HIV) (21%, 25.7% and 19.7%), Concerning the treatment outcome (2020 to 2022), cure in 63.4%,76.4%, 59.5%, loss of follow-up in 15%, 12.4%, 12.6% and death in 11.8%,7.7%, 11.7%.

Geographic distribution of Nontuberculous Mycobacteria disease in Brazil from 2013 to 2024



Conclusions: It is worth highlighting some important findings such as a higher prevalence of *M.kansasii* in males, almost exclusively in the pulmonary form with higher cure rates. In the states with the highest prevalence, São Paulo and Rio Grande do Sul presented *M.avium* as the most frequent species, in Rio de Janeiro the most frequently found species was *M kansasii*.

The diversity of strains in Brazilian regions may be due to the timely access to culture and identification of mycobacterial species, and risk factors associated with each species.

EP29 Breaking the cycle of M. tuberculosis infection

EP29-973-20 Prevalence and risk factors of latent tuberculosis infection in Rwanda, 2024

B. Rusisiro,[1] D. Runyambo,[1] J.D. Hagenimana,[1]
P. Rukundo,[1] F. Rwabukera,[1] P. Migambi,[1] [1]-, -, Kigali, Rwanda
e-mail: byiringiro.rusisiro@rbc.gov.rw

Background: Latent tuberculosis infection (LTBI) remains a major public health concern due to its potential to progress to active TB, especially in immunocompromised individuals. About a quarter of the global population is affected by LTBI. In recent years, Rwanda's Ministry of Health introduced tuberculosis preventive treatment (TPT) for people living with HIV/AIDS and household contacts aged 5 and above. However, WHO highlights other high-risk groups needing TPT. Understanding LTBI prevalence and its risk factors in Rwanda is crucial to guide effective TPT policies.
Design/Methods: A population-based survey using multistage cluster sampling design was used. Ninety (90) villages were randomly selected across the country, with 15 households randomly chosen in each village, and one participant selected per household. A well-structured questionnaire was administered to eligible participants in May – June 2024. IGRA tests were performed for all eligible participants, followed by GeneXpert testing and chest X-rays with integrated artificial intelligence for IGRA-positive participants, to rule out active or subclinical TB. Logistic regression was used to identify factors independently associated with LTBI positivity, as determined by a positive IGRA test, among participants without confirmed TB disease.
Results: Out of 1,350 participants, 363 were tested positive to IGRA, of which 34 were confirmed to have TB, and the prevalence of LTBI was 25.7% (329 out of 1,316). The factors that were associated with latent tuberculosis infection were male sex (AOR:1.4; 95%CI: 1.0–1.8), age group of 35-44 (AOR:2.1; 95%CI: 1.1-3.9), history of imprisonment (AOR:2.0; 95%CI: 1.0–4.1) and chronic diseases (AOR:1.9; 95%CI: 1.1-3.3).
Conclusions: One in four individuals has LTBI in Rwanda. Male sex, age 35–44, history of imprisonment, and chronic diseases were significantly associated with LTBI. These findings highlight the need of targeted prevention strategies for high-risk groups, to reduce further TB transmission.

EP29-974-20 Temporal trend of tuberculosis infection incidence in a priority municipality in Brazil (2019–2024)

H.S.D. Moura,[1] A.C.V. Ramos,[2] T.N.d. Prado,[3] J.Q.R. Paiva,[1]
R.B. Martins,[1] R.J. Rosa,[1] L.P. Ferezin,[1] N.M. Ribeiro,[1]
A.L.T. Vinci,[1] W.O.B. Bernardi,[1] M.C.T. Campos,[4] R.A. Arcêncio,[1]
[1]Ribeirão Preto School of Nursing at the University of São Paulo, Department of Maternal and Child Health Nursing and Public Health, Ribeirão Preto, Brazil, [2]State University of Minas Gerais, Nursing Department, Passos, Brazil, [3]Federal University of Espírito Santo, Nursing Department, Vitória, Brazil, [4]University of Brasília, Nursing Department, Brasília, Brazil
e-mail: thiagonprado@gmail.com

Background: The identification of Tuberculosis Infection (TBI) is a key strategy for controlling the progression to active tuberculosis (TB). Monitoring TBI incidence over time allows for the assessment of prevention policies' effectiveness and the identification of potential gaps in access to diagnosis and treatment. In this context, this study aimed to evaluate the temporal trend of tuberculosis infection incidence in Ribeirão Preto, São Paulo, from 2019 to 2024.
Design/Methods: Ecological study carried out in the municipality of Ribeirão Preto, São Paulo, Brazil, considering cases of Tuberculosis Infection (TBI) reported in the IL-TB system of the municipality. Notification rates for TBI were calculated between January 2019 and December 2024. The numerator included the total number of reported cases per month, while the denominator was the municipality's population, multiplication factor of 100,000 inhabitants. For time series analysis, the seasonal decomposition method using Loess (STL) was applied to extract the trend using RStudio® software. The Prais-Winsten regression assessed the growth, decline, or stability of the trend. When variation was detected, the Monthly Percent Change (MPC) and its respective 95% confidence interval (CI95%) were calculated using Stata 12.0 software.

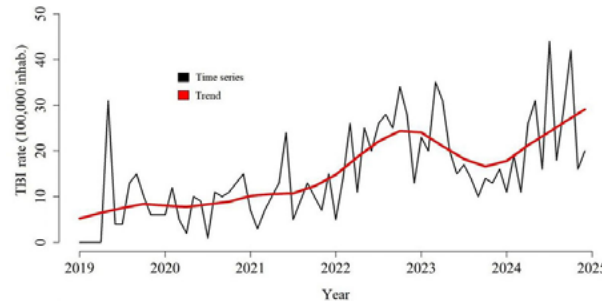


Figure 1. Temporal trend of tuberculosis case notification in Ribeirão Preto, São Paulo, Brazil (2019 - 2024).

Results: Figure 1 shows a predominantly increasing trend throughout the study period, with a brief decreasing trend between the beginning and end of 2023, followed by a return to growth in the subsequent months (MPC = 9.29; 95%CI = 5.79-12.91; p<0.01).

Conclusions: The increasing trend in TBI incidence in Brazil may be related to advancements in infection prevention strategies. The Ministry of Health has taken significant steps, including surveillance through the IL-TB system, incorporation of the IGRA test into the Unified Health System, and the introduction of new tuberculosis preventive treatment (TPT) regimens, such as 3HP.
These measures are expected to have a substantial impact on the End TB strategy, contributing to the goal of eliminating tuberculosis by 2050.

EP29-975-20 Epidemiology of tuberculosis infection among general population in a selected district of Bangladesh

T. Ibrahim,[1] S. Kabir,[1] S. Samsia Noor,[1] A.A. Rupa,[1] T. Rahman,[1] R. Sikder,[1] M.R. Haidar,[1] P. Samina,[2] S. Ahmed,[1] S.M.M. Rahman,[1] M.K.M. Uddin,[1] S. Banu,[1] [1]icddr,b, Infectious Disease Division, Dhaka, Bangladesh, [2]McMaster University, Centre for Health Economics and Policy Analysis (CHEPA), Ontario, Canada
e-mail: kmuddin@icddrb.org

Background: About 5-10% individuals infected with tuberculosis (TB) are at risk of developing active TB disease. In TB-endemic countries like Bangladesh, understanding the situation of TB infection (TBI) among general population is crucial. For the first time in Bangladesh, we assessed the epidemiology of TBI in a selected district using QuantiFERON TB Gold Plus (QFT) assay.
Design/Methods: We conducted a cross-sectional study in Narsingdi district from October 2023 to September 2025. Households (HH) were selected through multistage cluster sampling. The HH members were enrolled, asked for TB symptoms and interviewed after obtaining informed written consent. Whole Blood (4.0 mL) was collected from the participants to perform QFT test. Frequencies and mean used to report descriptive analysis, and p-value of <0.05 considered statistically significant and regression analysis applied to identify risk factors at 95% confidence interval (CI).
Results: Of 5,506 enrolled individuals with mean (±SD) age 36.6 (±18.0) years, 23 had TB symptoms and 5,483 were asymptomatic. Overall, 812 (14.8%) tested positive for QFT. Gender distribution differed significantly between QFT positive and negative groups, with higher proportion of males among tested positive, (60.3% vs 47.9%, p<0.001).
Higher percentage of participants with positive QFT results self-reported history of diabetes (61 individuals, 7.5%) and hypertension (84 individuals, 10.3%) compared to those with negative results (p<0.01).
Risk of TBI increased with age, highest odds were observed among 65+ age group (AOR: 5.23, 95% CI: 3.23–8.45). Individuals with history of TB were 2.4 times more likely to develop TBI (AOR: 2.42; 95% CI: 1.26–4.64).
Conclusions: One in every seven individuals was found to have TBI, lower than anticipated in a TB-endemic country. Risk of TBI was higher among older adults, male and individuals with a history of TB, diabetes or hypertension. Our findings highlighted importance of implementing targeted screening and prevention strategies among high-risk groups.

EP29-976-20 Temporal and geographic variations in TB case detection: A 2023 national analysis from Nigeria

E.J. Ikeh,[1] J. Ogwu,[2] M. Bathnna,[3] M. Yashim-Ankut,[4] T. Hosle,[4] O. Olupitan,[4] C. Mensah,[5] P. Dakum,[6] R. Iniobong,[7] O. Chijioke-Akaniro,[7] A. Reilly,[8] J. Kimeu,[8] [1]Institute of Human Virology Nigeria, Strategic Information, Abuja, Nigeria, [2]Institute of Human Virology Nigeria, Clinical Laboratory, Abuja, Nigeria, [3]Institute of Human Virology Nigeria, Research, Abuja, Nigeria, [4]Institute of Human Virology Nigeria, Prevention, Care & Treatment, Abuja, Nigeria, [5]Institute of Human Virology Nigeria, Office of the Chief Operating Officer, Abuja, Nigeria, [6]Institute of Human Virology Nigeria, Office of the Chief Executive Officer, Abuja, Nigeria, [7]National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Public Health Department, Abuja, Nigeria, [8]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Geneva, Nigerian Country Team, Geneva, Switzerland, Global Fund Country Team, Geneva, Switzerland
e-mail: eikeh@ihvnigeria.org

Background: Despite global TB control efforts, significant variations persist in case detection and laboratory confirmation rates across regions and seasons, impacting disease management. This study aims to analyze temporal and geographic variations in TB case detection and laboratory confirmation using data from the National Tuberculosis and Leprosy Control Programme (NTBLCP) in Nigeria.
Design/Methods: Programmatic data from the NTBLCP reference laboratory register was retrospectively analyzed for the period of January to December 2023.The dataset included, socio-demographic information data, specimen details, and laboratory results for Acid-Fast Bacillus (AFB) smear microscopy, culture, and drug susceptibility testing (DST) from 24,573 TB patients in all 36 states in Nigeria. Spatial analysis utilizing GIS mapping to identify geographic clusters of TB patients was conducted, while temporal trends were evaluated using interrupted time series analysis to account for seasonal variations and intervention impacts.
Results: The analysis revealed significant geographic disparities, with Kano and Kaduna accounting for 28.4% of national TB detections (p<0.001), while southeast states showed 42% lower confirmation rates than northern regions (95%CI:38-46%). Temporal patterns emerged with

March-May peaks (31% above average, p=0.002) and Q3 declines (19% reduction, 95%CI:15-23%). System performance varied substantially, with median processing times ranging from 5 days (Lagos) to 14 days (rural areas), while reporting delays were associated with 37% lower treatment initiation (aOR=0.63, 95%CI:0.55-0.72).
Conclusions: Targeted interventions should deploy mobile testing units to low-detection regions, implement seasonal staffing adjustments, and establish regional specimen transport hubs. Achieving 85% uniform detection across states could reduce national TB incidence by 23%.

EP29-977-20 Diagnostic integration for sustainability in resource limited countries: A case of Zambia

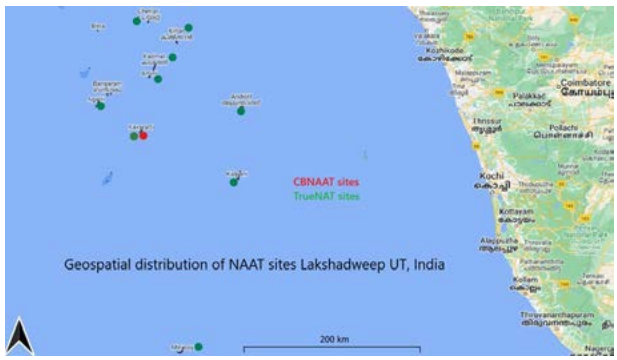
J. Mzyece,[1,2] M. Muvwimi,[1] A. Mubanga,[2] J. Chama,[3]
[1]Ministry of Health, Pathology and Laboratory Services Unit, Lusaka, Zambia, [2]Ministry of Health, National TB and Leprosy program, Lusaka, Zambia, [3]The Global Fund to Fight AIDS, Tuberculosis and Malaria,, Zambia Country Office, Lusaka, Zambia

Background and challenges to implementation: Prior to integration efforts, TB Gene-Xpert platforms in Zambia were significantly underutilized, with most facilities conducting less than one test per module per day for TB diagnostics alone. Zambia implemented a series of Diagnostic Network Optimization (DNO) initiatives to integrate multi-disease testing on TB GeneXpert platforms without negatively impacting TB services. This study aimed to evaluate the impact of successive DNO implementation on Gene-Xpert utilization and TB diagnostic testing.
Intervention or response: Using OptiDx software, we first established the baseline diagnostic network based on 2022 testing demand, referral linkages, testing sites, platforms, and costs for the HIV and TB programmes respectively. We incorporated programme expansion targets, including a 200% increase in TB testing demand from 230,000 to 450,000 GeneXpert tests, and expansion of the number of referring sites from 500 to over 2,000.
Results/Impact: The DNO output identified 25 sites out of the 298 that were operating above 90% utilisation with a turnaround time at 5 days. Twenty (20) microscopy sites were earmarked for placing GeneXpert machines. A total of 255 Genexpert sites were activated for EID, 196 for Viral Load and 48 for HPV. Cost savings from the service and maintenance contract were realized, resulting in a reduced surcharge of USD 1.20 price on all tests. TB testing volumes accounted for 82% of the total volumes after integration. The device utilisation moved from an average 50% to 80%.
Conclusions: Integration of TB, HIV infant diagnosis, HPV and VL for priority groups increased device use without affecting TB services. The increased testing volumes reduced the cost of service and maintenance. This indicates that integration of services on TB diagnostic platforms is key to sustainability while maintaining quality TB care and improving overall system efficiency in resource-limited settings.

EP29-978-20 Decentralized nucleic acid amplification testing and systematic active case finding for ending tuberculosis in the Lakshadweep Islands, India

M.J. C. G.,[1] G. A. V.,[2] S. Achanta,[3] A. T. N.,[3] A. Mohan,[3] M. Musthafa Khan,[1] A. Rouf,[1] T. Ahamed,[1] S. P. N.,[1] U. B. Singh,[4] [1]State TB Cell, Department of Health Services, UT of Lakshadweep, Kavaratti, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [3]Government of India - WHO Country Office for India, TB Technical Support Network, New Delhi,India, National TB Elimination Programme, New Delhi, India, [4]Central TB Division, MOHFW, New Delhi, India
e-mail: avgayathri@rntcp.org

Background and challenges to implementation: The Union Territory of Lakshadweep, an archipelago of ten inhabited islands in the Arabian Sea, faced significant logistical and geographical hurdles in ending tuberculosis (TB). Monsoon-related inaccessibility and limited diagnostic resources hindered timely TB detection and care.
To address these challenges, a decentralized strategy - combining systematic Active Case Finding (ACF) with island-level Nucleic Acid Amplification Testing (NAAT), was implemented in 2019.
Intervention or response: Quarlerly, population-wide ACF campaigns were conducted from 2019 to 2024 across all ten inhabited islands. Community health workers (ASHAs) administered standardized symptom screening tools at the household level, supported by chest radiography (where feasible) and facilitated sputum sample collection. NAAT machines were deployed on each island, enabling on-site testing and eliminating inter-island transport delays.
Community health workers were vital in mobilizing the population, providing health education, and ensuring treatment adherence. Due to connectivity limitations, data were recorded using paper-based tools and digitized retrospectively.
Results/Impact: Over the five years, 70,000 individuals (100%) were screened in each round. Cumulatively, 8,274 presumptive TB cases were tested via NAAT, with 58 confirmed cases (0.7%). The annual TB incidence decreased by 60%, from 31/100,000 in 2020 to 11/100,000 in 2024. The median diagnostic turnaround time reduced from 7-10 days to less than 24 hours post-NAAT decentralization. Treatment initiation rates improved to >95%, and preliminary data suggest a corresponding rise in treatment success rates.



Conclusions: This multi-component intervention, integrating quarterly systematic ACF with decentralized NAAT, demonstrated a substantial reduction in TB incidence and enhanced care cascade efficiency in this remote island setting. The Lakshadweep model highlights the effectiveness of geographically tailored, decentralized ending TB strategies, offering potential for replication in other hard-to-reach or insular populations globally.

EP29-979-20 Delays in TB treatment among people with pulmonary TB in East Africa: Findings from a prospective cohort study

K. Prabhudas-Strycker,[1,2] L. Diero,[3,4] W. Muyindike,[5,6] H. Byakagwa,[6] S. Kitur,[4] J. Mining'wo,[4] B. Ssekyanzi,[6] A. Byaruhanga,[6] F. Pabon-Rodriguez,[7] N. Navuluri,[8,9] K. Wools-Kaloustian,[2,4,10] L. Enane,[1,10] East Africa IeDEA Consortium [1]Indiana University School of Medicine, The Ryan White Center for Pediatric Infectious Disease and Global Health, Department of Pediatrics, Indianapolis, United States of America, [2]Indiana University School of Medicine, Division of Infectious Diseases, Department of Medicine, Indianapolis, United States of America, [3]Moi University College of Health Sciences, Department of Medicine, Eldoret, Kenya, [4]Academic Model Providing Access to Healthcare, (AMPATH), Eldoret, Kenya, [5]Mbarara University of Science and Technology, Department of Medicine, Mbarara, Uganda, [6]Mbarara Regional Referral Hospital, Department of Medicine, Mbarara, Uganda, [7]Indiana University School of Medicine, Department of Biostatistics and Health Data Science, Indianapolis, United States of America, [8]Duke University School of Medicine, Division of Pulmonary, Allergy, and Critical Care Medicine, Department of Medicine, Durham, United States of America, [9]Duke University, Duke Global Health Institute, Durham, United States of America, [10]Indiana University, Center for Global Health Equity, Indianapolis, United States of America
e-mail: kkstryck@iu.edu

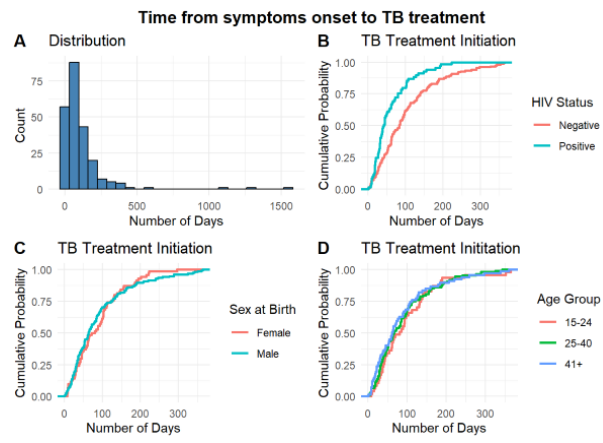
Background: Although timely tuberculosis (TB) treatment is crucial to ending the global epidemic, care delays remain a major challenge. Understanding factors associated with delayed TB care may inform programmatic interventions.

Design/Methods: The TB Sentinel Research Network of the International epidemiology Databases to Evaluate AIDS is a global prospective study of people aged ≥15 with pulmonary TB. At sites in Eldoret, Kenya, and Mbarara, Uganda, questionnaires ascertained timing from TB symptom onset to treatment initiation; number and setting of healthcare visits prior to TB diagnosis; symptoms; demographics; food insecurity; and TB- and HIV-related stigma. Robust negative binomial regression was used to examine factors associated with longer duration from TB symptom onset to treatment initiation.

Results: Among 239 participants—median age 33 years (IQR 25-44), 67% male, 30% people living with HIV (PLHIV), 50% urban—median duration from TB symptom onset to treatment initiation was 67 days (IQR 33-130) (Figure). The median number of healthcare visits prior to diagnosis was 2 (IQR 1-3).

Longer time to treatment was associated with female sex: adjusted incidence rate ratio (aIRR): 1.45, 95% CI (1.14-1.85) and previous care-seeking at a traditional healer, aIRR: 3.14 (2.15-4.61) or pharmacy, aIRR: 1.40 (1.09-1.79). Shorter duration to treatment initiation was associated with urban residence, aIRR: 0.74 (0.58-0.94), HIV-positive status, aIRR: 0.43 (0.33-0.57), and presenting with dyspnea, aIRR: 0.71 (0.54-0.93) or fatigue, aIRR: 0.45 (0.32-0.64).

Among PLHIV, perceived community HIV stigma was associated with delay, aIRR: 1.52 (1.05-2.18), but felt HIV stigma was associated with shorter time to TB treatment initiation, aIRR: 0.67 (0.47-0.97).

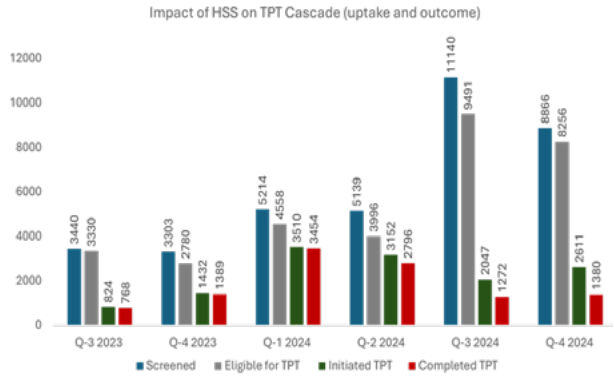


Conclusions: Women, rural residents, and persons without HIV were particularly affected by delayed TB treatment and should be targeted in TB case-finding efforts. Education and awareness efforts with pharmacies and traditional healers should be considered. Effects of HIV-related stigma should be examined further.

EP29-980-20 Building blocks for prevention: A health system strengthening approach to scaling up TB preventive treatment in Pakistan

K.U. Eman,[1] U.R. Lodhi,[1] B. Kirubi,[2] G.N. Kazi,[1] J. Creswell,[2] [1]Dopasi Foundation, Programs, Islamabad, Pakistan, [2]Stop TB Partnership, TB Reach, Geneva, Switzerland
e-mail: kinza_kz@yahoo.com

Background and challenges to implementation: Pakistan, one of the high TB burden countries, has historically struggled to implement TB preventive treatment at scale. Major barriers included provider knowledge gaps, human resource constraints, fragmented data-systems, and limited community-engagement. This initiative aimed to demonstrate how a health system strengthening model—combining digital tools, capacity building, multisectoral-coordination, and community-driven approaches—could effectively scale-up TPT access and adherence.
Intervention or response: Led by local stakeholders, the intervention implemented a health systems strengthening (HSS) model across three provinces, focusing on building capacity and enhancing service delivery. It trained 150 healthcare-providers, 200 Lady Health Workers (LHWs), and empowered TB survivors as TPT advocates. The ePreventTB digital platform, integrated with the national DHIS2 system, supported real-time data and stock management. Activities included household contact screening, outreach camps, and social support for adherence. Advocacy at district and provincial levels embedded TPT into planning. Challenges like drug-stockouts and lack of tools were addressed through emergency redistribution, interim regimens, and simplified recording and reporting systems.



Results/Impact: Over an 18-month period, a total of 37,102 individuals were screened, of whom 32,501 (88%) were found eligible for TB preventive treatment (TPT). Among those eligible, 13,576 (42%) initiated TPT, and 11,059 (82%) completed the regimen. The use of digital tools played a critical role in timely follow-up, effective monitoring, and improved continuity of care throughout the intervention. Resulted in a significant improvement compared to the previously negligible national coverage baseline. However, the progress was intermittently hindered by frequent shortages of TPT, which affected the number of individuals able to initiate treatment.
Conclusions: A HSS approach—centered on digital innovation, workforce development, and community engagement—can significantly boost TPT coverage, even amid logistical and supply chain challenges. Pakistan's experience demonstrates that institutional integration, responsive supply chain measures, adaptable tools, and community-driven delivery are critical for sustaining and scaling up TPT in high-burden settings.

EP29-981-20 Managing TB in situations of insecurity and conflict: Experiences from West and Central Africa

C.K. Houessinon,[1] A.P. Wachinou,[1,2] C. Merle,[3] D. Affolabi,[1,2] [1]West and Central African Regional Network for Tubersulosis control (WARN/CARN-TB), Executive Secretariat, Cotonou, Benin, [2]National Tuberculosis Program in Benin, Programme Management, Cotonou, Benin, [3]World Health Organization, the Special Programme for Research and Training in Tropical Diseases (TDR), Geneva, Switzerland
e-mail: ckevinhouessinon@gmail.com

Background: In West and Central Africa, political instability, terrorism, conflicts, natural disasters, and health emergencies hinder health care, including TB. We examined how these issues affect tuberculosis control and how National Tuberculosis Programs (NTPs) adapt in the region.
Design/Methods: A cross-sectional study was conducted among the 27 NTPs of the WARN/CARN regional TB network. A semi-structured questionnaire was administered by the WARN/CARN-TB executive secretariat to the NTP heads between April to September 2024 which sought to 1) map current security crises in the region(defined as an event or series of events representing a critical threat to the health, safety, security or well-being of a community or other large group of people, usually in a large area), 2) assess the impact of these crises on TB management and 3) collect information on mitigation strategies.
Results: Responses were received from 23 of the 27 countries in the network (85%) with 11 countries indicating current security crises (47.8%), most frequently due to terrorist attacks (45%). Socio-political instabilities (27%), internal armed conflicts (18%) and natural disasters (18%) were others causes of security crises in the region. Two countries reported multiple security crisis (18%). The impacts included disruption in drugs and diagnostics supplies, loss of patient follow-up, disrupted supervision activities and diminished TB financing. Various adaptation strategies were implemented, such as the use of digital tools for remote patient monitoring or supervision

activities, engaging the community and decentralizing TB services to expand the reach into communities. Security crises led to significant cross-border influxes of TB patients from neighboring countries presenting additional challenges for TB management and service provision.
Conclusions: These findings suggest that security crises are widespread and disruptive. This information will be utilized to create an SOP for NTPs, featuring the best current practices from the region.

EP29-982-20 Implementation of cascade monitoring of TB prevention in Ukraine: Achievements and challenges in the context of war

Y. Terleieva,[1] O. Medvedieva,[2] O. Pozdnyakov,[3] L. Prilepina,[4] O. Sakalska,[2] L. Markovtsiy,[5] N. Klymenko,[6] A. Kravchuk,[2] D. Levandovska,[7] N. Chursina,[8] O. Rossovska,[2]
[1]Public Health Center of the MOH of Ukraine, TB, Kyiv, Ukraine, [2]Public Health Center of the MOH of Ukraine, TB Management and Counteraction Department, Kyiv, Ukraine, [3]Public Health Center of the MOH of Ukraine, Epidemiological Surveillance Department, Kyiv, Ukraine, [4]Public Health Center of the MOH of Ukraine, Statistics and Analysis, Kyiv, Ukraine, [5]Zakarpattia Regional TB Centre, TB, Uzhhorod, Ukraine, [6]Donetsk Regional TB Centre, TB, Donetsk, Ukraine, [7]Cherkasy Regional TB Centre, TB, Cherkasy, Ukraine, [8]Volynskyi Regional TB Centre, TB, Lutsk, Ukraine
e-mail: i.terleieva@phc.org.ua

Background and challenges to implementation: According to the WHO, 25% of the world's population is infected with the mycobacterium tuberculosis. In the context of the war against Ukraine, due to population migration, destroyed infrastructure, constant rocket attacks, lack of human resources and limited access to medical care, especially in areas where active hostilities are taking place, the prevalence of TB is increasing. The introduction of short TB preventive treatment regimens will have significant benefits for both individuals and public health.
Intervention or response: Ukraine has implemented modern algorithms for the diagnosis and treatment of TB infection in national standards in accordance with the latest WHO recommendations and include diagnosis of TB infection among high-risk groups and short rifapentine preventive treatment regimens, regular cascade monitoring of examination, prescription of preventive treatment and tracking of treatment outcomes among both contact and other risk groups, such as people receiving immunosuppressive therapy, people with silicosis, and HIV infection.
Results/Impact: During the second half of 2024, 43502 people at risk for TB infection diagnosis and treatment were identified in Ukraine. After exclusion of TB, 38712 people (89%) were subject to TB infection diagnosis, 19090 (49%) were diagnosed, 4974 (26%) were diagnosed with TB infection, 12146 (28%) were indicated for preventive treatment (including those for whom TB diagnosis is not required - children under 5 years of age and PLHIV), and 9780 (81%) started treatment.
Conclusions: In the context of war, active expansion of access to TB diagnostics, implementation of cascade monitoring of TB diagnosis and treatment not only among contact persons but also among other priority groups is extremely important to reach all those who need it and, as a result, to avoid the negative consequences of increased TB infection.

EP30 Economic evaluations to improve TB care

EP30-983-20 Global impact of the BPaL/BPaLM regimens on tuberculosis treatment outcomes and costs: A modeling analysis

T. Ryckman,[1] D.W. Dowdy,[2] [1]Johns Hopkins School of Medicine, Division of Infectious Diseases, Baltimore, United States of America, [2]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology of Microbial Diseases, Baltimore, United States of America
e-mail: tryckma1@jh.edu

Background: The 6-month regimen of bedaquiline, pretomanid, and linezolid, with or without moxifloxacin (BPaL/BPaLM), is recommended by the WHO for treatment of most rifampin-resistant tuberculosis (RR-TB) and is being rapidly scaled up globally. BPaL/BPaLM is highly efficacious, safer, and cost-saving compared to previous RR-TB regimens. We estimated the global impact of BPaL/BPaLM on treatment outcomes and costs.
Design/Methods: Based on current regimen usage and country-reported projections, we estimated the proportion of people treated for RR-TB who would initiate BPaL/BPaLM and other categories of regimens in 215 countries over 2025-2034.
We also considered usage of these other regimens under a comparator scenario without BPaL/BPaLM. We combined estimates of regimen usage with data on regimen-specific treatment outcomes from operational research and projections of the number of people treated for RR-TB over time to estimate the numbers of people experiencing treatment success, failure, death, and loss-to-follow-up under each scenario.
We used Global Drug Facility prices and non-drug costs from the SLASH-TB model to estimate global savings from BPaL/BPaLM.
Results: We projected 2.0 million people would be treated for RR-TB over 2025-2034, with 1.8 million receiving BPaL/BPaLM under the BPaL/BPaLM scenario (Figure).
Under the comparator scenario without BPaL/BPaLM, we projected 1.4 million treatment successes (71% of people treated), 374,000 deaths (14%), 62,000 failures (3%), and 256,000 losses to follow-up (13%).
Depending on the extent to which early operational research-based outcomes can be replicated as BPaL/BPaLM is scaled up, treatment successes could increase to 1.6-1.8 million (78-91% of people treated) and deaths could decrease to 68,000-154,000 (3-8%). Drug and non-drug costs were projected to decrease from $976 million to $893 million and from $3.1 billion to $2.1 billion, respectively.
Conclusions: Over 10 years, anticipated uptake of BPaL/BPaLM could result in up to 416,000 additional treatment successes, 206,000 lives saved, and $1.1 billion in savings.

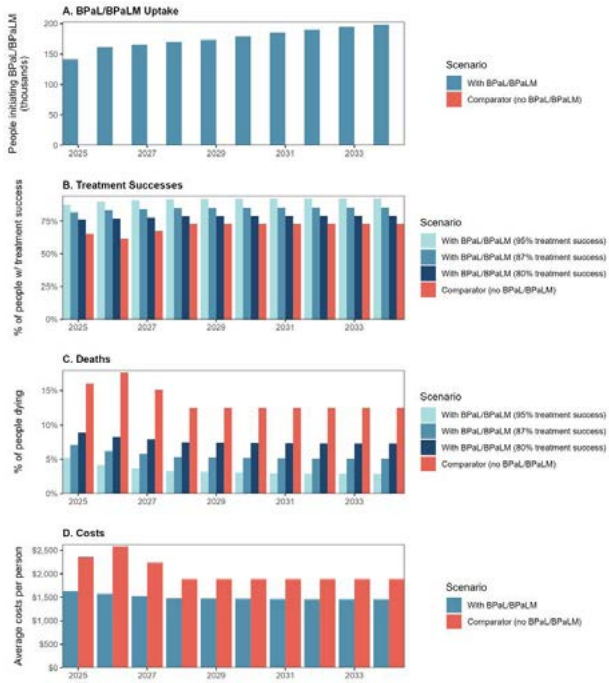


Figure: Projected treatment outcomes and drug costs with and without BPaL/BPaLM.
Figure shows number of people with RR-TB initiating BPaL/BPaLM (panel A), annual average treatment successes and deaths (panels B and C), and annual costs per person treated (panel D, with both drug and non-drug costs) from 2025-2034, under a scenario with current levels and anticipated scaleup of BPaL/BPaLM (blue bars) and a comparator scenario without BPaL/BPaLM (red bars). Treatment outcomes varied across three scenarios with BPaL/BPaLM that varied in the probability of treatment success among those initiating BPaL/BPaLM (95%, 87%, and 80%).

EP30-984-20 Evaluating the clinical and economic impact of isoniazid resistance detection in tuberculosis molecular testing in Indonesia

I.N.I.P. Dharmawan,[1] A. Fuady,[2] B.I.R. Sumroni,[3] S. Husna,[3] M.P. Wardoyo,[4] E. Anugrapaksi,[5] E. Burhan,[1] [1]Faculty of Medicine, Universitas Indonesia-Persahabatan Hospital, Department of Pulmonology and Respiratory Medicine, Jakarta Timur, Indonesia, [2]Faculty of Medicine, Universitas Indonesia-Dr. Cipto Mangunkusumo Hospital, Department of Community Medicine, Jakarta Pusat, Indonesia, [3]Respiratory Programmatic Implementation and Research Institute, Clinical Research, Jakarta Timur, Indonesia, [4]Respiratory Programmatic Implementation and Research Institute, Medical Scientific Writing, Jakarta Timur, Indonesia, [5]Respiratory Programmatic Implementation and Research Institute, Clinical Research, Jakart Timur, Indonesia
e-mail: ahmad.fuady@yayasanrpri.org

Background: Indonesia ranks as the second-highest tuberculosis (TB) burden country globally, with approximately 16% of TB cases estimated to be isoniazid (INH)-resistant. While rifampicin (RIF) resistance is currently prioritized in molecular testing, the limited detection of INH resistance may delay optimal treatment. Early identification of both RIF and INH resistance has the potential to inform more appropriate regimens, reduce poor treatment outcomes, and mitigate the risk of drug resistance amplification. This study evaluates the clinical and eco-

nomic impact of incorporating INH resistance testing alongside current RIF resistance testing within molecular diagnostic algorithms in Indonesia.
Design/Methods: A decision tree model was developed to compare outcomes between two diagnostic strategies:
1. Molecular testing for RIF resistance only, and;
2. Testing for both RIF and INH resistance.
The analysis was conducted from a societal perspective, using estimates based on 1,060,000 individuals undergoing molecular testing in Indonesia in 2023. Data sources included WHO reports, published literature, national program data, and patient surveys.
Outcomes evaluated included treatment success, failure, relapse, loss to follow-up, mortality, and resistance acquisition. Economic outcomes included diagnostic and treatment costs, and cost per successful TB treatment.
Results: Compared to RIF-only testing, incorporating RIF+INH resistance detection resulted in an estimated 20.7% increase in initial diagnostic and treatment costs in the first cycle. However, there were substantial cost reductions in subsequent treatment cycles due to fewer cases of relapse, treatment failure, and resistance acquisition in patients with INH-resistant TB. Costs related to loss to follow-up were also lower. Overall, the average direct medical cost per treatment success was reduced by approximately USD 9.
Conclusions: Expanding molecular testing to include INH resistance may improve treatment targeting and reduce long-term programmatic costs, despite higher initial expenditures.
These findings support further evaluation of broader drug resistance detection strategies to enhance TB care and control.

EP30-985-20 Cost impact of improving test performance in community screening

E. Venero-Garcia,[1] K.C. Horton,[1] A. Schwalb,[1] M.J. Harker,[1] L. Goscé,[1] L. O'Brien,[1] A. Gun,[1] T. Sumner,[1] R. Bakker,[1,2] T. Prys-Jones,[1] R.G. White,[1] R.M. Houben,[1] [1]London School of Hygiene and Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [2]KNCV Tuberculosis Foundation, KNCV Tuberculosis Foundation, The Hague, Netherlands
e-mail: Elena.Venero-Garcia@lshtm.ac.uk

Background: GeneXpert Ultra's specificity has usually been assessed among individuals who present in clinics with signs or symptoms suggestive of tuberculosis (TB). However, test performance is likely different in a community population, where lower disease prevalence would increase the number of false positive diagnoses, impacting both individuals treated and health system costs.
We evaluated the potential impact of improved specificity of GeneXpert Ultra on treatment costs for community screening.

Design/Methods: We adapted a deterministic TB model for South Africa, Brazil and India. Community screening was introduced with a five-year scale-up (2025–2030), continuing until 2035. From 2030, each year, the intervention screened 80% of adults who were not receiving TB treatment, using chest X-ray with confirmatory GeneXpert Ultra. We modelled four scenarios reducing the probability of a false positive result from GeneXpert Ultra by 50%, 75%, 90%, and 95%, and compared them to a baseline scenario with specificity from community-based studies and literature. We considered false positive diagnoses to include individuals with a positive GeneXpert Ultra result, but without bacteriologically non-confirmed or bacteriologically confirmed TB. Budget impact estimates were compared across scenarios to assess epidemiological and economic impact.
Results: Number of individuals initiating treatment was reduced by 14-17% (for 50% reduction) to 35-61% (for 95% reduction scenario). A 50% reduction in the probability of false positives decreased treatment costs from 64 to 787 million USD (14-30% of total treatment costs) across India, South Africa, and Brazil, while a 95% reduction led to savings of 122 million to 1.4 billion USD (27-56%) (Figure). Country-specific variations in impact on treatment costs were driven by DR-TB prevalence and regimen costs.

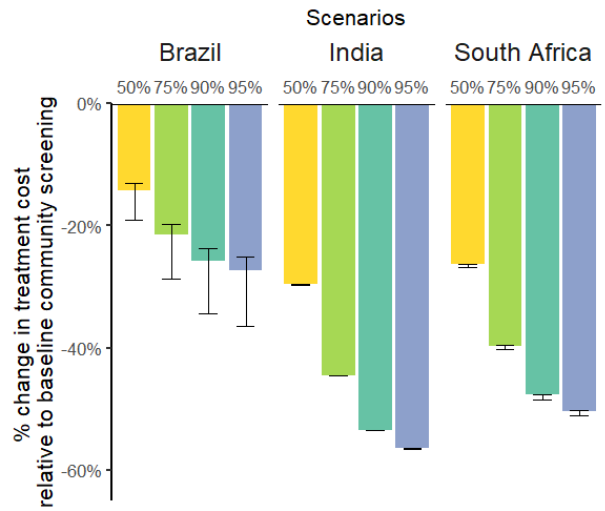

Figure. Proportional reduction in treatment costs of community screening - by country.

Conclusions: This study highlights the need to quantify test performance in real-world settings, including community screening, to avoid overestimating the impact on individuals and health system costs from overtreatment.

EP30-987-20 Chest X-ray and Xpert MTB Rif-Ultra more accurate but costlier than symptom-based screening for same day TB screening, diagnosis and treatment initiation

G. Amanya,[1] A. Mulindwa,[2] A. Burua,[3] D. Tugumisirize,[2] M. Nabukenya M,[3] T. Stavia,[2] R. Byaruhanga,[2] N. Modi,[2] L. Mukisamuzaale,[2] B. Ayebazibwe,[2] E. Tweyongyere,[2] S. Zawedde,[3] [1]National TB and Leprosy Programe, Infectious Diseases Institute, Kampala, Uganda, [2]National TB and Leprosy Programe, Communicable Disease Prevention and Control, Kampala, Uganda, [3]Makerere University, Infectious Diseases Institute, Kampala, Uganda
e-mail: geofreyamanya@gmail.com

Background: Uganda has implemented Mobile clinics fitted with Chest X-ray, CAD4TB and GeneXpert among high-risk patients. We thought to determine costs of conducting same-day TB screening, diagnosis, and treatment initiation.

Design/Methods: Costs were collected using a standardized WHO cost data collection tool on Fixed costs(van, license, servicing and maintenance), Variable costs(Testing and treatment costs, sputum cups, Xpert test) other costs like fuel, internet stationery, sample referral, human resource level of effort(LOE), we divided direct costs into capital and recurrent costs based on direct human resource contribution(ratios of LOE across all ACF activities, weighted based the total person-time contribution). This data was evaluated against service utilization (e.g. number of patients). The main outcomes of the analysis included 1) unit costs of key service/activity ACF components (calculated based on direct total costs of each discrete service/activity divided by the total number of patients who received the service); and 2) cost per yield (presumptive and confirmed TB diagnosis), we compared these to catastrophic costs covering all aspects.

COST CALCULATIONS

Fixed Costs	Over Study Period		Per Person Screened		Per Person Positive and		Percent of Costs
Van and License	UGX	198,814,177	UGX	34,516	UGX	2,485,177	23.4
Servicing and Maintenan	UGX	98,599,845	UGX	17,118	UGX	1,232,498	11.6
Annual Salary Costs							
Van Staff	UGX	245,314,936	UGX	42,589	UGX	3,066,437	28.9
Supportive Staff	UGX	92,620,800	UGX	16,080	UGX	1,157,760	10.9
Testing and Treatment Costs							
Sputum Cups	UGX	387,932	UGX	67	UGX	4,849	0.0
Xpert Tests	UGX	100,036,060	UGX	17,367	UGX	1,250,451	11.8
Treatment	UGX	33,286,000	UGX	5,779	UGX	416,075	3.9
Other Costs							
Fuel	UGX	77,063,569	UGX	13,379	UGX	963,295	9.1
Internet and Stationery	UGX	419,049	UGX	73	UGX	5,238	0.0
Sample Transport	UGX	2,409,813	UGX	418	UGX	30,123	0.3
TOTAL	UGX	848,952,182	UGX	147,388	UGX	10,611,902	100.0
	USD	229,217.09	USD	39.79	USD	2,865.21	100.0

Results: In six months, a total of 5760 people were screened with X-Ray, 1172 tested with Xpert and a total of 80 people were positive, 98% were treated and initiated on the same day. Annual salaries accounted for 40% of the total costs, followed by fixed at 32%, testing and treatment at 16%, and other costs at 9%. Total costs over the study period were 229,217 USD. It cost 39.8 USD per-person screened and 2,865.21 USD per-person positive and treated.

Background and challenges to implementation: Portable X-ray, CAD, and GeneXpert fitted on Mobile TB clinic for enhancing TB detection among high-risk patients, has been implemented in Uganda, we thought to determine mobile TB clinics costs of conducting same-day TB screening, diagnosis, and treatment initiation.

Intervention or response: Costs were collected using a standardized WHO cost data collection tool on Fixed costs(van, license, servicing and maintenance), Variable costs(Testing and treatment costs, sputum cups, Xpert test) other costs like fuel, internet stationery, sample transport, human resource level of effort(LOE), we divided direct costs into capital and recurrent costs based on direct human resource contribution (ratios of LOE across all ACF activities, weighted based the total person-time contribution). This data was evaluated against service utilization (e.g. number of patients) over the entire program. The main outcomes of the analysis included 1) unit costs of key service/activity components of the ACF intervention (calculated based on direct total costs of each discrete service/activity divided by the total number of patients who received the service); and 2) cost per yield (cost per presumptive TB patient identified and per confirmed TB diagnosis).

Results/Impact: In six months, a total of 5760 people were screened with X-Ray, 1172 tested with Xpert and a total of 80 people were positive, 98% were treated and initiated on the same day. Annual salaries accounted for 40% of the total costs, followed by fixed at 32%, testing and treatment at 16%, and other costs at 9%. Total costs over the study period were 229,217 USD. It cost 39.8 USD per-person screened and 2,865.21 USD per-person positive and treated.

Conclusions: In the short term, the mobile TB clinic model proved costly and exceeded typical benchmarks. We recommend scaling up this intervention beyond 6 months to maximize efficiencies and lower per-person costs, as marginal costs are expected to decrease significantly with increase in the number of people screened and treated, thereby averting future transmission and offsetting future societal burdens.

EP30-988-20 Patient and household costs of DR-TB care-seeking: Results from the Bring BPaL2Me trial in South Africa

K. Hirasen,[1] D. Evans,[1] C. Ramushu,[1] Y. Kadernani,[2] K. Lowensen,[2] K. Mlandu,[2] N. Ndjeka,[3] J.E. Farley,[2,4,5]
[1]Health Economics and Epidemiology Research Office (HE2RO), Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Johns Hopkins University, School of Nursing, Baltimore, United States of America, [3]South African National Department of Health, (NDoH), Pretoria, South Africa, [4]Center for Infectious Disease and Nursing Innovation, Johns Hopkins University, Baltimore, United States of America, [5]TB Research Advancement Center, Johns Hopkins University, Baltimore, United States of America
e-mail: khirasen@heroza.org

Background: Tuberculosis (TB), disproportionately affects the poor and marginalised. Pre-treatment costs can impede an already financially constrained individual/household, restricting care-seeking, and once in care, serve as a barrier to optimal treatment outcomes. We describe pre-drug-resistant (DR)-TB treatment patient and household costs in South Africa.
Design/Methods: As part of the Bring BPaL2Me cluster randomised trial, adults (≥18 years) initiating DR-TB treatment in South Africa's Eastern Cape and KwaZulu-Natal provinces were surveyed using the World Health Organization (WHO) patient cost instrument, retrospectively recalling costs associated with TB care-seeking prior to diagnosis. Costs were categorized broadly into direct (medical and non-medical), indirect (opportunity costs), and household/family costs, and stratified by pre-treatment provider. We present mean costs in 2025 United States Dollars (USD).
Results: A total of 569 patients initiated DR-TB treatment and completed the baseline patient cost survey between July 2023-March 2025. Participants were male (358; 62.9%), with a mean age of 38.8±11.8 years, and most living with HIV (304; 53.4%). Approximately, half (314; 55.2%) were diagnosed and initiated treatment at study enrolment, and half (255; 44.8%) sought care for their TB-symptoms, at up to 4 healthcare providers prior to diagnosis.
On average, pre-DR-TB treatment patient costs were $30.8 per patient, driven primarily by direct medical costs ($20.2) and specifically, hospitalisation ($78; n=11/569 (1.9%)), consultation ($10), and medication ($3.7) costs. This was followed by indirect costs ($15.4) and lastly by direct non-medical costs ($8.3), driven by transport and food costs across both outpatient visits and hospital admissions (Table 1).
Conclusions: Even before obtaining a formal diagnosis, patients incur costs of $30.8 across multiple healthcare providers (equivalent to a month's pre-diagnosis household income $32.4). In settings like South Africa, where TB services are provided at zero-cost, costs incurred whilst seeking a DR-TB diagnosis can be detrimental to patients' economic well-being and subsequent TB treatment.

Cost category	Description	Provider 1[1] (n=241)	Provider 2[1] (n=39)	Provider 3+[1] (n=9)	Total (N=255)

EP30-989-20 Catastrophic cost of TB-related death: Results from a cluster-randomised controlled trial in South Africa

K. Hirasen,[1] D. Evans,[1] L. Limakatso,[2,3] M.P. Abraham,[2] P. MacPherson,[4] N.A. Martinson,[2,5] [1]Health Economics and Epidemiology Research Office (HE2RO), Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Perinatal HIV Research Unit (PHRU), Infectious Diseases and Oncology Research Institute, University of the Witwatersrand, Soweto, Johannesburg, South Africa, [3]Africa Health Research Institute (AHRI), University of KwaZulu-Natal, Durban, South Africa, [4]School of Health & Wellbeing, University of Glasgow, Glasgow, United Kingdom of Great Britain and Northern Ireland, [5]Tshepong Hospital Complex, Department of Internal Medicine, University of the Witwatersrand, Klerksdorp, South Africa
e-mail: khirasen@heroza.org

Background: Tuberculosis (TB), disproportionately affects the poor and marginalised. While seeking diagnosis and completing treatment, 32-83% of patients/households incur catastrophic costs, defined as TB-related costs ≥20% of annual pre-TB household income. However, costs attributed to TB-related death are not well understood. This

is particularly pertinent, as TB is a leading cause of death in South Africa. We describe funeral/burial costs of TB-related death and the payment categories utilised to cover these expenses.

Design/Methods: As part of an intensified household contact tracing cluster-randomised trial, index TB-patients (living, or deceased ≤6 weeks after a confirmed TB diagnosis) residing in two high TB/HIV co-infection South African provinces (Free State, and Limpopo), were surveyed using a standardised patient cost instrument. Funeral and burial costs associated with TB-related death, payment categories utilised, and household income were recorded. Mean costs are presented in 2025 United States Dollars (USD).

Results: A total of 282 index TB-patients (or their households) were surveyed from April 2017-March 2019. Over 15-months of follow-up, 44 (15.6%) TB-related deaths were recorded, most occurring soon after TB diagnosis (41; 93.2%) within a mean of 36.3±67.4 days.

Average funeral/burial costs were $1,310 per household, paid for primarily through funeral insurance payouts ($731.9), household direct out-of-pocket payments ($409.3), guest contributions ($236.4) and household dissaving's (securing loan/s and/or selling assets) ($173.3). Across wealth quintiles, households had an average funeral/burial shortfall of $558. While more common among households in lower wealth quintiles (88.9%, 50%, and 46.2% in the bottom three quintiles, respectively), half of households with a TB-related death (21; 50%) experienced catastrophic costs (Table 1).

Table 1. Household cost of TB-related death and payment category/method by wealth quintile (N=44)

Expense and payment category (2025 USD* mean, std)	Wealth quintile‡ 1: 50-$648.3 p/y (n=11)	Wealth quintile‡ 2: $648.3-$1,945 p/y (n=4)	Wealth quintile‡ 3: $1,945-$2,269 p/y (n=13)	Wealth quintile‡ 4: $2,269-$4,537 p/y (n=7)	Wealth quintile‡ 5: >$4,537 p/y (n=9)	Total (N=44)
Funeral/burial expenses (A)	$1,335 ($764)	$1,680 ($2,154)	$905.0 ($647)	$1,557 ($847)	$1,640 ($1,060)	$1,310 ($991.0)
Household (out-of-pocket payments)† (B)	$93.3 ($177.7)	$1,195 ($2,231)	$447.6 ($695.6)	$328.5 ($331.7)	$448.6 ($468.3)	$409.3 ($826.6)
Guest contributions§ (C)	$212.2 ($276.3)	$249.9 ($445.7)	$59.0 ($78.9)	$172.9 ($156.6)	$650.6 ($409.2)	$236.4 ($324.1)
Household (dissaving's payments)¶ (D)	$194.0 ($283.5)	$51.3 ($46.2)	$235.7 ($559)	$4.3 ($9.7)	$234.1 ($303.2)	$173.3 ($360.3)
Funeral insurance pay-outs (E)	$577.1 ($342.4)	$244.9 ($221.8)	$372.9 ($376.9)	$1,476 ($1,256)	$1,162 ($1,330)	$731.9 ($975.8)
Total income (F)=(B+C+D+E)	$1,076 ($878.5)	$1,680 ($2,185)	$1,016 ($1,013)	$1,926 ($1,119)	$2,161 ($1,877)	$1,443 ($1,352)
Funeral/burial (shortfall)** (A-F)	$1,112 ($850.0)	$435.4 ($-)	$208.7 ($260.2)	$432.2 ($-)	$603.3 ($406.4)	$558.4 ($587.5)
Catastrophic costsΔ (n, %)	8 (88.9%)	2 (50.0%)	6 (46.2%)	3 (42.9%)	2 (22.2%)	21 (50.0%)

TB: tuberculosis; USD: United States Dollar; std: standard deviation; p/y: per year.

*Average exchange rate Q1 2025: 1 USD = 18.51 South African Rands (ZAR).

‡Wealth quintile based on annual pre-TB household income.

†Direct out-of-pocket payments made by household members.

§Financial contributions from guests visiting the household / at the funeral.

¶Funds sourced through securing loan/s and/or selling asset/s.

**Limited to patients/households were total funeral/burial expenses > total payments across payment categories (n=17). Funeral/burial costs exceeding total payments - (household direct out-of-pocket payments, guest contributions, household dissaving's and funeral insurance pay-outs).

ΔI(total funeral/burial expenses – funeral insurance pay-outs)/(annual pre-TB household income)I ≥ 20% threshold.

Average annual pre-TB household income = $2,703±$2,278

Conclusions: Without accounting for pre-diagnosis and on-treatment costs, half of households experiencing TB-related death incurred catastrophic costs resulting from funeral/burial expenses. Additionally, the cost of TB-related death ($1,310) was equivalent to half a year's household income ($2,710), likely financially devastating for surviving household-members.

EP30-990-20 Cost-effectiveness of community tuberculosis screening in South Africa

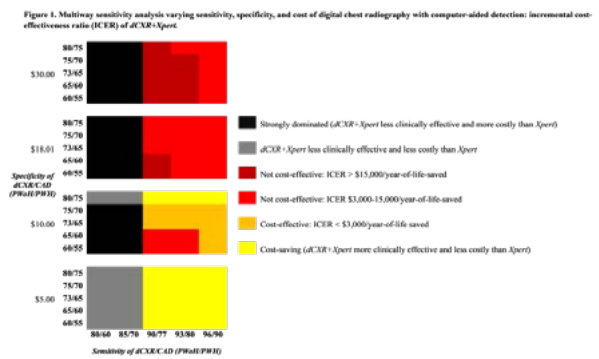
J.N. Deleger,[1] S.N. Khatami,[1,2] M.L. Jones,[1] M.S. Jalali,[2,3] A.D. Paltiel,[4,5] E.B. Wong,[6,7] K.A. Freedberg,[1,3,8] R. Wood,[9,10] C.R. Horsburgh,[11] K.P. Reddy,[1,3,12] [1]Massachusetts General Hospital, Medical Practice Evaluation Center, Boston, United States of America, [2]Massachusetts General Hospital, Institute for Technology Assessment, Boston, United States of America, [3]Harvard Medical School, N/A, Boston, United States of America, [4]Yale School of Public Health, Public Health Modeling Unit, New Haven, United States of America, [5]Yale School of Public Health, Department of Health Policy and Management, New Haven, United States of America, [6]Africa Health Research Institute, N/A, Durban, South Africa, [7]University of Alabama at Birmingham, N/A, Birmingham, United States of America, [8]Massachusetts General Hospital, Division of General Internal Medicine, Boston, United States of America, [9]Desmond Tutu Health Foundation, N/A, Cape Town, South Africa, [10]University of Cape Town, Department of Medicine, Cape Town, South Africa, [11]Boston University School of Public Health and School of Medicine, Departments of Epidemiology, Biostatistics, Global Health and Medicine, Boston, United States of America, [12]Massachusetts General Hospital, Division of Pulmonary and Critical Care Medicine, Boston, United States of America
e-mail: kpreddy@mgh.harvard.edu

Background: The World Health Organization recommends community-based tuberculosis active case finding using digital chest radiography with computer-aided detection (dCXR/CAD) and/or rapid molecular diagnostics, but the clinical and economic outcomes are unclear.

Design/Methods: Using a microsimulation model, we evaluated four community-based tuberculosis screening strategies for adults in South Africa: (1) dCXR/CAD (*dCXR*); (2) sputum Xpert Ultra (*Xpert*); (3) dCXR/CAD followed by confirmatory sputum Xpert (*dCXR+Xpert*); and (4) *No Screening*. In *dCXR+Xpert*, individuals with a negative sputum test or unable to provide sputum may be referred for empiric tuberculosis treatment. In the base case, tuberculosis disease prevalence (people without HIV [PWoH]/people with HIV [PWH]) was 0.64%/1.23%. Sensitivity/specificity/cost for dCXR/CAD were 90%/73%/$18 for PWoH and 77%/65%/$18 for PWH; for Xpert Ultra, they were 91%/99%/$29 for PWoH and 69%/98%/$29 for PWH. Model outcomes included life-years, costs, and incremental cost-effectiveness ratios (ICERs), where ICERs <$3,000/year-of-life saved (YLS) (opportunity cost-based threshold) would be cost-effective. We conducted sensitivity analysis around dCXR/CAD sensitivity/specificity/cost and other key parameters.

Results: In the base case, *dCXR* identifies the most individuals with tuberculosis but also produces the most false-positives, yielding higher life-years and costs as more people initiate tuberculosis treatment. *Xpert* yields the fewest number of individuals initiating tuberculosis

treatment, and *dCXR+Xpert* produces the fewest false-positives. At the lifetime horizon, *Xpert* and *dCXR* are both cost-effective (ICERs $1,060/YLS and $1,350/YLS). Given currently reported performance characteristics of dCXR/CAD and an estimated dCXR/CAD cost of $18/person, *dCXR+Xpert* could be cost-effective if tuberculosis prevalence (in PWoH/PWH) is ≥1.75%/3.38%. *dCXR+Xpert* could also become cost-effective when dCXR/CAD sensitivity or specificity are higher, or dCXR/CAD cost is lower (Figure 1).



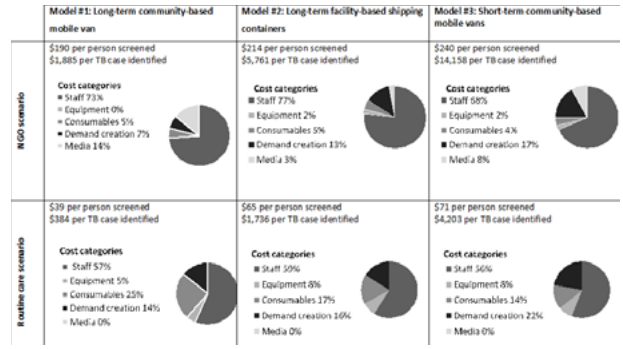
Conclusions: *Xpert* and *dCXR* are likely cost-effective community tuberculosis screening strategies in South Africa but may require substantial scale-up investments. Higher tuberculosis prevalence or technological advances or cost reductions for dCXR/CAD could make *dCXR+Xpert* a cost-effective alternative.

EP30-991-20 The impact and cost of using mobile digital X-ray units to detect pulmonary tuberculosis in South Africa

L. Coetzee,[1] D. Evans,[1] A. Fonanda,[2] H. Hausler,[3,4] L. Booyens,[3] J. Steingo,[3] K. Hirasen,[1] L. Jamieson,[1] M. Kubjane,[1] G. Meyer-Rath,[1,5] [1]Health Economics and Epidemiology Research Office, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Atlantic Institute, Global Fellows, Oxford, United Kingdom of Great Britain and Northern Ireland, [3]TB HIV Care, TB HIV Care, Johannesburg, South Africa, [4]University of Pretoria, Family Medicine, Pretoria, South Africa, [5]Boston University, Global Health, School of Public Health, Boston, United States of America
e-mail: lcoetzee@heroza.org

Background: Digital chest X-ray (dCXR) with computer-aided detection tools can assist in early TB diagnosis, closing diagnostic gaps left by symptom-based screening and limited access to confirmatory tests.
This study estimated the impact and cost of three dCXR delivery modes in detecting pulmonary TB (PTB): one long-term community-based mobile van (LT-vans), five long-term facility-based containers (LT-containers), and three short-term community-based mobile vans (ST-vans).

Design/Methods: We collected cost and outcome data alongside pilot implementation of nine dCXR units deployed in four districts across two provinces (Western Cape and KwaZulu-Natal) in South Africa for 1-19 months per district in 2020-2022. High TB prevalence sites were selected using geographic information system (GIS) hotspot mapping. Electronic study databases provided data on dCXR screening positivity. Economic and financial costs were estimated from the provider perspective in 2024 US$, based on micro-costing and expenditure analysis. Costs from pilot implementation were adjusted for routine implementation based on expert opinion.
Results: A total of 34,110 clients were screened using dCXR; 8,605 (25.2%) had an abnormal X-ray suggestive of TB, and 1,372 (4.0%) TB cases were identified. The average number of dCXR screenings per month and TB positivity (i.e., people diagnosed with TB divided by people screened with dCXR) per model were 189 (10.1%) for LT-vans, 434 (3.7%) for LT-containers, and 1,366 (1.7%) for ST-vans. The average economic (financial) cost was $190 ($103) per person screened for LT-vans, $214 ($125) for LT-containers, and $240 ($148) for ST-vans, and $1,885 ($1,021), $5,761 ($3,361) and $14,157 ($8,741) per TB case identified, respectively. The extent of media engagement, demand-creation activities, staff contingents, and salaries drove cost differences.



Conclusions: While the LT-vans reached underserved rural populations, ST-vans yielded the highest monthly volume. TB test positivity was highest for the LT-van, leading to the lowest costs per person screened and per TB case identified.

EP30-992-20 Cost-effective tuberculosis diagnosis: Evaluating sputum pooling with Xpert MTB/RIF Ultra in Rwanda

F. Hakizayezu,[1] J.C. Ngabonziza Semuto,[1] [1]Rwanda Biomedical Centre, Research Innovation and Data Science, Kigali, Rwanda
e-mail: francohakiza9@gmail.com

Background: This study explores the accuracy and reliability of a sputum pooling strategy using Xpert MTB/RIF Ultra to improve cost-effective TB diagnosis in Rwanda. Given the tool's high cost and the TB burden in low- and middle-income countries, the approach offers a potential solution for enhancing diagnostics in low-incidence areas.
Design/Methods: A cross-sectional study was conducted on sputum samples collected from individuals suspected TB-patients. Initially, samples were tested individually using Xpert MTB/RIF Ultra, followed by retesting the samples; each four samples pooled together following a pre-established standard operating procedure (SOP). Laboratory investigation were carried out at Rwanda National Reference Laboratory, a regional center of excellence for resistant TB diagnosis. Data were analyzed with StataSE 13 to measure and evaluate the specificity, sensitivity, negative predictive value (NPV), positive predictive value (PPV), and the cost and time savings of this pooling strategy.
Results: 1,380 sputum samples from Rwanda were included in this study. Our analysis showed that pooled testing for TB was effective, identifying 110 (7.9%) positive cases. This method had high accuracy with 97.5% agreement, 98% specificity, 90.4% sensitivity, 77.3% positive predictive value (PPV), and 99.3% negative predictive value (NPV). It also reduced costs by 41% (from 12,234 RwF to 5,013 RwF) and cut testing time by 42% (from 2.52 to 1.06 hours). A significant difference in CT values before and after pooling was found ($p = 0.00704$), though the effect size was small (Cohen's $d = 0.307$), indicating limited practical impact.
Conclusions: This study shows that the sample-pooling strategy using Xpert MTB/RIF Ultra effectively reduces testing costs and time in Rwanda, making molecular TB diagnostics more accessible. Given the country's low TB prevalence, pooling minimizes retesting, making it a practical and cost-efficient approach for community surveys targeting high-risk, asymptomatic individuals.

EP31 Everyone exposed deserves a chance: Contact investigation as a gateway to prevention

EP31-1000-20 Estimating the prevalence of tuberculosis infection in the EU/EEA: Results of feasibility assessment

I. Spruijt,[1] C. Mergenthaler,[2] M. Bakker,[2] F. Cobelens,[3,4] P. Dodd,[5] S. Hermans,[6,7] C. Mulder,[1] S. Rosales-Klintz,[8] [1]KNCV Tuberculosis Foundation, TBEHSI, The Hague, Netherlands, [2]KIT Royal Tropical Institute, Epidemiology, Amsterdam, Netherlands, [3]Amsterdam University Medical Centre, Department of Global Health, Amsterdam, Netherlands, [4]Amsterdam Institute for Global Health and Development, Epidemiology, Amsnethneterdam, Netherlands, [5]Sheffield Centre for Health and Related Research, Division of Population Health, School of Medicine and Population Health, Sheffield, United Kingdom of Great Britain and Northern Ireland, [6]Amsterdam Institute for Global Health and Development, Epidemiology, Amsterdam, Netherlands, [7]Amsterdam University Medical Center, Department of Infectious Diseases, Amsterdam, Netherlands, [8]European Centre for Disease Prevention and Control (ECDC), STI, Blood-Borne Viruses and TB , DPR, Stockholm, Sweden
e-mail: ineke.spruijt@kncvtbc.org

Background: The prevalence of TB infection (TBI) and subsequent risk of progression to tuberculosis (TB) disease among populations at high risk of TB in the European Union and European Economic Area (EU/EEA) is unknown, although these estimates are essential to guide targeted TB prevention interventions. To assess the feasibility of modelling country-specific estimates of TBI prevalence and progression to TB disease among at-risk populations, we examined the availability and coherence of TBI screening and TPT data in the EU/EEA.
Design/Methods: We invited national TB focal points to fill out a survey on TBI screening and TB preventive treatment (TPT) policies and practices, and data collection, including completeness and coherence of indicators for TB household contacts, migrants, persons experiencing homelessness, persons in detention, and persons with medical conditions. Survey results were scored against pre-determined modelling feasibility criteria.
Results: Of 30 invited countries, 26 provided a complete survey response. Twenty-four (92%) reported having TBI screening policies, of which 20 (83%) reported programmatic TBI screening (Table 1). Nine countries reported no systematic data collection regarding TBI testing nor TPT for any at-risk population. Data were most often collected on TB infection and/or TPT for household contacts (14 countries) and migrants (13 countries). We identified 12 countries for which modelling TBI prevalence among certain at-risk populations feasible: availability of data TB infection testing coverage and yield, disaggregated by sex, age, and country of origin with an estimated <10%

of reporting units having missing data. Main reasons why modelling was considered unfeasible were non-digitalized data, lack of data indicators, lack of disaggregated data, and fragmented and non-harmonized data collection practices.
Conclusions: Modelling of TBI prevalence and risk to disease progression estimation, which could guide implementation of targeted TPT interventions, is feasible in 12 countries. Subnational harmonization and digitalization of data collection could increase the feasibility of future TB modelling.

EP31-1002-20 'Ring Survey' - An innovative blending of active case finding and contact tracing activity under National TB Program. An insight from West Bengal, India

A. Dey,[1] S.K. Roy,[2] R. Mukherjee,[2] D. Deka,[1] B. Sengupta,[1] S. Chandra,[1] U.B. Singh,[3] B. Chaklader,[1] T.K. Saha,[2]
[1]Government of India-WHO Country office for India-Technical Support Network, National TB Elimination Program, New Delhi, India, [2]Government of West Bengal, Department of Health and Family Welfare, Kolkata, India, [3]Government of India, Department of Health and Family Welfare, New Delhi, India
e-mail: chakladerb@rntcp.org

Background and challenges to implementation: Contact tracing, which is the process of TB screening of the person living in same household of a Person with TB (PwTB), is in practice over the decades. Studies suggested that extra-household contacts are of similar risks of getting TB infection & active TB disease. Since 2024 the state has introduced an innovative active case finding strategy called ‚Ring Survey'
Intervention or response: Upon diagnosis of an infectious TB (microbiologically confirmed pulmonary TB), the "index case", respective health care workers visit 50 households around the index case to screen all the household contacts for TB symptoms within two weeks of the diagnosis of the index case.
Ring survey conducted elsewhere encircling an area covering 50-meter radius around index case. But the 50-meter radius might have variable number of households which makes field-operation complicated. So, the state decided to cover 50 households encircling an index case. If there are more than one index cases in same area there might be overlapping households (*Fig-1*)
Results/Impact: In 2024, total 2,335,963 households encircling 61510 index cases were surveyed. Total 7,104,650 household & extra-household contacts were screened and 289,868 presumptive TB identified & tested. Total 1,420 PwTB diagnosed. Number needed to screen (NNS) & number needed to test (NNT) was 5003 & 204 respectively. Mean age of the PwTB was 39.7 yrs (SD-17.7). 40.4% were female, 73.2% were pulmonary TB, 78.5% were bacteriologically confirmed and 1.9% were Drug-resistant TB.

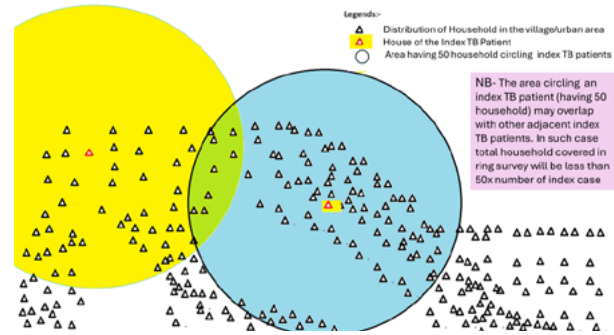


Fig-1. Guidance for house selection for Ring Survey under NTEP West Bengal.

Conclusions: Through the ring survey a higher proportion of female PwTB was detected in comparison to routine passive case findings (40% vs 30%). The overall yield of the ring survey may be further increased by conducting the survey at least twice including once at the end of treatment of the index case. This model may be replicated in other high burden areas with context-specific modification.

EP31-994-20 Uncovering the hidden threat: Contact investigation among clinically diagnosed TB cases in Lagos State

O. Daniel,[1] A. Agbaje,[2] C. Mensah,[3] P. Dakum,[3] A. Okungbure,[1] A. Alege,[4] B. Olaniyi,[1] R. Eneogu,[5] D. Nongo,[5] S. Labaran,[6] O. Akaniro,[6] M. Pedro,[7] [1]Institute of Human Virology Nigeria, Prevention Care and Treatment, Ikeja, Nigeria, [2]Institute of Human Virology Nigeria, Office of the CEO, Ikeja, Nigeria, [3]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [4]Society for Family Health, Community, Ikeja, Nigeria, [5]United States Agency for International Development, HIV/AIDS & TB office, Abuja, Nigeria, [6]National Tuberculosis, Leprosy and Buruli Ulcer Control Program, Public Health, Abuja, Nigeria, [7]Institute of Human Virology Nigeria, Strategic Information, Ikeja, Nigeria
e-mail: odaniel@ihvnigeria.org

Background and challenges to implementation: While global TB control has advanced, Nigeria remains one of the top eight contributors to the global TB burden. As per the 2024 WHO Global TB Report, over 361,000 TB cases were reported in Nigeria in 2023. However, significant gaps remain between estimated and notified cases. Traditionally, contact investigation (CI) in Nigeria excludes clinically diagnosed TB cases. The USAID TB-LON 3 project introduced a paradigm shift by including these cases in CI activities across Lagos State.
Intervention or response: From April to December 2024, CI was conducted for 1,346 clinically diagnosed TB index cases. Unlike traditional practice, these cases were systematically contact-traced. A cascade analysis was conducted using metrics such as CI coverage, screening rate,

TB yield, Number Needed to Screen (NNS), and Number Needed to Test (NNT). Preventive treatment uptake was assessed for 3HR, 6H, and 1HP regimens.
Results/Impact: Out of 1,346 index cases, 1,296 (96%) were contact traced, leading to 4,504 contacts identified and 4,506 individuals screened. Of these, 736 presumptive cases were recorded and 725 evaluated, resulting in 38 TB diagnoses (5% yield). The NNS and NNT were 119 and 19 respectively—figures comparable to those from bacteriologically confirmed cases.
Treatment enrollment stood at 95%, and 47% of eligible contacts were placed on TPT. These findings confirm that clinically diagnosed TB cases can also transmit TB and merit inclusion in CI protocols.
Conclusions: This analysis demonstrates that clinically diagnosed TB cases contribute significantly to transmission and should no longer be excluded from contact tracing protocols. A shift in policy could enhance TB case detection and accelerate progress toward TB elimination goals.

EP31-995-20 The new contact investigation model for comprehensive tuberculosis case finding by community in East Java Province, Indonesia

M. Sholehhudin,[1,2] E. Yuliana Ulya,[2] T. Lestari,[2] [1]Universitas Airlangga, Department of Health, Faculty of Vocational Study, Surabaya, Indonesia, [2]Bhanu Yasa Sejahtera Foundation, Community Empowerment, Surabaya, Indonesia
e-mail: m.sholehhudin@vokasi.unair.ac.id

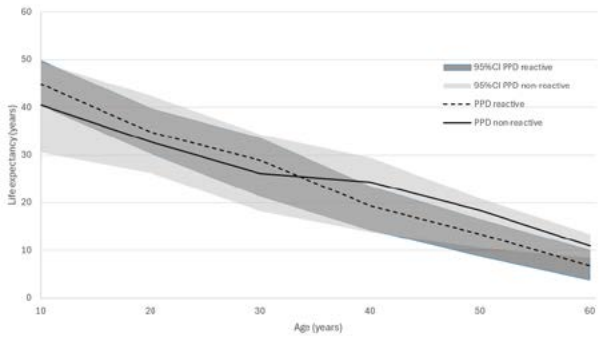
Background and challenges to implementation: Indonesia still has the second highest number of Tuberculosis cases in the world. The main problem is low TB case finding. The efforts have been carried out by Household Contact Investigation (HCI), but no significant results yet. To support the government, communities can encourage increased TB case finding through innovations with a new paradigm.
Intervention or response: The New Model was Non-household Contact Investigation (NHCI). A method with a broader reach and more comprehensive considerations. The first stage was identification of index cases data (people with TB). The most important is not only family members but also various communities that interacted with people with TB (PwTB).
The second stage involved mapping the location of PwTB's house and public places in their village area (e.g., village office hall, religious meetings, schools, place of worship, neighbors).
Then, carry out HCI & NHCI by socialization and TB symptom screening. Data was collected by Bhanu Yasa Sejahtera Foundation cadres in 29 districts using the questionnaire from Jan-Dec 2024.
Data were cleaned, validated, and tabulated in Excel. A total of 58 samples were processed and analyzed in SPSS with Mann-Whitney U test comparison approach.
Results/Impact: TB case finding results from NHCI activities were higher (13,095 activities got 4,501 TB cases) than HCI (27,918 activities got 3,917 TB cases). Based on the effectiveness difference test, there was a highly significant difference with a p-value < 0.001 (r = 0.52). Replication of this program for TB case finding in other areas would be more effective with the NHCI model (Median NHCI 0.277; Median HCI 0.078).
Conclusions: NHCI is more effective and finds more TB cases than HCI. Contact investigation activities should not only focus on family members but also all residents in the area where people with TB live. This model is also projected to reduce the stigma towards PwTB found early.

EP31-996-20 Latent tuberculosis infection and life expectancy: A long-term follow-up on a cohort tested with tuberculin skin test

M. Kruse Kristensen,[1,2,3] K. Djalo,[2] T. Engell-Sørensen,[1,2] C. Wejse,[1,3,2] F. Rudolf,[1,3,2] [1]Aarhus University Hospital, Department of Infectious diseases, Aarhus, Denmark, [2]The Bandim Health Project, Tuberculosis group, Bissau, Guinea Bissau, [3]Aarhus University, GLOHAU, Aarhus, Denmark
e-mail: maikenkrusekristensen@gmail.com

Background: One forth of the world population is estimated to be infected with *Mycobacterium tuberculosis* (Mtb) thereby representing a large reservoir from which the disease can reactivate with severe illnes and transmission as the fatal consequences. However, little is known about the lifetime consequences of tuberculosis infection (TBI) on general health besides the risk of reactivation.
Design/Methods: We conducted a restrospective follow-up study on a cohort of individuals tested with Purified Protein Derived(PPD) skin test in 1999-2000 in the capital of Guinea Bissau. The groups of PPD-reactive and -nonreactive were sought out to determine mortality during the follow-up period and to investigate subjects still alive in terms of reactivation/active Tuberculosis (TB) disease events, risk factors for TB, immunological reactivity towards Mtb and socioeconomic factors.
Results: A total of 384 (21%) individuals were identified and included. The life expectancy in the PPD-reactive group was 54 years (95%CI: 50;59), whereas it was slightly lower in the PPD-nonreactive group with a median of 50 years (95%CI: 40;59). Cox-regression analysis adjusting for age and present BCG scar yielded a hazard ratio for death in PPD-reactive of 1.06 (P=0.750), however, we found a significant interaction between age and PPD-reactivity resulting in disproportionally increasing HR for mortality in PPD-reactive and -nonreactive with increasing age. Likewise, PPD-reactivity was protective in indi-

viduals aged 0-20 years (HR: 0.32 (95%CI;0.11:0.91)) and increased the risk of mortality in individuals of 41 years and above (HR: 1.76 (95%CI;1.07:2.90)).



Conclusions: PPD-reactivity seems to be protective in children and young adults, but the effect is age-dependent and so it increases the risk of mortality in older individuals.

EP31-997-20 Enhancing TB contact investigation and TPT uptake through community volunteer engagement: Evidence from the Global Fund N-THRIP grant in Ondo State, Nigeria

V. Aganaba,[1] E. Oboku,[2] A. Agbaje,[3] P. Dakum,[3] O. Olupitan,[3] O. Akaniro,[4] D. Olugbenga,[5] F. Murtala-Ibrahim,[6] [1]Institute of Human Virology Nigeria, Strategic Information - Global Fund N-THRIP, Lagos, Nigeria, [2]KNCV Nigeria, Programs, Lagos, Nigeria, [3]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [4]National Tuberculosis and Leprosy and Burili Ulcer Control Program, Program Management Unit, Abuja, Nigeria, [5]Institute of Human Virology Nigeria, Programs/ Prevention Care & Treatment, Lagos, Nigeria, [6]Institute of Human Virology Nigeria, Strategic Information, Abuja, Nigeria
e-mail: oolupitan@ihvnigeria.org

Background: Tuberculosis (TB) contact investigation and tuberculosis preventive treatment (TPT) are essential strategies for interrupting TB transmission. In Ondo State, Nigeria, low TPT enrollment prompted strategic re-evaluation during the 2024 implementation of the Global Fund Grant Cycle 7 Nigeria-TB/HIV Reach Integration & Impact Project (N-THRIP) project. This study assessed the impact of leveraging community volunteers (CVs) on TB contact tracing and TPT uptake.
Design/Methods: This retrospective quantitative analysis reviewed routine Global Fund N-THRIP program data from Q1 to Q4 2024. Contact investigation and TPT cascade data were analyzed on a quarterly basis. Descriptive statistics were used to calculate proportions, rates, and quarterly improvements. Pearson's chi-square test evaluated differences in TPT uptake and contact investigation coverage across quarters ($p<0.05$). From Q3 2024, the program adopted the engagement of community volunteers (community members sensitized through short, targeted training or frequent engagement with health workers) who were deployed to conduct health education, mobilize community participation, and raise awareness on TB prevention. CVs also supported patient follow-up and treatment adherence, contributing to sustained demand and completion of preventive therapy.
Results: Marked improvements were observed post CV engagement. Contact investigation coverage rose from 98.2% in Q1 to 100% by Q3–Q4. Under-5 TPT uptake improved from 55.9% (Q1) to 100% (Q4), while uptake among contacts aged above 5 increased from 35.0% (Q1) to 93.8% (Q4), both statistically significant ($p<0.001$).

Period	Contacts of Index TB patients identified	Contacts of index TB patients screened	TPT Eligibility (Under 5yrs)	TPT enrolment (Under 5yrs)	TPT Eligibility (Over 5yrs)	TPT enrolment (Over 5yrs)	CI Cove-rage	TPT Uptake
Q1 2024	894	894	34	19	860	301	100%	36%
Q2 2024	1,027	1,027	59	44	954	200	100%	24%
Q3 2024	1,571	1,571	78	63	1,476	1,164	100%	79%
Q4 2024	1,595	1,595	109	109	1,486	1,394	100%	94%
Grand Total	5,087	5,087	280	235	4,776	3,059	100%	65%

Conclusions: The introduction of community volunteers significantly enhanced TB contact tracing and TPT enrollment in Ondo State. Their role in raising awareness, generating demand, and supporting adherence proved invaluable in addressing key barriers to preventive care. They also offer a replicable and sustainable model for strengthening and improving TB program performance in similar high-burden, resource-constrained settings.

EP31-998-20 Long-term impact evaluation of the National Latent Tuberculosis Infection Mass Screening Program among adolescents in South Korea

D. Kim,[1] D. Moon,[2] J. Lee,[3] Y. Yu,[4] J. Seo,[5] G.-R. Park,[4] H. Choi,[4] [1]Emory University, Rollins School of Public Health, Department of Epidemiology, Atlanta, United States of America, [2]Busan Center for Infectious Disease Control and Prevention, Infectious Disease Policy Analysis Team, Busan, Republic of Korea, [3]Hyo-tree Nursing Home, Hyo-tree Nursing Home, Incheon, Republic of Korea, [4]Korea University, Division of Health Policy and Management, Seoul, Republic of Korea, [5]Korea University, College of Health Science, Seoul, Republic of Korea
e-mail: k233kim@gmail.com

Background: In 2017, despite limited scientific evidence supporting the effectiveness of mass screening and preventive treatment (TPT) in adolescents with an extremely low risk for active TB progression, the South Korean government launched a national latent tuberculosis infection

(LTBI) mass screening program for high school students to identify LTBI cases and provide TPT. The study's objectives:(1)To assess the impact of LTBI mass screening and TPT on reducing active TB disease in low-risk groups;(2) To examine how factors such as socioeconomic position (SEP) and gender modify the active TB incidence based on the LTBI screening status.

Design/Methods: A retrospective cohort study analyzed data from 1,122,933 high school students (ages 15–19) from 2017 to 2022. TB incidence was compared between an intervention group (screened for LTBI) and a control group. Cox proportional hazards models and Kaplan-Meier survival analyses estimated the effects of LTBI screening and TPT, stratified by gender and SEP.

Results: Kaplan-Meier survival curves showed minimal differences between the control and intervention groups (Figure). After adjusting for household income, disability, diabetes, and vitamin D deficiency, the hazard ratio for TB incidence was higher in men than women (HR: 1.30, 95% CI: 1.08–1.56). The effect modification analysis indicated that participants with low SEP in the intervention group and high SEP in the control group had a 39% higher TB risk than the reference group (ERR: 0.40, 95% CI: 0.05-0.865, p = 0.022).

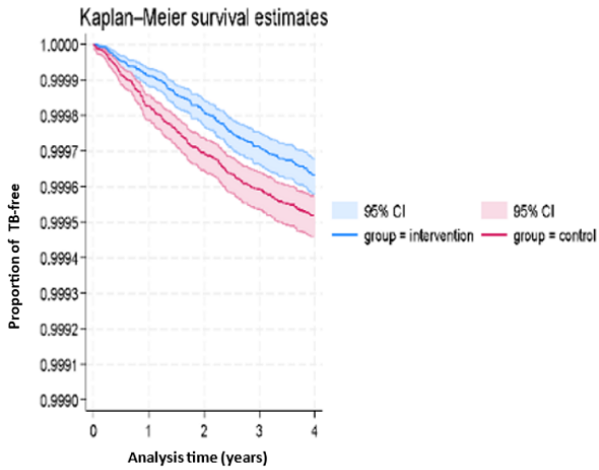


Figure. *Survival function estimated of overall control and intervention groups using the Kaplan-Meier methods, adjusted for household income, disability, diabetes mellitus, and vitamin D deficiency.*

Conclusions: This study suggests that South Korea's LTBI mass screening program had limited impact on ending TB in low-risk groups. The findings highlight that implementing mass screening and treatment in such populations may not yield meaningful public health benefits. Instead, it emphasizes the need for targeted approaches addressing gender and SEP disparities to enhance TB prevention and care, emphasizing that reducing active TB transmission may be more effective than mass screening.

EP31-999-20 Factors associated with 28-month TB incidence after isoniazid-rifapentine (3HP) among Ugandan adults with HIV

A. Musinguzi,[1] J. Kadota,[2] J. Katende,[1] A. Katamba,[3,4] D. Dowdy,[5] A. Cattamanchi,[2,3,6] F.C. Semitala,[1,7,8]
[1]Infectious Diseases Research Collaboration, Research, Kampala, Uganda, [2]University of California San Francisco, San Francisco, Center for Tuberculosis and Division of Pulmonary and Critical Care Medicine, San Francisco General Hospital, San Francisco, United States of America, [3]Walimu, Uganda Tuberculosis Implementation Research Consortium, Kampala, Uganda, [4]Makerere University College of Health Sciences, Clinical Epidemiology & Biostatistics Unit, Department of Medicine, Kampala, Uganda, [5]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States of America, [6]University of California Irvine, Division of Pulmonary Diseases and Critical Care Medicine, Irvine, United States of America, [7]Makerere University College of Health Sciences, Department of Medicine, Kampala, Uganda, [8]Makerere University Joint AIDS Program, Research, Kampala, Uganda
e-mail: amusinguzi@idrc-uganda.org

Background: The World Health Organization recommends weekly isoniazid-rifapentine (3HP) for tuberculosis (TB) prevention in people living with HIV (PLWH). The durability of protection afforded by 3HP in high-burden TB/HIV settings remains unclear.

As part of a randomized, pragmatic implementation trial of 3HP, we aimed to determine TB incidence over 28 months and factors associated with incident TB.

Design/Methods: Adult PLWH at an HIV clinic in Kampala, Uganda, received 3HP through facilitated directly observed therapy or facilitated self-administered therapy (SAT).

Participants were followed for at least 28 months from the initiation of treatment to determine TB status. Unadjusted competing risks survival regression models were used to assess for individual demographic and clinical factors associated with TB incidence, with all-cause mortality as a competing event.

Results: Between July 2020 and July 2022, 1655 PLWH were enrolled, and 1651 initiated treatment (median age 42 years; 68% female; 44% SAT; 94% completed treatment).

Participants contributed 4385 person-years (py) of follow-up after treatment initiation, during which 13 participants (0.8%) developed active TB and 13 (0.8%) died. The TB incidence rate was 2.97 episodes per 1,000 py (95% confidence interval, CI: 1.72-5.11).

Receiving 3HP via SAT (sub-hazard ratio, SHR: 7.05, 95% CI: 1.59-31.32, $p = 0.01$) and being male (SHR: 3.33, 95% CI: 1.10-10.12, $p = 0.03$) were associated with an increased risk of incident TB, whereas 3HP treatment completion (SHR: 0.22, 95% CI: 0.06-0.80, $p = 0.02$) was associated with a reduced risk of incident TB (Table 1).

Characteristic		TB Cases/PY, Rate/1000 PY (95% CI)	SHR (95% CI)	P Value
Sex	Female	5/2978, 1.65 (0.69-3.96)		
	Male	8/1407, 5.58 (2.79-11.15)	3.33 (1.10-10.12)	0.03
Study arm	DOT	2/2458, 0.80 (0.20-3.19)		
	SAT	11/1927, 5.61 (3.10-10.12)	7.05 (1.59-31.32)	0.01
3HP treatment completion	No	3/266, 11.09 (3.58-34.39)		
	Yes	10/4119, 2.38 (1.28-4.43)	0.22 (0.06-0.80)	0.02

PY = person-years; Rate = Crude TB incidence rate; SHR = sub-hazards ratio; SAT = self-administered therapy; DOT = Directly Observed Therapy

Table 1. Factors associated with 28-month TB incidence after one course of 3HP among adult people living with HIV in Uganda.

Conclusions: The 28-month incidence of TB was low among PLWH who received a single course of 3HP for prevention, suggesting that repeat 3HP administration is not needed within this period. Programs should focus on ensuring high adherence and treatment completion, particularly for self-administered therapy.

EP32 Building capacity in systems and people to deliver person-centred care

EP32-1003-20 Empowering health staff in the peripheral states of Himachal Pradesh and Odisha for better TB data management under national TB Elimination Program, India

A. Pradhan,[1] R. Kumar,[2] Q. Toufique,[3] A. Sharma,[4] R. Paikar,[5] D. Balasubramanian,[6] S. Sarangi,[6] I. Thior,[7] P. Nadol,[3] A. Date,[8] C. Ho,[9] H.S. Sandhu,[8] [1]Govt of Odisha, State TB Cell, Bhubaneswar, India, [2]Govt of Himachal Pradesh, State TB Cell, Shimla, India, [3]Centers for Disease Control and Prevention(CDC), Division of Global HIV and TB(DGHT), Delhi, India, [4]PATH, TB, Shimla, India, [5]PATH, TB, Bhubaneswar, India, [6]PATH, TB, Delhi, India, [7]PATH, TB, Washington, India, [8]US Centers for Disease Control and Prevention(CDC), Division of Global HIV and TB(DGHT), Delhi, United States of America, [9]US Centers for Disease Control and Prevention (CDC), GTB, Atlanta, United States of America
e-mail: qnb8@cdc.gov

Background and challenges to implementation: Optimal tuberculosis (TB) data quality management is crucial in high-burden countries like India. Despite availability of Ni-kshay, a real-time TB management information system, decision-making is often hindered by limited data analytic skills of the National TB Elimination Program (NTEP) staff. The Expand ELEVATE (Engaging Local Experts for Validating and Analyzing TB data to End TB in India)(E2) project in Himachal Pradesh and Odisha aimed to address the above issue.

Intervention or response:

Figure-1: pictures of capacity building at Una district and screenshot of AV shared by the state

In 2022-23, the E2 project trained 94 sub-district staff from 6 and 2 districts in Himachal Pradesh and Odisha respectively on accessing data from Ni-kshay portal, preparation, analysis and data visualization using MS Excel. During 2022 to 2024, mentoring visits and virtual training sessions were conducted and hands-on support provided, including key program indicators (KPI) analysis and action plan development. In May 2024, E2 project recorded and circulated four audio-visual materials in local-language on data analytics and usage of Ni-kshay

for staff use. Based on project advocacy, NTEP mandated monthly KPI analysis by sub-district staff, with oversight from district staff for accountability.

Results/Impact: By 2024, trained sub-district teams began independent data analyses. Additionally, in Himachal Pradesh, their independent data analysis improved data quality and saved 2.5 person-days per month, earlier being spent on analytic tasks. By Q4 2024, 32% (30 of 94) of staff shared their newly acquired skills with peers, addressing gaps and improving 67% (37 of 55) of identified KPIs across both states. The states found the intervention beneficial, advocating for geographic expansion, and ongoing staff training in data analytics.

Conclusions: The initiative improved efficiency of sub-district staff in data analytics for timely and decentralized decision-making, fostered a culture of data use, accountability and made available time for other programmatic activities. This initiative has demonstrated a sustainable peer-training approach and thereby contributing to health system strengthening.

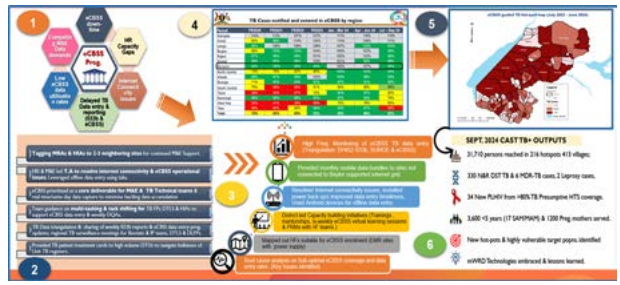
EP32-1004-20 Accelerating eCBSS access and utilisation to enhance TB/HIV program implementation through multifaceted, district-led quality improvement initiatives in mid-Western Uganda: The Bunyoro region success story!

R. Kamara Atuhaire,[1] E. Muwanguzi,[2] G. Namboozo,[2] R. Jjuuko Kyakuwa,[2] C. Epidu,[1] B. Nsangi Kintu,[2] D. Lukoye,[3] R. Oceng,[2] E. Tumwiine,[2] D. Birungi,[1] A. Maganda,[2] D. Kiragga,[4] [1]Baylor College of Medicine Children's Foundation - Uganda, Directorate of Programs (HIV/TB Care & Treatment), Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation - Uganda, Directorate of Strategic Development, Monitoring & Evaluation, Kampala, Uganda, [3]Centres for Disease Control and Prevention (CDC) - Uganda, Health Services Branch, Kampala, Uganda, [4]Baylor College of Medicine Children's Foundation - Uganda, Executive Director's Office, Kampala, Uganda
e-mail: rkamara@baylor-uganda.org

Background and challenges to implementation: In 2020, Uganda's Ministry of Health launched eCBSS to improve TB and leprosy case management. Built on DHIS-2, it integrates with existing data streams, supports offline capture, and enables real-time data entry via Android devices, enhancing efficiency and care. Bunyoro struggled with poor outcomes due to data gaps. A root cause analysis identified limited human resources and poor internet connectivity as key barriers to optimal system performance.

Intervention or response: Using a CQI approach, Baylor Foundation Uganda, MoH, HISP, and district local governments implemented collaborative interventions to improve TB DTU-eCBSS coverage and utilisation. We mapped eligible HFs, focused on district-led QI capacity building, and trained regional trainers, Biostatisticians, DTLS, IP, and 10 high-volume DTU staff. TOTs trained 87 additional DTUs; MRAs & HIAs were tagged to 2–3 nearby sites for cost-effective M&E; supported offline data entry via phones/tabs; facilitated staff performance monitoring, multi-tasking, and task shifting for real-time data entry; conducted weekly DQAs; integrated eCBSS into TB surveillance meetings; provided TB client cards, power backups, and monthly data bundles to sites without IP-supported internet.

Results/Impact: Bunyoro region made significant progress, with DTU coverage increasing from 9% (10/114) in 2020 to 85% (97/114) in September 2024. 21 newly accredited DTUs to be enrolment in 2025, and the eCBSS-TB data entry rate is 95%. CAST+ TB case finding improved by 30%, from 230 (March 2024) to 330 (Sept. 2024), driven by eCBSS-guided hotspot mapping, and the cost of the CAST TB+ campaign dropped from $150 to $30 per patient.



Conclusions: District-led eCBSS continuous quality improvement (CQI) initiatives are key to scaling up the program and enhancing data use. Timely data entry and backlog clearance enable effective TB hotspot mapping and patient monitoring, improving outcomes. By increasing efficiency in TB/HIV program implementation, eCBSS strengthens surveillance and response, with continued investment promising greater data-driven public health impact.

EP32-1005-20 Evaluating the contributions and challenges of community pharmacies and over-the counter medicine shops in tuberculosis case detection and treatment initiation in Ghana

C. Femeyibor,[1] L. Amoah-Larbi,[2] R.S. Adzesi,[3] E.A. Ampofo,[2] J. Amoah-Larbi,[2] A.I. Tsiboe,[2] Y. Adusi-Poku,[4] R.P. Frimpong-Mansoh,[4] [1]University of Ghana, Public Health, Accra, Ghana, [2]Ghana National TB Voice Network, Civil Society, Accra, Ghana, [3]University of Ghana, Statistics and Actuarial Science, Accra, Ghana, [4]Ghana Health Service, National TB Programme, Accra, Ghana
e-mail: femeyiborcharity@gmail.com

Background and challenges to implementation: In Ghana, individuals with persistent cough often seek initial care from over-the-counter medicine sellers (OTCMS) rather than formal health facilities, leading to missed opportunities for early TB detection. To address this, the National TB Programme (NTP), through the Public–Private Mix (PPM) intervention, engages OTCMS to screen and refer people with presumed TB symptoms. This intervention aims to strengthen community-level surveillance, expand case detection beyond the formal health system, and ensure timely linkage to diagnostic and treatment services.
Intervention or response: Aurum institute Ghana and the Ghana National TB Voice Network trained staff in 80 selected sites from 4 regions (Western, Ashanti, Greater Accra and Northern) on the use of the revised NTP TB symptom screening tool. The intervention trained 42 TB Champions to assist the pharmacies & OTCMS in screening and sample transportation. Samples of presumed clients were transported to testing hubs and follow-ups were done by TB Champions. All bacteriologically diagnosed clients were referred into care and initiated on treated. Contact tracing of index clients was done and eligible contacts were enrolled on TB treatment preventive therapy (TPT). The data for this intervention was collected from April 2024 to February 2025.
Results/Impact: A total of 13,523 individuals were screened, 4,672(34.5 %) were identified as presumptive TB cases. About 2,748(58.8%) sputum samples were collected and tested. Out of the 2,748 samples tested, 98(3.6 %) were bacteriologically confirmed positive and 3 clinically diagnosed. 98(97%) individuals were successfully initiated on TB treatment. This represents a high treatment initiation rate.
Conclusions: The engagement of pharmacies & OTCMS in TB screening under the Global Fund GC7 intervention proved to be an effective strategy for improving early TB detection and treatment initiation in Ghana. The approach leveraged the accessibility of community pharmacies & OTCMS to bridge gaps in TB case detection and advanced timely referrals for diagnosis and care.

EP32-1006-20 Improving tuberculosis knowledge among community health cadres through national training: Evidence from pre- and post-test evaluation in 229 districts in Indonesia

I.T. Mulyandari,[1] E. Varella,[1] N. Sofarianty,[1] D. Alief,[1] R. Hidayat,[1] P. Hidayat,[1] P. Rahmadian,[1] B. Nababan,[1] [1]Consortium Penabulu-STPI, Principal Recipient of the Global Fund TB Community, Jakarta, Indonesia
e-mail: Erman.varella@penabulu-stpi.id

Background and challenges to implementation: Community health cadres play a crucial role in TB control in Indonesia, particularly in contact investigation (CI) and tuberculosis preventive treatment (TPT). In 2025, a nationwide training was implemented to strengthen cadres' capacity, involving 5,230 participants over a two-day session covering five key modules: Basic TB Information, Integrated CI-TPT, Community Outreach, Communication, and Recording and Reporting.
Intervention or response: The study aimed to evaluate the effectiveness of this training program in enhancing participants' knowledge and comprehension across the five core competency areas through a pre- and post-training assessment.
The study aimed to evaluate the effectiveness of this training program in enhancing participants' knowledge and comprehension across the five core competency areas through a pre- and post-training assessment.
Results/Impact: Results revealed an overall knowledge improvement of 15.01%, with the mean score increasing from 74 in the pre-test to 85 in the post-test. The greatest gains were observed in CI and TPT-related questions—for instance, a 20% increase in correctly identifying the source of index cases. Despite these positive outcomes, some areas showed persistent gaps. Understanding of the roles of community health cadres and treatment supervisors (PMOs), as well as certain documentation procedures, remained suboptimal. The lowest post-test performance was 64% correct on questions regarding patient monitoring forms. In the two months following the training, cadres screened 236,195 household contacts and high-risk groups (HRG), leading to the detection of 83,306 TB cases and over 6,000 HRG individuals commencing TPT. Key challenges included reluctance of contacts to visit health facilities and limited access to diagnostic services.
Conclusions: The national TB cadre training program significantly improved participant knowledge, particularly in CI and TPT. Nonetheless, targeted reinforcement in cadres' roles and reporting procedures is warranted. Continuous mentoring and periodic refinement of training modules are recommended to further strengthen cadre competencies and support TB control efforts.

EP32-1007-20 Enhancing tuberculosis case manager training through leader-guided discussions in Taiwan

I-W. Chang,[1] T.Y. Tsai,[2] Y.Z. Lin,[1] J.-Y. Wang,[3,4] [1]Taiwan Society of Tuberculosis and Lung Disease, Secretariat, Taipei, Taiwan, [2]National Taiwan Univerisity Hospital, Center for Infection Control, Taipei, Taiwan, [3]National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan, [4]Taiwan Society of Tuberculosis and Lung Disease, Taiwan Society of Tuberculosis and Lung Disease, Taipei, Taiwan
e-mail: iwchang@ntu.edu.tw

Background and challenges to implementation: Training for tuberculosis case managers (TCMs) in Taiwan includes initial training (IT) for foundational knowledge and refresher training (RT) to enhance practical skills through small group discussions. Previously, discussions were self-directed with occasional support from a senior TCM. In 2023, experienced TB case managers led each group, introducing a reward system to incentivize performance. This study explores the transition from loosely facilitated to leader-guided discussions and its impact.
Intervention or response: Semi-structured interviews were conducted with nine senior case managers who served as counselors before 2022 and discussion leaders after 2023. The interviews were transcribed and analyzed using thematic analysis to identify key patterns and insights.
Results/Impact: Analysis showed that pre-2022 discussions lacked structure due to absent leadership, often leading to disorganized sessions. Post-2023, the introduction of senior case managers as leaders significantly improved discussion effectiveness.
Some leaders encouraged quieter participants to share experiences, facilitating meaningful engagement even for those less familiar with TB. However, some leaders focused on preparing presentation slides with a few experienced members to win rewards, rather than facilitating the group as a whole.
While the reward system motivated participation, it also led to dominance by experienced participants, undermining group balance.
Conclusions: The study highlights the critical role of leadership in effective group discussions and the need for consistent standards and teaching objectives among leaders. It suggests that leaders should evolve towards facilitators, encouraging broad participation beyond directing content. Revising the reward system and training leaders in facilitation techniques are recommended to maximize benefits for all trainees. Future research could explore the long-term impacts of these changes on training outcomes.

EP32-1010-20 Pathways to enhance presumptive TB examination rate (PTER)/100,000 population and its impact in TB cases notification in the state of Uttar Pradesh (UP), India

S. Bhatnagar,[1] B.K. Shetty,[2] R. Tripathi,[2] Y. Kharkwal,[2] P. Singh,[2] H. Himanshu,[2] R. Washington,[2] M. Ahmad,[2] [1]State Medical & Health Department, State Tuberculosis Cell,, Programs, Lucknow, India, [2]India Health Action Trust, Programs, Lucknow, India
e-mail: stoup@rntcp.org

Background and challenges to implementation: UP, the largest State of India contributes to 16% of the country's population and 22% of its TB case notification. The Central TB Division (CTD), Ministry of Health & Family Welfare, Government of India in 2022 estimated the state's TB incidence rate of 265 (233–307) per100,000 population which translates into 1.07 million people with TB. In 2022, the state notified 0.517 million. To enhance the TB detection, the state set a Presumptive TB Examination Rate (PTER) target of 2,000 per 100,000 population by 2024.
Intervention or response: Evidence indicated that 64% of individuals with TB symptoms did not seek care from a qualified doctor. State adopted three pathways to enhance PTER. 1) Screening of Individuals with TB symptoms at Ayushman Arogya Mandirs (AAM), the Sub centers, which are managed by Community Health Officers 2) Enhance private sector engagement through patient provider support agencies (PPSA), that engage with private healthcare facilities to improve TB notification and public health actions and 3) Enhance TB screening and testing among out-patient attendees in public health facilities to 5%. With the guidance from the State TB Program, India Health Action Trust (IHAT) developed guidelines, conducted training, established systems for specimen transportation to laboratories, monitored progress and generated evidence for the state to take actions to improve performance.
Results/Impact: The PTER increased from 801 (2022) to 1298 (2023) to 2196 (2024). TB case notification increased from 0.519 million (2022), to 0.623 million (2023) to 0.681 million (2024); resulting in increase in Annual TB Case Notification rate from 218 (2022) to 260 (2023) to 270 (2024); approaching the CTD 2022 estimated TB incidence rate of 265 (233–307)/100,000.

Years	2022	2023	2024
Presumptive TB Examination Rate (PTER)/100,000 Population	801	1298	2196
Notification of TB cases Every Year	5,18,126	6,23,210	6,82,275
Case Notification Rate (CNR)/100,000 Population	218	260	270

Data Source India TB Report 2023, Annexure M, Lab Reports 2023 and 2024 and Ni-kshay Dashboard)

Conclusions: Elimination of TB is only possible if there is increase in PTER. Enhancing PTER using critical patient pathways resulted in increased TB case notification in the State of Uttar Pradesh India.

EP32-1011-20 Kanniq, a confluence of rivers: Inuit determine how lay public health workers can lead the transformation towards person-centered TB care in Nunavik, Quebec, Canada

G. Sandy,[1] B. Geboe,[2,3] D. Tooktoo,[4] S. Tukalak,[2] A. Dunn Suen,[2] S. Law,[2,3] S. White-Dupuis,[5] Q. Nappaaluk,[6] M. Emudluk Sr.,[7] L. Watt,[8,5] N.I. MacDonald,[9] F. Ahmad Khan,[3,2,10] [1]Nunavik Regional Board of Health & Social Services, Department of Public Health, Kuujjuaq, Nunavik, Canada, [2]Research Institute of the McGill University Health Centre, Respiratory Epidemiology & Clinical Research Unit, Montreal, Canada, [3]McGill University, Respiratory Division, Department of Medicine, Montreal, Canada, [4]Research Institute of the McGill University Health Centre, Respiratory Epidemiology & Clinical Research Unit, Kuujjuarapik, Nunavik, Canada, [5]Puvaqatsianirmut, Nunavik Lung Health Steering Committee, Kuujjuaq, Nunavik, Canada, [6]Community Leadership, Mayoress, Kangiqsujuaq, Nunavik, Canada, [7]Puvaqatsianirmut, Nunavik Lung Health Steering Committee, Kangiqsualujjuaq, Nunavik, Canada, [8]Ungava Tulattavik Health Centre, Executive Director, Kuujjuaq, Nunavik, Canada, [9]Silattusarniq Community Solutions Consulting, Inuit-led research, Nunavik, Canada, [10]Institut nordique du Québec & McGill University, Northern Research Chair in Respiratory Health & Health Services, Montreal, Canada
e-mail: glenda.sandy.ciussscn@ssss.gouv.qc.ca

Background: Nunavimmiut—Inuit indigenous to Nunavik (in Quebec, Canada)—face tuberculosis rates over 150-times the provincial average of Quebec. Colonial legacies and healthcare inequities fuel this disparity. Nunavimmiut are actively reclaiming self-determination over public services. Within a predominantly non-Inuit healthcare workforce, new Public Health Officer (PHO) positions aim to increase Inuit presence. This study identified PHO roles that will effectively address Nunavimmiut tuberculosis needs.
Design/Methods: A community-based participatory action research project working with Nunavik's health authorities, leaders, and an Inuit steering committee. Indigenous researchers (First Nations & Nunavimmiut) conducted interviews and focus groups with Nunavimmiut about tuberculosis and healthcare experiences. Iterative data analyses used constructivist grounded theory and Indigenous Research Methodology within a reconciliation framework, considering service delivery challenges observed in outbreaks occurring during the research. PHO roles were mapped from identified needs.
Results: From 2022-2023, we interviewed 156 Nunavimmiut (71 interviews, 33 focus groups) in 5 Nunavik communities and Montreal. While experiences varied, key hardships arising from tuberculosis services included feeling uninformed, discrimination and cultural/language barriers in healthcare, disruptive displacement for screening and diagnosis, vulnerability during isolation, financial strain, stigma, and logistical challenges of clinic-based directly observed therapy. Support for greater Inuit representation in care was widespread. Observations pointed to PHO roles that prioritize fostering understanding of tuberculosis and its cascades of care; identifying individual/family needs and expected challenges (including logistical, material, social) that health services should address through supportive measures; and leading activities to enhance community engagement in tuberculosis care and destigmatization. Lack of space and resources, challenges in translating medical terminology, uncertainties around training, and healthcare worker unfamiliarity with PHO roles were identified as implementation challenges.
Conclusions: Nunavimmiut endorse having PHOs in tuberculosis care. PHO roles should prioritize ensuring health services provide culturally relevant informational, social, and material support to individuals and families aligned with person-centered care.

EP32-1012-20 Local action for global goals: A tuberculosis education project in southern Brazil

L. Baio de Souza,[1] F. de Paulo Pedroso,[1] H. do Carmo Antonio,[1] M. Vinícius Ferreira Resente,[1] R. Meggiato Nabas,[1] F. Beraldi de Magalhães,[2] G. Tavares Magnabosco,[1] [1]State University of Maringá, Department of Nursing, Maringá, Brazil, [2]Faculdades Pequeno Príncipe, Health Department, Curitiba, Brazil
e-mail: gtmagnabosco@uem.br

Background and challenges to implementation: Tuberculosis (TB) remains a persistent global public health challenge, particularly in countries with significant social and economic disparities. In response, the Brazilian Ministry of Health launched the "National Plan to End Tuberculosis as a Public Health Problem," which was subsequently adapted by the state of Paraná into its own "State Plan to End Tuberculosis." These plans emphasize the importance of health education, capacity building, and effective surveillance at the local level as key strategies for eliminating TB. In this context, a university extension project was developed to support the training of healthcare professionals across the state.
Intervention or response: The project began with internal planning meetings and team training, followed by the development of structured educational interventions. Training for healthcare workers focused on the clinical management and epidemiological surveillance of TB, utilizing lectures, interactive workshops, group dynamics, and case-based discussions. Educational tools such as di-

agnostic and treatment flowcharts and a treatment monitoring card were designed to support daily practice. To promote community awareness, accessible materials were produced, including interactive banners with QR code access and a puppet theater targeting children.

Results/Impact: A total of 14 training sessions were conducted: four in Regional Health Units, nine in Basic Health Units, and one in a public square in Maringá. Approximately 200 individuals participated, with Community Health Agents and Endemic Control Agents representing the largest share, followed by nurses and physicians.

Conclusions: This extension project contributed meaningfully to TB care efforts in Paraná by enhancing the capacity of frontline health professionals. By fostering knowledge translation into practice, the initiative aligns with the broader public health objective of eliminating TB as a public health threat through integrated and community-based approaches.

EP32-1013-20 Integrated TB-mental health services in Nigeria: A task-shifting model for underserved communities

M. Njoku,[1] O. Ezeakile,[1] C. Eze,[2] N. Murphy-okpala,[1] A. Meka,[1] C. Nwafor,[1] N. Ekeke,[1] D. Egbule,[1] J. Chukwu,[3] C. Esekhaigbe,[4] O. Chijioke-Akaniro,[5] B. Kirubi,[6] [1]RedAid Nigeria, Programmes, Enugu, Nigeria, [2]RedAid Nigeria, MEAL, Enugu, Nigeria, [3]German Leprosy and TB Relief Association, Programmes, Enugu, Nigeria, [4]Initiative for Prevention and Control of Diseases, Programmes, Nasarawa, Nigeria, [5]National Tuberculosis and Leprosy Control Programme, Monitoring and Evaluation, Abuja, Nigeria, [6]STOP TB Partnership, TB REACH, Geneva, Sweden
e-mail: njokumartin1@gmail.com

Background and challenges to implementation: Nigeria is among the 30 high TB, TB/HIV, and drug-resistant TB burden countries. Additionally, Nigeria has a high prevalence of mental disorders, with depression and substance use disorders being major public health concerns. Although studies have shown that there is a strong relationship between TB and depression, little has been done to address the mental health challenges of TB patients in Nigeria. This is probably because there's shortage of mental health experts in the country. The Psychiatrist to population ratio is 1:1,000,000.

This project implemented a community-facility task-shifting model to bridge gaps in TB-depression-substance use disorder care.

Intervention or response: Over 18 months, 131,820 persons were screened across 10 LGAs using Community Health Workers and facility-based screening officers trained in PHQ-9/ Alcohol, Smoking and Substance Involvement Screening Test. Mental health providers were trained using the WHO-mhGAP. While lay counselors provided basic mental health services at the community level, non-specialist health workers provided counselling as well as pharmacotherapy in the facilities. Referrals were made to mental health experts for severe cases. Data were analyzed for yield, treatment linkage, and operational challenges.

Results/Impact: TB-Depression Comorbidity: 1 in 2 diagnosed TB cases (832/1,666) had depressive symptoms.

- TB-SD Comorbidity: 1 in 5 diagnosed TB cases (385/1,666) had substance use disorder
- Community Integration: 20 lay counsellors provided mental health services to 150(95%) out of the 158 TB patients who had depressive symptoms and 66 (87%) out of the 76 who had SD.
- Facility Integration: 48 health workers provided mental health interventions for 593 (88%) of TB/Depression and 275(89%) of the 309 TB/SD cases at facility level.

Conclusions: Task-shifting to lay counselors and non-specialist health workers improved access to integrated care. Policy implications include scaling simplified screening tools and embedding mental health into national TB programs.

EP33 Characterising the drivers and impacts of TB- related stigma across different contexts

EP33-1014-20 Toward a conceptual understanding of intersectional stigma and resilience in DRTB-HIV coinfection

A. Daftary,[1,2] J. Zelnick,[3] B. Seepamore,[4] J. Yushkov,[5] K. Reis,[6] X. Lu,[7] R. Boodhram,[2] K. Guzman,[8] K. Naidoo,[2] R. Perumal,[2] M. O'Donnell,[8] KR. Amico,[9] PRAXIS Study Team [1]York University, School of Global Health and Dahdaleh Institute of Global Health Research, Toronto, Canada, [2]CAPRISA, MRC-HIV-TB Pathogenesis and Treatment Research Unit, Durban, South Africa, [3]Touro University, Graduate School of Social Work, New York, United States of America, [4]University of KwaZulu-Natal, Social Work, Durban, South Africa, [5]McGill University, School of Population and Global Health, Montreal, Canada, [6]University of Washington, Internal Medicine, Seattle, United States of America, [7]Columbia University, Division of Pulmonary, Allergy, and Critical Care Medicine, New York, United States of America, [8]Columbia University, Department of Medicine, Division of Pulmonary, Allergy, and Critical Care Medicine, New York, United States of America, [9]University of Michigan, Department of Health Behavior Health Equity, School of Public Health, Ann Arbor, United States of America
e-mail: jacquelyn.yushkov@mail.mcgill.ca

Background: South Africa has the world's largest DRTB-HIV syndemic. Affected people encounter multilevel challenges, including external and internal stigma. We explored intersectionalities in DRTB-HIV stigma to conceptualize interventions.
Design/Methods: Qualitative research was nested into a trial aimed at improving adherence to all-oral treatment regimens among adults with DRTB-HIV in Durban. From April 2019-April 2020, in-depth interviews were conducted with ~10% of trial participants reporting extreme stigma scores (<7 and >12) on a study-derived stigma measure. Stigma and intersectionality theories supported thematic analysis.
Results: Fourteen consenting participants (24-48 years, 57% women) completed interviews; 12 lived in informal settlements, 6 had primary education only, and 6 had adherence challenges. All had lived with HIV prior to DRTB. Participants felt stigmatized from both conditions but revealed unique drivers, impacts, intensities, and capacities to resist each. External DRTB stigma, driven by fear of infectiousness, manifested as physical separation and ostracization within homes, communities, clinics and workplaces, and diminished emotional and material support. External HIV stigma, driven by mistrust and assumed wrongdoing, manifested as teasing, gossiping, and partner rejection. Internal stigma was attributed to DRTB, driven by repeat mistreatment, guilt, lost productivity, and treatment pessimism; leading to embarrassment, social withdrawal, and mental distress. Stigma experiences were compounded by poverty and fraught gender-relations. Positive treatment responses and guarded disclosures (sharing TB over DRTB or HIV) helped participants to resist dominant drivers of stigma. Time, diagnosis acceptance, and personal priority-setting built resilience. Longer life-experiences with HIV and ART stability enabled many participants to deflect and develop resilience to HIV stigma.

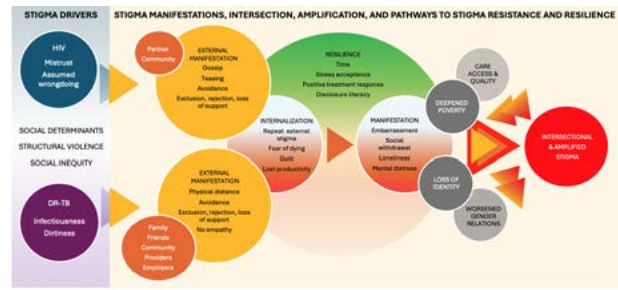


Figure. Heuristic representation of intersectional stigma in people with DRTB and HIV

Conclusions: The confluence of stigmas related to DRTB and HIV provokes amplified, intersectional stigma in people affected by both. Positive messaging supporting DRTB-HIV treatment and recovery, psychosocial assistance addressing prevailing inequities, and people-centered approaches to DRTB notification, disclosure and isolation may alleviate stigma, and potentially enable adherence and mental well-being.

EP33-1015-20 The landscape of TB stigma in Nepal: Contextual evidence of stigma levels, manifestations, and experiences among people with TB

G. Shrestha,[1] R.P. Koirala,[1] M.K. Sah,[1] D. Panday,[1] B. Rai,[1] R. Dhital,[1] M. Caws,[1,2] K. Dixit,[1] [1]Birat Nepal Medical Trust, Department of Research, Kathmandu, Nepal, [2]Liverpool School of Tropical Medicine, Department of Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: gyanendra@bnmt.org.np

Background: An estimated 69000 Nepali people develop tuberculosis (TB) annually, yet only half are diagnosed and treated in government system. TB-related stigma represents a significant barrier contributing to this diagnostic gap. Nepal's unique and complex traditional culture complicates stigma research due to societal constructs and diverse ethnic interpretations of disease causation. We explored culturally diverse manifestations, experiences, and levels of stigma among people with TB.
Design/Methods: From March to December 2024, we conducted a cross-sectional study across six districts in Nepal. We interviewed 60 individuals with TB (equal male/female) in intensive treatment phase from high TB

notification DOTS centers and analysed stigma levels and manifestations using Stop TB Partnership's validated TB-stigma assessment tool. Open-ended responses were transcribed, translated, and analysed thematically.

Results: The study cohort (n=60) included 75% (45/60) participants aged 25-64 years predominantly from rural poor communities. The cohort's stigma level was 69%. The majority experienced self-stigma, manifested as keeping their distance from others (58/60;97%), selective disclosure (55/60;92%), and guilt (49/60;82%). Participants experienced feeling hurt by others' reactions (53/60;88%), losing friends after disclosure (52/60;87%), and experiencing loneliness (45/60; 75%).

Qualitative findings revealed gender-independent enacted stigma manifested through physical distancing and separation of personal items within households, resulting in reduced communication, isolation, and emotional distress. Anticipated stigma led to fear of social discrimination, job loss, and selective disclosure outside the family. Following disclosure, participants reported experiencing hatred, family and friend abandonment, education disruption, and employment termination. Females of all ages commonly mentioned social rejection from neighbors and reduced family care.

Conclusions: TB-related stigma is highly prevalent among people with TB in Nepal, causing negative psychosocial impacts. People with TB face stigmatization from family and community members. Integrating peer support mechanisms, such as TB clubs and family-centered counseling, into national TB program could mitigate stigma and improve timely TB diagnosis and care.

EP33-1016-20 Tuberculosis stigma and health-seeking behavior: Results from the 2022 Nairobi, Kenya tuberculosis prevalence survey

K. Reis,[1] J.R. Ong'ang'o,[2] L. Njagi,[2] R. Kiplimo,[3] K.H. Tram,[1] T.R. Hawn,[4,1] V. Nduba,[2] D.J. Horne,[1,4] J.M. Ross,[1]
[1]University of Washington, Department of Medicine, Seattle, United States of America, [2]Kenya Medical Research Institute, Centre for Respiratory Diseases Research, Nairobi, Kenya, [3]AMREF Health Africa, Health Systems Strengthening Directorate, Nairobi, Kenya, [4]University of Washington, Department of Global Health, Seattle, United States of America
e-mail: jross3@uw.edu

Background: Interventions to reduce tuberculosis (TB), including active case-finding, require an understanding of the population distribution of TB stigma. The impact of stigma on the TB care cascade is complex and incompletely understood.

Design/Methods: We conducted a cluster-based TB prevalence survey in 2022 among adults in nine communities of Nairobi, Kenya. TB stigma was defined as endorsing any of the 10 stigma attitudes in a validated TB stigma questionnaire. Participants were screened using WHO 4-symptom screening for TB (W4SS) and asked about health seeking behaviors. Multi-level logistic regression models including a random variable at the community level were used to determine correlates of individual TB stigma. Logistic regression models were used to determine association between individual, household, and community-level stigma and individual health seeking behavior.

Results: Of 6366 surveyed individuals, 1631/6366 (25.6%) reported any TB stigma, and community prevalence of TB stigma ranged from 20.4-43.2% (chi-squared test p-value <0.001). In a model adjusted for demographic/clinical variables significantly associated with TB stigma in uni-variable analysis, individual TB stigma was associated with younger age (odds ratio (OR) 0.97 (0.97-0.98), p<0.001), female sex (1.16 (1.00-1.33), p=0.047) and HIV-status (1.86 (1.21-2.87), p=0.005).

Among individuals reporting ≥1 W4SS symptom, higher community-level prevalence of TB stigma was associated with higher odds of seeking health care (adjusted OR 1.37 (1.05-1.77), p=0.018) (per 10% increase in community TB stigma prevalence) (Table 1). Individual and household TB stigma were not significantly associated with health seeking behavior.

	OR	p-value	aOR†	p-value
Individual TB stigma	1.20 (0.79-1.83)	0.392	1.18 (0.77-1.82)	0.453
Household TB stigma‡	1.03 (0.98-1.08)	0.310	1.02 (0.97-1.08)	0.415
Community TB stigma‡	1.29 (1.00-1.66)	0.052	1.37 (1.05-1.77)	0.018

Individual TB stigma was defined as an individual who reported any of the surveyed TB stigma attitudes.
Household TB stigma was defined as frequency of individuals in a household reporting any of the surveyed stigma attitudes.
Community TB stigma was defined as frequency of individuals in a community reporting any of the surveyed stigma attitudes.
*W4SS symptoms are cough, night sweats, fever, and weight loss
†Adjusted for correlates of TB stigma (age, sex, HIV-status)
‡Reported per 10% increase in frequency of TB stigma per household/community

Table 1: Logistic regression analysis to determine associations between TB stigma at the individual, household, and community levels, and likelihood of health seeking behavior among individuals reporting ≥1 WHO 4-symptom screening for TB (W4SS) symptom (n=1121).*

Conclusions: Within a high-TB prevalence, urban environment, TB stigma was common, differed in frequency across communities, and correlated with social and demographic factors. We found an association between increased community-level TB stigma and health seeking behavior, suggesting a complex interplay between TB stigma and gaps in TB diagnosis, and supporting further investigation into the impact of TB stigma on the care cascade.

EP33-1017-20 Stigma's dual shadow: TB-HIV misconceptions affect patients and health workers in West Nile, Uganda

L. Ocen,[1] S. Najjingo,[1] J. Muhangi,[1] R. Tamale,[1]
[1]Uganda Episcopal Conference, Uganda Catholic Medical Bureau, Kampala, Uganda
e-mail: locen@ucmb.co.ug

Background: West Nile, Uganda, bears a high TB burden compared to the national average. To compound this, TB-HIV stigma persists, affecting both patients and health workers (HCWs). We explored the magnitude and effects of TB stigma in Zombo district to guide interventions.
Design/Methods: We conducted a cross-sectional survey of 275 people with or who had TB (PWTB) (177 pulmonary TB, 89 unknown type) and 47 HCWs in Zombo district. Using the Van Rie Self-Stigma Scale (0–4: strongly disagree to strongly agree). PWTB item A7 ("I am afraid to tell others I have TB because they may think I also have HIV/AIDS") and HCW items (e.g., A1: "nervous about treating TB patients") were analyzed for prevalence, mean scores, and care inhibition using Stata V.17. Self-stigma scores (max 48) and agreement rates (≥3) were used to assess the impact of stigma on TB care access and service delivery.
Results: Among PWTB, 42.5% (117/275) feared disclosing TB due to perceived HIV/AIDS stigma (mean 0.34, SD 0.81), exceeding clinic avoidance (16.7%) and family disclosure fears (25.5%). Self-stigma averaged 25.1; 36.4% scored high. Men (45.3%) and ages 25–44 (44.7%) showed the highest agreement (p=0.14). Care inhibition was low (9.1%), suggesting internalized stigma.
Only 7.6% were HIV-positive, indicating TB stigma's independence. Among HCWs, 76.6% (36/47) felt nervous treating TB patients (mean 0.77), with 48.9% facing stigma, especially in clinics (36.2%). Nurses (52.9%) reported higher stigma than doctors (35.7%).
Conclusions: Stigma linking tuberculosis to HIV/AIDS drives patient fears, prioritizing secrecy over openness, yet not deterring care. Healthcare workers, especially nurses, who are a critical cadre in TB management, face stigma that erodes confidence in TB care. Tailored educational initiatives and specialized training must address misconceptions to promote stigma-free, confident care in high-burden settings.

EP33-1018-20 Assessing the impact of stigma on access to TB services in Zimbabwe

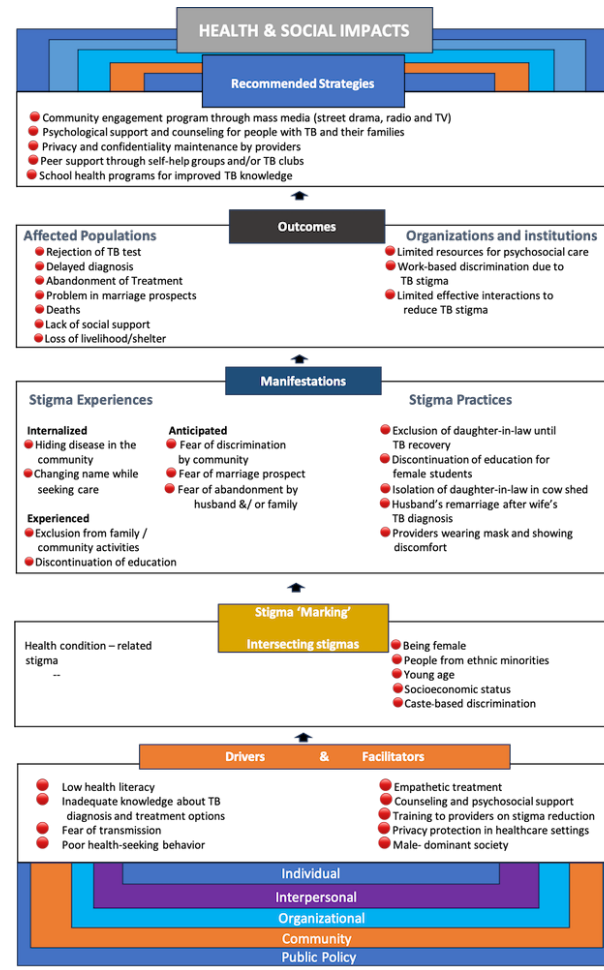
D.D. Tobaiwa,[1] K. Mutungamiri,[2] [1]Jointed Hands Welfare Organisation, Programs, Gweru, Zimbabwe, [2]Jointed Hands Welfare Organisation, Strategic Information, Gweru, Zimbabwe

Background: Tuberculosis (TB)-related stigma is a critical barrier to accessing healthcare services, adherence to treatment, and overall well-being of people with TB (PWTB). This study aimed to assess the extent and sources of stigma inhibiting access to TB services among PWTB in Zimbabwe. The assessment sought to identify key stigma-related barriers and inform targeted interventions.
Design/Methods: A nationally representative cross-sectional survey was conducted, involving 416 PWTB from diverse settings across Zimbabwe. Data were collected through structured interviews using a standardized TB stigma assessment tool. The survey measured stigma in various domains, including self-stigma, stigma within families, communities, workplaces, and healthcare facilities. Descriptive and inferential statistical analyses were performed to quantify stigma prevalence and its association with service utilization barriers.
Results: Findings revealed that stigma in the community (22%) was the most significant barrier to accessing TB services, followed by self-stigma (10%) and stigma within the family/home (10%). Workplace stigma (6%) and stigma in healthcare facilities (5%) were also reported, albeit at lower levels. The cumulative impact of these stigmas contributed to delays in seeking diagnosis and treatment, social isolation, and reduced adherence to TB care protocols.
Conclusions: TB stigma remains a significant impediment to service uptake in Zimbabwe, particularly at the community level. Targeted interventions, including community awareness campaigns, healthcare provider training, and psychosocial support for PWTB, are recommended to mitigate stigma and improve health outcomes. Addressing self-stigma and family-level discrimination through counselling and peer support groups can further enhance treatment adherence and reduce TB-related suffering. The findings underscore the urgent need for stigma reduction initiatives within national TB programs.

EP33-1020-20 Healthcare providers' perception of tuberculosis-related stigma: Drivers and manifestations within Nepal's cultural contexts

K. Dixit,[1] J. Gurung,[1] R.P. Koirala,[1] M.K. Sah,[1] D. Panday,[1] B. Rai,[1] G. Shrestha,[1] M. Caws,[1,2] R. Dhital,[1] [1]Birat Nepal Medical Trust, Department of Research, Kathmandu, Nepal, [2]Liverpool School of Tropical Medicine, Department of Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: kritika@bnmt.org.np

Background: An estimated 69,000 Nepalis develop tuberculosis (TB) annually, yet only half are diagnosed and treated in government system. TB-related stigma represents a significant diagnostic barrier, complicated by Nepal's unique cultural interpretation of disease.
This study explored culturally diverse stigma drivers, manifestations, experiences, and outcomes from healthcare providers' perspectives.
Design/Methods: Between March and December 2024, we conducted a cross-sectional qualitative study in six districts of Nepal. Using semi-structured guides, we interviewed 20 community TB care providers and explored stigma manifestations, gender and ethnic variations, and impact on diagnosis and care.
Audio-recorded interviews were transcribed, translated and thematically analysed. The results were mapped using the health and stigma framework domains: Drivers, facilitators, marking, manifestations, and outcomes.
Results: TB stigma was driven by poor socioeconomic conditions and social disparities. Positive facilitators for reducing stigma included provider training on stigma identification and reduction, psychosocial counseling to people with TB and family members, confidentiality maintenance, and community campaigns in local language.
Gender and ethnic minority status intersected with TB stigma, manifesting as internalized stigma–disease concealment, name and identity changes for TB registration; anticipated stigma– fear of family and/or community abandonment.
Discriminatory practices were reported by females with TB, especially younger individuals, such as discontinuation from education, being sent to paternal homes, isolation in cow sheds, and marriage difficulties, leading to test refusal, delayed diagnosis, and deaths. Males experienced better outcomes partly due to mobility autonomy, facilitating improved access to diagnosis and care.
Conclusions: TB stigma was perceived to be driven by and intersected with sociocultural factors among people with TB in Nepal, disrupting access to TB diagnosis and care. The results show that people-centered support interventions such as psychosocial counseling, peer support for people with TB and family, and gender-sensitive TB care are required to overcome TB stigma and improve timely TB diagnosis and care.



EP33-1021-20 Manifestations of stigma related to unhealthy alcohol use and its impact among people with tuberculosis or HIV coinfection in Pune, India

S. Bagchi,[1,2] G. Dhumal,[1,2] R. Borse,[3] A. Kakrani,[4] N. Abhivant,[5] A. Gupta,[6] G. Chander,[7] N. Suryavanshi,[1,2] H. Hutton,[8] HATHI study team [1]Johns Hopkins Centre for Infectious Diseases in India, Johns Hopkins School of Medicine, Division of Infectious Diseases, Pune, India, [2]Byramjee Jeejeebhoy Government Medical College, Johns Hopkins University, Clinical Research Site (BJGMC-JHU-CRS), Byramjee Jeejeebhoy Government Medical College, Johns Hopkins University, Clinical Research Site (BJGMC-JHU-CRS), Pune, India, [3]Byramjee Jeejeebhoy Government Medical College,Sassoon General Hospital, Jai Prakash Narayan Road, Pune, Maharashtra, India, Department of Medicine, Pune, India, [4]Dr. D.Y. Patil Medical College and Research Centre, Department of Medicine, Pune, India, [5]Byramjee Jeejeebhoy Government Medical College,Sassoon General Hospital, Jai Prakash Narayan Road, Pune, Maharashtra, India, Department of Psychiatry, Pune, India, [6]Johns Hopkins University, School of Medicine, Division of Infectious Diseases, Baltimore, United States of America, [7]University of Washington, Division of General Internal Medicine, Seattle, United States of America, [8]Johns Hopkins University, School of Medicine, Department of Psychiatry and Behavioral Sciences, Baltimore, United States of America
e-mail: nsuryav1@jhmi.edu

Background: Stigma negatively affects the treatment of Tuberculosis (TB), HIV, and unhealthy alcohol use (UAU). Although UAU often co-occurs with TB and HIV, little is known about the stigma faced by people with TB or HIV coinfection (PWTB/HIV), and how health providers (HPs) and community perceive PWTB/HIV with UAU. Our study qualitatively examines stigma manifestations of UAU among PWTB/HIV and its effects on their psychological well-being, using the Health Stigma and Discrimination Framework by Stangl et al. (2019), which classifies stigma manifestations into stigma experiences (perceived, experienced, and self-stigma) and practices (prejudices and discriminatory behavior).

Design/Methods: Between March and August 2021, 3 focus group discussions (FGDs) with HPs from TB/HIV clinics and 20 in-depth interviews (IDIs) with PWTB/HIV, their families, and senior HPs from TB/HIV clinics were conducted in Pune, India. FGDs and IDIs were audio-recorded, transcribed, translated, and analyzed in MAXQDA using thematic analysis.

Results: We conversed with 33 HPs (24 males, 9 females), 12 PWTB/HIV with UAU (11 males, 1 female), and 5 family members (3 males, 2 females). Key findings included: *Perceived Stigma:* PWTB/HIV and their families, reported fears of discrimination and alienation from society, and their HPs associated with diagnosis of UAU. *Experienced Stigma:* PWTB/HIV reported experiencing a lack of empathy and trust from HPs, families, and community. *Prejudices:* HPs, male PWTB/HIV, and families perceived female PWTB/HIV with UAU as 'unchaste'. HPs and families believed that PWTB/HIV with UAU lack treatment adherence and ability to manage alcohol abstinence sustainably. (Table 1) *Stigma Consequences:* PWTB/HIV reported loneliness, helplessness, low self-esteem, and concealed their drinking from families and HPs as consequences of perceived and experienced stigma.

Stigma Experiences			Stigma Practices	
Perceived stigma	Experienced Stigma	Self-Stigma	Prejudices	Discriminatory behaviors
PWTB/HIV reported: 1. Fear of being neglected by health providers due to their unhealthy alcohol use (UAU). 2. Fear of being labeled as a 'bad person' by the neighborhood due to their UAU and disease conditions. 3. Fear of being labeled as 'an irresponsible and bad person' by their family members if they disclose their UAU and disease conditions. 4. Fear of being blamed by family and society for their UAU as the cause of their disease condition. Families of PWTB/HIV reported: 5. Fear of social alienation due to the presence of UAU and disease conditions in their household.	PWTB/HIV reported: 1. Receiving negative social labels such as 'irresponsible, immoral' etc. from some community members due to their UAU and disease condition. 2. Receiving a lack of empathy while seeking healthcare and a lack of trust in their ability related to alcohol abstinence from some health providers due to their UAU while attending clinics. 3. Neglect and lack of trust in their ability to alcohol abstinence received from family members. 4. Social alienation faced by the PWTB/HIV and their family members from the community due to their UAU and disease conditions.	1. Low self-esteem and negative self-image reported by the PWTB/HIV	1. Health providers do not trust PWTB/HIV with UAU to accurately report their alcohol use or adhere to alcohol abstinence. 2. Health providers reported low confidence in PWTB/HIV with UAU to moderate or quit alcohol use. 3. Low confidence among family members in PWTB/HIV with UAU regarding their ability to moderate or quit alcohol. 4. Health providers, family members, and male PWTB/HIV perceived female PWTB/HIV with UAU as "unchaste"	1. Some health providers mentioned that they sometimes rebuke and feel irritated with the PWTB/HIV and their family members while dealing with PWTB/HIV with UAU.

Table 1: Manifestations of Stigma related to unhealthy alcohol use (UAU) among people with Tuberculosis or HIV coinfection (PWTV/HIV).

Conclusions: Stigmas on UAU negatively impact PWTB/HIV's psychological well-being, potentially affecting their treatment adherence. Future research should prioritize combining stigma-reduction interventions at individual and community levels while treating PWTB/HIV with UAU, thereby enhancing patient-centered care.

EP33-1022-20 Determinants of tuberculosis-related stigma among school-aged adolescents in Bangkok, Thailand

S. Moonsarn,[1] S. Singha,[1] [1]World Vision Foundation of Thailand, Principal Recipients of the Global Fund, Bangkok, Thailand.
e-mail: sarut_moonsarn@wvi.org

Background and challenges to implementation: TB remains a major public health issue in Thailand and globally, with stigma significantly affecting those impacted. Several factors contribute to TB-related stigma, including limited knowledge, low awareness, and negative perceptions about the disease.
Notably, high school students have been reported to exhibit stigmatizing attitudes toward individuals with TB, reflecting the influence of these factors among adolescents. However, there is still limited data focusing on the underlying causes of TB stigma among age group.
Intervention or response: Since the objective to explore factors associated with TB stigma among school adolescents in Bangkok, Thailand. A descriptive study design was employed. The participants were school adolescents aged 15-19 years old, who were studying in grades 10-12 in Bangkok, Thailand. A systematic sampling was used for the selection of the participants.
Data were collected by questionnaires consisting of the following four parts including
1. Demographic characteristics,
2. TB knowledge,
3. TB attitudes, and;
4. TB stigma.
Descriptive statistics were used to summarize the data, while Chi-square tests and Fisher's exact tests were employed to examine associations between variables.
Results/Impact: This study found that factors related to demographic characteristics significantly associated with TB stigma were sex, age, classes, and type of accommodation (p-value < 0.05).
Similarly, attitudes toward pulmonary TB were significantly associated with TB stigma (p-value= 0.014), while knowledge about pulmonary TB was no associated with TB stigma.
Conclusions: Several factors have been associated with TB-related stigma, including sex, age, grade level, type of accommodation, and attitudes toward pulmonary TB. The study suggests that targeted interventions should be implemented to improve TB knowledge, promote positive attitudes toward pulmonary TB, and strengthen advocacy and social mobilization.
These efforts are essential to reduce TB stigma and discrimination both direct and indirect within educational institutions such as public and private schools, vocational colleges, and universities.

EP33-1023-20 The change in the level of TB stigma in Ukraine during 2020-2024

N. Savchenko,[1] D. Tygach,[2] V. Denysenko,[1] [1]Charity Organization „100% LIFE", Advocacy, Kyiv, Ukraine, [2]Charity Organization „100% LIFE", Advocacy, Kyiv, Ukraine
e-mail: n.savchenko@network.org.ua

Background: Stigmatization of tuberculosis (TB) is one of the most significant social factors hindering equal access to medical services for people with tuberculosis (PWTB). It prevents timely seeking of medical help, negatively impacts treatment adherence, leads to deteriorating health conditions, and violates human rights. The impact of stigma across personal, family, medical, community, and legal environments was studied in Ukraine (2020–2021, 2023–2024).
Design/Methods: Two mixed-methods studies were conducted from June 2020 to March 2021 and from April 2023 to June 2024. The StopTBPartnership research tool was used to assess TB stigma. In both studies, the representative sample included 1,770 PWTB, 89 family members of PWTB, 82 community members, and 362 healthcare workers, all surveyed using semi-structured questionnaires developed for each group to assess stigma at various stages of TB treatment. The responses were analyzed and compared over time.
Due to COVID-19 in the first study and the war in the second study, data were collected remotely by trained interviewers. A desk analysis of the policy and legal environment was conducted in 2020 and 2023, and four focus groups were held to determine the stigma in legislation and the political environment.
Results: Between 2021 and 2024, self-stigmatization among PWTB and anticipated stigma in the community and healthcare decreased. Legal conditions improved, but secondary stigma within families increased. Details are provided in the table below.

Indicator	2021	2024
Self-stigmatization (PWTB)	47%	42%
Secondary stigma (family)	42%	45%
Anticipated stigma (community)	70%	52%
Anticipated stigma (healthcare)	63%	61%
Harm in legal environment	54%	21%

Conclusions: It is necessary to conduct educational campaigns to raise awareness about tuberculosis, based on respecting the rights of PWTB and ensuring access to medical services. To protect the rights of PWTB, it is necessary to continue improving the legal environment. Social and professional reintegration of PWTB must be ensured.

EP34 Advanced tools and strategies to enhance detection

EP34-1024-20 Person-centered solution to repeat sputum collection increases TB diagnosis in Manila, Philippines

M.D.K. Galvan,[1] K.J. Agawin,[2] M. Fernandez,[2] G. Babiker,[2] R. Castro,[3] F. Hossain,[4] C. Hewison,[5] [1]Médecins Sans Frontières, Operational Research Department, Manila, Philippines, [2]Médecins Sans Frontières, Medical Department, Manila, Philippines, [3]Manila Health Department, Health Department, Manila, Philippines, [4]Médecins Sans Frontières, Medical Department, Tokyo, Japan, [5]Médecins Sans Frontières, Medical Department, Paris, France
e-mail: cathy.hewison@paris.msf.org

Background and challenges to implementation: Sputum Xpert testing plays a critical role in confirming tuberculosis (TB). However, challenges arise when initial results — MTB detected trace, Invalid/Error, or initial MTB detected Rif resistance detected — require patients to resubmit sputum sample for re-testing. Tondo, in Manila, Philippines is a densely populated area, with highly mobile and socioeconomically impoverished population. Médecins Sans Frontières (MSF) launched community-based Active TB Case Finding (ACF) with immediate on-site sputum collection for persons with presumed TB.
Despite timely availability of results, many people requiring repeat sputum testing fail to submit second sample to the health facility therefore delaying or foregoing treatment altogether. We describe a patient centered response to improved repeat testing.
Intervention or response: Competing everyday priorities such as work, and childcare were identified as major reasons for not submitting a second sample to the health facility for repeat testing. In response, MSF implemented a decentralized approach to sputum recollection in 2024. Instead of asking patients to resubmit sample to the health facility, sputum recollection was done directly at the household by MSF outreach nurses then transported to the laboratory for Xpert testing.

INDICATOR	2023	2024
Xpert tests done	5455	5052
Required repeat testing	203 (3.7%)	167 (3.3%)
Repeat test done	73 (40%)	139 (83%)
Diagnosed with TB	61 (84%)	104 (75%)
Drug-susceptible TB	54 (89%)	94 (90%)
Drug-resistant TB	7 (11%)	10 (10%)

Results/Impact: In 2023, before the implementation of household sputum collection, 203 participants required repeat testing and only 40% (73/203) were able to submit second specimen to the health facility, of which 84% (61/73) were diagnosed with TB. In 2024, when MSF started household sputum recollection, of 167 ACF participants needing repeat testing, 83% (139/167) successfully submitted sample, of which 75% (104/139) were diagnosed with TB.
Conclusions: A decentralized approach to sputum recollection is patient centered and effectively increases TB diagnosis in an impoverished and densely populated area. This intervention highlights the importance of adaptable, patient-centered strategies in addressing public health challenges, which may be replicated elsewhere and be scaled up through local partnerships and capacity building of community health workers to conduct sputum collection.

EP34-1025-20 Accuracy of computer aided detection (CAD) for TB screening among ex-miners in Mafeteng District, Lesotho

L. Oyewusi,[1] L. Maama,[1] M. Anatole,[1] T. Raleting,[1] T. Moshoeshoe,[2] L. Matakane,[1] M. Khesa,[1] [1]Ministry of Health, National TB and Leprosy Program (NTLP), Maseru, Lesotho, [2]EGPAF, TB Program, Maseru, Lesotho
e-mail: loyewusi2015@gmail.com

Background and challenges to implementation: Improving TB case finding in Lesotho has become a priority in the quest to end TB. With a TB incidence of 661 per 100,000 population, Lesotho remains a high TB burden setting with a significant gap of 63% in TB case notification. To improve TB case detection, Lesotho adopted the WHO recommendation, following the findings of the TB prevalence survey, and introduced the use of CXR with CAD for TB screening. A campaign to screen ex-miners was launched in Mafeteng district in an attempt to find the missing people with TB.
Intervention or response: The Lesotho Ministry of Health deployed mobile X-rays with AI to the district, mainly for community TB screening among ex-miners. TB screening was conducted at the centre of excellence set up previously under the World Bank project for ex-miners. 740 ex-miners were screened using CXR+CAD and symptom-based screening. Sputum samples collected from these individuals were sent for GeneXpert analysis at the district laboratory for bacteriological confirmation.
Results/Impact: Of the 740 ex-miners screened, AI indicated that 200 (27%) had abnormal findings, but 135 (68%) of them were suggestive of TB. Of the 135 ex-miners, 116 (86%) were initiated on 1st line TB treatment without bacteriological confirmation but based solely on AI interpretation, while the remaining 19 (14%) were not evaluated.
Upon receipt of the GeneXpert results, all 135 ex-miners tested negative for TB and were subsequently referred to the district hospital for further evaluation and appropriate treatment.

Conclusions: The use of CXR with AI can increase efficiency in finding more people with TB when used correctly as a screening tool rather than diagnostic, especially in ex-miners with a previous history of lung damage or silicosis.
GeneXpert remains the initial test for TB disease; over-reliance on the use of CXR + CAD alone in ex-miners can lead to unnecessary TB treatment.

EP34-1026-20 Active TB case finding amidst insecurity: Wellness On Wheels (WOW) experience In Benue State Nigeria

F. Mathew,[1] B. Odume,[2] J. Diara,[3] [1]KNCV Nigeria, ACF, Benue, Nigeria, [2]KNCV Nigeria, Management, Abuja, Nigeria, [3]KNCV Nigeria, Program, Benue, Nigeria
e-mail: mfila@kncvnigeria.org

Background and challenges to implementation: According to the Punch newspaper (19 July, 2024), 50 rural communities in Benue state recorded at-least 135 attacks leading to deaths of over 2,600 people, many of whom are women and children. This has left hundreds displaced, wounded, raped and others kidnapped. Benue has 23 LGAs of which 18 have been affected by insecurity and continuous attacks by armed attackers.
As a result, population displacement, malnutrition and overcrowded living conditions especially in the IDP camps and banditry affected areas increases TB transmission.
Intervention or response: KNCV Nigeria is a non profit organization implementing a USAID grant, TB local organization network (TB LON) project across 14 states in Nigeria to fight against TB and other highly infectious diseases of public health concern.
Security planning, risk assessment, collaboration with relevant stakeholders, Local government TB supervisors and community leaders was done to ascertain the risk level before engaging in any community.
The WOW truck contains an xray unit(for chest xray) and 2 genexpert machines (for confirmatory test) all powered by 4 solar panels
The WOW truck was deployed to screen consenting adults for TB in Gwer west and east, Naka, Aondona, Otukpo, Guma, Gbajimba, Daudu, Ortese, Kwande, Vandekiya, Konshisha and Gboko.
Results/Impact: Across Benue state from January to December 2023, the WOW truck screened a total of 38,059 people, identified 3,001 presumptives, evaluated 3,001, diagnosed 621 TB cases and enrolled 617. The intervention stood among other interventions as it has the lowest number needed to test(NNT) as well as number needed to screen(NNS). The WOW truck gains more attention due to the fact that it served as a diagnostic and advocacy tool.
Conclusions: Insecurity often leads to displacement, TB programs must be adaptable to the high mobility of affected population, ensuring the continuity of essential health services in regions where insecurity poses significant barriers to healthcare delivery.

EP34-1027-20 Chest X-ray referral and financing partnership to enhance TB diagnosis in South Jakarta, Indonesia

A. Aji,[1] N. Nuriyani,[1] N. Nurliyanti,[1] [1]Stop TB Partnership Indonesia, Program, South Jakarta, Indonesia
e-mail: nurliyanti@stoptbindonesia.org

Background and challenges to implementation: In Indonesia, individuals with suspected tuberculosis (TB) initially undergo molecular rapid testing using sputum samples at primary healthcare centers (PHCs). For those with negative results but persisting clinical symptoms, a chest X-ray (CXR) is required for further assessment. However, limited CXR infrastructure at PHCs and lack of national health insurance coverage create access barriers. In 2024, an estimated 1.9 million presumptive TB cases with negative sputum tests remained unevaluated by CXR, representing a major gap in the diagnostic cascade.
Intervention or response: To address this, Stop TB Partnership Indonesia (STPI), the South Jakarta City Health Office, and two private laboratories initiated a corporate-funded public-private partnership across 10 PHCs. Through this initiative, individuals presumed to have TB are referred by PHCs to the nearest participating laboratory. STPI developed a simple digital referral system that allows PHCs to submit patient referrals, which in turn prompts laboratories to provide CXR services at no cost to patients. Once the examination is completed, the laboratories upload the CXR results back to the PHCs through the same digital platform, enabling timely follow-up. Financial coverage conducted through monthly reimbursement claim submissions by laboratories to STPI.
Results/Impact: In four months, 188 patients were referred for CXR; 158 (84%) completed the examination. Of these, 93 (59%) returned to PHCs for further assessment, resulting in 20 confirmed TB diagnoses (figure)—a yield of 12.6%, significantly higher than the 4.8% average in national active case finding. This highlights the value of CXR in high-risk, sputum-negative individuals. Despite strong uptake, post-CXR drop-off underscores the need for improved patient navigation and follow-up.
Conclusions: This intervention demonstrates the feasibility of public-private partnerships in closing diagnostic gaps for TB. Its high diagnostic yield and operational practicality suggest strong potential for integration into national TB programs, particularly to strengthen the diagnostic pathway for sputum-negative individuals in resource-limited settings.

EP34-1028-20 Enhancing TB prevention and care efforts among high-risk population: Results from hospital-based targeted service delivery point screening in Nasarawa State, Nigeria

C. Igwetu,[1] M. Tukur,[1] L. Ugochukwu,[1] J. Emefieh,[1] B. Odume,[2] [1]KNCV Nigeria, Technical and Program Department, Federal Capital Territory, Nigeria, [2]KNCV Nigeria, Technical and Program Department, FCT Abuja, Nigeria
e-mail: cigwetu@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains a major global health challenge, particularly among high-risk and underserved populations. Despite their vulnerability and contribution to the global TB burden, these groups are often not adequately prioritized in TB control efforts. Effective TB management depends on timely and accurate diagnosis, prompt treatment initiation, and consistent adherence to treatment regimens. This study assessed TB yields across various hospital service delivery points (SDPs) in Nasarawa State to evaluate case detection and treatment initiation outcomes, thereby informing strategies for strengthening TB control among high-risk populations.
Intervention or response: From January to December 2023, the USAID-funded TB LON 1&2 project, implemented by KNCV Nigeria, intensified TB case-finding interventions across health facilities in Nasarawa State. TB screening was conducted at eight predefined hospital service delivery points (SDPs), targeting all patients and their accompanying relatives. Individuals identified as presumptive TB cases were evaluated and, if confirmed positive, promptly initiated on treatment. All data were documented in national registers and tracked using the COMMCARE app.

Hospital risk group	# of clients screened for TB	#presumed to have TB	#Evaluated for TB	# Diagnosed with TB	#Started on treatment	%TB yield
Accident and emergency	872	14	14	1	1	7%
Antenatal Clinic	5772	215	198	6	6	3%
Art clinic	20583	1995	1937	177	167	9%
Immunization	333	16	16	1	1	6%
Diabetes	591	36	34	2	2	6%
Elderly	9358	6%	64	74	69	9%
MOPD	4292	154	143	20	20	14%
POPD	6182	373	348	30	30	9%
Total	47,983	3,759	3554	311	296	9%

Results/Impact: A total of 47,983 individuals were screened. Among these, 3,759 were identified as presumptive TB cases, with 3,554 (94%) undergoing further evaluation. This led to the diagnosis of 311 TB cases, and 296 (95%) of them were initiated on treatment. TB yields varied across service delivery points, with the highest observed at the MOPD (14%) and ART clinic (9.1%). The Geriatric unit (8.6%) and POPD also had significant yields, indicating the TB burden among elderly clients and children. The lowest yield was recorded among pregnant women.
Conclusions: Targeted TB testing should be prioritized to increase yield, especially amongst high-risk populations. We recommend tailoring TB screening strategies and prioritizing resource allocation based on risk profile and TB yield within hospital settings, as this supports global efforts toward universal health coverage and ensures inclusive access to care, leaving no one behind.

EP34-1029-20 The contribution of screening to global TB notification

C. Miller,[1] A. Kanchar,[1] M. Zignol,[1] D. Falzon,[1] [1]World Health Organization , Global Programme on Tuberculosis & Lung Health, Geneva, Switzerland
e-mail: cmiller@who.int

Background and challenges to implementation: Progress towards the End TB Strategy goals of finding all people with TB, and thereby reducing TB incidence, has stalled. The 2023 UN High-Level Meeting on Tuberculosis (TB) set new targets to achieve at least 90% TB treatment coverage by 2027. Global TB notification has increased in the wake of the COVID-19 pandemic. However, a gap of close to 3 million TB cases remains when compared with global TB incidence. Systematic TB screening and active TB case finding (ACF) efforts need to be stepped up to bridge this gap.
Intervention or response: We used country data collected annually by WHO for the Global TB Report to calculate the proportion of TB notifications deriving from screening and ACF in 2023.

Map. Percentage of people newly diagnosed with TB (new and relapse cases) reported through TB screening efforts, 2023.

Results/Impact: In 2023, 114 countries reported the number of people newly diagnosed with TB who were identified through provider-initiated screening and ACF

efforts in high-risk groups such as contacts, people living with HIV, people in prisons and mining communities, and through community-based ACF efforts among high-risk groups and facility-based screening of people with diabetes and other risk factors. In the 114 countries, a median of 12% [IQR: 3-29%] of the total new and relapse cases reported originated from screening and ACF activities.

Of 66 high-priority countries, 52 reported that in 2023 a median of 89% [IQR: 25-100%] of administrative levels regularly undertook screening and ACF using chest X-ray, a critical screening tool.

Conclusions: Despite a non-negligible contribution of screening activities to global TB notification and widespread availability of chest X-rays at peripheral levels, TB treatment coverage remains suboptimal. Chest X-ray coverage and screening activities need to be expanded in high-burden communities and countries, alongside greater access to accurate chest X-ray interpretation (including computer-aided detection software) and confirmatory testing.

EP34-1030-20 Mapping margins: A geospatial and programmatic analysis of TB loss-to-follow-up in border districts of Tamil Nadu, India

A. Frederick,[1] M.M. Regy,[2] S. Achantas,[2] K.V. Suma,[2] N. Thiliban,[2] D. C,[2] J.G. Thampi,[2] U.B. Singh,[3]
[1]Department of Health and Family Welfare, Department of Health and Family Welfare, Chennai, India, [2]Government of India WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [3]Ministry of Health & Family Welfare, Government of India, Central TB Division, New Delhi, India
e-mail: minittamr@rntcp.org

Background: Tamil Nadu, a geographically expansive state in southern India, shares borders with four other states and one union territory—regions that often function as programmatic peripheries with potential systemic vulnerabilities. This study evaluates whether Tuberculosis Units (TUs) located in border districts exhibit a higher burden of Loss to Follow-Up (LFU), conceptualizing LFU not only as a program outcome but as a geographically patterned, system-mediated phenomenon.

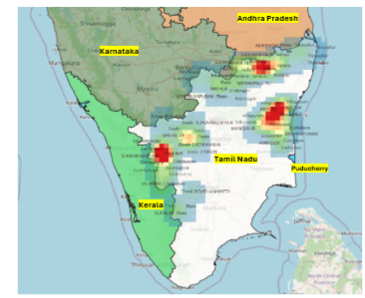
Objectives:

i. To compare LFU proportions among TB cases notified in 2022, between border and non-border districts, following a two-year outcome ascertainment period.
ii. To map the spatial distribution of LFU using QGIS and examine clustering patterns in TUs near state borders

Design/Methods: A TU-level operational analysis was conducted using 2022 National TB Elimination Programme (NTEP) data. Eight border districts were purposively selected to represent all neighboring states/UTs, along with eight centrally located non-border districts. LFU was defined as the proportion of cases lost to follow-up, excluding transfers. Spatial distribution was visualized using QGIS v3.40.3. Statistical comparisons were made using the Mann-Whitney U test after normality assessment via the Shapiro-Wilk test.

Results: Analysis from 234 TUs (127 border, 107 non-border) showed significantly higher LFU in border TUs (mean ± SD: 2.76 ± 2.65%; median: 1.89%) than in non-border TUs (1.58 ± 1.89%; median: 0.99%) (Mann-Whitney U = 8554.5, $p < 0.001$). QGIS mapping revealed that while LFU hotspots were observed in border TUs of Coimbatore, Villupuram, and Vellore, spatial heterogeneity persisted beyond administrative boundaries.

Figure 1: Spatial Distribution of TB Loss to Follow-Up cases (%) across Border district TUs of Tamil Nadu, 2022*



Inference: Geospatial mapping reveals distinct LFU hotspots in border districts, notably in Villupuram, Vellore and Coimbatore. While higher LFU rates cluster along some border regions, the distribution is heterogenous and non-uniform, with isolated hotspots also appearing beyond border zones.

Conclusions: Higher LFU in border TUs highlights the vulnerability of peripheral programmatic zones. However, significant spatial heterogeneity suggests that localized health-system factors, not geography alone, influence treatment retention. Integrated geographic and programmatic surveillance is vital for targeted interventions.

EP34-1031-20 Community health workers as frontline soldiers in TB prevention and care in Anambra State, Nigeria: Successes and challenges

S. Oguejiofor,[1] U. Chukwulobelu,[1] O. Akaniro,[2] O. Olarewaju,[2] S. Chinkata,[3] [1]Anambra State Ministry of Health, Tuberculosis Unit, Public Health/Disease control, Awka, Nigeria, [2]Federal Ministry of Health, Abuja, NTBLCP Global fund Unit, Abuja, Nigeria, [3]Abia State Ministry of Health, Tuberculosis Unit, Public Health/Disease control, Abia, Nigeria
e-mail: suzynelly733@gmail.com

Background and challenges to implementation: Tuberculosis (TB) continues to pose a major public health threat, especially in low-resource settings like Anambra State, South-eastern Nigeria, which is one of the TB high burden states. Community Health Workers (CHWs) play a vital role in connecting national TB programs with hard-to-reach populations. However, challenges such as irregular training, poor remuneration, weak supervision, fragmented data systems, and lack of sustainable financing hinder effective CHW integration. Additional barriers like stigma, low health literacy and weak community ownership also reduce program effectiveness.
Intervention or response: To address these issues, TB programs in Anambra State implemented a comprehensive strategy involving CHW training on active case finding, contact tracing, sputum collection and health education. Community sensitization was enhanced through peer-led campaigns and engagement of local leaders. CHWs also supported defaulter tracing and psychosocial care. Routine supervision and performance monitoring were strengthened, with the introduction of electronic tools like the COMMTB App for patient tracking.
Also use of PDX (Portable Digital X-ray) to conduct screening during outreaches in the community also contributed to case detection. Data collection and analysis were conducted monthly to monitor progress and outcomes.
Results/Impact: CHWs significantly boosted TB case notifications in Anambra State, contributing 62.75% (8,238 cases) in 2023 and 51.26% (5,530 cases) in 2024. Communities experienced improved TB awareness and reduced stigma. Treatment success rates increased, and loss to follow-up declined. Programs with structured CHW training, regular stipends, and effective supervision showed better outcomes. Persistent gaps included digital literacy and sustainable funding.
Conclusions: CHWs are crucial in enhancing TB response through community engagement and patient-centered support. Their integration into TB control efforts must be strengthened via standardized training, sustainable financing, digital tools, and supportive policies. Empowering CHWs as long-term partners is essential for TB elimination, with potential for adaptation in other high-burden settings.

EP34-1032-20 TB incidence and impact of mass screening and treatment for latent tuberculosis infection among North Korean refugees

Y. Yu,[1] J. Lee,[2] D. Moon,[3] J. Seo,[1] D. Kim,[4] G.-R. Park,[1] H. Choi,[1] [1]Korea University, Division of Health Policy and Management, Seoul, Republic of Korea, [2]Hyo-tree Nursing Home, Incheon, Republic of Korea, [3]Busan Center for Infectious Disease Control and Prevention, Infectious Disease Policy Analysis Team, Busan, Republic of Korea, [4]Emory University, Department of Epidemiology, Atlanta, United States of America
e-mail: uyeye9555@gmail.com

Background: Tuberculosis (TB) remains a public health concern, and North Korean refugees are a high-risk group due to the high TB burden in their country of origin and healthcare access barriers. In 2014, South Korea implemented a mass latent TB infection (LTBI) screening and treatment program for this population. This study evaluated its impact on reducing the incidence of active TB.
Design/Methods: Using the National Health Information Database (NHID), we conducted a retrospective cohort study including 33,304 North Korean refugees who entered South Korea from 2008 to 2019. Participants were classified into an intervention group (n=10,772, entered 2014–2018) and a control group (n=18,597, entered 2008–2013).
The primary outcome was active TB, identified via ICD-10 codes. We used Kaplan-Meier survival curves and Cox proportional hazards models to compare TB incidence between groups.
Results: The 5-year cumulative incidence of TB decreased from 781.9 to 284.6 per 100,000 person-years (PY) over the study period. The intervention group had a significantly lower incidence rate than the control group, with a rate difference of -246.2 per 100,000 PY (95% CI: –319.6 to –172.8) and an adjusted hazard ratio (HR) of 1.54 (95% CI: 1.31–1.81). When excluding TB cases diagnosed within six months of entry (concurrent TB), the HR increased to 1.80 (95% CI: 1.50–2.16).
However, among adults aged 65 and older, no protective effect was observed. The program's protective effect was maintained for up to five years post-entry but gradually declined afterward.
Conclusions: The LTBI screening and treatment program was associated with a reduced risk of active TB among North Korean refugees.
However, its effectiveness was not evident in older adults, highlighting the need for age-sensitive approaches and sustained, targeted TB control policies for vulnerable populations.

EP34-1033-20 Screening for TB using ultraportable handheld X-ray with AI for early detection of disease in Bihar, India

P. Das,[1] G. Kumar,[1] S.S. Abraham,[2] S. Mannan,[3] U.C. Tripathi,[4] B.K. Mishra,[5] S. Bhagat,[6] [1]William J Clinton Foundation, TB, Patna, India, [2]William J Clinton Foundation, TB, New Delhi, India, [3]William J Clinton Foundation, Infectious Diseases, New Delhi, India, [4]World Health Organization, TB, Patna, India, [5]State Health Society, Government of Bihar, TB, Patna, India, [6]State Health Society, Government of Bihar, State Health Society, Patna, India
e-mail: pdas@wjcf.in

Background and challenges to implementation: National Tuberculosis Prevalence Survey in India (2019-21) highlighted the benefit of chest radiography for TB screening but availability, accessibility and capacity constraints at peripheral public health institutions (PHI) limit its uptake. TB case finding in Bihar, India has conventionally been passive, relying upon symptomatic screening.
Intervention or response: During December 2024-March 2025, Bihar implemented a 100-day intensified case finding campaign across select (n=10) districts, including Darbhanga, Muzaffarpur and East Champaran. The state deployed six ultraportable handheld X-ray devices, equipped with artificial intelligence (AI)-based interpretation with support of William J Clinton Foundation (WJCF) across the above named three districts, having a combined population of ~16.87 million. Community-based active case finding (ACF) camps were organized with systematic mobilization of key vulnerable population (KVP).
Results/Impact: 503 ACF camps were organized, screening 49,044 beneficiaries from the KVP for TB symptoms and radiological presentation. 30% beneficiaries (14,849/ 49,044) reported at least one symptom; 10% (5,137/49,044) of screened beneficiaries had TB suggestive X-ray. Sputum samples of beneficiaries who were symptomatic and/or had a radiograph suggestive of TB were tested for confirmation of diagnosis. Of the 15,450 samples, 74% (n=11,374) were tested using nucleic acid amplification tests (NAAT) and remaining through smear microscopy. 336 patients with bacteriologically confirmed TB were diagnosed and initiated on treatment, ~16% of whom were asymptomatic.

		Chest X-ray status			Sputum test status			
District	Number of ACF camps done	People screened with chest X-ray	People with TB Suggestive chest X-ray	People with other Chest Abnormalities	No. of samples tested with NAAT	NAAT Positive	No. of samples tested with smear microscopy	Smear Positive
Darbhanga	167	16545	1763	3606	3999	133	977	36
Muzaffarpur	171	17384	1612	3076	2140	64	2681	11
East Champaran	165	15115	1762	3120	5235	92	418	0
Total	503	49044	5137	9802	11374	289	4076	47

Figure 1: District-wise details of camps and beneficiaries screened and diagnosed with TB.

Conclusions: AI-enabled ultraportable X-ray can potentially increase TB case finding, especially amongst the asymptomatic individuals. Evidence generated from the 100-days ACF campaign prompted the government of Bihar to initiate procurement of 122 ultraportable X-ray devices for active community-level TB screening across all 38 districts through a tender process.

EP35 Integrating systems to improve TB care outcomes

EP35-1034-20 The effectiveness of community engagement in improving drug-resistance TB service delivery and enrolment outcomes in Kogi State

C.I. Stephen,[1] B. Nwaogu,[2] O. Queen,[2] A. Stephen,[1] A. Aderonke,[3] T. Adetiba,[3] C. Adesigbin,[4] S. Dimang,[4] A. Reilly,[5] M. Zamzu,[5] R. Komolafe,[6] [1]Association for Reproductive and Family Health, TB&HIV, Lokoja, Nigeria, [2]Association for Reproductive and Family Health, TB&HIV, Abuja, Nigeria, [3]Global Fund N-THRIP, Institute of Human Virology, Nigeria (IHVN), Abuja, Nigeria, TB&HIV, Abuja, Nigeria, [4]National TB and Leprosy and Buruli Ulcer Control Programme Nigeria, TB&HIV, Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Grant Management Division, Geneva, Switzerland, [6]Kogi State TB and Leprosy and Buruli Ulcer Control Programme, TB&HIV, Lokoja, Nigeria
e-mail: musa.c@arfh-ng.org

Background and challenges to implementation: Drug-resistant tuberculosis (DR-TB) remains a significant public health challenge in Nigeria, a country with one of the highest DR-TB burdens in Africa. In Kogi State, the prevalence of multidrug-resistant TB (MDR-TB) has increased, particularly in the Eastern Senatorial District (Ankpa, Dekina, Olamaboro, Ofu). Between 2019 and 2023, TB control efforts were hindered by socio-economic factors, stigma, cultural beliefs, and health system constraints, leading to enrolment gaps in DR-TB treatment. Limited healthcare accessibility, inadequate patient follow-up, fear of hospitalization, and reliance on traditional healing practices contributed to delays in diagnosis and treatment initiation.
Intervention or response: The Kogi State Tuberculosis, Leprosy, and Control Program (STBLCP) implemented targeted strategies to close the enrolment gap. These included intensified community engagement, stigma-reduction campaigns, training of healthcare providers on patient-centred approaches, and the use of patient tracking systems to reduce loss to follow-up. Additionally, community health workers and linkage coordinators were engaged to facilitate case finding and treatment initiation. Efforts were also made to integrate DR-TB services into primary healthcare settings to improve accessibility. A survey was conducted to determine the causes of these gaps.
Results/Impact: Between 2019 and 2023, DR-TB case notifications increased, yet enrolment on treatment lagged behind diagnoses. In 2019, 46 DR-TB cases were diagnosed, but only 33 (71.7%) were enrolled on treatment. By 2023, 70 cases were diagnosed, with 61 (87.1%) enrolled. Despite these improvements, gaps persisted due to social stigma, financial constraints, and health system inefficiencies. Notably, loss to follow-up, alternative treatment-seeking behaviours, and delayed care-seeking remained key challenges.
Conclusions: Addressing the DR-TB enrolment gap requires a multi-faceted approach, including enhanced community sensitization, financial support mechanisms, and improved patient tracking systems. Strengthening healthcare infrastructure, expanding diagnostic services, and fostering collaboration with community stakeholders will be essential to achieving Nigeria's End TB Strategy goals and ensuring equitable access to DR-TB treatment.

EP35-1035-20 Challenges, progress and opportunities towards TB elimination in New South Wales, Australia

E. Donnan,[1,2] C. Furlong,[1] J. Pett,[1] E. Ulbricht,[1,3] P. Massey,[4,5] V. Sintchenko,[2,6] B. Marais,[2,7] [1]Health System Support Group, Health Protection NSW, Sydney, Australia, [2]University of Sydney, Sydney Infectious Diseases Institute (Sydney ID), Sydney, Australia, [3]South Western Sydney Local Health District, Respiratory and Sleep Medicine Department, Liverpool Hospital, Liverpool, Australia, [4]Hunter New England Local Health District, Hunter New England Population Health, Newcastle, Australia, [5]James Cook University, School of Medicine and Dentistry, Douglas, Australia, [6]New South Wales Health Pathology - Institute of Clinical Pathology and Medical Research, New South Wales Mycobacterium Reference Laboratory, Westmead, Australia, [7]The Children's Hospital at Westmead, Infectious Diseases and Microbiology, Westmead, Australia

Background and challenges to implementation: Australia is a low tuberculosis (TB) incidence country, with stable incidence rates; <10/100,000 population for more than 30 years. In 2024, there were 523 people diagnosed with TB in the state of New South Wales (NSW) corresponding to a notification rate of 6.3 per 100,000 population. Notification rates are tied closely to migration patterns, with 91% of people diagnosed with TB born overseas and approximately 5% local transmission per year.
Intervention or response: We critically evaluated elements of the WHO 'Towards Tuberculosis Elimination Action Framework for low incidence countries' in the context of NSW, Australia.
We analysed population, migration, and programmatic TB data and critically reflected on clinical and public health management, as well as evolving challenges and opportunities for TB elimination.
Results/Impact: Most WHO key priorities and actions are embedded in NSW policy. There has been progress in implementation and/or improvements in
1. Enhanced data capability and reporting,
2. Tracking key indicators including TB death reviews,

3. Integration of genomics into TB care and control,
4. Universal contact screening and
5. Increased migrant screening and follow-up.

TB care is free of charge and there has been increased focus on patient-centred care. Patient management is supported by expert panel review for rifampicin-resistant TB and other complex patients, and increased access to TB medications via the Global Drug Facility. TB-specific education opportunities and networks within NSW Health maintain connectedness and workforce competency.

Conclusions: Whilst TB elimination remains out of reach in NSW with increasing migration from high TB incidence countries, significant progress has been made in NSW to enhance patient care and disease control, supported by genomics to track local transmission and data optimisation for better monitoring and reporting. Further opportunities include increased primary care involvement in screening and TB preventive treatment, and better cultural engagement of affected communities.

EP35-1036-20 Performance-based incentives to improve quality of TB care at primary healthcare providers in Indonesia

I.A. Isturini,[1] T.T. Pakasi,[2] N. Badriyah,[2] N.I. Amalia,[3] K. Pratiwi,[3] A.A. Mailana,[3] D.P. Pramesti,[3] L. Devega,[3] A.B. Wicaksono,[4] [1]Ministry of Health of Republic of Indonesia, Communicable Disease Control Department, South Jakarta, Indonesia, [2]Ministry of Health of Republic of Indonesia, National Tuberculosis Program, South Jakarta, Indonesia, [3]Ministry of Health of Republic of Indonesia, National Tuberculosis Program, Central Jakarta, Indonesia, [4]USAID Long Term Exceptional Technical Assistance Project (LEAP), Technical Department, South Jakarta, Indonesia

Background and challenges to implementation: Indonesia has the world's second-highest tuberculosis (TB) burden (GTB, 2024). Despite the highest TB notifications in 2024, 58% of cases were managed at secondary facilities (NTP, 2025). Primary healthcare (PHCs) plays a significant role in TB management, however, 39% of TB patients were referred by PHCs to secondary facilities, with 97% involving uncomplicated TB cases suitable for primary-level management (NHI, 2019).

This practice increases healthcare costs and worsens treatment outcomes. The Ministry of Health Indonesia, in collaboration with partners, piloted the performance-based incentive for primary healthcare providers.

Intervention or response: Between July 2023 to June 2024, Innovative TB Financing were implemented across 675 primary healthcare providers in six Indonesia, including a two-tiered performance-based incentives for PHCs: ~$3 per patient completing the intensive phase (2 months) of TB treatment and ~$7 per patient achieving full treatment completion. In addition, technical assistance was provided during the pilot.

Results/Impact: Compared to the previous year's period, TB case notification increased by 9.7% across all piloted PHCs, exceeding the national increase of 3.3%. Notably, private PHCs notified a 95% increase, substantially higher than the national average of 37%. The treatment success rate (TSR) at PHCs in the piloted districts also improved from 81% to 90%, higher than the TSR of PHCs at the national level, which is 89%.

Conclusions: Performance-based incentives demonstrated efficacy in enhancing TB case detection and improving care quality across PHC providers. Therefore, this innovative financing model will be expanded at the national level to strengthen TB management at the primary care level.

EP35-1037-20 Discrete choice experiment suggests that person-centered treatment support could be achieved by offering a choice between two interventions

C. Yuen,[1] A.K. Millones,[2] J. Galea,[3] S. Shin,[1] H. Campos,[2] A. Condeso,[2] C. Vargas,[2] J. Jimenez,[2] H. Jenkins,[4] L. Lecca,[2] [1]Brigham and Women's Hospital, Division of Global Health Equity, Boston, United States of America, [2]Socios En Salud Sucursal Peru, Tuberculosis, Lima, Peru, [3]University of South Florida, School of Social Work, Tampa, United States of America, [4]Boston University School of Public Health, Biostatistics, Boston, United States of America
e-mail: Courtney_Yuen@hms.harvard.edu

Background: Treatment support should address the most important barriers to adherence, but these barriers differ among people with TB. Understanding heterogeneity in treatment support needs is important for designing person-centered programs.

Design/Methods: We administered a discrete choice experiment asking people newly diagnosed with TB in Lima, Peru what support interventions would best help them complete treatment. We used a community-engaged process to identify five interventions designed to promote treatment adherence by addressing different domains of health care accessibility according to the "5 A's" conceptual framework. We presented hypothetical intervention packages comprising combinations of community-based treatment, conditional cash transfers, counseling, a social worker visit, and anti-stigma training for health center staff. Analysis was conducted using hierarchical Bayes modeling followed by latent class analysis, then logit regression to identify factors associated with probability of class membership.

Results: There were five classes among 284 respondents. Class 1 (26%) viewed all interventions positively and prioritized community-based treatment; age 15-24 was associated with class membership (OR versus age ≥45 = 2.1, 95% CI 1.1-3.7). Class 2 (23%) viewed all interventions positively and prioritized cash transfers. Classes 3

and 4 each viewed one of the interventions negatively, with class 3 (27%) rejecting counseling and class 4 (16%) rejecting cash transfers. Formal sector employment was borderline significantly associated with class 4 membership (OR=1.6, 95% CI 1.0-2.7). Class 5 (8%) prioritized cash transfers and viewed both community treatment and anti-stigma intervention negatively; male sex was non-significantly associated with class membership (OR=3.3, 95% 0.9-11.9).
Conclusions: Overall, people with TB in Lima, Peru identified community treatment and conditional cash transfers as the most important forms of treatment support, but neither was acceptable to everyone, and their relative priority varied. Offering a choice between the two would promote patient-centered care by giving each person a form of support they prioritize.

EP35-1038-20 Providers' perceptions of integrating mental health care in TB services in the Free State, South Africa

C. Heunis,[1] G. Kigozi-Male,[1] [1]University of the Free State, Centre for Health Systems Research & Development, Bloemfontein, South Africa
e-mail: KigoziGN@ufs.ac.za

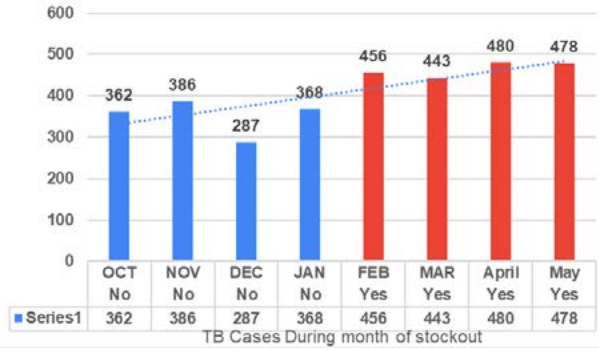
Background: Highlighting their crucial role in implementing global and national mental health care (MHC) decentralisation and integration policies, this study examined public healthcare providers' perceptions of MHC integration within tuberculosis (TB) programme services in the Free State province.
Design/Methods: A qualitative design was employed, incorporating 13 key informant interviews that were thematically analysed. The study utilised the Consolidated Framework for Implementation Research (CFIR) alongside the World Health Organization's health systems building blocks framework to investigate providers' perceptions of barriers and facilitators.
Results: Regarding the CFIR 'innovation' domain, providers emphasised the importance of health education for TB patients and their families. In the 'outer setting' domain, they identified significant barriers to MHC-TB integration, such as stigma and perceptions of MH disorders as witchcraft. Providers also noted limited support from non-governmental organisations and insufficient financing, exacerbated by poverty and unemployment. For the 'financing' and 'medicine' building blocks, a dedicated budget for MHC and a consistent drug supply were respectively seen as potential facilitators. 'Inner setting' barriers included 'workforce'-related issues, such as professionals' reluctance to engage with MH issues. In respect to 'individuals' or 'people,' providers highlighted shortages of social workers, nurses, doctors, psychiatrists, and psychologists, leading to missed essential MH support.
Conclusions: Findings underscore that MHC-TB integration in the Free State is essential yet complex. Providers' perceptions highlighted the crucial role of 'individuals' or 'people' both as barriers and facilitators in such integration. Perceived challenges included stigma and inadequate resources. Providers also stressed the need for enhanced health education for patients and families, as well as improved training for healthcare providers. MHC-TB integration requires a holistic strategy addressing contextual factors highlighted by the CFIR and strengthening all health systems building blocks – particularly the 'people' component. These efforts are essential for transforming MHC and improving outcomes for TB patients with co-morbid MH conditions.

EP35-1039-20 Strengthening TB drug supply chains to reduce stockouts: Lessons from Nasarawa State, Nigeria

K. Obideje,[1] C. Ogoamaka,[2] P. Opara,[3] S. Omotayo,[1] T. Amos,[4] [1]KNCV NIGERIA, Strategic Information, Lafia, Nigeria, [2]KNCV NIGERIA, Programme, Abuja, Nigeria, [3]KNCV NIGERIA, Programs, Lafia, Nigeria, [4]KNCV NIGERIA, Programme, Lafia, Nigeria
e-mail: kobideje@kncvnigeria.org

Background: The consistent availability of Tuberculosis (TB) drugs is critical to the success of TB prevention programs, particularly in high-burden regions like Nasarawa State, Nigeria. However, the state has experienced recurrent stockouts of TB drugs, primarily due to inefficiencies in the supply chain management (SCM) process.
This study provides actionable recommendations for policymakers, program implementers, and stakeholders to strengthen the TB drug supply chain in Nasarawa State.
Design/Methods: A mixed-methods approach was employed, combining descriptive surveys and interviews conducted between October 2023 and May 2024, while inferential statistics (Wilcoxon signed-rank test) were applied to determine statistical significance in case diagnosis before and during stockout. Fifty-seven Directly Observed Treatment (DOT) centers were randomly selected across urban (40%) and rural (60%) areas, including hard-to-reach locations and pretested questionnaires were administered to 114 respondents, including DOT officers (70%), healthcare providers (20%), and supply chain managers (10%) to determine the causes of TB drug stock out.
Results: A mixed-methods approach was employed, combining descriptive surveys and interviews conducted between October 2023 and May 2024, while inferential statistics (Wilcoxon signed-rank test) were applied to determine statistical significance in case diagnosis before and during stockout. Fifty-seven Directly Observed Treatment (DOT) centers were randomly selected across urban (40%) and rural (60%) areas, including hard-to-

reach locations and pretested questionnaires were administered to 114 respondents, including DOT officers (70%), healthcare providers (20%), and supply chain managers (10%) to determine the causes of TB drug stock out.



Background and challenges to implementation: The consistent availability of Tuberculosis (TB) drugs is critical to the success of TB prevention programs, particularly in high-burden regions like Nasarawa State, Nigeria. However, the state has experienced recurrent stockouts of TB drugs, primarily due to inefficiencies in the supply chain management (SCM) process.

This study provides actionable recommendations for policymakers, program implementers, and stakeholders to strengthen the TB drug supply chain in Nasarawa State.

Intervention or response: A mixed-methods approach was employed, combining descriptive surveys and interviews conducted between October 2023 and May 2024, while inferential statistics (Wilcoxon signed-rank test) were applied to determine statistical significance in case diagnosis before and during stockout. Fifty-seven Directly Observed Treatment (DOT) centers were randomly selected across urban (40%) and rural (60%) areas, including hard-to-reach locations and pretested questionnaires were administered to 114 respondents, including DOT officers (70%), healthcare providers (20%), and supply chain managers (10%) to determine the causes of TB drug stock out.

Results/Impact: This study identifies critical gaps in TB drug SCM in Nasarawa State, including inadequate SCM training for 84% of DOT officers, the absence of flowcharts in 70% of facilities, and underutilized stock cards of 73%.

Stockouts, particularly in rural and hard-to-reach areas, correlated with TB case increases from 362 in October to 478 in May, with a p-value of 0.02. Rural and hard-to-reach areas experienced more frequent stockouts due to logistical challenges and infrequent visits by the state pharmacies.

Conclusions: To prevent TB drug stockouts, this study recommends revising standard operating procedures, developing stock shortage prevention guidelines, and enhancing intra-state drug transfer logistics. Regular SCM training for DOT officers, strengthening monitoring and evaluation systems, and mandating TB stock card utilization across all facilities are essential. These measures will ensure consistent drug availability and improve TB prevention outcomes in Nasarawa State.

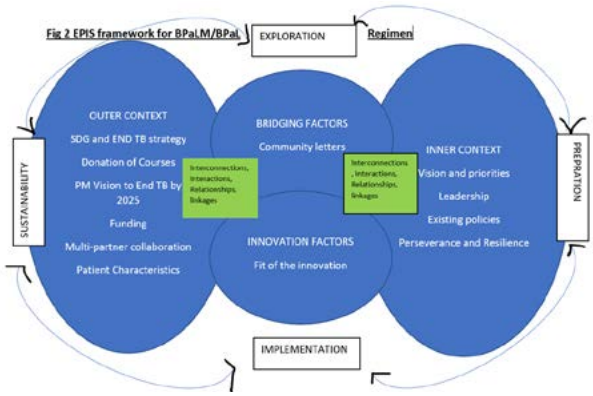
EP35-1040-20 Exploring and preparing for BPaLM adoption in India: A system-level analysis using the EPIS framework

S. Mattoo,[1] S. Chauhan,[2] H. G,[2] U. Singh,[1] S. Chandra,[2] S. Joshi,[2] [1]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India
e-mail: chauhans@rntcp.org

Background and challenges to implementation: India bears 26% of the global burden of drug-resistant tuberculosis (DR-TB), with low treatment success and high mortality rates. The WHO-recommended 6-month BPaLM regimen offers a shorter, safer, and more effective all-oral treatment. In response, the National TB Elimination Programme (NTEP) began systematically assessing its feasibility and programmatic integration. This study evaluates those preparatory and exploratory efforts toward BPaLM adoption in India.

Intervention or response: The EPIS (Exploration, Preparation, Implementation, Sustainment) framework guided the analysis of early BPaLM adoption in India, focusing on the exploration and preparation phases. A document review of national guidance, trial evidence, meeting records, and global policy informed the study. Strategic and operational activities were examined across four EPIS domains—outer context, inner context, bridging factors, and innovation fit—to identify key enablers and barriers.

Results/Impact: The exploration phase identified critical challenges in managing DR-TB in India, including limited treatment options, treatment adherence, high mortality, and substantial health system costs. Global evidence from landmark trials (Nix-TB, ZeNix, TB PRACTECAL) demonstrated the BPaLM regimen's superior efficacy, safety, and cost-effectiveness, prompting national interest. During the preparation phase, NTEP initiated studies for effectiveness of BPaLM in Indian population and Health Technology Assessment (HTA) with the support of Indian Council of Medical Research, developed guidance document, and secured stakeholder engagement s. Interim trial results showed >90% treatment success and strong safety profile. The initial implementation aligned with national priorities and was driven by four enablers: strong policy leadership (**inner context**), global partnerships and resource support (**outer context**), community advocacy (**bridging factors**), and regimen simplicity with patient and system-level benefits (**innovation fit**)—collectively laying the foundation for nationwide scale-up.



Conclusions: By focusing on exploration and preparation phases, the study highlights often-overlooked factors critical for successful implementation. This approach offers a replicable model for introducing complex health innovations in high-burden settings.

EP35-1041-20 Challenges in TB referral processes and health workers' perspectives in Indonesia: A qualitative study

A. Fitriangga,[1] G. Archangela Alexandra,[2] IW.G.A. Eka Putra,[3] [1]Universitas TanjungPura, Community Medicine, Pontianak, Indonesia, [2]Indonesia Tuberculosis Research Network, Community Health, Jakarta, Indonesia, [3]Universitas Udayana, Public Health, Denpasar, Indonesia
e-mail: afitriangga@medical.untan.ac.id

Background: According to the 2023 WHO Global Tuberculosis (TB) Report, Indonesia reported an estimated 1,060,000 TB cases, with an incidence rate of 385 per 100,000 population. While drug-susceptible TB (DS-TB) notification rates have improved—reaching 77% of the estimated total cases—the gap between case detection and treatment initiation has widened, increasing from 8% in 2021 to 12% in 2023. This treatment enrollment gap can result in delayed care, worsening health outcomes, and continued TB transmission. A functional TB referral system is essential to ensure timely linkage to care. This study aimed to explore healthcare workers' perspectives on barriers affecting TB referral effectiveness in Indonesia.
Design/Methods: A qualitative analysis was conducted using data from 80 TB program stakeholders across various districts and cities in Indonesia. Participants included TB program managers, technical officers, and field staff from district and city health offices. A structured questionnaire was distributed, focusing on perceived barriers in TB referral processes. Data were analyzed using NVivo software, with thematic coding guided by a literature-informed framework on TB referral system challenges.
Results: Several key barriers were identified, including inadequate communication between health facilities, limited patient access due to geographic and financial constraints, and a lack of standardized referral protocols. Health workers also reported challenges in coordinating follow-up procedures, while patients faced delays from administrative and bureaucratic inefficiencies. These issues collectively hinder the continuity and quality of TB care.
Conclusions: mproving TB referral processes requires multi-level interventions. These include strengthening inter-facility communication, developing clear referral guidelines, investing in healthcare staff capacity building, and providing logistical and financial support to patients. Addressing these systemic gaps is crucial to bridging the case detection-to-treatment initiation divide and achieving improved TB control outcomes in Indonesia.

EP35-1042-20 Empowering change: A study on the role of TB champions in strengthening National TB Elimination Programme indicators in Union territory, Chandigarh in India

R. Rana,[1] S. Singh,[2] U. Singh,[3] S. Chandra,[4] D. Agarwal,[5] P. Kapoor,[4] P. Kaur Samra,[4] N. Sinha,[6] A. Bhardwaj,[7] M. K,[6] N. Kumar,[3] [1]Government of Chandigarh, Dept of Health and Family Welfare, UT Chandigarh, Chandigarh, India, [2]Government of India, Department of Health and Family Welfare, Chandigarh, India, [3]Government of India, Ministry of Health and Family Welfare, New Delhi, India, [4]Government of India- WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [5]Government Medical College and Hospital, Sector 32, Department of Pulmonology, Chandigarh, India, [6]TB Alert India, Program Management, Chandigarh, India, [7]National Task Force, Medical colleges Task force, Chandigarh, India
e-mail: dirhealth-gmsh16@chd.nic.in

Background and challenges to implementation: The Ayushman Arogya Mandirs (AAMs) are local health facilities aiming to provide comprehensive, universal, and free primary healthcare services, focusing on wellness and expanding services closer to communities. The study aims to assess the impact of TB champions placed at these health facilities on National TB Elimination Program (NTEP) indicators through community mobilization, encouraging the symptomatic to come forward for testing and promoting adherence among the diagnosed cases.
Intervention or response: The Government of Chandigarh collaborated with a non-government organisation, IMPACT-India Project, implemented by TB Alert India, where 50 TB Champions were trained in December 2024. A gap analysis was done for all the AAMs across the city based on their case referral, notification, and treatment success rates. These trained champions were strategically placed across 30 selected low-performing AAMs out of 50 AAMs in the city. Their responsibilities included active case finding, contact tracing, adherence support,

TB awareness, and strengthening community engagement with TB services, particularly in underserved areas. Nikshay (India's web-based surveillance system) was used to extract data analysed in SPSS ver 22.

Results/Impact: Data from Quarter 1 (January to March) of 2024, when TB Champions were not deployed, was compared with Quarter 1(January- March) of 2025, when they were deployed. The results of this intervention are in Table 1.

Indicator	Q1 (January to March) 2024	Q1 (January to March) 2025	Increase (%)
Total TB cases notified	1,606	1,800	12%
Notifications from AAMs	507	581	15%
Household contacts initiated on TB Preventive Treatment	272	490	80%
Adherence Monitoring (Manual)	79%	89%	10%
Treatment Outcomes (Entered During Quarter 1)	119	231	94%

Table 1: National TB Elimination Program monitoring indicators for Chandigarh city (January- March 2024 vs January- March 2025)

This intervention significantly enhanced key NTEP indicators in Chandigarh ($p<0.05$). It led to increased TB case notifications, improved reporting, with a notable rise in notifications from AAMs and a significant improvement in treatment outcome reporting.

Conclusions: The survivor-led approach of TB Champions has effectively bridged service gaps and empowered local communities. Chandigarh's success suggests that this model can be replicated and scaled in other high-TB-burden regions, enhancing awareness and support for prevention and treatment efforts.

EP35-1043-20 Innovative models for TB/HIV integrated service delivery among pregnant women in an unconventional setting in Ogun State, Nigeria

O. Edwin,[1] A. Ibitunde,[1] F. Muse,[1] T. Lawal,[1] L. Folorunso,[1] O. Kolade,[1] A. Agbaje,[2] P. Dakum,[2] O. Chijioke-Akaniro,[3] C. Adesigbin,[3] M. Zamzu,[4] J. Kimeu,[4] [1]Damien Foundation Belgium (Nigeria Project), Programme, Ibadan, Nigeria, [2]Institute of Human Virology, Nigeria, Programme, Abuja, Nigeria, [3]National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Programme, Abuja, Nigeria, [4]Global Fund Country Team, Programme, Geneva, Switzerland
e-mail: fadeyi.muse@dfbnigeria.org.ng

Background and challenges to implementation: Pregnant women living with HIV are at higher risk for tuberculosis (TB), yet TB screening and treatment services are often underutilized in antenatal care (ANC) settings. In Ogun State, Nigeria, an innovative TB/HIV integration model was introduced in faith-based and traditional birth attendant (TBA) facilities, where many pregnant women seek maternal care. This study evaluates the impact of this approach on TB case detection, treatment initiation, and maternal health outcomes.

Intervention or response: A mixed-methods study was conducted across selected faith-based and TBA facilities in Ogun State, where TB/HIV integrated screening and treatment services were introduced. Interventions included:

- On-site TB/HIV screening for pregnant women during ANC visits.
- Task-shifting to trained TBAs and religious leaders to facilitate case identification and referral.
- Use of mobile sputum collection and GeneXpert testing for rapid TB diagnosis.
- Pre- and post-intervention data were analyzed to assess changes in TB case detection rates, HIV-TB co-treatment initiation, and maternal health outcomes. Qualitative feedback from pregnant women and healthcare providers was also collected.

Results/Impact: The intervention resulted in a 42% increase in TB case detection among pregnant women compared to conventional ANC settings. Treatment initiation for TB/HIV co-infected women improved by 30%, with faster turnaround times due to on-site specimen collection and GeneXpert testing. Community acceptance of TB/HIV services within faith-based and TBA settings increased, leading to improved health-seeking behaviour. Challenges included initial resistance from traditional birth attendants, requiring extensive stakeholder engagement and training.

Conclusions: Integrating TB/HIV services into faith-based and TBA facilities significantly improved TB case detection and treatment among pregnant women in Ogun State, Nigeria. Scaling up this community-accepted model could bridge gaps in maternal TB/HIV care, especially in regions with low health facility utilization. Continued investment in capacity-building, digital health solutions, and community engagement is recommended for sustainability.

EP36 TB and comorbidities including mental health

EP36-1044-20 Optimising TB care: Differentiated TB care on affected person's outcome (Interventional study in Haveri district, Karnataka)

H. G,[1] S. Mattoo,[2] N. Mn,[3] S Ghatage,[1] S.S. Aithal,[1] K Krishnappa,[1] S. Achanta,[1] A Agadi,[4] A. S,[5] U. Singh,[2]
[1]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [2]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [3]District Tuberculosis Centre, National TB Elimination Programme, Ballari, India, [4]Basaveshwara Medical College and Hospital & Research Institute, Department of Community Medicine, Chitradurga, India, [5]Arogya Soudha, State Tuberculosis Cell, Karnataka, Bangalore, India
e-mail: gangaiahh@rntcp.org

Background and challenges to implementation: The End TB Strategy visions TB-free world, aiming for zero deaths and disease. In 2021, Karnataka reported 80,435 persons with TB (PwTB), with 7% TB fatality rate, while Haveri district, with limited tertiary health care, had a 9% TB fatality rate among its 1,322 PwTB. Early risk assessment during treatment initiation, with regular monitoring and clinical care, enhances treatment success. This intervention focused on catering differentiated care to all PwTB to assess impact on outcome.
Intervention or response: A training module was devised for the Primary Health Care Medical Officers (PHC MOs) and their staff during April and May 2022. Monthly clinical evaluations of PwTB were conducted on designated day, and PwTB were triaged based on vital signs, overall health condition, adverse drug reactions, and treatment progress. As per need, PwTB was referred to secondary or tertiary level of care. The effectiveness was evaluated by comparing outcomes among notified PwTB between June to August of 2021 and 2022. Data was collected using Excel and analyzed using SPSS software.

Outcome	2021	2022	P value
Success rate	342 (78%)	370 (87%)	
Death	42 (9.6%)	26 (6%)	<0.001
Loss to follow up	22 (5%)	11 (3%)	
Treatment failure	7 9 (1.6%)	1 (0%)	

Table: PwTB Outcome before and after the introduction of Differential TB care.

Results/Impact: A total of 438 and 426 PwTB were notified during June to August in 2021 and 2022 respectively. 341 PwTB (85%) of 2022 cohort were offered clinical evaluation. 2% of the PwTB had uncontrolled diabetes, adverse drug reaction who were referred for higher management.
Conclusions: The differentiated TB care resulted in favourable outcome in the intervention cohort. Implementation of same across the country is crucial strategy for reduction in TB deaths.

EP36-1045-20 Predictive analysis of all-cause mortality of initial-treated people with pulmonary TB complicated by hypertension

A. Cao,[1] Y. Nie,[2] Z. Zhong,[3] Y. Pei,[3,4] P. Deng,[1] H. Xie,[5] Y. Leng,[6,7] [1]University of South China, The Affiliated Changsha Central Hospital, Department of Cardiology, Changsha, China, [2]University of South China, The Affiliated Changsha Central Hospital, Department of Laboratory Medicine, Changsha, China, [3]University of South China, The Affiliated Changsha Central Hospital, Center of Tuberculosis Diagnosis and Treatment, Changsha, China, [4]University of South China, Technology Demonstration Base for Tuberculosis Diagnosis and Treatment in Hunan Province, Changsha, China, [5]University of South China, The Affiliated Changsha Central Hospital, Department of Science and Education, Changsha, China, [6]University of South China, The Affiliated Changsha Central Hospital, Changsha Tuberculosis Research Institute, Changsha, China, [7]University of South China, Changsha Technology Innovation Center for Tuberculosis Diagnosis and Treatment, Changsha, China
e-mail: lyp0626@aliyun.com

Background: To investigate the risk factors for all-cause mortality of initial-treated pulmonary tuberculosis patients complicated by hypertension and construct a predictive model.
Design/Methods: We conducted a retrospective analysis of the clinical data of inpatients with initial-treated pulmonary tuberculosis complicated by hypertension from 2019 to 2021 in Changsha Central Hospital. Patients' survival status and cardiovascular events were collected through telephone follow-up. LASSO regression was utilized to screen predictive variables, and binary logistic regression identified mortality risk factors. A predictive nomogram model was developed utilizing R software and subsequently verified for precision and dependability.
Results: Among the 1,014 patients, there were 100 (9.86%) deaths and 82 (8.09%) cardiovascular events. LASSO regression screened out 13 predictive variables. Multivariate logistic regression analysis revealed that smoking history, sputum bacteriology, pleural effusion, coronary heart disease, and chronic kidney disease were independent risk factors. Based on the training set data, a nomogram prognostic model was developed, showing an AUC of 0.712 (95% CI: 0.777-0.847), with 50.0% sensitivity and 84.3% specificity. The model's fit was confirmed through internal and external validations.

Conclusions: The prediction model constructed in this study has high predictive ability and satisfactory clinical efficacy, and can provide an effective individualized prediction tool for assessing all-cause mortality risk in patients with initial-treated pulmonary tuberculosis complicated by hypertension.

EP36-1046-20 Associations between mental health diagnoses and prior TB infection among community members in Eastern Cape Province, South Africa

C. Bush,[1] D. Olivier,[2] K. Fiphaza,[2] A. Daftary,[3] A. Medina-Marino,[2] A. Kipp,[1] [1]East Carolina University, Public Health, Greenville, United States of America, [2]University of Cape Town, The Desmond Tutu HIV Centre, Cape Town, South Africa, [3]York University, School of Health Policy & Management, Toronto, Canada
e-mail: bushc24@students.ecu.edu

Background: South Africa is one of the top eight countries globally burdened by tuberculosis. Many factors are associated with tuberculosis infection including clinical, demographic, and modifiable risk factors. Mental health includes a wide variety of disorders, but studies associating them with tuberculosis commonly focus on depression alone.
Design/Methods: A community household survey was conducted June 2022 through January 2023 in East London, Eastern Cape Province, South Africa, as a part of a multi-level study of social determinants and tuberculosis outcomes. Heads of households (HoH) from 93 study communities were surveyed. The presence of a mental health condition was defined as at least one self-reported mental health diagnosis (depression, anxiety, PTSD, bipolar disorder, panic, suicidality, alcohol/substance use disorder, or schizophrenia). Logistic regression was performed to determine the associations of mental health on prior tuberculosis infection, adjusting for demographic and socioeconomic factors.
Results: Among 3,869 HoH surveyed, 10.6% reported ever having tuberculosis, and 5.6% reported a mental health diagnosis. Depression was the most commonly reported mental health diagnosis (2.1%) followed by alcohol/substance use disorder (0.7%). Having any mental health diagnosis was associated with prior tuberculosis (OR=2.226, 95% CI: 1.551-3.195) after adjusting for confounders. Both alcohol/substance use disorder (OR = 4.550, 95% CI: 2.052, 10.085) and depression (OR = 2.039, 95% CI: 1.121, 3.709) were individually associated with prior tuberculosis in logistic regression models as the sole mental health disorder. Fisher exact tests for PTSD (0.21%) and bipolar disorder (0.26%) were also significant, but with such a small sample size additional analyses were unreliable. Being older, male, lower income, and lower education were associated with prior tuberculosis.
Conclusions: Mental health diagnoses are often underreported and vary widely in their biological, immunological, and behavioral characteristics. Further research is warranted on the association of individual disorders on tuberculosis infection.

EP36-1047-20 Computer-aided detection of cardiomegaly during TB screening: Prevalence and association with hypertension

J. Sung,[1,2] P. Kitonsa,[2] A. Nalutaaya,[2] P. Biché,[2,3] K. Ndyabayunga,[2] I. Mugabi,[2] I. Naluyima,[2] W. Kamya,[2] J. Magezi,[2] D. Dowdy,[2,3] A. Katamba,[2,4] E. Kendall,[1,2,3] [1]Johns Hopkins University School of Medicine, Division of Infectious Diseases, Baltimore, United States of America, [2]Walimu, Uganda Tuberculosis Implementation Research Consortium, Kampala, Uganda, [3]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States of America, [4]Makerere University College of Health Sciences, Department of Medicine, Clinical Epidemiology and Biostatistics Unit, Kampala, Uganda
e-mail: jsung21@jhmi.edu

Background: The burden of uncontrolled hypertension is substantial across sub-Saharan Africa. Computer-aided detection (CAD) software for TB screening can estimate the cardiothoracic ratio, which may identify individuals at risk of uncontrolled hypertension. There is potential to integrate hypertension screening, guided by CAD-interpreted cardiothoracic ratios, into large-scale TB screening activities, but this approach has not been evaluated.
Design/Methods: We conducted X-ray-based TB screening in peri-urban and rural Uganda using CAD software interpretation (qXR v3; Qure.ai). The software was programmed to indicate cardiomegaly when posteroanterior chest X-rays had cardiothoracic ratios >0.6.
All participants with CAD-interpreted cardiomegaly ("cardiomegaly") were offered blood pressure screening; other participants were offered blood pressure screening on request.
We estimated the prevalence of cardiomegaly in the screening population and the prevalence of hypertension among participants with and without cardiomegaly.
Results: We screened 87,998 individuals aged ≥15 years for TB using CAD-assisted chest X-ray between November 2022 and March 2025. CAD identified 10% (8,732) of TB screening participants as having cardiomegaly. Among participants with cardiomegaly, 49% (3,632/7,447) had elevated blood pressure (systolic ≥140 mmHg or diastolic ≥90 mmHg), versus 17% (1,152/6,768) of participants without cardiomegaly who requested blood pressure measurement ($p<0.01$).
The prevalence of severely elevated blood pressure (systolic ≥180 mmHg or diastolic ≥110 mmHg) was 12% (895/7,447) versus 3% (195/6,768). Of participants with cardiomegaly and elevated blood pressure, only 23%

(337/1,486) reported taking anti-hypertensive medications (Table). CAD-interpreted cardiomegaly was more common in women than in men (13% vs. 5%, $p<0.01$), but among those with cardiomegaly, the prevalence of elevated blood pressure did not differ by sex (49% vs. 48%, $p=0.53$).

	CAD-interpreted cardiomegaly (n=7,447)	No CAD-interpreted cardiomegaly (n=6,768[x])	p-value[#]
Age in years, median (IQR)	51 (40-63)	38 (26-50)	<0.01
Male sex, n (%)	1,758 (24%)	3,426 (51%)	<0.01
Elevated blood pressure, n/N (%) (systolic ≥140mmHg and/or diastolic ≥90mmHg)	3,632 (49%)	1,152 (17%)	<0.01
Severely elevated blood pressure, n/N (%) (systolic ≥180mmHg and/or diastolic ≥110mmHg)	895 (12%)	195 (3%)	<0.01
Hypertension diagnosis and treatment status[†], n/N (%)			
Known hypertension, on treatment	337/1,486 (23%)	159/1,200 (13%)	
Known hypertension, not on treatment*	531/1,486 (36%)	346/1,200 (29%)	<0.01
No known hypertension	618/1,486 (42%)	695/1,200 (58%)	

[x] Of 80,551 participants without cardiomegaly, 6,768 requested and underwent blood pressure measurement.
[#] By chi-squared test
[†] Hypertension treatment history was collected from a subset of consecutive participants who underwent blood pressure measurement.
* Had not taken any anti-hypertensives in the past 4 weeks.

Conclusions: CAD identified a high burden of undetected cardiomegaly and associated untreated hypertension among TB screening participants in Uganda. Integrating cardiomegaly assessment into CAD-based TB screening has the potential to aid early detection of cardiovascular disease.

EP36-1048-20 Clinicopathological features and diagnostic challenges in concurrent intestinal TB and colorectal cancer: A retrospective cohort study from a TB-endemic region

L. Shi,[1] Y Pei [1]The Affiliated Changsha Central Hospital, Hengyang Medical school, University of South China, Department of Tuberculosis, Changsha, Hunan, China
e-mail: 124463122@qq.com

Background: The coexistence of intestinal tuberculosis (ITB) and colorectal cancer (CRC) poses significant diagnostic challenges due to overlapping symptoms and histopathological complexities, particularly in tuberculosis-endemic regions. Despite their individual global health burdens, the clinicopathological interplay of ITB-CRC comorbidity remains poorly characterized, contributing to delayed diagnoses and adverse outcomes. This study aims to elucidate the clinical, endoscopic, and histopathological features of concurrent ITB-CRC to improve diagnostic accuracy and therapeutic strategies.

Design/Methods: A retrospective cohort analysis was conducted on nine histopathologically confirmed ITB-CRC cases at Changsha Central Hospital (2012–2022). ITB diagnosis required caseating granulomas with Langhans giant cells, acid-fast bacilli positivity, or TB-DNA PCR. CRC was confirmed via hematoxylin-eosin staining and immunohistochemistry (CK20/CDX2). Exclusion criteria included metachronous post-treatment diagnoses of either condition. Clinical, laboratory, imaging, endoscopic, and therapeutic data were analyzed descriptively under ethical approval.

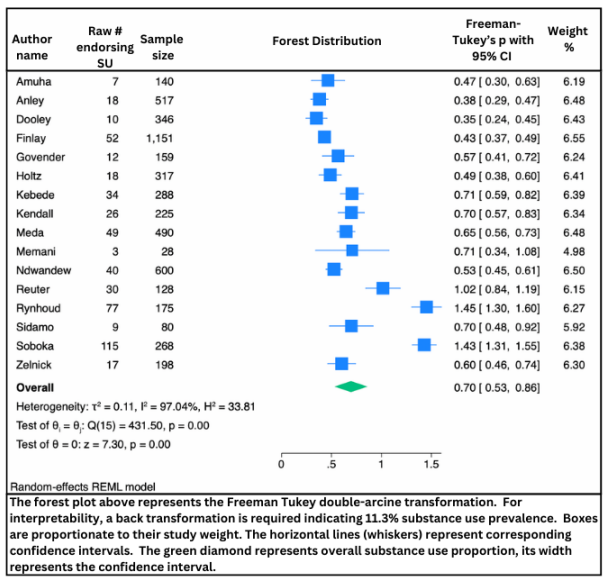
Results: The cohort (male predominance: 77.8%; median age: 68 years) presented nonspecific symptoms: abdominal pain (77.8%), weight loss (44.4%), and anorexia (44.4%). Concurrent pulmonary tuberculosis (77.8%), universal inflammatory marker elevation (ESR/CRP), anemia (55.6%), and hypoalbuminemia (55.6%) were prevalent. Elevated preoperative CEA (6/8) correlated with advanced CRC stages. Imaging revealed bowel wall thickening (100%) and abdominal masses (33.3%). Colonoscopy detected ulcerative lesions (71.4%), with biopsy confirming adenocarcinoma (5/7) or cytological atypia (2/7). ITB-CRC colocalized in the ascending colon (33.3%), all histologically adenocarcinoma. Surgical resection (77.8%) combined with anti-tuberculosis therapy (66.7%) was primary management. Mortality reached 33.3% in untreated patients, while ATT intolerance (11.1%) and non-compliance (22.2%) worsened outcomes.

Conclusions: ITB-CRC comorbidity presents with nonspecific symptomatology, necessitating heightened clinical suspicion in elderly patients. Endoscopic-histopathological integration is critical for differentiation in endemic regions. Multidisciplinary strategies combining ATT and oncological interventions are imperative to mitigate diagnostic delays. Despite limitations (small sample size, retrospective design), this largest regional case series highlights the need for context-specific diagnostic algorithms to optimize outcomes in dual-pathology cases.

EP36-1049-20 Substance use prevalence during TB treatment: A systematic review and meta-analysis in the African region

A. Bergman,[1] I. Jung,[1] E. Di Giacomo,[2] A. Leonard,[2] S. Heysell,[3]
[1]University of Virginia, School of Nursing, Charlottesville, United States of America, [2]Johns Hopkins University, School of Nursing, Baltimore, United States of America, [3]University of Virginia, School of Medicine, Charlottesville, United States of America
e-mail: dhm8ax@virginia.edu

Background: There are several reviews evaluating alcohol use and tuberculosis (TB), but analyses with other types of substance use (SU) are lacking. Our aim was to systematically review and summarize the prevalence of illicit SU among people with TB and to synthesize the impact of SU on TB outcomes in Africa. Our secondary aim was to characterize methods of SU measurement in TB research.
Design/Methods: We systematically searched PubMed, Embase and CINAHL to identify relevant articles. Using the PRISMA method, two individuals reviewed texts for inclusion, a third author resolved disagreements. We included peer-reviewed research conducted in Africa that evaluated prevalence of substance use among people with TB and correlated SU with a TB related outcome. To stabilize variance of proportion in SU prevalence we used the Tukey-Freeman double-arcine transformation with a restricted maximum-likelihood random-effects model.



The forest plot above represents the Freeman Tukey double-arcine transformation. For interpretability, a back transformation is required indicating 11.3% substance use prevalence. Boxes are proportionate to their study weight. The horizontal lines (whiskers) represent corresponding confidence intervals. The green diamond represents overall substance use proportion, its width represents the confidence interval.

Results: 19 studies conducted between 2006-2024 were included, representing 5,475 participants. Most studies were conducted in South Africa (n=9) and Ethiopia (n=6); all used self-reported SU data and primarily measured khat/marijuana use. No studies evaluated opiate use. SU prevalence ranged from 3-48% across studies with an estimated pooled prevalence of 11.3% using 17/19 studies. 14 studies evaluated a relationship between substance use and TB care engagement with conflicting results. Heterogeneity prevented a pooled estimate of effect size. Most studies evaluated SU as a dichotomous variable. Two studies that used a validated instrument yielded considerably higher endorsement of SU.
Conclusions: Studies were split on whether SU significantly affected TB care engagement. Some variability in these findings is likely attributable to heterogeneous definitions of SU and in SU data collection. To ascertain the true prevalence of SU during TB treatment and to rigorously evaluate correlations between SU and care engagement, we must capture the spectrum of SU from beneficial to harmful use and differentiate between categories of substances.

EP36-1050-20 Double burden of mental health issues and TB among people with drug-sensitive and drug-resistant TB in rural India

R. Marbate,[1] S.K. Singh,[2] C. Mahadevan,[3] S. Kanchan,[1] M. Brouwer,[4] T. Garg,[5] B.K. Mishra,[6] S. Bhagat,[6] U. Aqil,[7] G. Raikwar,[8] M. Kumar,[1] M. Bhardwaj,[9] [1]Innovators in Health (India), Operations, Samastipur, India, [2]Innovators in Health (India), MIS, Samastipur, India, [3]Innovators in Health (India), Monitoring and Evalution, Samastipur, India, [4]PHTB Consult, Monitoring and Evaluation, Haren, Netherlands, [5]Stop TB Partnership, Innovations and Grants, Geneva, Switzerland, [6]State Health Society, Government of Bihar, Patna, India, [7]Government of India - WHO, National TB Elimination Program, Delhi, India, [8]Government of India - WHO Country office for India, TB Technical Support Network, National TB Elimination Program, Delhi, India, [9]Innovators in Health (India), Organization, Samastipur, India
e-mail: chandanm@innovatorsinhealth.org

Background and challenges to implementation: Beyond its physical health implications, TB may impact mental well-being, leading to increased rates of anxiety, depression and social stigma among affected individuals. To improve the well-being and treatment success in people with susceptible TB (PwDSTB) and people with drug-resistant TB (PwDRTB), we need to address both physical and psychological needs through comprehensive care strategies.
Intervention or response: In an active case-finding intervention from November 2023 to December 2024, 18+ yrs Person with TB (PwTB) screened for mental health issues in rural Bihar using the WHO "**Self-Reporting Questionnaire (SRQ-20)**". This 20-item tool assesses cognitive themes (difficulty in thinking, decision-making, daily activities), somatic themes (frequent headaches, loss of appetite, digestive issues, sleep disturbances), severe anxiety and depression themes (feelings of fear, sadness, worthlessness, suicidal thoughts). PwTB scoring over 15 or reporting suicidal tendencies were considered screening

positive. Collected data of PwTB screened positive were analyzed to determine the prevalence of mental health issues.

Results/Impact: Among 397 PwDSTB, 209 (53%) females, 188 (47%) males and among 122 PwDRTB, 42 (34%) females, 80 (66%) males were identified with mental health issues. Notably, 48% of PwDSTB and 72% of PwDRTB with mental health issues were young adults (18–39 years old).

Thematic analysis was done for PwTB reporting all symptoms from each category. In PwDSTB, 69 (17%) reported somatic symptoms, 90 (23%) had cognitive symptoms,104 (26%) experienced severe depression and anxiety. In PwDRTB, 46 (38%) reported somatic symptoms, 56 (46%) had cognitive symptoms, 52 (43%) experienced severe anxiety and depression.

	Mental Health Issues among DSTB			Mental Health Issues among DRTB		
Themes	Somatic Symptoms n=69	Cognitive Symptoms n=90	Severe Anxiety and Depression symptoms n=104	Somatic Symptoms n=46	Cognitive Symptoms n=56	Severe Anxiety and Depression symptoms n=52
Female	41 (59%)	49 (54%)	69 (66%)	17 (37%)	19 (34%)	22 (42%)
Male	28 (41%)	41 (46%)	35 (34%)	29 (63%)	37 (66%)	30 (58%)

Table. Thematic analysis of Mental health issues among PwTB

Conclusions: This study found that PwDRTB more often reported somatic, cognitive and severe anxiety and depression symptoms than PwDSTB. Prevalence of symptoms of severe depression and anxiety were more amongst females (DSTB-69%, DRTB-42%) and young adults (DSTB-58%, DRTB-77%) than cognitive symptoms and somatic symptoms. This highlights the need for gender and age-sensitive interventions to improve TB treatment outcomes.

EP36-1051-20 Empowering adults with TB in Indonesia through a community-based, peer-led psychosocial support intervention to reduce stigma and depression: A qualitative study from the TB-CAPS project

M.A.N. Haya,[1] M. Haniifah,[1] F.R. Hardy,[1] D.F.A. Haq,[1] E.R. Febriani,[2] A.F. Rifky,[2] F.F. Yani,[2] F. Agiananda,[3] A. Fuady,[1] T. Wingfield,[4,5] [1]Universitas Indonesia, Community Medicine, Faculty of Medicine, Jakarta, Indonesia, [2]Universitas Andalas, Pediatrics, Padang, Indonesia, [3]Universitas Indonesia, Psychiatry, Faculty of Medicine, Jakarta, Indonesia, [4]Liverpool School of Tropical Medicine, Clinical Sciences and International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland, [5]Liverpool School of Tropical Medicine, Centre for Tuberculosis Research Departments of Clinical Sciences and International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland

Background: Working with multisectoral stakeholders, we co-developed "TB-CAPS": a community-based, peer-led psychosocial support intervention consisting of individual counselling and tuberculosis (TB) survivor-led group sessions. The intervention was implemented in two Indonesian cities with high TB burden: Padang and Depok.

This study evaluated the acceptability and scalability of the intervention from the perspective of people with tuberculosis who had participated.

Design/Methods: A qualitative study with a phenomenological approach was conducted with participants who received our community-based, peer-led TB-CAPS psychosocial support intervention. We purposively invited: participants who had attended TB-CAPS intervention activities to focus group discussions (FGD); and participants who had minimal engagement with activities to in-depth interviews (IDIs). We applied thematic analysis using MAXQDA24 software.

Results: A total of 16 people with TB participated in two FGDs (13 people) and 3 people in in-depth interviews. Key themes that emerged were:

1. Empowerment through adequate information;
2. Motivation to complete treatment from peers' shared experiences and support;
3. Support [IFP1] for wider scale-up of the TB-CAPS intervention.

The intervention was reported to reduce self-stigma and empower participants through information sharing. The participants expressed that the individual and group counselling gave participants the chance to ask more questions, thus addressing their concerns. The support they received from peers in the group sessions were a motivation to complete treatment and be 'free' of tuberculosis. The benefits and knowledge obtained made participants supportive and willing to contribute to the scale-up of the TB-CAPS intervention to reach more people with TB.

Conclusions: Community-based, peer-led psychosocial support, which combined individual and monthly group counselling, was well received among adults with TB in Indonesia. The intervention was considered beneficial and scalable. A randomized-controlled trial evaluation to evaluate the effectiveness and cost-effectiveness of the TB-CAPS intervention at scale in Indonesia is planned.

EP36-1052-20 Pharmacokinetics of concomitant drug-resistant TB and hepatitis C treatment in Georgia: Preliminary results from the DARE TB/HCV study

M. Buziashvili,[1] C. Peloquin,[2] N. Shurghaia,[1] M. Kipiani,[1] R. Kempker,[3] [1]National Center for Tuberculosis and Lung Diseases, Scientific Research, Tbilisi, Georgia, [2]University of Florida, Infectious Diseases Pharmacokinetics Lab, Gainsville, United States of America, [3]Emory University, School of Medicine, Atlanta, United States of America
e-mail: buziashvili.mari@gmail.com

Background: High prevalence (2-27%) of hepatitis C virus (HCV) coinfection among drug-resistant tuberculosis (DR-TB) patients in Eastern Europe and Central Asia necessitates evidence-based guidelines for concomitant treatment.
Currently, no data exists on pharmacokinetics (PK) of anti-TB drugs and direct-acting antivirals (DAAs) for HCV when administered simultaneously.
Design/Methods: A prospective PK study enrolled DR-TB patients receiving oral anti-TB drugs – bedaquiline (Bdq), pretomanid (Pa), linezolid (Lzd), with or without moxifloxacin (Mfx) – concomitantly with HCV DAAs – sofosbuvir (SOF) and velpatasvir (VEL).
We aimed to evaluate PK parameters of anti-TB drugs administered before and after initiating HCV treatment, and PK parameters of DAAs among DR-TB patients, with serial serum samples collected at baseline, 2, 6, 12, and 24-hours post-drug administration. Serum drug concentrations were measured using High-Performance Liquid Chromatography/Mass Spectrometry (HPLC-MS).
Results: Seven patients (mean age 54, 6 males, 6 smokers) were included. Six patients initiated anti-TB treatment first, followed by DAAs ~1 month later. Baseline liver fibrosis stages were advanced (F3 or cirrhosis) in 5 participants. All 7 participants achieved a negative HCV RNA viral load post-treatment; available sustained virologic response (SVR) at 6 months was 100% (3/3). All 7 participants had a favorable (cured/completed) TB treatment outcome.
Mean anti-TB drug concentrations for the five patients assessed thus far pre- and post-DAA initiation, where as follows (Cmax, mcg/mL): Bdq – 1.42/0.86, Pa – 2.42/2.83, Lzd – 6.75/11.16, and Mfx – 1.69/2.40, respectively. After initiation of DAAs (SOF mean C_{max} – 1 mcg/mL [VEL–under analysis]), preliminary PK data suggested comparable serum concentrations for all anti-TB drugs, indicating no significant immediate drug-drug interactions affecting anti-TB drug levels. Complete PK parameters are currently under analysis.
Conclusions: Preliminary PK analyses indicate successful outcomes for concomitant DR-TB and HCV treatment without significant interactions. This study provides essential clinical pharmacology data informing future TB/HCV treatment guidelines and supports expanding the regional co-treatment initiative.

EP37 Beyond the cure: Addressing TB sequelae, relapse and reinfection in long-term health

EP37-1053-20 Evaluation of sequalae after treatment completion in people with pulmonary TB in Bamako, Mali

F. Sanogo,[1] B. Diarra,[1] B. Baya,[1] F.G. Traore,[1] N. Ballo,[1] N. Telly,[2] M. Konate,[2] A.B. Cisse,[3] M. Antonio,[4] B.C. deJong,[5] A. Rosenthal,[6] S. Doumbia,[1] [1]University of Sciences, Techniques and Technologies of Bamako, University Clinical Research Center (UCRC), Bamako, Mali, [2]Ministry of Health and Social Development, Mali TB, HIV/AIDS, and Hepatitis control program, Bamako, Mali, [3]Ministry of Health and Social Development, National Institute of Public Health, Bamako, Mali, [4]London School of Hygiene and Tropical Medicine, Vaccine Theme, Banjul, Gambia (Republic of The), [5]Institute of Tropical Medicine, Mycobacteriology Unit, Antwerpen, Belgium, [6]National Institutes of Health, Office of Cyberinfrastructure and Computational Biology (OCICB), Bethesda, United States of America
e-mail: bdiarra@icermali.org

Background: Tuberculosis (TB) is a chronic, contagious infection with a very favorable course of treatment, but the after-effects are frequent and can threaten the patient's functional or even vital prognosis. These sequelae can give rise to co-morbidities that have a negative impact on patients' social, mental and professional lives.
The aim of this study was to evaluate TB sequelae by chest x-rays and spirometry in patients who had completed TB treatment in Bamako
Design/Methods: This was a pilot study conducted at the University Clinical Research Center (UCRC) from November 2023 to January 2024. The study population consisted of previously pulmonary TB treated patients 7-10 years ago. Each patient provided a sputum and blood for culture, Xpert MTB/RIF and biochemical tests respectively. Sequelae were evaluated with chest X-rays and spirometry.
Results: Of the 966 TB patients (with and without HIV) which were followed between 7-10 years after treatment completion, 72 were evaluated. The mean age was 42.01±12.07 years, and all had negative culture and negative Xpert MTB/RIF results. Based on the American Thoracic Society (ATS)-definition, 63(87.5%) had abnormal lung function, of whom 28 (44.4%) were categorized as obstructive, 25(39.7%) as restrictive, and 10(15.9%) as mixed (obstructive and restrictive) at spirometry.
In addition, biochemical parameters showed elevated transaminase (ALT, AST) and creatinine levels at 28.8% and 8% respectively. Moreover, questions relating to mental and physical health showed that 16.4% and 23.3% of our participants had experienced jaundice and edema since the TB episode, and over 60% complained of fatigue, breathing difficulties and nervousness.
Conclusions: This preliminary study shows that although underreported, many TB cured patients in Mali have impactful lung damage leading to sequela and a poor quality of life. A large study involving concomitant and previously treated patients is needed to evaluate the appearance and the early management of these sequelae.

EP37-1054-20 Post-TB lung function among adults screened for chronic obstructed pulmonary disease in Nepal, Peru and Uganda: A post-hoc analysis of the GECO study

N. Foster,[1] J. Barber,[2] N. Robertson,[3] T. Siddhartan,[4] O. Flores-Flores,[5] W. Checkley,[6] J. Hurst,[1] GECO Study Investigators [1]University College London, Respiratory Medicine, London, United Kingdom of Great Britain and Northern Ireland, [2]University College London, Department of Statistics, London, United Kingdom of Great Britain and Northern Ireland, [3]Johns Hopkins University, Internal Medicine, Baltimore, United States of America, [4]University of Miami, School of Medicine, Miami, United States of America, [5]Universidad de San Martin de Porres, School of Medicine, Lima, Peru, [6]Johns Hopkins University, Division of Pulmonary and Critical Care, Baltimore, United States of America
e-mail: foster. nicola@gmail.com

Background: Prior tuberculosis is an important risk factor for chronic airflow obstruction. Whether individuals have lung function impairment prior-to or after tuberculosis and associated risk factors remain unclear. In a post-hoc analysis of the Global Excellence in COPD Outcomes (GECo) study of COPD case-finding in Nepal, Peru, and Uganda, we examined the association between previous TB and chronic respiratory disease (CRD) as well as the relative timing of lung function impairment and tuberculosis.
Design/Methods: Participants were screened for COPD using questionnaires followed by post-bronchodilator spirometry. COPD was defined as FEV_1 to FVC ratio less than the fifth percentile of the GLI mixed-ethnic population reference lower limit of normal. Data on self-reported long-term conditions and time since diagnosis were collected. We used logit regression models to compare the odds of COPD in those with previous treated tuberculosis versus those without.
Results: Among 10,648 study participants, the prevalence of previous tuberculosis was 4%(n=430); COPD was 9%(n=993) and CRD 5%(n=534). Median age at tuberculosis diagnosis was 32 (IQR 23-45) years.
Among those with previous TB, 12% (53/430) had been diagnosed with CRD. Of those with TB and CRD, 25%(13/53) were diagnosed with CRD before TB, and 75%(40/53) with TB before developing CRD. Median time to CRD diagnosis after TB was 20 years (IQR: 8-27). After adjusting for age, sex, time since diagnosis with TB, and smoking status, individuals with previous tu-

berculosis had a 2.45 (95% CI: 1.89-3.19) times greater odds of COPD compared to those without. Respiratory lung function and symptoms were associated with COPD among those with previous TB.
Conclusions: Prior TB diagnosis is a significant predictor of COPD among this diverse Global South population. Further analyses of risk factors and other long-term conditions will provide valuable insights.

EP37-1055-20 Post-TB chronic pulmonary aspergillosis: Phenotypic heterogeneity and independent predictors of adverse treatment outcomes

Y. Yang,[1] Q.-L. Yang,[1] W. Zhao,[2] R. Zhu,[1] Q. Ruan,[1] [1]National Medical Center for Infectious Diseases, Huashan Hospital, Fudan University, Infectious Diseases, Shanghai, China, [2]Hangzhou Red Cross Hospital, Thoracic Surgery, Hangzhou, China
e-mail: qlyang10@fudan.edu.cn

Background: Post-tuberculosis chronic pulmonary aspergillosis (Post-TB CPA) represents a clinically prevalent comorbidity and imposes a substantial burden across tuberculosis-endemic regions. The study aimed to delineate the clinical phenotypes of post-TB CPA patients and identify independent predictors of adverse treatment outcomes.
Design/Methods: We retrospectively analyzed post-TB CPA patients admitted to Hangzhou Red Cross Hospital between January 2020 and December 2023. Patients were categorized into two groups based on clinical outcomes after 12 months follow-up. Logistic regression was used to identify independent predictors of adverse treatment outcomes.

Risk Factors	Odds ratio (95% CI)	P Value
Surgery	0.735(0.132~4.08)	0.724
Antifungal Treatment > 3 Months	0.038(0.003~0.431)	0.008
SAIA	14.356(2.923~70.504)	0.001
ESR > 30mm/h	5.276(1.505~18.491)	0.009
Pulmonary Fibrotic Lesions	5.03(1.437~17.612)	0.012

ESR-Erythrocyte Sedimentation Rate; SAIA:Subacute Invasive Pulmonary Aspergillosis

Table. Logistic Regression Analysis of Predictors of Adverse Treatment Outcomes in Post-Tuberculosis CPA Patients.

Results: A total of 109 patients with post-TB CPA were included. Adverse treatment outcomes occurred in 33.9% (37) of patients. Subacute invasive pulmonary aspergillosis (*OR* = 14.356, 95% *CI*: 2.923–70.504, *P* = 0.001), elevated erythrocyte sedimentation rate (*OR* = 5.276, 95% *CI*: 1.505–18.491, *P* = 0.009), and pulmonary fibrosis (*OR* = 5.03, 95% *CI*: 1.437–17.612, *P* = 0.012) were independent predictors of poor outcomes. Antifungal treatment ≥ 3 months significantly reduced progression risk (*OR* = 0.038, 95% *CI*: 0.003–0.431, *P* = 0.008). Surgery showed a protective effect in univariate analysis but not after adjustment for confounders.
Conclusions: Post-TB CPA poses a significant threat to long-term respiratory health. Early identification of high-risk patients and ensuring at least 3 months of antifungal therapy may improve outcomes.
These findings underscore the need for structured post-TB follow-up to improve health and well-being after TB cure.

EP37-1056-20 Identifying gaps in post-TB screening through a comparative study of national guidelines in high-burden countries: A scoping review

V. Prasad,[1] J.E. Golub,[2,1] S.R. Cox,[1] [1]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States of America, [2]Johns Hopkins School of Medicine, Medicine, Baltimore, United States of America
e-mail: scox26@jhmi.com

Background: Recurrent tuberculosis (TB) and post-TB lung disease (PTLD) are important threats to TB survivors in high burden settings. Recurrent TB represents a significant proportion of incident TB cases globally, and up to two-thirds of TB survivors are estimated to develop PTLD. However, these estimates are likely inaccurate due to lack of screening, or screening with sub-standard methodologies.
This scoping review aimed to summarize and identify gaps in screening guidelines for both recurrent TB and PTLD, as well as management guidelines for PTLD.
Design/Methods: We reviewed the most recent versions of publicly available national TB guidelines from the 30 high burden countries as defined by the World Health Organization.
We conducted full-text reviews of each guideline, extracted data on the methodology, frequency and duration of post-TB follow-up and PTLD management, and compared recommendations across countries. We used computer-aided translation for non-English guidelines.
Results: We identified 20 high burden countries with publicly available national guidelines on post-TB interventions.
Few countries (n=6) recommended routine screening for recurrent TB detection in the first 12 months following treatment completion (Table).
When guidelines were present, they were primarily for drug resistant TB (DR-TB) survivors. References to PTLD were rare (n=2) and lacked detail on diagnosis, follow-up, or clinical management.
Guidelines for two countries, Ethiopia and South Africa, had clear protocols for PTLD management, in addition to recurrent TB screening.

Country	Patient profile	Screening methodology	Duration	Frequency	PTLD follow up recommendation
Ethiopia	DR-TB	Symptom assessment, sputum smear microscopy and culture, DST is symptomatic, chest x-ray if clinically indicated	12 months	3rd, 6th, 12th month after treatment completion	Screen, diagnose and manage if any of post TB sequalae are developed
India	DR-TB	Symptom assessment, chest x-ray, smear microscopy/culture if symptomatic	24 months	Every 6 month after treatment completion	No
Myanmar	DR-TB	Symptom assessment, sputum smear microscopy and culture, chest x-ray, DST if culture positive	24 months	Every 6 month after treatment completion	No
Namibia	DR-TB	Symptom assessment, sputum microscopy and culture	12 months	Every 3 months after treatment completion	No
Philippines	DR-TB	Symptom assessment, chest x-ray, smear microscopy and culture	12 months	Every 6 month after treatment completion	No
South Africa	DR-TB	Symptom assessment, sputum smear microscopy and culture	12 months	Every 6 month after treatment completion	Functional respiratory assessment and long term follow up by pulmonary services in tertiary centers.

Table detailing post-TB follow-up recommendation and PTLD management

Conclusions: Findings indicate a need for national TB programs to adopt structured, inclusive post-treatment monitoring policies for both drug-sensitive and drug-resistant TB. Incorporating PTLD and recurrent TB screening and management into such programs would likely lead to improvements in patient outcomes.

EP37-1057-20 Optimising active detection of recurrent TB: An individual-based modelling analysis informed by Indian cohorts

E. Kendall,[1] S. Cox,[2] A. Kadam,[3] A. Hnin Moe,[1] G. Lele,[3] M. Barthwal,[4] N. Gupte,[3] A. Gupta,[1] P. Chandrasekaran,[5] S. Gaikwad,[6] J. Golub,[1] V. Mave,[3] TB Aftermath, TB-DM, and RePORT India study teams [1]Johns Hopkins University School of Medicine, Department of Medicine Division of Infectious Diseases, Baltimore, United States of America, [2]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States of America, [3]Johns Hopkins India, Center for Infectious Diseases in India, Pune, India, [4]Dr. D.Y. Patil Vidyapeeth, Dr. D.Y. Patil Medical College, Hospital and Research Centre, Pune, India, [5]National Institute for Research in Tuberculosis, Department of Clinical Research, Chennai, India, [6]BJ Government Medical College and Sassoon General Hospitals, Department of Pulmonary Medicine, Pune, India
e-mail: emily.kendall@gmail.com

Background: People recently treated for TB face substantial risk of recurrence. Active case-finding (ACF) is recommended, but the optimal timing and approach are uncertain.

Design/Methods: We developed an individual-based model of people recently treated for TB in India, informed by cohort data on recurrent TB: incidence, symptoms, and predictive accuracy in the TB Aftermath trial and asymptomatic recurrence in earlier studies (CTRIUMPh and TBDM). The model represented the timing, symptoms, sputum NAAT positivity, and routine diagnosis of recurrent TB. Within 1000 simulated cohorts (representing parameter uncertainty) of 100,000 patients each, we modeled symptom screening at specified times after treatment completion, and considered targeting of high-risk individuals and/or addition of NAAT testing.

We estimated months of symptomatic TB and of "infectious" (sputum+, regardless of symptoms) TB averted, compared to no ACF, for cost-equivalent screening options.

Results: Within the simulated cohort, incidence of recurrent TB peaked at 4 (3-5) months post-treatment, and prevalence of undiagnosed symptomatic TB peaked at 6 (5-7) months. The primary intervention – symptom screening at 6, 12, and 18 months – averted 12% (IQR 10-14%) and 11% (9-12%) of time with symptomatic and infectious TB, respectively. Shifting screening earlier (3, 6, and 9 months) detected more TB but did not further reduce time with TB (Table) because it missed people with especially long disease courses in lower-risk time intervals or patient subgroups.

Targeted sputum screening further reduced time with infectious TB, but frequent sputum screening of high-risk patients was more efficient (Table). Impact on time with symptomatic TB nearly doubled if the initial screening visit also improved subsequent care-seeking and passive detection (Table).

Variation of post-treatment active case finding intervention*	Time points (months post treatment)	Included patients†	Screening for asymptomatic TB?	Recurrent TB identified through ACF (per 100,000 patients)	Mean days with symptoms, all recurrent TB	% reduction in time with symptomatic TB	% reduction in time with infectious TB
Primary intervention**	6, 12, & 18	All	No	836 (694, 1006)	30 (26, 35)	12% (10, 14)	11% (9, 12)
Earlier ACF timing	3, 6, & 9	All	No	1056 (900, 1228)	30 (27, 36)	11% (9, 13)	11% (10, 13)
More frequent ACF, risk-targeted	3, 6, 9, 12, 15, & 18	Highest-risk 62%	No	1229 (1020, 1432)	29 (26, 34)	14% (13, 16)	14% (12, 16)
With sputum testing, risk-targeted	6, 12, & 18	Highest-risk 62%	Yes (if high risk)	1118 (930, 1297)	30 (26, 35)	11% (10, 13)	13% (11, 15)
Early sputum testing for high-risk patients; periodic phone screening for all	3 (targeted), 6, 12 & 18	Highest-risk 40% for initial home/sputum visit; all for subsequent phone calls	Yes (if high risk)	916 (766, 1084)	30 (27, 36)	10% (8, 12)	13% (11, 14)
Sensitivity analysis: Intervention improves care-seeking (after a home visit, patients seek passive diagnosis 20% faster indefinitely)	6, 12, and 18	All	No	794 (645, 936)	27 (24, 32)	20% (18, 22)	15% (13, 17)

* For all variations, the first screening time point occurs at home, and later screening is by telephone.
** Based on Aftermath trial intervention
† For targeted interventions, coverage is chosen to match the cost of the primary intervention, and the targeted patients are those with the highest predicted risk based on a prediction model that uses characteristics measurable at the end of their earlier treatment course.

Table: Modeled interventions and key summary outcomes (median and IQR across simulated cohorts)

Conclusions: Screening for recurrent TB could reduce morbidity and transmission. Under resource constraints, risk-targeted symptom screening could be more efficient than universal or non-symptom-gated strategies. Counseling and support to facilitate prompt symptom-driven care-seeking could also reduce time with undiagnosed TB.

EP37-1058-20 Unveiling the dynamics of post-TB recurrence screening among TB healthcare workers in Pune, India: A normalisation process theory perspective

R. Shrisunder,[1] P. Kulkarni,[1] A. Kadam,[1] S. Cox,[2] J. E. Golub,[2,3] M. Barthwal,[4] A.I. Kakrani,[5] S. Valawalkar,[1] C. J. Hoffmann,[3] V. Mave,[1] N. Suryavanshi,[1] TB Aftermath study group [1]Johns Hopkins Centre for Infectious Diseases in India, CIDI, Pune, India, [2]Johns Hopkins Bloomberg School of Public Health, Public Health, Baltimore, United States of America, [3]Johns Hopkins School of Medicine and Health, Medicine, Baltimore, United States of America, [4]DY Patil University, Respiratory Medicine, Pune, India, [5]DY Patil University, Academic Collaboration, Pune, India
e-mail: pkulka10@jhu.edu

Background and challenges to implementation: Recurrent tuberculosis (TB) poses hurdles to global TB elimination, necessitating robust post-treatment screening. TB *Aftermath*, a hybrid trial in India, assesses whether phone screening is non-inferior to home-based screening at detecting TB recurrence among TB survivors. This substudy describes healthcare workers'(HCWs) perspective on acceptability of post-TB screening strategies.

Intervention or response: Twelve in-depth interviews were conducted with HCWs from National Tuberculosis Elimination Program (NTEP) and those hired from TB aftermath study across six tuberculosis units (TUs). Thematic analysis, guided by four constructs of Normalization Process Theory (NPT) viz., coherence, collective action, cognitive participation & reflexive monitoring, examined how home-based and phone screening are integrated into routine practice.

Results/Impact: All HCWs expressed coherence describing their roles specific to intervention. They recognized the significance of screening in reporting recurrent cases. HCWs prioritized home-based over phone screening emphasizing direct symptom identification. They acknowledged phone screening practical, being less resource-intensive yet effective in identifying symptomatic patients.
Engagement of NTEP staff with TB survivors and household contacts was facilitated by pre-established rapport. Most HCWs expressed strong commitment with both the screening intervention, recognizing its impact on early recurrence identification. Both strategies were seamlessly integrated into daily activities of NTEP staff, with study staff often supporting the process.
Integration of home-based screening into routine workflows were taxing due to time constraint. Despite contact tracing, data entry in Nikshay digital portal, aligning visits as per patients' availability, mobile connectivity, stigma and geographical constraints, HCWs recognized the effectiveness of systematic recurrence screening through structured workflows. Study staff supported with consistent patient engagement. Thus, NTEP HCWs emphasized need for additional manpower, resources and incentives for sustainable scale-up in healthcare system.

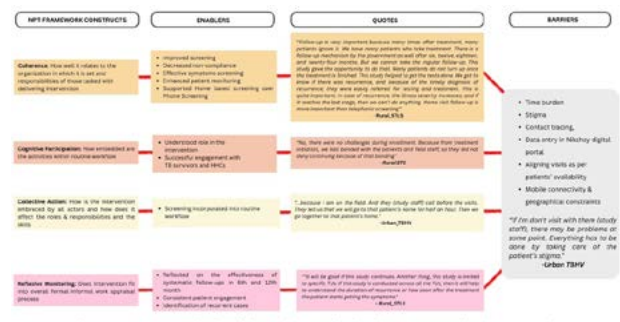


Figure 1: NPT Framework Identifying Enablers and Barriers in Home-Based & phone screening

Conclusions: HCWs effectively integrated post-TB screening into routine practice, despite constraint they had study staff as additional manpower. Strengthening organizational support, optimizing workflows, addressing structural barriers are critical for scalability and sustained impact.

EP37-1060-20 Assessment of TB reinfection rates among previously treated people in Nigeria (October 2022 – June 2024): Implications for targeted intervention strategies

U. Bassey,[1] B. Odume,[2] J. Diara,[2] E. Chukwu,[2] C. Abagwalatu,[3] J. Ongbabo,[3] N. Thompson,[3] [1]KNCV Nigeria, Medical Laboratory Science, Makurdi, Nigeria, [2]KNCV Nigeria, Central Management, Abuja, Nigeria, [3]KNCV Nigeria, Monitoring and Evaluation, Makurdi, Nigeria
e-mail: uduakbassey81@gmail.com

Background and challenges to implementation: Tuberculosis (TB) reinfection among previously treated patients is a significant public health challenge, particularly in high-burden regions like Nigeria. Reinfection could result from continued exposure to the disease. Understanding the rate of reinfection among previously treated patients is vital to improving TB control strategies.
The objective is to determine TB reinfection and DRTB infection rates in people who have completed TB treatment in Benue State, Nigeria
Intervention or response: This retrospective cross-sectional study was conducted from October 2022 to June 2024 in Benue State, Nigeria, using community awareness campaigns to identify the people who had previously completed TB treatment. A total of 1,062 previously treated TB patients were identified. Their sputum samples were collected and tested using GeneXpert MTB/RIF assays to detect Mycobacterium tuberculosis (MTB) and rifampicin-resistant TB (DRTB). Descriptive statistical analysis was used to determine the rate of reinfection and drug-resistant strains.
Results/Impact: Of the 1,062 previously treated TB patients identified, 185 (17.4%) were reinfected with MTB, and 15 (1.4%) were diagnosed with DRTB. The results indicate a considerable reinfection rate.
Conclusions: The findings underscore the need for enhanced intervention strategies aimed at reducing TB reinfection rates among previously treated patients. Strengthened follow-up protocols and community-based infection control measures, coupled with public awareness campaigns, are essential in addressing reinfection risks and preventing the spread of drug-resistant TB.

EP38 Uniting forces: Collaborative strategies and policies driving TB progress

EP38-1061-20 Sustaining the lifeline: Empowering counties to drive costed integrated specimen referral plans for TB diagnostics

J. Marcomic,[1] J. Ogoro,[2] N. Bowen,[3] L.O. Odeny,[1] T. Kiptai,[1] B. Ulo,[1] [1]Amref Health Africa in Kenya, Global Fund TB, Nairobi, Kenya, [2]Ministry of Health, National TB Program, Kenya, Kenya, [3]Ministry of Health, Division of National Laboratory Services (DNLS), Nairobi, Kenya
e-mail: james.marcomic@amref.org

Background and challenges to implementation: Timely diagnosis is essential for effective TB control in Kenya. However, many counties face challenges due to fragmented and under-resourced specimen referral systems. Amid declining donor support, there is an urgent need for counties to adopt sustainable, locally driven solutions. In response, Amref Health Africa, in collaboration with the Ministry of Health, supported the development of County-Specific Operational Plans (CSOPs), tailored to each county's diagnostic capacity, transport systems, and resource availability for effective implementation of the Integrated Specimen Referral System (ISRS).
Intervention or response: A structured operational assessment was conducted across all 47 counties. A standardized data collection tool was developed and administered by trained County and Sub-County Medical Laboratory Coordinators. Data collected included facility mapping, TB diagnostic capacity, equipment functionality, human resource availability, laboratory operational hours, transport routing, vehicle and motorbike requirements, inter-facility distances, and projected operational costs. The data were validated and analyzed to generate costed, context-specific ISRS designs for each county.
Results/Impact: Fifteen counties have developed tailored CSOPs for ISRS implementation. Of these, two counties have allocated budget lines and procured motorbikes for TB specimen transport. Eleven diagnostic sites were earmarked for upgrading from spokes to hubs to expand testing capacity and reduce referrals. Additionally, 80% of non-functional diagnostic equipment were repaired in preparation for implementation. Encouraged by this model, local implementing partners have initiated CSOP development in the remaining 32 counties, generating momentum for national scale-up.
Conclusions: County-led development of costed ISRS models through CSOPs presents a scalable, sustainable approach to strengthening TB diagnostic networks in resource-constrained settings. This model promotes government ownership, enhances resilience beyond donor cycles, and supports equitable access to timely TB diagnosis across Kenya and other high-burden LMICs.

EP38-1062-20 Improving TB detection in vulnerable urban populations through integrated health services: Evidence from two districts in Greater Accra, Ghana

R.S. Adzesi,[1] C. Femeyibor,[1] L. Amoah-Larbi,[2] E.A. Ampofo,[2] A.I. Tsiboe,[2] J. Amoah-Larbi,[2] R.P. Frimpong-Mansoh,[3] Y. Adusi-Poku,[3] [1]University of Ghana, Statistics and Actuarial Science, Accra, Ghana, [2]Ghana National TB Voice Network, Civil Society Organisation, Accra, Ghana, [3]Ghana Health Service, National TB Control Programme, Accra, Ghana
e-mail: rsadzesi@gmail.com

Background and challenges to implementation: A major challenge to TB control in Ghana is low case detection, mainly due to passive case-finding methods. This intervention aimed to enhance TB detection in high-risk slum areas of Greater Accra, Ghana through active case-finding and integrated health services.

Intervention or response: Integrated community-based active TB case-finding activities were carried out among slum and ghetto dwellers in the La Dadekotopon and Korle Klottey districts of the Greater Accra Region, Ghana. The intervention combined TB screening with HIV testing, malaria testing, blood sugar and blood pressure checks, and employed a mobile X-ray van to facilitate on-the-spot TB diagnosis. To encourage participation, free insecticide-treated bed nets (ITNs) were distributed to all people screened.

The screening activities were led by ten nurses from ART clinics and DOTS centres, with support from two radiographers who operated the X-ray machine. Six TB Champions were deployed to support community mobilization efforts, which were further strengthened through announcements via community information centers and mobile vans. Data on attendance, presumptive TB cases based on radiological, bacteriological and clinical diagnosed cases were collected and analysed.

Results/Impact: A total of 1,243 individuals were screened, with 894 identified as presumptive TB cases. Of these, 546 sputum samples were collected, and 347 individuals undertook chest X-ray. 26 X-rays were suggestive of TB, and 87 individuals were bacteriologically confirmed as TB positive by GeneXpert MTB. All confirmed cases were initiated on treatment.

This integrated approach significantly reduced diagnostic delays and improved case detection among high-risk groups. Community mobilisation through peer leaders and ghetto influencers contributed to turnout and enhanced local ownership of the TB response.

Conclusions: The integrated, community-based TB screening approach proved effective in enhancing case detection among urban marginalised populations. By combining health services and leveraging peer-led mobilisation, the intervention reduced diagnostic delays, improved access to care and early TB treatment initiation.

EP38-1063-20 Evaluating community-based initiatives on TB knowledge and attitude in Nasarawa, Nigeria: A machine learning comparison of survey responses

N. Zoakah,[1] C. Ugwu,[1] J. Bimba,[1] C. Aneke,[1] G. Moses,[1] K. Aliyu,[1] [1]Zankli Research Centre, Research, Karu, Nigeria
e-mail: nathanzoakah@gmail.com

Background: Nigeria continues to face insufficient Tuberculosis (TB) knowledge which poses a barrier to successful healthcare initiatives. Research shows that community involvement through trained volunteers and local networks significantly boosts Tuberculosis knowledge and reduces stigma.

A community-based initiative in Nasarawa State worked to correct TB misconceptions through collaboration with market leaders along with religious leaders and community members. Insights from the baseline survey directed the Local Tuberculosis Action Group (LTAG) to launch specific initiatives. A follow-up survey assessed changes in community awareness and perceptions.

We used machine learning models to analyze response shifts to evaluate the changes more effectively. The research examines TB initiative effects in two Local Government Areas (LGAs) and demonstrates how data-driven methods can assess public health results.

Design/Methods: This cross-sectional study surveyed 3,333 households during baseline and endline in Karu and Keffi LGAs. The data analysis stage included exploratory data analysis followed by data preprocessing and model training with Naïve Bayes, Logistic Regression, Decision Tree, and Random Forest algorithms. The evaluation of model performance used accuracy, precision, recall, and Receiver Operating Characteristics- Area Under the Curve (ROC-AUC) scores.

Results: The study results show considerable advancements in TB awareness and perception after the program implementation. The Random Forest algorithm achieved superior predictive accuracy, AUC and recall score with a 31.67% rise in knowledge and attitude scores from baseline to endline assessments.

The endline assessment revealed substantial performance gains for all models as evaluation metrics rates surpassed 95%, confirming the success of targeted community initiatives.

S/N	Algorithm	Accuracy (Baseline)	Accuracy (Endline)	AUC (Baseline)	AUC (Endline)	Precision (Baseline)	Precision (Endline)	Recall (Baseline)	Recall (Endline)
1.	Naïve Bayes	65.45	95.74	70.57	98.71	73.96	98.98	69.05	96.17
2.	Logistic Regression	64.66	96.80	71.30	98.23	75.76	98.99	64.08	97.38
3.	Decision Tree	63.14	97.69	69.11	98.02	75.21	99.39	61.53	97.99
4.	Random Forest	67.15	98.82	72.37	99.82	74.17	99.14	73.85	99.53

Conclusions: The implementation of community-based initiatives led to substantial improvements in TB knowledge and attitudes among participants. The Random Forest machine learning model demonstrated its capability in assessing public health awareness changes and affirmed its usefulness for intervention evaluations. The study demonstrates that utilizing data-driven methods enhances TB response strategies for improved public health evaluation.

EP38-1065-20 Words matter: Caregiver-health worker communication when using paediatric TB treatment decision algorithms

S. Payotte,[1] Z. Onivogui,[2] A. Salifou,[3] E. Briskin,[4] J. Armour-Marshall,[4] F. Nackers,[4] B. Schramm,[1] C. Hewison,[5] H. Huerga,[4] G. Scarpa,[4] [1]Epicentre, Field Epidemiology, Paris, France, [2]Epicentre, Field Epidemiology, Conakry, Guinea, [3]Epicentre, Field Epidemiology, Maradi, Niger, [4]Epicentre, Field Epidemiology, Brussels, Belgium, [5]Médecins Sans Frontières, Operational Centre Paris, Paris, France
e-mail: Sofia.payotte@epicentre.msf.org

Background: Childhood tuberculosis (TB) remains a significant threat in sub-Saharan Africa, often going undiagnosed. To tackle this, the WHO developed Treatment Decision Algorithms (TDAs) that prioritize clinical evaluations and rely on effective communication between health workers (HWs) and caregivers.
This qualitative study aims to understand the communication experiences of caregivers and HWs during TDA implementation for children living with HIV (CLHIV) in Guinea, and for malnourished children in Niger.
Design/Methods: We conducted 50 interviews with caregivers of children with presumptive TB (25 CLHIV and 25 malnourished), and 11 interviews and 4 focus group discussions with HWs involved in TDA implementation. Critical discourse analysis was applied considering subjects' identities, their positions in the care pathway and comparisons across patient groups, healthcare facilities, and national contexts.
Results: Results revealed differing social dynamics in how HWs and caregivers perceive their roles. In Niger, HWs noted that TDA use was limited by communication barriers with caregivers, and some expressed stigmatizing assumptions about mothers of malnourished children (e.g., "*they are unable to estimate the duration of symptoms*"). Caregivers viewed TB as dangerous but often positioned themselves as "*uninformed*" reflecting internalized social judgments, leaving TB management to HWs (e.g., "*We can't understand it, we're villagers*").
In contrast, in Guinea, HWs treating CLHIV described the impact of organizational barriers on communication with caregivers (e.g. lack of time). Caregivers of CLHIV saw themselves as "*health partners*," sharing a good understanding of the TB diagnostic process. They were comforted that TB can be effectively treated; however, the TB diagnosis often remained a family secret due to fear of stigmatization.
Conclusions: Results highlight that communication between HWs and caregivers was shaped by their experiences of pre-existing care pathways and sociocultural beliefs. Implementation of TDAs is an opportunity to support and improve child and family focused communication strategies in different contexts.

EP38-1066-20 Assessment of the social support available to TB-affected communities in Viet Nam

R. Forse,[1,2] M.T. Duarte Alberto Dos Santos,[2] T. Nghiem,[3] N. Pham,[3] A. Codlin,[1,2] L.N.Q. Vo,[4,2] A. Cross,[5] H.B. Nguyen,[6] L.V. Dinh,[6] J. Huh,[7] [1]Friends for International TB Relief (FIT), Management, Ho Chi Minh City, Viet Nam, [2]Karolinska Institutet, Department of Global Public Health, Solna, Sweden, [3]Friends for International TB Relief (FIT), Program, Ha Noi, Viet Nam, [4]Friends for International TB Relief (FIT), Management, Ha Noi, Viet Nam, [5]Stop TB Partnership, Strategic Initiatives, Geneva, Switzerland, [6]National Lung Hospital, Management, Ha Noi, Viet Nam, [7]Stop TB Partnership, External Affairs & Strategic Initiatives (EASI), Geneva, Switzerland
e-mail: rachel.forse@tbhelp.org

Background: As low-income countries graduate to middle-income countries, they transition away from donor-financing and are pushed towards high-income health system models, where decentralization ensures alignment between budget allocation and regional needs. As Viet Nam faces this transition, this study conducted a comprehensive assessment of tuberculosis (TB) support programs across its 63 provinces to monitor the decentralisation process and inform policy-makers on local needs and challenges.
Design/Methods: In 2024, a cross-sectional survey was conducted across all provinces. The survey focused on the types of support packages offered, funding sources, and dedicated provincial-level TB-specific plans. A provincial-level scoring system was developed, informed by participatory workshops with TB survivors and healthcare providers. Provincial profiles from the survey were matched against the scoring system to map the provincial level of support offered to people with TB.
Results: Health insurance enrollment was the most common support package, reported in 76.2% of provinces, while livelihood support packages were the least common, reported in 9.5% of provinces. There were a total of 332 different support packages reported across the 63 provinces. Most support packages were funded by PASTB, the Global Fund, and national budgets, with only 4% funded by provincial budgets.

Conclusions: These findings highlight a high variability of support available for people with TB throughout the country, and show that access to social protection is highly fragmented, with several packages for the same kind of support being offered within provinces. These findings also indicated that funding for the support of people with TB is still not very decentralized and is still dependent on external aid. This work is essential for shaping global frameworks to ensure comprehensive support for TB patients, aligning with commitments made at the 2023 UN High-Level Meeting on TB. Addressing these challenges is critical for Viet Nam's health system transition and for meeting global TB care goals.

EP38-1067-20 Breaking barriers: Assessing community-led, rights-based, and gender-transformative TB responses in conflict-affected zones of Tigray, Ethiopia

Z. Trife,[1] G. Dessalegn,[2] A. Endale,[3] A. Bati,[2] L. Seyoum,[2] D. Gemtesa,[4] B. Tadesse,[2] H. Terefe,[2] T. Mebrate,[2]
[1]REACH Ethiopia, Monitoring, Evaluation and Research, Addis Ababa, Ethiopia, [2]REACH Ethiopia, Program Management, Addis Ababa, Ethiopia, [3]Dire Dawa University, Public Health, Dire Dawa, Ethiopia, [4]REACH Ethiopia, M&E, Addis Ababa, Ethiopia
e-mail: getachew.wd@reachet.org.et

Background: Tuberculosis (TB) remains a pressing public health challenge, especially in conflict-affected regions like Tigray, Ethiopia, where health systems have collapsed, and service access is severely constrained. Community-led, rights-based, and gender-transformative (CRG) TB approaches offer a pathway to equitable and people-centered care.
This study assessed the implementation of CRG-TB programming in the war-affected Central and Northwest Zones of Tigray in 2024.
Design/Methods: A cross-sectional study design using mixed methods was employed. Quantitative data were collected from 425 respondents (56.2% female; mean age 43.4±15.0 years), including TB patients, survivors, families, healthcare providers, and community members. Qualitative data were gathered through 6 focus group discussions (56 participants), 24 key informant interviews (KIIs), and 12 health facility observations.
The study explored barriers related to availability, accessibility, acceptability, and quality (AAAQ) of TB services, alongside CRG dimensions.
Results: Around 42.5% of participants rated TB service availability as poor or very poor, while 46.1% and 52.6% reported poor accessibility and quality, respectively. Acceptability was rated positively by 84.7%. However, only 25.9% reported community engagement in TB programming. Just 11.3% had participated in TB rights advocacy, and 8.7% had opportunities to exercise their rights. Only 15.8% believed the TB program considered gender dynamics. Qualitative findings revealed deep-rooted barriers including stigma, lack of privacy, dismantled community platforms (HDA/WDA), gender-based discrimination, limited legal support, and healthcare worker capacity gaps. Stigma and discrimination were consistently cited across all respondent types as key deterrents to seeking or adhering to TB care.
Conclusions: The study highlights critical gaps in CRG-TB implementation in Tigray, particularly due to conflict-related service disruption, low community involvement, weak rights frameworks, and minimal gender integration. Recommendations include rebuilding TB infrastructure, strengthening legal protections, revitalizing community platforms, and embedding gender-sensitive and rights-based approaches into TB programming to improve outcomes in conflict-affected settings.

EP38-1068-20 Putting the pedal to the metal by integrating HIV screening services to other health services through community-led initiatives: Results from GFATM supported project in India

K. Biswas,[1] R. Rana,[1] B. Borah, Md. Asif [1]Plan International (India Chapter), Programme, Delhi, India e-mail: rahoolbi@gmail.com

Background and challenges to implementation: Complementing Govt. of India's effort to end AIDS by 2030 and eliminate TB, Plan India is implementing One Stop Center (OSC) project in 25 Indian states through community led Innovative strategy with Key and Bridge Population groups.
Intervention or response: Strategic approaches remained A) to ensure HIV testing by reaching out to new & uncovered Key & Bridge Population, B) to ensure viral suppression for all clients identified as HIV positive and ensuring prevention for all have been identified as negative.
Generative digital intelligence guided process deployed to ensure follow up, re-testing and re- linking of the client diagnosed.
Results/Impact: A total of 150K Transgender, PWID, Truckers and Migrants registered in OSC project. Around 85% (n=148,464) clients received HIV testing and around 1.5 thousand clients newly diagnosed as HIV positive; and successfully linked with treatment services. HIV Positivity remained 3.64% (n=8,879) among transgender, 5.70% (n=13,018) among the PWID and 0.41% (103,664) among the trucker and migrants receiving HIV testing. Most (98%) of the registered client received TB 4s screening. Around 66% of total registered client received STI screening services, Viral hepatitis screening was accessed by 21% of registered client. A bouquet of value-added services was provided i.e. 88% of the clients received general Health check-ups including Blood Pressure & Blood

Sugar etc., 83% of the clients received counselling on ART adherence, Counselling on IEC, prevention & risk reduction etc. Clients received awareness on legal aid, TG Shelter Homes, Drug De-Addiction and rehabilitation. More than 31% of the registered client received condom. Around 7% of the registered client reached with Social welfare and entitlement scheme services.

Conclusions: Integrating HIV and Tuberculosis screening with other health service packages has resulted in increased HIV/ TB screening and diagnosis. Provision of general health services with value-added services at OSC has attracted KPs to the centre otherwise remained hidden.

EP38-1069-20 Beyond the Pill: Person-centred support for drug-resistant TB treatment adherence in Delhi (Lessons from the Dream Delhi Project)

S. Nath,[1] S. Nath,[2] J. Lordson,[3] R. N,[4] [1]Baptist Church Trust Association, Public Health, New Delhi, India, [2]Baptist Church Trust Association, Administration and Finance, New Delhi, India, [3]CCRP, Research, Trivandrum, India, [4]KSSM, Public Health, Trivandrum, India
e-mail: drsudhinath@gmail.com

Background and challenges to implementation: India accounts for 27% of global drug-resistant Tuberculosis (DR-TB) cases. Delhi has the highest prevalence of DR-TB in India. About one-third of DR-TB patients in Delhi were either not initiated on treatment or were lost to follow-up. In 2018, 18% of DR-TB patients in Delhi were lost to follow-up. Socioeconomic factors, including poverty, malnutrition, lack of funds for transport, lack of social support, and mental health issues, have been documented to impact treatment adherence of DR-TB patients. Currently, there is no mechanism for the early identification of high-risk patients who may not complete their treatment.

Intervention or response: We developed a screening tool to identify the needs of DR-TB patients for food support, transportation support, and mental health support and categorized patients into low risk and high risk for treatment non-adherence.

Nutritional support was provided using high calorie and protien rich food grains per month not only for patient but as a family ration packets . Transportation support for healthcare visits was provided through nutritional vendor as door step delivary mechanism for the malnurished and deblitated patients . Vocational training skill such as tailoring and computer skills were offered to eligible patients.

Results/Impact: From April 2022 to July 2023, the Dream Delhi Project enrolled 1,200 DR-TB patients from the following five urban areas of Delhi: Lok Nayak ,Malviya Nagar, Nehru Nagar, Patparganj, and Shadara. A total of 301 patients received nutritional support, 174 received transportation support, 42 received multiple counselling support, and 41 received vocational support. Lost to follow-up were 118 patients (9.8%), nearly half of the previously reported value of 18%.

Conclusions: Need assessment and patient-centred delivery of social support along with treatment can significantly reduce nonadherence to DR-TB treatment ; urgent need for mechanisms to identify patients who are at high risk due to social, economic, and mental health problems.

EP38-1070-20 Stakeholder perspectives on new TB vaccine introduction in Indonesia: Concerns and priorities

S.R. Hadinegoro,[1] A. Fuady,[2] N.D. Putri,[1] N. Soeharno,[3] A.S. Zhafira,[1] P. Wicaksana,[1] M.S. Valeria,[1] R. Clark,[4] R. White,[4] [1]Universitas Indonesia, Pediatrics, Jakarta, Indonesia, [2]Universitas Indonesia, Community Medicine, Faculty of Medicine, Jakarta, Indonesia, [3]Universitas Indonesia, CHEPS Faculty of Public Health, Jakarta, Indonesia, [4]London School of Hygiene and Tropical Medicine, Infectious Disease Epidemiology and Dynamics, London, United Kingdom of Great Britain and Northern Ireland
e-mail: ahmad.fuady01@ui.ac.id

Background: New TB vaccines are seen as key to global TB elimination efforts, but implementation challenges remain uncertain. As the country with the world‘s second-highest TB burden, Indonesia has participated in vaccine trials. Following a 2024 national workshop on new TB vaccine acceptance, this study further explored stakeholders‘ concerns about introducing the vaccines in Indonesia.

Design/Methods: A multi-stakeholder consultation was held, inviting 28 representatives from government agencies, TB and vaccine experts, and international partners (WHO, UNICEF). Data were collected in an in-person group meeting using an individual questionnaire featuring both multiple-choice and open-ended questions. Analysis employed a mixed-methods approach combining quantitative assessment with qualitative thematic analysis.

Results: Of 28 invitees, 23 participated the study and completed the questionnaire (9 government, 10 experts, 4 international partners), representing expertise in vaccine (7), TB (9), and policy development (7). Primary concerns centred on vaccine efficacy (19/23) and comparative effectiveness against other TB control interventions (18/23). Most participants (15/23) would reject vaccines with efficacy <50%, while seven required minimum 60-80% efficacy. Most (23/23) respondents supported vaccine introduction without requirement of complete local manufacturing capability, and all identified financ-

ing as the critical implementation challenge. Participants emphasized that financial barriers could be overcome through strengthened political commitment, including strategic advocacy to governing political parties.
The previous workshop suggested that the vaccine would be targeted to the general population due to high incidence, and this workshop highlighted additional targeting to high-risk populations: people living with HIV/AIDS (21/23), those with diabetes (18/23), and household contacts of TB patients (18/23); and specific populations: adolescents (16/23), adults (14/23) and healthcare workers (14/23).
Conclusions: TB vaccine introduction in Indonesia requires addressing concerns about efficacy and securing sustainable financing through advocacy for political commitment. Stakeholders recommend targeting both general and high-risk populations. These findings can guide evidence-based planning for future TB vaccine deployment in high-burden settings.

EP39 Engaging private sector to innovate finding TB

EP39-1071-20 Leveraging an intermediary organisation to enhance private sector TB detection in Lagos State, Nigeria

N. Umerah- Nwosu,[1] A. Agbaje,[2] A. Gemmani,[3] B. Olaniyi,[4] G. Ifeanyi-UKaegbu,[4] G. John,[5] R. Eneogu,[6] O. Oyelaran,[7] D. Olugbenga,[4] I. Okekearu,[8] D. Sokoya,[9] [1]Loving Gaze, St Kizito Clinic, Lagos, Nigeria, [2]Institute of Human Virology Nigeria, Projects, Abuja, Nigeria, [3]Loving Gaze, Clinical, Lagos, Nigeria, [4]Institute of Human Virology Nigeria, Projects, Lagos, Nigeria, [5]Loving Gaze, Intermediary Organisation, Lagos, Nigeria, [6]USAID, TB, Abuja, Nigeria, [7]USAID, TB/HIV, Abuja, Nigeria, [8]Society for Family Health, Projects, Abuja, Nigeria, [9]Lagos State Ministry of Health, LSTBLCP, Lagos, Nigeria
e-mail: ndnwosu@yahoo.com

Background and challenges to implementation: Tuberculosis (TB), despite being curable, remains a leading cause of death globally and in Nigeria, which ranks among the top 10 high-TB-burden countries with an incidence of 219 per 100,000. Lagos State with a population estimated at 18 million persons, alone contributes approximately 11% of the national burden. More than 76% of TB cases remain undetected each year, largely due to stigma, knowledge gaps, and poor access to diagnosis and treatment—especially within the 52% of Nigerians who seek care from the private sector.
Traditional public-private mix (PPM) models, coordinated solely by government actors, have yielded limited success, prompting a shift towards utilizing intermediary organizations (IOs) for more effective engagement. An IO plays coordination, mobilisation, supervision, mentoring, sustainability and catalytic roles.

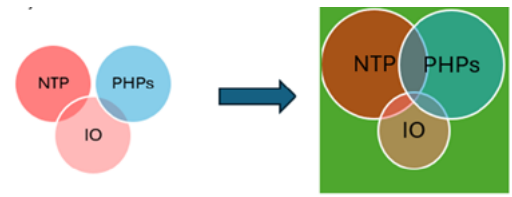

Figure 1: Illustrating the role of Intermediary Organisation creating an enabling environment between PHPs and the National TB Program (NTP)

Intervention or response: Project Description: Under the USAID-funded TB Local Organization Network (TB-LON 3), Loving Gaze, a Nigerian NGO, was engaged as an IO to enhance private sector participation in TB control in Lagos State.
Building on prior success under the USAID SHOPS Plus project, Loving Gaze deployed a tailored model to engage 1,757 private healthcare providers through training, mentorship, and supportive supervision. Key innovations included the use of a modified screening algorithm,

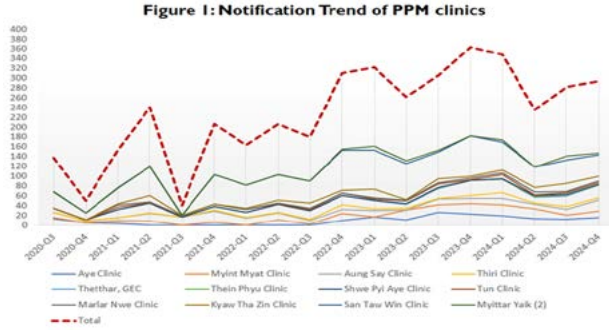
virtual TB networks, and logistical/incentive support for diagnostics, treatment, and TB preventive therapy—all aligned with national guidelines.
Results/Impact: The intervention led to the notification of 13,200 TB cases and 19,484 contact follow-ups by private providers by the end of the project. This significantly reduced the proportion of missing TB cases and improved access to TB services across formal and informal private care networks.
Conclusions: The IO model demonstrates strong potential to sustainably scale up private sector TB response. National programs should consider adopting this approach to strengthen provider networks, expand screening, and enhance equitable access to TB services—crucial for achieving the End TB Strategy goals.

EP39-1072-20 Finding TB through the intensified Integrating Screen-For-All (SFA) approach in routine primary care services to improve TB detection in Myanmar Medical Association private-public mix clinics

T. Maung,[1] H.T. Oo,[1] A.M. Thu,[1] A.P.S. Phoo,[2] K.Z. Thann,[2]
[1]Myanmar Medical Association, TB Program, Yangon, Myanmar, [2]PATH, Myanmar Country Program, Yangon, Myanmar
e-mail: drtnmg@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a significant public health threat in Myanmar, where delays in diagnosis contribute to ongoing transmission and sub-optimal outcomes. In Private-Public Mix (PPM) clinics, TB case finding has traditionally relied on passive approaches, evaluating only presumptives who disclose TB symptoms. This strategy can often miss individuals with less obvious symptoms or those unaware of TB symptoms.
Intervention or response: Myanmar Medical Association (MMA) introduced an Intensified Case Finding (ICF) approach, Screen-for-All (SFA) in selected PPM clinics. This approach actively screened all clinic clients and their attendees for presumptive TB symptoms using a standardized SFA checklist, regardless of their complaints during visits. Symptomatic individuals were referred for chest X-ray (CXR) and/or sputum testing.
The approach was integrated into existing TB care workflows beginning in Q4 2022. A retrospective review of TB notification trends was conducted to compare data before and after implementation. Structured surveys assessed feasibility, acceptability, and implementation challenges among 12 clinic providers.
Results/Impact: The TB notification more than doubled from 70 PwTB per quarter before Q4 2022 to 160 PwTB in 2023 following the implementation of SFA approach and continued remaining steady (Figure1: Notification Trend of PPM Clinics). All providers agreed the approach integrates well within existing workflows; 92% found the register easy to use. While most clinics screened fewer than 50% of attendees daily, all respondents believed SFA led to earlier TB detection and reduced transmission. Key barriers included patient resistance (50%), limited consultation time (33%), and sputum transport issues (25%). Providers recommended sustaining the SFA approach, additional clinic staff training, and enhanced patient education.

Figure 1: Notification Trend of PPM clinics



Conclusions: The intensified symptom screening approach (SFA) enhanced TB detection in PPM clinics. Mutual engagement between clinic attendees and providers demonstrated SFA's feasibility and acceptability within the PPM context. These findings support scaling up ICF strategies to strengthen TB control efforts in similar high-burden settings.

EP39-1073-20 Making a case for poor-performing facilities in TB disease identification in the private sector: Avoiding throwing the baby out with the bathwater

H.U. Garba,[1] A. Ogar,[1] T. Aniagolu,[2] M. Bajehson,[3] A. Okoh,[4] M. Sheshi,[4] B. Odume,[4] M. Bathnna,[5] T. Adetiba,[5] O. Chijioke-Akaniro,[6] A. Reilly,[7] [1]KNCV Nigeria, Program, Kaduna, Nigeria, [2]K, Program, Kaduna, Nigeria, [3]KNCV Nigeria, Program, Kano, Nigeria, [4]KNCV Nigeria, Program, Abuja, Nigeria, [5]IHVN, Program, Abuja, Nigeria, [6]National Tuberculosis, Buruli Ulcer and Leprosy Control Program, Monitoring and Evaluation, Abuja, Nigeria, [7]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Program, Geneva, Switzerland
e-mail: husman@kncvnigeria.org

Background and challenges to implementation: Tuberculosis remains a significant public health concern, necessitating proactive detection strategies, particularly within the private sector. As a Sub-Recipient under the Global Fund CPPM GC-7 Grant, KNCV Nigeria has a goal of increasing private sector contributions to national TB disease notification towards achieving the END TB goal. Despite huge efforts in proactive case-finding, some private health facilities have low TB disease detection due to

fundamental gaps in their operations. These „poor-performing" facilities are typically perceived as „High Investment-Low Yield" locations and deprioritized or omitted from interventions due to need for resource optimization, thereby neglecting their contextual constraints and latent potential.

Intervention or response: A targeted performance improvement plan was implemented across 7 selected low-performing private facilities. This plan involved reorientation of healthcare providers on WHO TB symptom checklist, integrating digital screening tool (MATSAPP), strengthening referral linkages to diagnostics sites and ensuring continuous oversight by KNCV employed Adhoc staff. Additionally, Incentivized engagement was incorporated to enhance TB patient care and sustain involvement during treatment. Active monitoring of performance was instituted to assess facility TB presumptive identification, TB detection, and treatment enrollment during the period.

Results/Impact: Initial assessments revealed that poor-performing facilities often faced challenges such as low TB awareness, competing health priorities, staff attrition, and inadequate diagnostic capacities. Following the intervention, presumptive TB identification rose from 211 in Q2 2024 to 686 in Q4 2024. TB cases increased from 21 to 62 within the same period. Despite a lower conversion rate than high-performing facilities, these facilities showed a consistent increase in case notification thus validating the targeted support.

Conclusions: The performance improvement plan with strategic interventions has shown to significantly improve presumptive TB and positive TB detection in private sector health facilities, which were hitherto poor performing. Sustained engagement of all private health providers, regardless of initial performance, is critical to achieving TB elimination goals.

EP39-1074-20 STEPS toward excellence: Ensuring quality of TB care at Yashoda Super Speciality Kaushambi, a private hospital in Uttar Pradesh, India

C. Gupta,[1] U. Arora,[2] A. Kumar Sinha,[3] R.K. Mani,[4] N. Srivastava,[5] M. Rajiv,[5] R. P S,[5] J. Jaju,[5] [1]Yashoda Superspeciality Hospital, Kaushambi, Infectious Disease, Ghaziabad, Delhi NCR, India, [2]Yashoda Superspeciality Hospital, Kaushambi, Administration, Ghaziabad, Delhi NCR, India, [3]Yashoda Superspeciality Hospital, Kaushambi, Pulmonary,Critical Care and Sleep Medicine, Ghaziabad, Delhi NCR, India, [4]Yashoda Superspeciality Hospital, Kaushambi, Clinical Services and Pulmonology, Ghaziabad, Delhi NCR, India, [5]International Union Against Tuberculosis and Lung Disease, The Union, Delhi NCR, India
e-mail: chhavi13.86@gmail.com

Background and challenges to implementation: There were concerns about the suboptimal quality of TB care from private sector including lack of systems for treatment adherence support and a high loss to follow-up rates. Yashoda Super Speciality Hospitals Kaushambi, a 500 bedded private tertiary care centre, was the first facility in Northern India to implement the STEPS (System for TB Elimination by Private Sector) to ensure standards of TB care to all the clients reaching them.

Intervention or response: STEPS center is established as a single window mechanism (Figure1) by the hospital management and works under a Medical Officer (STEPS Nodal Officer) assisted by a Physician Assistant (STEPS Lead).

The STEPS center works with all stakeholders like clinicians, clients, laboratory, pharmacy, nursing, and medical record departments in a hub and spoke model. The center supports clinicians and clients to ensure standards of TB care by ensuring all individuals with presumed TB are tested using a molecular test, supported for treatment adherence through counseling and weekly phone calls and their contacts are investigated. The center notifies all individuals with TB and reports their treatment outcomes. The entire process fosters customer loyalty through an 'after- sales care model'.

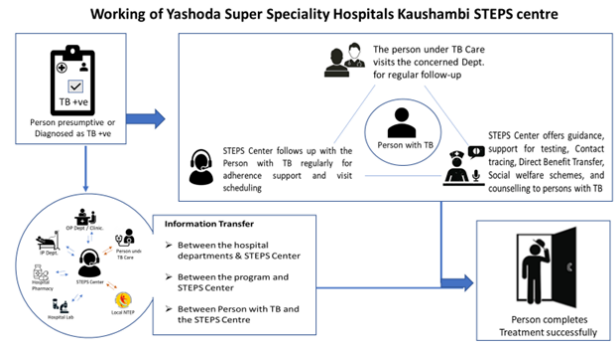


Figure 1. Working of Yashoda Super Speciality Hospitals Kaushambi STEPS centre.

Results/Impact: TB notification has doubled since initiation of STEPS centre (445 from March2024-Feb2025 compared to 226 from March2023-Feb2024), with documented improvements in the microbiological confirmation (40% vs 26%), lost to follow up rates (4% Vs 17%), rifampicin sensitivity testing (97% Vs 37%), HIV testing (100% Vs 72%) and reported treatment outcomes (84% Vs 37%). Total additional expense for implementing STEPS for the hospital per 100people with TB diagnosed in a year was 573 USD while additional business returns for the hospital was 1145 USD.
Conclusions: Models like STEPS where private hospitals assuming accountability to ensure standards of TB care to the clients reaching them is possible and it improves the standards of TB care.

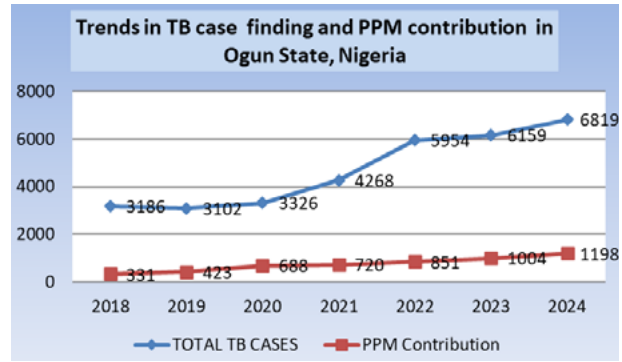
EP39-1075-20 Private public mix (PPM) as a key driver of finding TB in Ogun State (2018-2024)

T.K. Olusola,[1] F. Soyinka,[1] M.A. Tijani,[1] O. Edwin,[2] L. Folorunso,[2] E. Salau,[2] C. Mensah,[3] A. Agbaje,[3] O. Chijioke-Akaniro,[4] S. Dimang,[4] J. Kimeu,[5] M. Zamzu,[5] [1]Ogun State Ministry of Health, Public Health, TBLCP, Abeokuta, Nigeria, [2]Damien Foundation Belgium (Nigeria Project), Programme, Ibadan, Nigeria, [3]Institute of Human Virology, Nigeria, Programme, Abuja, Nigeria, [4]National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Programme, Abuja, Nigeria, [5]Global Fund Country Team, Programme, Geneva, Switzerland
e-mail: maotijani@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a significant public health challenge in Nigeria, which ranks sixth globally and first in Africa among high TB-burden countries, with an estimated incidence rate of 219 per 100,000 population (WHO, 2021). Despite improvements in TB treatment coverage (70%), Nigeria is among the 14 countries with the highest burden of TB, TB/HIV co-infection, and multidrug-resistant TB (MDR-TB).
This study evaluates the impact of engaging multiple tiers of the Private Public Mix (PPM) approach in reducing the TB case detection gap in this high-burden context.
Intervention or response: A multi-tiered PPM model was implemented in collaboration with partners beginning in 2018.

- **Scheme 1** involved Private Proprietary Medicine Vendors (PPMVs), who identified and referred individuals with presumptive drug-sensitive (DS-TB) and drug-resistant TB (DR-TB).
- **Scheme 2** included stand-alone laboratories and non-NTP facilities that screened, diagnosed, and referred individuals with TB to DOTS centers.
- **Schemes 3 and 4** offered diagnostic services, treatment, and ongoing care.
- Linkage Coordinators ensured that every individual identified with presumptive or confirmed TB was successfully linked to care. Data from all schemes were analyzed to assess their contribution to TB case detection over time.

Results/Impact: Between 2018 and 2024, TB case notifications increased from 3,186 to 6,819. PPM contributions rose from 331 cases (10%) in 2018 to 1,198 cases (18%) in 2024. A notable surge occurred in 2020, with 688 cases detected, underscoring the critical role of private providers during the COVID-19 pandemic.



Conclusions: Strengthening collaboration between public health systems and private healthcare providers has significantly improved TB case detection and treatment access in Ogun State.
This study emphasizes the value of inclusive, multi-tiered partnerships in closing TB detection gaps and supports broader adoption of PPM models in national TB control strategies.

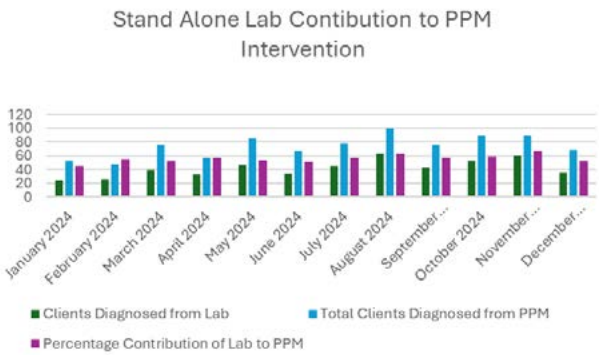
EP39-1076-20 Stand-alone lab intervention: A key driver to scaling up TB diagnosis in the Public Private Mix (PPM) model: A KNCV Nigeria experience

I. Edo,[1] B. Odume,[2] M. Sheshi,[2] P. Opara,[3] O. Salau,[4] [1]KNCV Nigeria, Programs, Jos, Nigeria, [2]KNCV Nigeria, Programs, Abuja, Nigeria, [3]KNCV Nigeria, Programs, Lafia, Nigeria, [4]KNCV Nigeria, Strategic Information, Lafia, Nigeria
e-mail: iedo@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains a major public health concern in Nigeria, with low case detection, especially in the private sector. To bridge this gap, private healthcare providers were introduced to strengthen TB control efforts. Engaging Standalone laboratories with high client volumes as a TB screening center became necessary to serve as a strategic solution towards improving TB case finding.
Intervention or response: To strengthen TB case detection through private sector engagement, a hub-and-spoke model was implemented, linking standalone laboratories

(spokes) with private hospitals (hubs) participating in the PPM intervention. Selected laboratories were engaged as collaborators and their staff were trained on TB screening, identification of presumptive, and on efficient referral system. Initial screening was conducted at the labs, and individuals presumed of having TB were referred to designated hub hospitals for confirmatory diagnosis using GeneXpert and other appropriate diagnostic tools. Once diagnosed, TB patients at the hub hospitals were promptly linked to treatment services through the support of TBLS and DOTS providers.

Results/Impact: From January 2024 to December 2024, a total of 30,875 clients were screened from the standalone labs across Plateau state, 108 TB cases with average of 9 per month were diagnosed and notified, thereby contributing significant 12% to the overall PPM case notification in the state as depicted below.



Conclusions: Scaling up this model in the future to other settings and strengthening referral linkages will expand TB control. Policymakers and implementers of TB programs must consider independent labs as key partners in the fight against TB, ensuring continued engagement, capacity building, and mainstreaming in national TB strategies.

EP39-1077-20 Enhancing finding TB and strengthening the cascade of care: A public private mix approach in Ghana

E. Sam,[1] N. Asare,[1] G. Okyere,[1] D. Dornor Lomokie,[1] F. Ayichuru,[1] A. Koyaara,[1] N.K. Quakyi,[1] Y. Adusi- Poku,[2]
[1]The Aurum Institute Ghana, International Division, Accra, Ghana, [2]National Tuberculosis Programme, Ghana Health Service, Accra, Ghana

Background and challenges to implementation: In Ghana, the private sector accounts for approximately 40% of healthcare services but remains under-engaged in tuberculosis (TB) screening and management. Over-reliance on public facilities for TB detection has contributed to persistent shortfalls in annual TB notification targets, exacerbating gaps in diagnosis and treatment follow-up. Additionally, limited capacity and insufficient infrastructure within private healthcare settings hinder their potential to effectively manage TB care, presenting a barrier to national TB elimination goals.

Intervention or response: To address these challenges, Aurum Institute Ghana, under Global Fund Grant Cycle 7, collaborated with Regional and District Health Management Teams to enhance private-sector engagement in TB case detection across Ashanti, Greater Accra, Western, and Northern regions.

The intervention included 90 high-volume private health facilities and 80 private pharmacies or over-the-counter medicine shops (OTCMs) across 27 districts. Twenty GeneXpert machines were strategically installed using a hub-and-spoke model for efficient sputum transport.

A total of 375 healthcare providers were trained to systematically screen outpatients using TB symptom-based registers and provided comprehensive, patient-centred care aligned with national standards.

Additionally, 37 TB Champions were trained to support with screening, sputum transport, linkage to care, contact tracing, and preventive therapy. Chest X-rays were provided at designated free sites for sputum-scarce clients, and diagnosed cases were promptly initiated or referred for treatment.

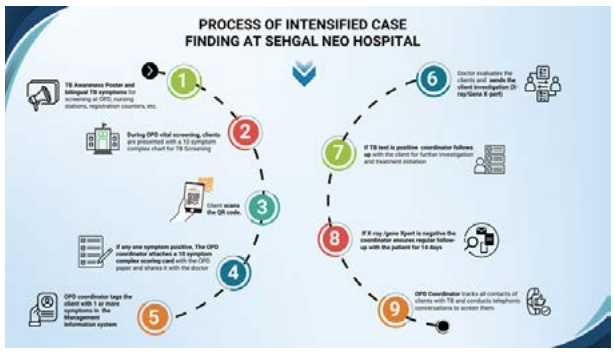
Results/Impact: From January to December 2024, 197,011 clients were screened, identifying 22,786 presumptive TB cases. Of these, 11,945 (52.4%) underwent testing, resulting in 528 bacteriologically confirmed, 68 clinically diagnosed, and 6 extrapulmonary cases. Of the 602 total cases notified, 589 (98%) were initiated on treatment successfully, representing 3% of Ghana's national TB notification in 2024.

Conclusions: Strengthening private-sector engagement significantly enhances TB case detection and continuity of care, demonstrating the need for sustained investment and strategic alignment with private stakeholders.

EP39-1078-20 Private provider-initiated facility based intensified case finding for TB: Experiences from a private hospital in New Delhi, India

N. Sehgal,[1] M. Jain Sehgal,[2] J. Khullar,[3] P. Rajput,[4] M. Rajiv,[5] N. Srivastava,[5] R. PS,[5] J. Jaju,[5] [1]Sehgal Neo Hospital, Medical Director & Head of Department Minimal Access, Bariatric & General Surgery, New Delhi, India, [2]Sehgal Neo Hospital, Pediatrics & Neonatology, New Delhi, India, [3]Sehgal Neo Hospital, Internal medicine, New Delhi, India, [4]Sehgal Neo Hospital, Quality, New Delhi, India, [5]International Union Against Tuberculosis and Lung Diseases, The Union, New Delhi, India
e-mail: narinsehgal@gmail.com

Background and challenges to implementation: New Delhi is the state in India with a high prevalence of TB (>700/100,000). More than half of the people with TB symptoms seek care from private providers. A significant delay for diagnosis of TB has been documented in the state, especially among those reaching the private sector.
Intervention or response: An intensified case finding (ICF) has been launched by Sehgal Neo Hospital, a 100 bedded private hospital in New Delhi, India, as a part of their social commitment, where they pictorially displayed 10 common symptoms of TB in key areas of the hospital such as the OPD, emergency room, dialysis area, X-ray room, wards, and pharmacy. A QR code was displayed at each location, allowing clients reaching the hospital to scan the code and complete the TB screening questionnaire. A hospital staff, nominated by the hospital administration, followed up with the individuals found positive for any symptoms on a real time basis and guided them to the doctor for further evaluation and care.



Results/Impact: A total of 15,731 individuals were screened for tuberculosis during January 24-March 24, 2025. Of these, 835 were identified as individuals with presumed TB and 688 underwent further testing and 35 were diagnosed to have TB and all were initiated on treatment. Average number of people tested for TB per month increased by 2.1 times and average number of TB diagnosed per month increased by 2.5 times during the intervention period as compared to prior to the intervention.

Conclusions: The QR code based screening process streamlines TB screening into a contactless and fast screening reducing the delays in diagnosis and treatment. Minimal resource requirement & simplicity in this model advocates for its replication across all hospitals. It also demonstrates the accountability of private health care sector in Ending TB.

EP39-1079-20 Innovative approach to finding TB in the private sector: Results from stand-alone (SALs) private laboratories in Benue State

O.A. Joseph,[1] O. Salau,[2] J.C. Diara,[3] [1]KNCV Nigeria, Strategic Information, Benue, Nigeria, [2]KNCV Nigeria, strategic information, Nasarawa, Nigeria, [3]KNCV Nigeria, Management, Benue, Nigeria
e-mail: aongbabo@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge in Nigeria, despite effective prevention and treatment options. Over 60% of individuals initiate care in the private sector, yet TB case-finding efforts have focused mainly on public facilities, creating detection gaps. Stand-Alone Laboratories (SALs), widely used for diagnostics, are an underutilized resource for TB detection. Leveraging these labs through structured strategies is essential to improving early diagnosis and ensuring timely linkage to care.
Intervention or response: A cross-sectional descriptive study evaluated the effectiveness of the SAL intervention to improve TB case detection and treatment linkage in Benue State. The intervention involved 30 SALs from January 2023 to December 2024.
Trained lab personnel screened all clients and their accompanying partners for TB symptoms using a standardized checklist. Presumptive cases were referred to diagnostic centers under a hub-and-spoke model for bacteriological confirmation using molecular tools—GeneXpert, TB LAMP, or Truenat—in line with NTBLCP guidelines. Confirmed tuberculosis (TB) cases were immediately enrolled for treatment at Directly Observed Treatment (DOT) facilities. Corresponding case data were duly recorded in the National TB Registers and reported via the District Health Information System (DHIS2) platform following national reporting guidelines.
Results/Impact: Over two years, 105,928 individuals were screened across the 30 SALs. Of these, 5,696 (5%) were presumptive TB cases. All were evaluated, with 412 (7.2%) confirmed positive. All diagnosed patients (100%) were successfully initiated on treatment.
TB case detection increased by 64% between 2023 and 2024, while evaluated presumptive cases rose by 40%, underscoring the intervention's role in improving early identification and care linkage.

Year	Screened	Presumptive	Evaluated	Diagnosed	Treatment
2023	50819	2374	2374	156	156
2024	55109	3322	3322	256	256
Total	105928	5696	5696	412	412

Table.TB cases identified under stand-alone laboratories (SALs) in two years.

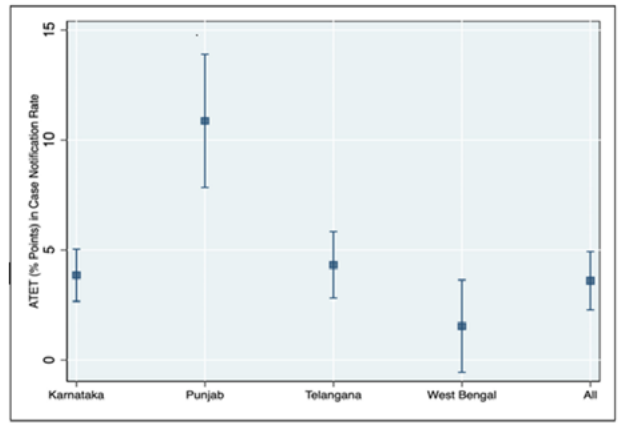
Conclusions: Private sector engagement through SALs is essential to closing TB detection gaps. Scaling and sustaining this model can significantly strengthen national TB control efforts.

EP39-1080-20 Impact of a large-scale private sector intervention on TB notifications and treatment outcomes in India: A difference in difference analysis

A. Kalra,[1,2] R. Rao,[3] F.M. Marx,[1,4] A.K. de Villiers,[1] A. Civan,[1] S.S. Chadha,[2] U.B. Singh,[3] C.M. Denkinger,[1]
[1]Heidelberg University Hospital, Heidelberg University, Department of Infectious Disease and Tropical Medicine, Heidelberg, Germany, [2]FIND, Programmes, Delhi, India, [3]National TB Elimination Programme, MoHFW, Central TB Division, Delhi, India, [4]Stellenbosch University, South African Centre for Epidemiological Modelling and Analysis, Stellenbosch, South Africa
e-mail: draakshikalra@gmail.com

Background and challenges to implementation: Over half of Tuberculosis (TB) patients in India initially seek care in private-sector, necessitating their engagement to achieve End TB goals. However, large-scale, sustainable interventions targeting the private-sector remain limited.
Intervention or response: To engage the private-sector, "Joint Effort for Elimination of Tuberculosis" (JEET) project was implemented by FIND in collaboration with National TB Elimination Programme (NTEP) and supported by the Global Fund between 2018–2021.
The Patient Provider Support Agency (PPSA) model under the project was deployed in 21 districts across five states in India (Andhra Pradesh, Telangana, Karnataka, Punjab, and West Bengal) to facilitate TB diagnosis and treatment adherence through a hub-and-spoke model.
Data from the Government's *Ni-kshay* portal were analyzed for 2017 (baseline) to 2021 to assess trends/rates in private-sector TB notifications and treatment outcomes. Difference-in-Difference analysis was performed to compare notifications from implementation and non-implementation districts in the same states.
Results/Impact: Private-sector case notification rates increased from 34 per 100,000 population in 2017 to 102 in 2021. Treatment success rates improved from 81% in 2017 to 92% in 2021. However, disruptions due to COVID-19 led to temporary decline in notifications during 2020 (from 86 per 100,000 population in 2019 to 72 in 2020), followed by recovery in 2021. The analyses (figure-1) showed significant Average Treatment Effect on the Treated (ATET) of 3.59% points (95%CI: 2.34–4.93) across implementation districts compared to non-implementation districts. Punjab demonstrated the highest ATET at 10.86% points (95%CI: 7.98–14.03). Results were held up under the parallel trend assumptions.

Figure 1: Average Treatment Effect on the Treated for the project implementation districts as Treatment Group, 2017-2021 (Andhra Pradesh was excluded from the analysis as all districts were covered under the JEET project)



Footnote: Average Treatment Effect on the Treated (ATET) estimates the causal effect of an intervention specifically on those who received the treatment. Under the JEET project, it quantifies the difference in outcomes between districts implementing the PPSA model (treatment) and non-implementing districts, isolating the intervention's impact on the targeted population.

Conclusions: Project demonstrated significant improvements in TB care through private-sector engagement. The robust design and measurable impact across districts in India could make this a replicable model for improving TB care in other high-burden countries. To sustain the gains, PPSA model is being scaled-up in 438 districts through domestic resources supporting India's progress toward TB elimination.

EP40 Burning planet, broken systems: Addressing TB at the crossroads of climate inequality

EP40-1081-20 Impact of climate change on TB in East Africa: Development and validation of a conceptual framework

D. Chemtob,[1] F. Cobelens,[2] A. Desgrées du Loû,[3] M. Savy,[4] B. Joshi,[1] E. Roux,[5] F. Klaassen,[2] R.E. Sanya,[6] J.B. Isunju,[7] G. Amanya,[8] A. Ronoh,[9] M. Bonnet,[1]
[1]INSERM/IRD, TransVIHMI, Montpellier, France, [2]Amsterdam University Medical Centers, AIGHD, Amsterdam, Netherlands, [3]INSERM/IRD, CEPED, Paris, France, [4]IRD, MoISA, Montpellier, France, [5]IRD, ESPACE-DEV, Montpellier, France, [6]African Population Health and Research Center, Health and Well Being Unit, Nairobi, Kenya, [7]Makerere University School of Public Health, Disease Control & Environmental Health Department, Kampala, Uganda, [8]Ministry of Health, National Tuberculosis and Leprosy Program, Kampala, Uganda, [9]Ministry of Health, National Tuberculosis and Leprosy Program, Nairobi, Kenya
e-mail: daniel.chemtob@ird.fr

Background: Several of the pathways proposed in the recent (2025) WHO research framework linking Climate Change (CC) and tuberculosis (TB) need to be underpinned by real-world TB data to provide recommendations to policymakers for effective adaptation of the health system response during climate shocks.
We aim to obtain robust evidence on how future climate shocks/gradual CC can compromise progress to TB elimination in two highly climate-sensitive regions (Karamoja-Uganda and Turkana- Kenya), through an interdisciplinary approach.
Design/Methods: The CLIMATE consortium, started early 2024, brings together public health, climate, nutrition, demography and modelling experts together with the National TB and Leprosy Programs of Uganda and Kenya. A conceptual framework was prepared, based on narrative literature reviews and expert consultations. The first ecological epidemiologic study spanning 18 years was performed in Karamoja, the second is in preparation in Turkana.
The findings will be used to correlate, at district level, climate data to historical food insecurity/undernutrition and TB notification and outcome data, to enable modelling of TB epidemic projections according to different future climatic scenarios.
Results: The conceptual framework (see Figure) was developed and identified potential interactions between CC and TB through
1. Water and food insecurity/undernutrition,
2. Access to/quality of health care, and;
3. Mobility/migration.
At the Union conference, data from the ecological studies will be available to validate our conceptual framework.

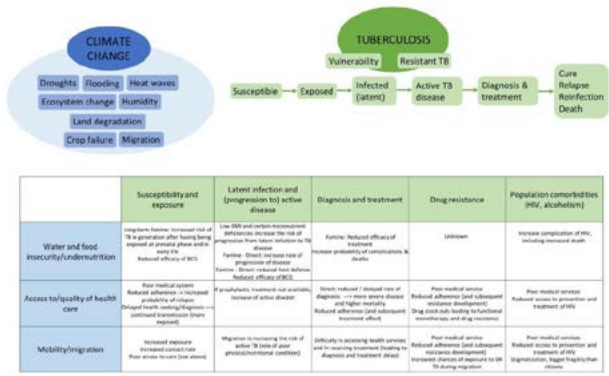


Figure. Research conceptual framework of the impact of climate change on tuberculosis elimination.

Additional findings available will include ethnographic surveys with TB-affected communities on mobility to better understand and document TB control service resilience through their experience in terms of diagnostic and treatment pathways; and semi-structured interviews with health care workers and policy makers, to assess barriers and opportunities for adaptation of strategies for climate resilient TB services in this region.
Conclusions: The CLIMATE consortium projects will contribute to better understanding, anticipating and preparing the response to the impact of CC on TB in Uganda and Kenya.

EP40-1082-20 TB integrated screening at the coalface of climate-change: Lessons about what works from a qualitative study with Pacific-island leaders and donors

M. Coleman,[1,2,3] B. Marais,[2,4] S. Bernays,[5,3] [1]LMU Munich, University Hospital, Division of Infectious Diseases and Tropical Medicine, Munich, Germany, [2]University of Sydney, Sydney Infectious Diseases Institute (Sydney ID), Sydney, Australia, [3]London School of Hygiene & Tropical Medicine, Clinical Research Department, London, United Kingdom of Great Britain and Northern Ireland, [4]University of Sydney, WHO Collaborating Centre for Tuberculosis, Sydney, Australia, [5]University of Sydney, School of Public Health, Sydney, Australia
e-mail: mikaela.coleman@sydney.edu.au

Background: In Pacific-island nations, climate pressure, low national income, surging non-communicable diseases (NCDs) and the *status quo* of endemic tuberculosis undermine the political imperative to adopt strategies driving elimination. Community-wide screening for tuberculosis could reduce tuberculosis incidence, yet country-level uptake of this WHO-endorsed strategy in the Pacific is limited.
It is widely assumed that this poor uptake results from deficient political will and perceptions of excessive costs or scepticism towards feasibility. We interviewed senior

country health leaders and regional donors to ascertain whether these assumptions align with the perspectives of those making decisions in the Pacific.

Design/Methods: Adopting an iterative approach, we conducted qualitative research using semi-structured key-informant interviews with national leaders from 6 high-incidence Pacific small island nations (tuberculosis incidence >50/100,000) and with 5 health donor and technical assistance organisations to explore perceptions towards community-wide tuberculosis screening in the Pacific.

Results: Interviews reveal that a narrow disease focus does not reflect the holistic way tuberculosis is viewed by either funders or national leaders in the Pacific. Participants identified NCDs and climate change (and its impact on mental health) as key considerations that add dimension to the challenge of ongoing tuberculosis transmission. Countries unanimously reported that integrated population-wide activities to prevent tuberculosis, NCDs and improve mental health were essential to attract and retain political buy-in, meet community felt needs, minimise stigma and–thereby– improve tuberculosis program uptake and effectiveness in the Pacific. However, successful integration required Ministry of Health and inter-donor cooperation, which were constrained by rigid funding structures and healthcare-worker attrition.

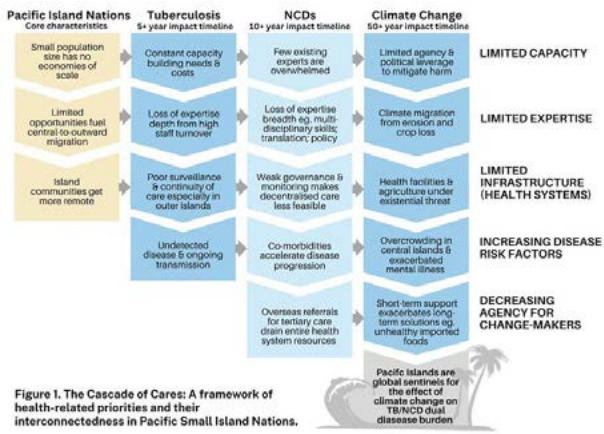

Figure 1. The Cascade of Cares: A framework of health-related priorities and their interconnectedness in Pacific Small Island Nations.

Conclusions: In the Pacific, needful improvements in tuberculosis screening do not result from a lack of political will, but rather highly constrained political choices in attending to multiple competing health priorities. Integrated, multi-disease screening may reduce competition between priorities and improve screening uptake if structural barriers can be overcome.

EP40-1083-20 Environmental impact assessments in TB healthcare settings in Nigeria: The gap between identification and action

N. Nwokoye,[1] P. Ajiboye,[2] B. Goncalves Tasca,[3] B. Odume,[4] K. Kremer,[3] P. de Haas,[3] R. Iniobong Akpakpan,[5]
[1]KNCV Nigeria, Laboratory Services, Abuja, Nigeria, [2]KNCV Nigeria, Technical Division, Abuja, Nigeria, [3]KNCV Tuberculosis Foundation, TB Elimination and Health System Innovations, The Hague, Netherlands, [4]KNCV Nigeria, Executive Director, Abuja, Nigeria, [5]Nigeria Ministry of Health, NTBLCP, Abuja, Nigeria
e-mail: nnwokoye@kncvnigeria.org

Background: Healthcare contributes to global environmental impacts, accounting for approximately 1% to 5% of total global impacts depending on the indicator, and exceeding 5% in some countries. Environmental Impact Assessment (EIA) tools are used to evaluate the potential environmental impacts of implementing and carrying out tuberculosis (TB)-related projects and routine activities. The tools identify potential positive and negative environmental outcomes and inform measures to minimize harm.

Design/Methods: Between 2022 and 2024, we conducted structured EIAs to evaluate environmental compliance in 1,847 TB health facilities across 14 states in Nigeria. The assessments focused on waste disposal, waste minimization practices, infection control, and carbon footprint reduction. Methods included direct observation of activities and work processes during site visits, and interviews with healthcare workers.

Results: About 85% of facility staff demonstrated general awareness and basic knowledge of biosafety and infection control protocols, and there was good compliance with personal protective equipment use. Critical gaps were identified, such as the absence of a designated area for sputum collection, poor waste disposal mechanisms, and a lack of structured training for staff on biosafety and infection control. Some questions of the assessment tool were not applicable to all facility levels, and the most significant gap was the lack of a clear follow-up mechanism to address the issues identified.

Conclusions: As the climate crisis intensifies, EIAs are increasingly mandated by funding agencies to ensure environmental responsibility in project design and implementation. Our study shows the usefulness of EIAs in identifying good practices and gaps in managing environmental impact of TB health facilities. However, lack of dedicated funding and a clear strategy for addressing the identified gaps limits their use. Future projects should incorporate standardized assessments per facility level and actionable mitigation strategies to ensure environmental monitoring and management plans are linked to budget allocations and follow-up mechanisms.

EP40-1084-20 Early results from a scoping review examining the intersection of TB and climate change through critical social science and One Health perspectives

S. Sodhi,[1,2,3] C. Agbor,[4] C. Devine,[3,4] N. Tatty,[3] M. Anwar,[1] A. Orchanian-Cheff,[2] R. Rusu,[5] H. Lum-Gerry,[4] D. Lightfoot,[3] A. Daftary,[4] [1]University of Toronto, Family and Community Medicine, Toronto, Canada, [2]University Health Network, Family and Community Medicine, Toronto, Canada, [3]SeeChange Initiative, Montreal, Canada, [4]York University, Dahdaleh Institute of Global Health Research, Toronto, Canada, [5]McGill University, School of Global and Public Health, Montreal,

Background: Tuberculosis (TB) disproportionately affects marginalized populations. Climate change is increasingly recognized as a determinant of TB transmission and outcomes, yet social, ecological, and structural factors linking the two remain underexplored.
Design/Methods: We conducted a scoping review using a critical social science lens and the One Health framework to examine literature on TB and climate change.
As a secondary objective, we also assessed whether any marginalized or underrepresented communities (including Indigenous communities) were included.
We searched the following databases on November 21, 2024: Ovid MEDLINE; Ovid Embase; Cochrane Database of Systematic Reviews; Cochrane Central Register of Controlled Trials; Ovid Emcare Nursing; and Scopus.
We screened 3,111 peer-reviewed abstracts, and identified studies addressing TB in relation to environmental determinants such as air pollution, temperature variations, and food insecurity. Full text screening and additional data extraction is in process.
Results: Among 335 abstracts reviewed, key themes included air pollution (n=110), climate variability (n=308), and occupational exposures (n=23) as TB risk factors. Most studies focused on low- and middle-income countries, particularly China (n =90), India (n =16), and sub-Saharan Africa (n = 18).
Focus on populations considered to be at greater risks for both TB and climate change, including Indigenous populations (n=29) and islander communities (n=2) or populations displaced due to extreme weather events or climate-related hazards (n=10), was limited.
Emerging findings suggest that climate change exacerbates TB risk through structural vulnerabilities, particularly food insecurity and migration. Equity-focused approaches, such as social determinants or One Health were seldom applied.
Conclusions: Although equity-oriented frameworks are increasingly used in climate change research, they are largely absent in TB-focused studies. Given shared social determinants, future research could prioritize structural drivers, community resilience, and inclusive policies. Addressing TB in a changing climate requires strategies that bridge social, environmental, and biomedical perspectives, and that centres the voices and needs of affected communities.

EP40-1085-20 Air pollution and its toll: Unmasking the impact on TB in FCT, Kogi, and Nasarawa states

U. Ekwugha,[1] H.T. Ogunsakin,[2] O. Onitiju,[1] B. Nwaogu,[1] H.R. Bello,[3] A. Adekunle,[3] R. Iniobong,[4] U. Ochuko,[4] M. Zamzu,[5] J. Ssekitooleko,[5] [1]Association For Reproductive and Family Health, TB/HIV, FCT, Nigeria, [2]Association For Reproductive and Family Health, TB/HIV, Ilorin, Nigeria, [3]Institute of Human Virology, Nigeria (IHVN), Global Fund N-THRIP, FCT, Nigeria, [4]National TB and Leprosy and Buruli Ulcer Control Programme Nigeria, Global Fund N-THRIP, FCT, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Geneva, Switzerland, Grant Management Division, Geneva, Switzerland
e-mail: ekwugha.u@arfh-ng.org

Background: Tuberculosis (TB) remains a significant public health threat in Nigeria, exacerbated by emerging environmental risks. While traditional factors like HIV co-infection and malnutrition are well-documented, rising evidence suggests that air pollution particularly fine particulate matter (PM2.5), industrial emissions, and indoor smoke play a critical role in TB transmission and treatment outcomes. While studies in high-pollution regions such as India and China have demonstrated strong links between air pollution and TB burden, limited data exist for Nigeria.
This study assessed the association between environmental pollution and TB incidence and treatment outcomes in FCT, Kogi, and Nasarawa States, focusing on urban pollution hotspots.
Design/Methods: A retrospective analysis of 3,500 TB case notifications and treatment outcomes from 2022 to 2024 was conducted. Pollution data, including air quality indices (AQI) and PM2.5 levels, were sourced from the National Environmental Monitoring Agency (NEMA). Statistical correlations were analyzed using Pearson correlation and multiple linear regression models to determine the impact of pollution on TB incidence and treatment success. Data triangulation from hospital records, environmental reports, and demographic profiles validated the findings.
Results: TB incidence was 47% higher in high-pollution areas compared to cleaner zones ($p < 0.05$). Treatment success rates were significantly lower in polluted areas (62% vs. 80%, $p < 0.01$), likely due to pollution-induced respiratory stress, delayed healthcare-seeking, and increased exposure to secondary infections. Prolonged exposure to indoor biomass smoke and industrial emissions were identified as key factors affecting TB treatment outcomes.

Conclusions: Environmental pollution significantly influences TB incidence and treatment outcomes in FCT, Kogi, and Nasarawa States. To strengthen TB control, government agencies should integrate air quality monitoring into TB surveillance programs, promote cleaner cooking fuels, and enforce stricter emission regulations. Further research is needed to uncover causal pathways and develop targeted public health interventions.

EP40-1086-20 Is TB prevalence higher in cities or rural areas? A systematic review and meta-analysis of prevalence surveys

S.A. Mortazavi,[1] N.A. Swartwood,[2] K.C. Horton,[3] N. Singh,[2,4] M.H. Can,[2] H. Cui,[2] D.K. Ryuk,[5,2] N.A. Menzies,[2] P. MacPherson,[1] [1]University of Glasgow, School of Health & Wellbeing, Glasgow, United Kingdom of Great Britain and Northern Ireland, [2]Harvard T.H. Chan School of Public Health, Department of Global Health and Population, Boston, United States of America, [3]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [4]NYU Grossman School of Medicine, Department of Population Health, New York, United States of America, [5]Seoul National University College of Medicine, Department of Preventive Medicine, Seoul, Republic of Korea
e-mail: alireza.mortazavi.med@gmail.com

Background: The world is rapidly urbanising, but how this affects TB epidemiology remains poorly understood. We investigated differences in the prevalence of pulmonary TB between urban and rural settings, and how these differences vary across World Health Organization (WHO) regions.
Design/Methods: We conducted a systematic review and meta-analysis of nationally representative and subnational TB prevalence studies published from 1993 through 2024 that reported urban-rural-stratified estimates of TB prevalence. Bayesian multilevel meta-regression was used to estimate the urban-to-rural prevalence ratio of bacteriologically confirmed pulmonary TB and its determinants.
Results: We screened 5,650 studies, of which 201 progressed to full-text review. Ultimately, 46 studies from four WHO regions (26 countries; 1,938,498 participants [39% urban, 61% rural]) reporting urban-rural stratified TB prevalence estimates were included in the final analysis.
Meta-regression estimated an 8% higher prevalence of bacteriologically confirmed TB in urban compared to rural areas (prevalence ratio [PR]: 1.08; 95% credible interval [CrI]: 0.67–1.56), although estimates varied across WHO regions. The African Region (PR: 1.24; 95% CrI: 0.96–1.60) showed higher TB prevalence in urban than rural areas. The South-East Asia Region (PR: 1.08; 95% CrI: 0.79–1.43) and the Eastern Mediterranean Region (PR: 1.08; 95% CrI: 0.67–1.63) showed broadly similar prevalence in urban and rural settings. In contrast, estimated urban TB prevalence was lower in the Western Pacific Region (PR: 0.92; 95% CrI: 0.59–1.30).

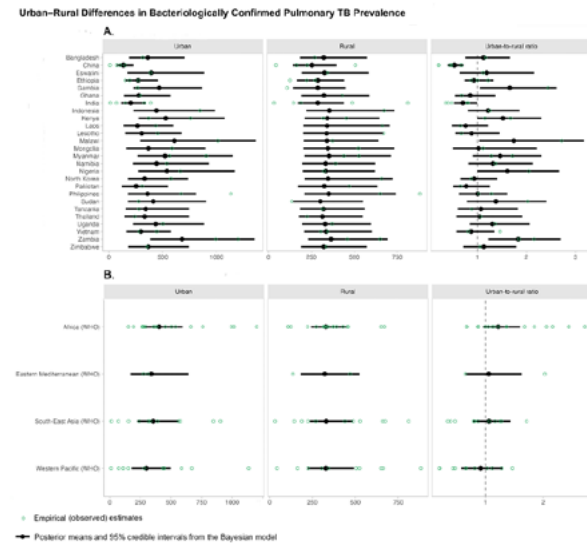

Figure 1. Urban–rural differences in bacteriologically confirmed pulmonary TB prevalence across countries and WHO regions (prevalence reported per 100,000 population).
Panel A: Country-level estimates; Panel B: WHO region-level estimates.

Conclusions: These findings highlight regional differences in TB prevalence between urban and rural areas, emphasising the need to understand local transmission dynamics. As urbanisation accelerates, its impact on TB prevalence should be examined more closely to inform effective public health planning.

EP40-1087-20 Outdoor air pollutants impair host immunity via TNF-α and IL-8 suppression, elevating pulmonary TB risk: A two-stage study

J. Wang,[1] Z. Li,[1] [1]Nanjing Medical University, Department of Epidemiology, School of Public Health, Nanjing, China
e-mail: jmwang@njmu.edu.cn

Background: Previous studies have linked outdoor air pollution to an increased risk of pulmonary tuberculosis (PTB), yet the underlying biological mechanisms remain unclear. This study aimed to explore whether air pollutants alter PTB immunity-related cytokines, thereby influencing PTB susceptibility.
Design/Methods: A two-stage study was conducted. In Stage 1, plasma cytokine concentrations (TNF-α, IFN-γ, IL-2, IL-4, IL-8, IL-10, IL-12, IL-17A, IL-23) were com-

pared between 125 newly diagnosed PTB cases and 518 healthy individuals using generalized additive models (GAM) adjusted for demographics, lifestyle factors, and environmental variables (air pollutants and meteorological data at lag 0–14 days).
In Stage 2, the effects of air pollutants (SO_2, NO_2, PM_{10}, $PM_{2.5}$, CO) on PTB immunity-related cytokines were evaluated in healthy individuals using GAM with adjustments for covariates.
Results: TNF-α and IL-8 were significantly elevated, while IL-17A was reduced in PTB cases compared to healthy controls. Among healthy individuals, SO_2 exposure was negatively associated with TNF-α (−86.12% decrease per 10-μg/m³ increase, 95% CI: −96.26, −48.55). PM_{10}, $PM_{2.5}$ and CO were negatively correlated with IL-8 (−22.70%, −32.16%, and −99.00% decreases, respectively).

Table. Percentage changes in pulmonary tuberculosis immunity-related cytokine concentrations and their 95% confidence intervals for each 10-μg/m³ (1-mg/m³ for CO) increase in ambient air pollutant concentrations at lag 0-14 days*.

Air pollutant	TNF-α	IL-8	IL-17A
SO_2	−86.12 (−96.26, −48.55)	−73.41 (−99.58, 1587.22)	−55.10 (−93.61, 215.47)
NO_2	−8.30 (−22.90, 9.07)	−30.11 (−61.32, 26.27)	−15.21 (−34.71, 10.11)
PM_{10}	−5.74 (−12.44, 1.47)	−22.70 (−37.27, −4.75)	−2.88 (−13.17, 8.62)
$PM_{2.5}$	−7.12 (−16.30, 3.07)	−32.16 (−49.27, −9.28)	−5.06 (−19.00, 11.26)
CO	24.16 (−70.83, 428.43)	−99.00 (−99.99, −27.38)	−31.44 (−92.80, 552.75)

*: Adjusted for sex, age, body mass index, smoking status, and average temperature, average wind speed, and average relative humidity at lag 0-14 days.

Conclusions: Outdoor air pollutants may reduce TNF-α and IL-8 expression, weakening host defense against Mycobacterium tuberculosis infection and increasing PTB risk. These findings highlight potential immunological pathways linking air pollution to PTB pathogenesis.

EP40-1088-20 Social-behavioural determinants shaping TB service uptake among household contacts of people with TB in the Eastern Cape, South Africa

L. de Vos,[1] N. Bedingfield,[2] O. Awoke,[3] K. Fiphaza,[1] D. Olivier,[1] A.M. Kipp,[4] A. Medina-Marino,[1,5] A. Daftary,[3,6] [1]Desmond Tutu Health Foundation, University of Cape Town, Cape Town, South Africa, [2]McGill University, McGill International TB Research Centre, Montreal, Canada, [3]York University, School of Global Health, Toronto, Canada, [4]East Carolina University, Brody School of Medicine, Department of Public Health, Greenville, United States of America, [5]University of Pennsylvania, Department of Psychiatry, Philadelphia, United States of America, [6]CAPRISA MRC, TB-HIV Pathogenesis Unit, Durban, South Africa
e-mail: lindsey.devos@hiv-research.org.za

Background: Household contact investigations (HCI) can "find TB" and mitigate notification gaps. However, outcomes remain suboptimal in South Africa. MISSED OUTCOMES is a mixed methods study underway in a peri-urban and rural region of the Eastern Cape exploring the impacts of HCIs. We explored decision-making regarding TB testing among household contacts (HHCs).

Design/Methods: Between July 2024 and March 2025, HHCs screened at home and referred regardless of symptoms were purposively recruited for interviews focused on household TB, social context, family dynamics, risk perceptions, and care-seeking practices. We conducted thematic analysis using constant comparison, team discussions, and memos, with coding focusing on TB testing decisions.
Results: Participants included 30 consenting HHCs (60% women, 30% heads of household; relation to person on treatment, mean household size N=5); 40% presented for testing. Participants held diverse understandings about HCI visits.
While many recognized the need for TB screening, others believed visits were for general health, index follow-up, or were unaware of the household's status. HHCs were accepting of the person on treatment, particularly due to perceived adherence.
Both presenters and non-presenters experienced respiratory symptoms and fever, but TB testing decisions varied. Presenters had multiple health concerns, including hypertension, and felt encouraged by referral. They also showed greater trust in medical care.
Non-presenters reported conflicting commitments (e.g., employment, childcare) and noted that being on treatment reduced household transmission concerns. Some felt at low risk, especially after previous TB testing, treatment experiences, or perceived curability, and reported they would seek care only if symptoms worsened/ resembled TB disease.

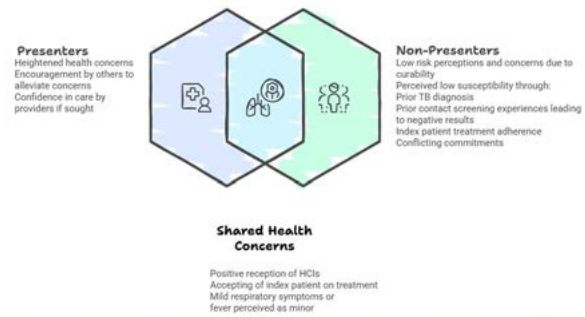

Figure 1. Household Contact TB Testing Decisions Based on Referrals: Similarities and Divergences Through the Lens of HCIs

Conclusions: Familiarity and trust in healthcare may enable HHCs to access timely TB screening and testing services. However, previous exposure or familiarity with TB care may counterintuitively hinder uptake.
Point-of-care testing, universal testing of all HHCs, and counselling on TB reinfection, risk, prevention, and recovery may enhance HCI outcomes.

EP40-1089-20 Social inequities in TB treatment uptake: Results from a qualitative intersectional gender research study in Eastern Cape province, South Africa

J. Chikovore,[1] A. Davids,[2,3] M. Magampa,[4] T. Gumede-Mazwai,[2] L. Molopa,[5] A. Lutshethu,[2] Z. Gavu,[1] S. Bukachi,[6,7] C. Kharel,[8] M. Otmani del Barrio,[8] [1]Human Sciences Research Council, Public Health, Societies and Belonging, Durban, South Africa, [2]Human Sciences Research Council, Public Health, Societies and Belonging, Pretoria, South Africa, [3]Nelson Mandela University, Faculty of Health Sciences, Gqeberha, South Africa, [4]Human Sciences Research Council, Impact Centre, Pretoria, South Africa, [5]Human Sciences Research Council, Public Health, Societies and Belonging, Cape Town, South Africa, [6]University of Nairobi, Institute of Anthropology, Gender and African Studies (IAGAS), Nairobi, Kenya, [7]University of Durham, Department of Anthropology, Durham, Kenya, [8]World Health Organisation, UNICEF/UNDP/World Bank/WHO Special Programme for Research and Training in Tropical Diseases (TDR), Geneva, Switzerland
e-mail: jchikovore@hsrc.ac.za

Background: Tuberculosis (TB) persists as a major global health challenge. Tuberculosis largely affects marginalized and vulnerable populations, necessitating an equity-centric response. We used an intersectional gender lens to understand TB treatment non-uptake in a high-TB-burden setting.
Design/Methods: This qualitative study, carried out in South Africa within a multi-country consortium on gender and intersectionality in infectious diseases, combined focus group discussions with community members (age- and gender identity-stratified), in-depth interviews with persons with TB (PwTB) who had not initiated treatment (age- and gender identity-varied); and key informant interviews with health workers and managers. Data were collected during November 2022 - April 2023 and analyzed using modified grounded theory.
Results: Findings reiterate how the *apartheid* policy's systematic social, economic and cultural exclusion and separation of people by race groups, left a legacy of steep inequalities, and communities living under difficult conditions, with poor amenities and social connectedness, high unemployment, and low unstable incomes. Intersections of gender identities with age, race, locality, household circumstances, social change, and historical factors, among others, have shaped livelihoods, gender roles, and activity patterns, in turn, affecting disease exposure and information and healthcare access for different ethnicities, gender identities, and age groups.
Access to campaign information also emerged as gendered. For instance, unlike women, men were reportedly indifferent to information, especially when feeling they did not have disease. The overbearing precarity also implied campaign recommendations were inactionable, which damaged men's sense of manhood.
Additionally, men reported feeling emasculated when shepherded during information outreach activities.
Conclusions: Interventions to end TB need to pay attention to structural vulnerabilities. Campaigns and healthcare also need to utilize delivery modes tailored to different groups' needs.
In addition, it is important to address anxieties and mental struggles of PwTB. All this requires centring voices of communities and affected persons when designing, implementing, and evaluating interventions.

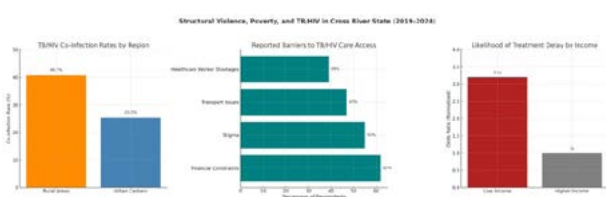
EP40-1090-20 Structural violence, poverty, and TB/HIV in Cross River State, South-South Nigeria: A social science perspective on health inequities

S. Batur,[1] [1]KNCV Nigeria, Monitoring and Evaluation, Abuja, Nigeria
e-mail: sbatur@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) and HIV/AIDS remain significant public health challenges in Nigeria, with a disproportionate impact on impoverished and marginalized communities. Cross River State, located in South-South Nigeria, experiences a high burden of TB/HIV co-infection, worsened by structural violence, poverty, and systemic healthcare inequities.
Structural violence—manifested through inadequate healthcare infrastructure, socioeconomic deprivation, and policy failures—creates barriers to diagnosis, treatment, and care thereby increasing TB and HIV-related morbidity and mortality.
Objective: This study examines the intersection of structural violence, poverty, and TB/HIV co-infection in Cross River State, highlighting the socio-economic and systemic barriers to effective disease management.
Intervention or response: A mixed-methods study was conducted from 2019 to 2024:

- **Quantitative:** Analysis of TB/HIV prevalence and socioeconomic data.
- **Qualitative:** In-depth interviews with 150 patients and 30 healthcare workers across Cross South and North regions.

Key variables included income, access to care, treatment adherence, and systemic health limitations.
Results/Impact:



TB/HIV co-infection rate in Cross River State was found to be 32.5% among TB patients, significantly higher in impoverished rural areas (40.7%) compared to urban centers (25.3%). Key barriers to care included financial constraints (62%), transportation difficulties (47%), stigma (55%), and healthcare worker shortages (39%). Patients in low-income brackets had a 3.2 times higher likelihood ($p < 0.01$) of experiencing treatment delays compared to those with better financial stability.

Additionally, 73% of surveyed healthcare workers reported inadequate resources andpoor healthcare infrastructure is as major obstacle to TB/HIV management.

Conclusions: Structural violence and poverty significantly contribute to TB/HIV disparities in Cross River State, South-South Nigeria.

Addressing these health inequities requires targeted policies, increased healthcare funding, expanded social protection programs, and community-based interventions to improve access to diagnosis, treatment, and care.

Strengthening TB/HIV response strategies in impoverished communities is crucial to achieving equitable healthcare and reducing disease burden.

EP41 What do you need? Innovation to realise the delivery of person-centred care

EP41-1091-20 Improved treatment success rate among drug-susceptible people with TB through pre-treatment and routine counselling addressing stigmatisation in Delta State, Nigeria

C. Ezeanya,[1] C. Gweba,[1] C. Osakwe,[1] H.B. Raji,[2] T. Adetiba,[2] C. Mgbemena,[2] O. Olupitan,[2] P. Dakum,[3] O. Chijioke-Akaniro,[4] E. Ubochioma,[4] J. Ssekitooleko,[5] M. Zamzu,[5] [1]Institute of Human Virology Nigeria, Program Coordinating Unit (PCU), GF-NTHRIP, Delta, Nigeria, [2]Institute of Human Virology Nigeria, Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria, [3]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [4]National TB and Leprosy Control Programme, Public Health, Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Geneva, Nigerian Country Team, Geneva, Switzerland
e-mail: cezeanya@ihvnigeria.org

Background and challenges to implementation: The WHO End TB Strategy targets major reductions in TB burden by 2035, but poor treatment outcomes persist, especially in high-burden countries like Nigeria. In Delta State, stigmatization leads to treatment default and loss to follow-up. Internal assessments linked non-adherence to fear of discrimination, denial, and inadequate psychosocial support.

These challenges were particularly evident among patients in private sector facilities under the Public-Private Mix (PPM) approach, contributing significantly to suboptimal treatment success rates.

Intervention or response: To address this, the Institute of Human Virology Nigeria (IHVN), through the Global Fund PPM grant, in collaboration with the Delta State TB and Leprosy Control Program, implemented a stigma-reduction and psychosocial support intervention from Q1 2021 to Q4 2023.

The intervention aimed to improve treatment outcomes by integrating structured pre-treatment and routine counselling sessions into the care pathway for Drug Susceptible TB (DS-TB) patients.

Key stakeholders engaged included DOTS officers, Local Government TB Supervisors (LGTBLS), treatment supporters, and the patients themselves. A series of capacity-building sessions were conducted to train healthcare providers on effective counselling techniques, patient-centered communication, stigma identification, and emotional support.

In addition, feedback mechanisms such as quarterly patient satisfaction interviews and focus group discussions were used to evaluate patient experiences, inform counselling content, and promote continuous quality improvement.

Results/Impact: The number of Drug-Susceptible-TB (DS-TB) patients enrolled in treatment increased from 395 in 2021 to 1,313 in 2023. Corresponding treatment success rates improved steadily from 69%(274/395) in 2021, to 78%(778/993) in 2022, and 86%(1,135/1,313) in 2023.

Patients reported reduced stigma, improved self-confidence, and greater willingness to complete treatment. Health providers demonstrated increased capacity to offer supportive, stigma-sensitive care.

Conclusions: Targeted pre-treatment and routine-counselling addressing stigmatization significantly improved treatment outcomes. This patient-centered approach is a scalable, low-cost strategy for addressing stigma-related barriers and should be integrated into national TB programs, particularly within PPM models and high-burden settings.

EP41-1092-20 NGO experience in expanding video-DOT support for people with TB via smartphone provision in Ukraine

Y. Sheremeta,[1] N. Balaian,[1] D. Skirgiko,[1] O. Hazizova,[1]
[1]Charitable Organization „100 PERCENT LIFE", Global Fund Project Management Team, Kyiv, Ukraine
e-mail: y.sheremeta@network.org.ua

Background and challenges to implementation: Video-DOT (vDOT) is an innovative solution, allowing patients to take their medication at home while healthcare providers monitor them remotely via video calls. However, factors such as stigma, long travel distances, lack of transportation, and busy schedules create barriers to consistent treatment monitoring. As technology becomes more widely accessible, vDOT has gained traction as an alternative, leveraging smartphones and internet access to make treatment more flexible and accessible.

However, limited smartphone access, especially in rural and low-income communities, remains a barrier. Even when devices are available, some patients struggle to use video platforms without guidance.

Intervention or response: To address these barriers, an NGO initiative in Ukraine focused on expanding vDOT support for TB patients by providing smartphones. The key components of the intervention include:

1. Provision of smartphones;
2. Remote monitoring;
3. Training and support;
4. Continuous engagement;
5. Addressing stigma;
6. Integration with local health systems;
7. Monitoring and evaluation.

Results/Impact: Since June 2024, the vDOT expansion initiative has been implemented under the Global Fund project by CO „100 PERCENT LIFE" in two regions of Ukraine.

A total of 74 TB patients, including 22 with drug-resistant TB and 52 with drug-sensitive TB, received smartphones. The intervention aimed to enhance adherence and improve outcomes through remote monitoring. Of the 74 patients, 50 successfully completed treatment, 3 died and 3 were lost to follow-up. This approach demonstrates the potential of using technology to support TB treatment in underserved areas, though challenges like retention and mortality persist.

Conclusions: NGOs providing smartphones for vDOT is a transformative approach in the fight against TB. By integrating technology into treatment, NGOs bridge the gap between patients and healthcare providers, ensuring adherence even when clinic visits are difficult.

This approach not only strengthens TB control but also highlights the role of digital health in overcoming delivery challenges in resource-limited settings.

EP41-1093-20 Understanding mental health of individuals who successfully complete their anti-TB treatment: A study from Pune City, India

L. Naga Rajeev,[1] S. Ambike,[1] H. Chaugule,[1] T. Sawant,[1] H. Rathod,[1] S. Atre,[1] [1]Dr. D. Y. Patil Medical College Hospital and Research Centre, Community Medicine, Pune, India

Background: Tuberculosis (TB) remains a major public health challenge and India carries a fourth of the global burden of TB. The World Health Organization reports that >40% of patients with TB face depression and other mental health issues.

However, there is a dearth of literature on mental health of cured individuals. Our study aimed at exploring this issue.

Design/Methods: The study was cross-sectional. We randomly selected 100 individuals [(27 with multidrug-resistant TB (MDR-TB) and 73 with non-MDR-TB)] who recently completed their anti-TB treatment under the National TB Elimination Program (NTEP) in Pune. These individuals were interviewed using Diagnostic and Statistical Manual (DSM-5).

Data on depression, anxiety, somatic symptoms, suicidal ideation, and psychosis were analysed using Fisher's exact and Chi-square tests, while the logistic regression assessed the odds of mental health conditions between the two groups.

Results: Depression was more significant in Non-MDR-TB group than MDR-TB (20.5% vs 3.7%; P=0.02). Anxiety was reported 'mild' in both groups (74%). Over two-thirds of individuals experienced somatic symptoms (Non-MDR-TB: 71.2%, MDR-TB: 66.7%).

Psychotic symptoms (41.1% vs. 25.9%) and suicidal ideation (54.8% vs. 37%) respectively were also higher in Non-MDR-TB group. Logistic regression showed significantly higher odds of depression (OR = 4.70, [95% CI: 1.5,

15.2]; P= 0.01) in Non-MDR-TB, while other associations were not statistically significant. Our study showed individuals with non-MDR-TB seemed to have a higher mental health burden than those with MDR-TB.

Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge and India carries a fourth of the global burden of TB. The World Health Organization reports that >40% of patients with TB face depression and other mental health issues. However, there is a dearth of literature on mental health of cured individuals. Our study aimed at exploring this issue.

Conclusions: Our study indicates mental health burden even among cured individuals. Most non MDR-TB individuals had first-time encounter to TB and their lack of ability to cope up with the disease seemed to affect their mental health.

On the contrary, many individuals with MDR-TB have prior experience of anti-TB treatment and disease coping ability. Our study underscores the need for organising mental health services for the cured individuals as needed.

EP41-1094-20 Enhancing drug-resistant TB treatment compliance through community support: Lessons learned from the community-based drug-resistant programme in Indonesia

R.A. Afifah,[1] B. Nababan,[1] B. Adhitya,[1] I. Suryana,[1] F.M. Aulia,[1] R.W. Khumaeroh,[1] I.N. Aini,[1] M.S. Susilastuti,[1] M. Farikha,[2] [1]Consortium Penabulu-STPI, Principal Recipient of the Global Fund TB Community, South Jakarta, Indonesia, [2]MoH of Republic Indonesia, Directorate of Communicable Disease, Directorate General of Disease Control, Ministry of Health Republic of Indonesia, South Jakarta, Indonesia
e-mail: betty.nababan@penabulu-stpi.id

Background: Drug-resistant tuberculosis (DR-TB) elimination in Indonesia remains a challenge, especially in increasing successful treatment outcomes. Despite the treatment from healthcare, community-based patient support also plays a vital role in ensuring DR-TB treatment enrollment and adherence.

Penabulu-STPI Consortium as Principal Recipient of The Global Fund has been supporting DR-TB patients primarily through routine community assistance since the patient was diagnosed in 30 provinces and 190 districts in Indonesia.

Design/Methods: This study was conducted in a cohort retrospective by using routine data from Patient Supporters reported monthly. It analyzed the DR-TB newly confirmed cases from January -December 2024 received through a data interoperability mechanism with the National TB Information System and assisted during the same period. Successful community assistance was defined as the patient who enrolls in the treatment within 2 months after diagnosis and has completed the treatment. Descriptive analysis and logistic regression were performed to identify the predictors of successful community assistance.

Results: There were 2,965 DR-TB confirmed cases that met the sample criteria. As many as 71,1% have enrolled, with 52,1% starting the treatment within 2 months after diagnosis. Among those, 50,9% have completed the treatment, and the remaining were lost to follow-up, treatment failures, and passed away.

The patients who were assisted 4-5 times every month (aOR: 4,9, CI: 3,1 – 7,7, p: 0,001), assisted by face-to-face and virtual sessions including home visits at least 1 time every month (aOR: 10,08, CI: 6,8 -14,8, p: 0,001), and had upper secondary school (aOR:1,4, CI: 1,1 – 1,8, p: 0,021) more likely to have a successful treatment compared to those assisted less than 4 times without home visits and lower education level.

Background and challenges to implementation: Increasing treatment enrollment and completion of drug-resistant tuberculosis (DR-TB) in Indonesia remains a challenge. Despite the treatment from healthcare, community-based patient support also plays a vital role in ensuring DR-TB treatment enrollment and adherence. Penabulu- STPI Consortium as Principal Recipient of The Global Fund has been supporting DR-TB patients through routine community assistance in 30 provinces and 190 districts in Indonesia.

Intervention or response: Penabulu-STPI Consortium has started providing support to DR-TB patients as early as the patient was diagnosed and conducted the routine community assistance in-person sessions, also distributing "enabler" funds to support the cost incurred due to the enrollment and treatment process. We analyzed data collected from the monthly activity report of DR-TB patient assistance from January to December 2024.

Descriptive analysis and multiple logistic regression were performed to identify the aspects of community intervention that determined timely enrollment (within 2 months after being diagnosed) and successful treatment.

Results/Impact: 2,965 newly confirmed DR-TB cases were assisted in 2024 and ended the treatment in March 2025. Among 1511 cases (51%) who enrolled timely and completed the treatment, 81,4% assisted with in-person sessions 2-4 times each month, 86.3% with home visit sessions, and 80,9% received enabler support regularly.

Multivariable analysis shows that the patients who were assisted in-person weekly, including home visits, were more likely to have a timely enrollment and successful treatment compared to those assisted bi-weekly or less and without home visits (aOR: 4,9, CI: 3,1 – 7,7, p: 0,001).

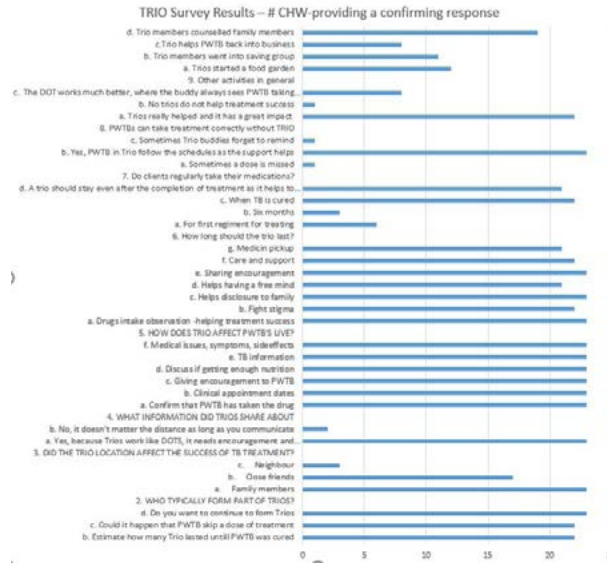
The treatment side effects, patient supporters' coverage, geographical situation, and patients with frequent travel are the main challenges in providing intensive community support.

Conclusions: Community support through weekly in-person sessions, including home visits, has proven effective in improving drug-resistant enrollment and treatment completion. Collaboration with the local government, healthcare, and cross-sectoral partners needs to be strengthened in improving the patient-centered DR-TB support.

EP41-1095-20 The TRIO model: A community-led triad approach to improve TB adherence and psychosocial support in Zambia

E. Machisa,[1] C. Chanda,[2] A. Mwale,[3] C. Phiri,[4] A. Hoejrup,[4] [1]Federation for Associations connected to the International Humana People to People, Projects and Program Development, Shamva, Zimbabwe, [2]National Ministry of Health, National TB and Leprosy program, Lusaka, Zambia, [3]Development Aid from People to People in Zambia, Programs, Lusaka, Zambia, [4]Development Aid from People to People, Partnerhip team, Lusaka, Zambia
e-mail: Emelly.machisa@humana.org

Background and challenges to implementation: Tuberculosis (TB) remains a leading cause of mortality in Zambia, with an incidence case of 283/100,000 people. Despite high TB treatment success rates (93% for new/relapse cases, 2022), treatment non-adherence remains a barrier to successful treatment outcomes. Stigma, economic barriers, misinformation and fragmented support systems lead to high loss to follow-up and drug resistance.
Intervention or response: To address this, DAPP (local NGO) implemented an innovative TRIO model — a person-centred intervention pairing people with TB (PWTB) with two treatment supporters (family members/trusted friends) (n=2,752) to strengthen adherence and social support in three high-burden districts of Lusaka (2022–2024).
The TRIO model integrates evidence-based strategies shown to improve adherence through peer support including:
1. Structured support groups where person on treatment shares experiences and receives support.
2. Family direct observation therapy (C-DOT), ensuring treatment adherence in a non-coercive manner.
3. Health literacy, empowering people to take ownership of their health.
4. CHWs peer paired- support to PWTB addresses barriers early.
Program evaluation was conducted using structured interviews with 23 CHWs out of 50 after two years of program across three districts with 1,5 million populations.
Results/Impact: CHWs reported that all 1,376 PWTB forming a TRIO completed their treatment. CHWs indicated that TRIOs improved family knowledge, support for PWTB and reduced stigma. PWTB experienced increased care, support and mental well-being. CHWs reported improved nutrition and faster recovery. These results, higher than baseline, contrast with a 90% completion rate in control shanty compounds of Lusaka without the TRIO model. See Table 1.



Conclusions: The TRIO model demonstrates the potential of community-led interventions to strengthen resilience and promote long-term engagement in TB care. To further scale this intervention, it is recommended: Policy advocacy to incorporate TRIOs into national TB adherence strategies under community health. Continuous routine training for healthcare providers to embed TRIO approaches in routine TB care.

EP41-1096-20 Barriers and facilitators in TB nutritional support: A CFIR framework-based qualitative study of TB champions' experiences with Nikshay Poshan Yojana and Nikshay Mitra Yojana

A. Shendge,[1,2] A. Mahotra,[3] A. Duhan,[4] [1]O.P Jindal Global University, Office of Strategic Initiative and Institutional Research, Sonipat, India, [2]Global Coalition of TB Advocates, Global Coalition of TB Advocates Youth, Sonipat, India, [3]TAPAS Nepal, Implementation Research, Katmandu, Nepal, [4]O.P Jindal Global University, Office of Career Services, Sonipat, India
e-mail: atul.shendge@jgu.edu.in

Background: Nutrition is an important aspect of TB healing. In India, Nikshay Poshan Yojana (NPY) is implemented by the National TB Elimination Programme (NTEP) for financial support, while Nikshay Mitra Yojana (NMY) brings more of a community-based support. The present study intended to look for implementation and effectiveness of these schemes in the experiences and perceptions of TB Champions.

Design/Methods: This qualitative descriptive study used semi-structured in-depth interviews with 16 TB Champions in India. Data were analyzed using thematic analysis and framed along the five domains of the Consolidated Framework for Implementation Research (CFIR) which helped elicit barriers and facilitators in the implementation of NPY and NMY as viewed by these key community actors.
Results: Key Insights from the TB champions
NPY: Champions appreciated NPY's financial aid but reported frequent delays and inconsistencies in the disbursement of funds, decreasing its impact.
NMY: NMY enabled community support but it was also affected by irregular and unequal assistance due to the voluntary nature of donors.
Outer setting: Stigma, socio-economic barriers, and limited awareness among patients hindered the use of the scheme.
Inner setting: In health care system settings, poor coordination across the gaps and lack of support from staff acted as barriers toward effective implementation.
The role of TB Champions: Champions have played the greatest role in lobbying for patients but have been burned out, inadequately trained, and never formally acknowledged or compensated.
Implementation Process: Challenges included the limited usability of the Nikshay portal and poor monitoring and feedback systems. There socio-geographic challenges further hinders the uptake of the scheme by the rural population.
Conclusions: The study unravels fundamental gaps of implementation in NPY and NMY which inhibit effective nutritional support. Real-time fund tracking, standard support packages, training and stipends for TB Champions, community-based enrollment, and structured partnerships creating a stronger person-centered TB care are recommended.

EP41-1097-20 TB and social protection: Coverage and execution of the Food Assistance Programme in the State of Rio de Janeiro, Brazil

Y.M. Alves,[1,2] R.B.V. Tavares,[1,2] V.M.S. Araújo,[2] D.S. Duarte,[2] V.C. Lima,[2] M. Guazzi,[3] M. Martins,[4] C.M. Morgado,[5] R.A. Arcêncio,[1,2] E.L.N. Maciel,[6,2] [1]University of São Paulo at Ribeirão Preto College of Nursing, Maternal-Infant and Public Health, Ribeirão Preto, Brazil, [2]Brazilian Tuberculosis Research Network (REDE-TB), Projects, Rio de Janeiro, Brazil, [3]Rio de Janeiro State Health Department, Social Assistance, Rio de Janeiro, Brazil, [4]Rio de Janeiro State Health Department, Tuberculosis, Rio de Janeiro, Brazil, [5]Pan American Health Organization, Tuberculosis, Rio de Janeiro, Brazil, [6]Federal University of Espírito Santo, Nursing, Vitória, Brazil
e-mail: yan.alves@usp.br

Background: Tuberculosis (TB) is a socially determined disease, with treatment adherence strongly influenced by socioeconomic conditions. To mitigate these effects, the state of Rio de Janeiro implemented the Food Assistance Program for individuals undergoing treatment for drug-susceptible TB (PAATB). This study aimed to analyze the coverage and magnitude of PAATB implementation by municipality, in order to identify critical areas for strengthening social support actions.
Design/Methods: This descriptive study used 2024 data from the Food Assistance Support System (SISAA-RJ). All municipalities with granted benefits were analyzed. Coverage was calculated as the proportion of active benefits relative to those granted, and classified as high (≥80%), moderate (60–79%), or low (<60%). Municipalities were ranked by the volume of benefits granted to highlight those with the greatest programmatic impact.

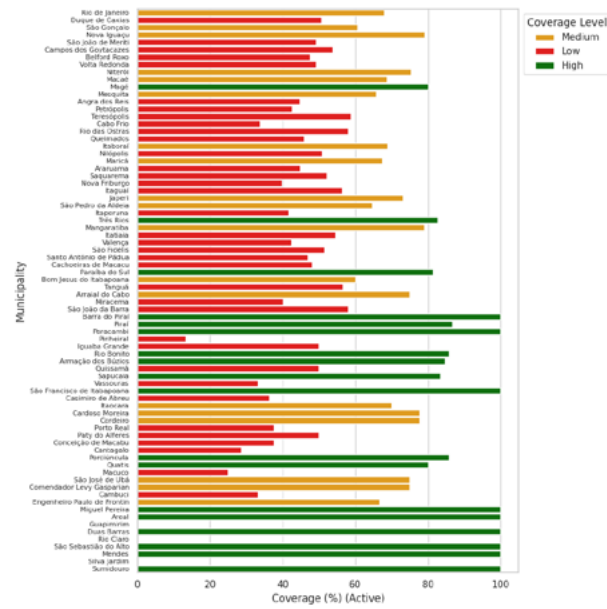


Figure 1 - Benefit Coverage and Volume by Municipality – PAATB, Rio de Janeiro, 2024.

Results: More than 10,000 benefits were granted across the state. The highest volumes were concentrated in the municipalities of Rio de Janeiro, Duque de Caxias, and São Gonçalo. Despite the high number of concessions, these areas showed only moderate or low coverage. The figure illustrates that municipalities with the greatest TB burden also face significant challenges in sustaining benefit provision, which may compromise treatment adherence and overall effectiveness.
Conclusions: The analysis revealed mismatches between the scale of program execution and the quality of support continuity. Identifying municipalities with low coverage and high programmatic impact is crucial to reorient intersectoral strategies and ensure continuity of patient-centered TB care.

EP41-1098-20 Impact of livelihood support on the treatment of drug-resistant TB: An excerpt from rural India

C. Mahadevan,[1] S.K. Singh,[2] N. Nazir,[3] R. Marbate,[3] N. Nisha,[3] M. Brouwer,[4] T. Garg,[5] B.K. Mishra,[6] U. Aqil,[7] G. Raikwar,[8] M. Kumar,[3] M. Bhardwaj,[9] [1]Innovators In Health (India), Monitoring and Evaluation, Samastipur, India, [2]Innovators In Health (India), MIS, Samastipur, India, [3]Innovators In Health (India), Operations, Samastipur, India, [4]PHTB Consult, M&E, Haren, Netherlands, [5]Stop TB Partnership, Innovations and Grants, Geneva, Switzerland, [6]Government of Bihar, Health Department, Patna, India, [7]World Health Organization, NTEP, Darbhanga, India, [8]World Health Organization, NTEP, Begusarai, India, [9]Innovators In Health (India), Organization, Samastipur, India
e-mail: chandanm@innovatorsinhealth.org

Background and challenges to implementation: Drug Resistant-Tuberculosis remains a social disease closely tied to poverty. Financial hardships, job insecurity and healthcare costs contribute to poor treatment outcomes. Integrating interventions that enable PwDRTB to bolster their livelihood status and enhance their treatment compliance are needed.
Intervention or response: To restore the lost livelihood due to the diagnosis of DR-TB, a livelihood initiative was implemented among PwDRTB and their family members in 3 rural districts of Bihar, under TB Reach Wave 9 project.
Monetary support in range of $33 to $105 was provided to set up mini-shops, vegetable shops, sewing machines and accessories, and other prospects. Amongst PwDRTB initiating their treatment between 2022 and 2024, livelihood support was provided to 101 PwDRTB or their family members.
Results were compared between the ones receiving the support and the ones who didn't receive it within the same geography and similar socio-economic conditions.
Results/Impact: An increase of 6% in the median income of family earned from the first month (Median $11.69, IQR $11.69) to the sixth month (Median $12.49, IQR $11.01) after providing livelihood support was evident. 89% of PwDRTB successfully completed their treatment among the outcomes declared.
Contrasting treatment success (72%) was evident in those not provided with livelihood support (p<0.05, OR 0.322 95% CI 0.145-0.716).

	Livelihood support provided (n=90)		Livelihood support not provided (n=93)	
	Males (n=29)	Females (n=61)	Males (n=71)	Females (n=22)
Successfully treated	24 (83%)	56 (92%)	50 (70%)	17 (77%)
Unsuccessful outcome	5 (17%)	5 (8%)	21 (30%)	5 (23%)

Table. Treatment outcomes of Livelihood support provided v/s Livelihood support not provided.

Conclusions: Our findings suggest that the sustainable person-centered care of livelihood support improved PwDRTB's family income. It positively impacts treatment outcomes with 89% of the PwDRTB provided with livelihood support successfully completing the treatment and a lower probability of an unsuccessful outcome.

EP41-1099-20 Leveraging community treatment supporters (CTS) to improve TB treatment outcomes: Evidence from Papua New Guinea's urban TB response

D. Livingstone,[1] F. Danos,[2] S.P. Akena,[2] E.P. Ikedit,[3] [1]World Vision International, Health, New Delhi, India, [2]World Vision PNG, Health, Port Moresby, Papua New Guinea, [3]World Vision International, Health, Kampala, Uganda
e-mail: simonpeter_akena@wvi.org

Background and challenges to implementation: Papua New Guinea (PNG) has one of the highest tuberculosis (TB) burdens in the Western Pacific, with an estimated 44,000 cases in 2022 and an incidence rate of 432 per 100,000 population (WHO Global TB Report 2023). The National TB Strategic Plan aims to reduce this to 350 per 100,000 by 2026. Achieving this requires improved treatment outcomes, yet the national treatment success rate averages only 74% (range: 42–94%) due to persistent challenges in accessibility, affordability, and availability of services.
Intervention or response: World Vision implements the Global Fund TB grant across 12 of PNG's 21 provinces. To strengthen the TB care cascade, Community Treatment Supporters (CTS) were introduced. These trained and incentivized volunteers—often former TB patients—support active case finding, contact tracing, patient referrals, and directly observed treatment (DOTS).

To assess the CTS model's effectiveness, we compared treatment outcomes in two urban provinces with similar TB caseloads. In the National Capital District (NCD), the CTS program has been operational for several years, transitioning from World Bank to Global Fund support. In 2024, 94 CTS volunteers managed 30–40 patients each, receiving a monthly stipend of 720 PNG Kina (~USD 173). In contrast, Morobe Province only introduced CTS in 2024, and the program is not yet fully integrated into the health system.

Results/Impact: NCD's mature CTS program achieved a treatment success rate of ~90%, compared to ~77% in Morobe. The structured, community-led approach in NCD improved treatment adherence, follow-up, and case management. In Morobe, limited rollout and supervision have restricted program impact, though there is strong potential for scale-up.

Conclusions: Engaging Community Treatment Supporters shows good promise in urban TB control. Scaling up this approach in high-burden areas like Morobe, with strong supervision and sustainable incentives, is key to achieving national TB targets.

EP41-1100-20 Acceptability of integrated TB, hypertension and diabetes screening in health facilities and active case finding in Cambodia

S. Chay,[1] A. Tan,[2] C.Y. Huot,[3] S.H. Muy,[4] B. Chhun,[5] J. Brophy,[6] K. Seak,[7] S. Scotney,[8] [1]Clinton Health Access Initiative, TB Program, Phnom Penh, Cambodia, [2]Clinton Health Access Initiative, New Initiatives, Phnom Penh, Singapore, [3]Ministry of Health, National Center for Tuberculosis and Leprosy Control, Phnom Penh, Cambodia, [4]Ministry of Health, Preventive Medicine Department, Phnom Penh, Cambodia, [5]Clinton Health Access Initiative, Malaria, Phnom Penh, Cambodia, [6]Clinton Health Access Initiative, Clinical Sciences Team, Ottawa, Canada, [7]Clinton Health Access Initiative, TB and ATscale, Phnom Penh, Cambodia, [8]Clinton Health Access Initiative, Cambodia Office, Phnom Penh, France
e-mail: schay@clintonhealthaccess.org

Background and challenges to implementation: Integrated service delivery (ISD) aims to improve healthcare access and efficiency, particularly in high-burden settings. This study assessed acceptability of ISD for TB and non-communicable disease (NCD) screening for hypertension and diabetes mellitus (DM) in Cambodia.

Intervention or response: A TB Reach-funded ISD project (Project Boost) was implemented over 20 months in Kampong Chhnang province, integrating screening for TB, hypertension and DM for clients attending health centers and community-based active case finding (ACF) events. During the project's last 5 months (August-December 2024), 110 patients and 90 healthcare workers (HCWs) were recruited for survey questionnaires; 12 patients and 12 HCWs were also selected for in-depth interviews. Data was collected via Khmer-language questionnaires and interviews, with responses translated and analyzed by a social anthropologist using Sekhon's framework of acceptability.

Results/Impact: High ISD acceptability was found among both HCWs and patients. HCW acceptability was primarily driven by perceived higher quality and effectiveness of care (>90% reporting ISD saved time/money for clients and enabled HCWs to deliver better care). Patient acceptability was linked to convenience and benefits (99% reported time/effort savings and improved impression of healthcare quality).

Both groups cited distance to health center and long wait times as barriers to care, which ISD addressed. While HCWs perceived ISD as more time-consuming, >90% reported seeing clients in <30 minutes, and 98% preferred delivering multiple services simultaneously.

The main challenge for HCWs was inconsistent NCD commodity availability. ACF events were favorably perceived by clients as significantly closer to home than health centers. 98% of people diagnosed with TB felt ISD contributed to earlier TB diagnosis.

Conclusions: ISD for integrated TB/NCD screening demonstrates high acceptability among Cambodian HCWs and patients. Integrating services is feasible and addresses key barriers to care. Successful scale-up, however, requires improved coordination across national disease programs, particularly for reliable commodity supply.

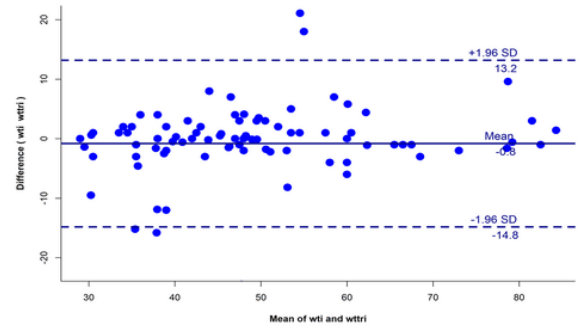
EP42 Innovating TB care: Triage, technology, mobility and workforce solutions for better outcomes

EP42-1101-20 Role of triage audit in an ongoing differentiated TB care initiative to reduce TB deaths in Tamil Nadu, India

A Jeyakumar,[1] S Kalaiselvi,[2] D. Nair,[3] R Vijayaprabha,[4] D. Kabir,[4] M Jeen Melfha,[4] H.D. Shewade,[4] T. Bhatnagar,[1] K Gayathri,[1] R.S. Vaman,[5] S. Shanmugasundaram,[4] A. Frederick,[6] [1]ICMR National Institute of Epidemiology, ICMR School of Public Health, Chennai, India, [2]All India Institute of Medical Sciences, Madurai, Community and Family Medicine, Madurai, India, [3]ICMR-National Institute of Research in Tuberculosis (ICMR-NIRT), Clinical Research, Chennai, India, [4]ICMR National Institute of Epidemiology, Division of Health Systems Research, Chennai, India, [5]Assistant Director of Health Services, District Hospital, Kasargod, India, [6]Directorate of Medical and Rural Health Services, State TB Office, Government of Tamil Nadu, Chennai, India
e-mail: hemantjipmer@gmail.com

Background: Starting April 2022, Tamil Nadu implemented the Tamil Nadu-*Kasanoi Erappila Thittam* (TN-KET), India's first state-wide differentiated TB care initiative aimed at reducing TB deaths. All adults (≥15 years) with drug-sensitive TB notified from public facilities are triaged at diagnosis. Those identified with very severe undernutrition, respiratory insufficiency or poor performance status (triage-positive) are prioritized for comprehensive assessment and inpatient care. Despite achieving targets of triage coverage (>90%) and admission rates (>90% among triage-positive patients), 11 districts failed to meet 30% relative reduction in TB death rates. Suboptimal triaging quality could be a potential reason behind this shortfall.
Design/Methods: For those diagnosed between July 2022 and June 2023 in all 30 districts, we investigated the accuracy of triage coverage by comparing true triage coverage, calculated by tracking eligible from *Ni-kshay* to TB SeWA (Severe TB Web Application of TN-KET), with the reported triage coverage based on aggregate numbers reported in quarterly performance reviews. During a triage audit conducted between October 2024 and February 2025 in 11 districts, TB SeWA triaging data was compared with investigator's triaging data (repeat assessments in field) within few weeks of diagnosis.
Results: Distirct level reported triage coverage was higher (14-17%) than the true triage coverage. Of 91 assessed, body mass index values differed significantly, with a mean difference of 3 kg/m² (SD 1.4) between TB SeWA data and investigator assessment. It was higher in TB SeWA data, highlighting potential inaccuracies. While SPO_2 (oxygen saturation) and respiratory rate were consistently documented, only 27% persons with TB reported leg swelling assessments having being done during triaging.

Figure. Bias and agreement limits for weight measures in triage audit conducted in Tamil Nadu, 2024-25



Conclusions: Districts not achieving TB death rate reduction should cross-check their reported triage coverage with true triage coverage and randomly cross-check TB SeWA triage data. Over time, this should improve triage quality, increasing the chances of adults with TB receiving appropriate care.

EP42-1102-20 Why oxygen plants fail: A case study from The Gambia

J. Sampson,[1] R. Alezz,[2] S. Jarso,[3] [1]Johns Hopkins University School of Medicine, Anesthesiology and Critical Care Medicine, Baltimore, United States of America, [2]Johns Hopkins University, Chemical and Biomedical Engineering, Baltimore, United States of America, [3]Johns Hopkins University School of Medicine, Radiology, Baltimore, United States of America
e-mail: sjarso1@jh.edu

Background: Reliable medical oxygen access is critical but remains a challenge in many low- and middle-income countries (LMICs). At Edward Francis Small Teaching Hospital (EFSTH) in The Gambia, three newly installed Pressure Swing Adsorption (PSA) plants, intended to ensure local supply, rapidly became non-functional. This study aimed to systematically analyze the root causes of these failures to inform future oxygen system implementations.
Design/Methods: A mixed-methods case study was conducted at EFSTH. We employed a Failure Modes and Effects Analysis (FMEA) framework. Quantitative data were gathered via structured surveys with clinical staff rating failure mode severity, frequency, and detectability. Qualitative data on installation, operational, and maintenance issues were collected through unstructured interviews and site reviews with biomedical technicians. An engineering team performed root cause analysis on the qualitative data, integrated with prioritized FMEA modes.
Results: Multiple critical failure modes were identified across all plants, including catastrophic installation errors (improper wiring/grounding, bypassed filters), component failures (booster explosion), and rapid performance

degradation. Installation within shipping containers with minimal environmental protection likely exacerbated vulnerability to technical failures. Root cause analysis revealed systemic deficiencies: inadequate technical expertise, insufficient training, poor installation oversight (Access); diffuse roles and lack of performance benchmarks (Accountability); and prohibitive financial constraints (severe budget shortfalls hindering maintenance/spares) coupled with inadequate electrical infrastructure (Sustainability). These failures resulted in continued oxygen scarcity, rationing, reliance on unsafe clinical practices, and lack of essential accessories.
Conclusions: The EFSTH case demonstrates that capital investment in PSA plants is insufficient for success. Failures stemmed from neglecting the broader implementation ecosystem. Sustainable oxygen access requires comprehensive planning addressing technical training, installation quality assurance, clear accountability structures, long-term funding for maintenance and operations, and robust infrastructure. A holistic, lifecycle approach is essential for future oxygen system investments in LMICs.

EP42-1103-20 Digital technology use and perceptions of VDOT in TB care in São Paulo State, Brazil

Y.M. Alves,[1] T.Z. Berra,[1] R.B.V. Tavares,[1] M.A.P. Popolin,[2,1] M.E.P. Pelodan,[1] A.F. Tártaro,[1] A.C.V. Ramos,[3] J.Q.R. de Paiva,[1] J.G.d.A. Ballestero,[1] A.A. Monroe,[1] M.D.P. Serrano-Gallardo,[4] R.A. Arcêncio,[1] [1]University of São Paulo at Ribeirão Preto College of Nursing, Maternal-Infant and Public Health, Ribeirão Preto, Brazil, [2]Federal University of Tocantins, Nursing Department, Ribeirão Preto, Brazil, [3]State University of Minas Gerais, Nursing Department, Passos, Brazil, [4]Universidad Autónoma de Madrid, Departamento de Enfermería. Facultad de Medicina, Madrid, Spain
e-mail: yan.alves@usp.br

Background: Following the COVID-19 pandemic, the incorporation of digital technologies into tuberculosis (TB) care has gained prominence, particularly in treatment monitoring and adherence support. Among these innovations, Video Directly Observed Therapy (VDOT) has been proposed as a scalable and potentially cost-effective alternative to traditional in-person Directly Observed Therapy (DOT). However, the successful implementation of such digital health strategies depends on more than technological availability—it requires equitable access to devices, digital literacy, and the sociocultural acceptability of remote monitoring. This study aims to characterize access to digital technologies and examine perceptions of VDOT among individuals undergoing TB treatment in São Paulo State, Brazil.
Design/Methods: This is a descriptive cross-sectional study involving 26 participants diagnosed with active tuberculosis in 2024. Data were collected using an electronic form via REDCap and subsequently analyzed. Variables included smartphone ownership, internet and app usage, familiarity with video recording, and opinions regarding VDOT.
Results: Among participants, 24 (92.3%) owned a mobile phone with internet access, and 22 (84.6%) reported daily use of WhatsApp, indicating a high level of digital connectivity. Furthermore, 20 individuals (76.9%) felt confident recording and sending videos. Despite this, only 9 participants (34.6%) expressed initial interest in engaging with VDOT strategies. Reported reasons for refusal included feelings of embarrassment, fear, or anticipated difficulties with the technology. Although digital infrastructure appears to be in place, VDOT was perceived as feasible by only 11 participants (42.3%), suggesting that sociocultural and usability barriers may significantly influence its acceptance.
Conclusions: Despite the widespread use of smartphones and messaging applications, the acceptance of VDOT remains limited among individuals undergoing tuberculosis treatment in São Paulo. Effective implementation strategies must go beyond technological availability and incorporate culturally sensitive, educational, and patient-centered approaches to support digital adherence.

EP42-1104-20 Evaluation of TB screening coverage among workers in Lagos State

K. Akande,[1] [1]University of Lagos, Microbiology, Lagos, Nigeria
e-mail: ayooluwaakande@gmail.com

Background: Insufficient tuberculosis (TB) screening coverage among the working population is concerning. Little to no screening for TB poses health risks such as the continuous spread of TB, underdiagnosis, delayed treatment, emergence of multi-drug-resistant TB, and even death if untreated. Considering that the working population is the most transient and active subset of the society, interacting with colleagues from various parts of Lagos, they are more likely to infect their household with TB if infected at work. The aim of this study was to examine screening coverage among Lagos workers.
Design/Methods: From February to July 2024, a cross-sectional study was conducted using the non-probability sampling method, resulting in 310 consenting adults who work and live in Lagos, Nigeria. A standardized and pretested Google Form questionnaire was used to obtain sociodemographic data (age, gender, highest level of education, local government region, and employment status) from deidentified consenting adults. Descriptive analysis was utilized.
Results: This study revealed 54.8% of the 310 consenting participants have never been screened for TB, with the highest from the information communication technology industry (25.9%), and only 4.8% who were ever screened for TB first learned about TB from the health-care provid-

ers (Table 1). Also, it would have been expected that all workers should have been screened for TB during their pre-employment health screening, but only one participant admitted to being screened prior to employment. These results reveal there is an urgent need for active TB screening (verbally or via portable digital x-ray) in our health-care facilities, including referral health facilities (community pharmacies, laboratories, and patent medicine vendors).

Job Industry	Frequency (N) = 310	Never Screened for TB	Screened for TB and Introduced to TB at Work	Screened for TB and Introduced to TB in School	Screened for TB and Introduced to TB during Pre-employment Health Screening	Screened for TB and Introduced to TB by Friends and Family	Screened for TB and Introduced to TB by Health-Care Provider	Screened for TB and Introduced to TB via Media
Business, Arts and Entertainment	35	21 (12.4%)	0 (0.0%)	7 (7.5%)	0 (0.0%)	2 (12.5%)	1 (6.7%)	4 (28.6%)
Civil Service and Law Enforcement	11	5 (2.9%)	0 (0.0%)	4 (4.3%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	2 (14.3%)
Education and Agriculture	16	12 (7.1%)	0 (0.0%)	3 (3.2%)	0 (0.0%)	1 (6.3%)	0 (0.0%)	0 (0.0%)
Energy, Manufacturing and Construction	67	34 (20.0%)	0 (0.0%)	21 (22.6%)	0 (0.0%)	5 (31.3%)	4 (26.7%)	3 (21.4%)
Healthcare	77	29 (17.1%)	1 (100%)	33 (35.5%)	0 (0.0%)	7 (43.8%)	6 (40.0%)	1 (7.1%)
Information and Communications Technology	66	44 (25.9%)	0 (0.0%)	17 (18.3%)	1 (100.0%)	1 (6.3%)	1 (6.7%)	2 (14.3%)
Others	33	24 (14.1%)	0 (0.0%)	5 (5.4%)	0 (0.0%)	0 (0.0%)	3 (20.0%)	1 (7.1%)
Services	5	1 (0.6%)	0 (0.0%)	3 (3.2%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	1 (7.1%)

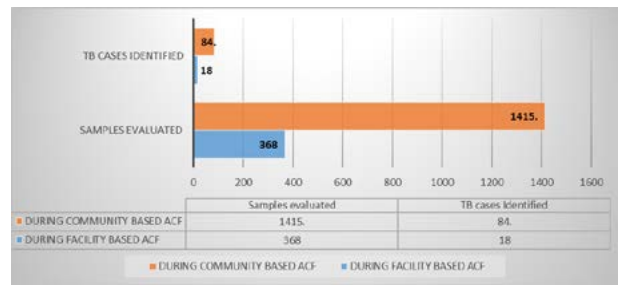
Table 1: History of Tuberculosis Screening by Job Industry among Lagos State's Workers.

Conclusions: This study was able to examine tuberculosis screening coverage among the workers in Lagos, and this is very significant to limiting the spread of TB, early diagnosis of TB, prompt treatment of TB, early contact tracing, and ultimately ending tuberculosis in the country.

EP42-1105-20 Increasing utilisation rate and access to TB diagnostics through mobile community intervention efforts: A case study of Primary Health Centre, Jaji

V.-I.T. Ovoh,[1] S. Balogun,[1] N. Nwokoye,[1] B. Odume,[1] S. Danfari,[2] T. Theodore,[1] Z. Mangoro,[3] [1]KNCV Nigeria, Technical Programs, Abuja, Nigeria, [2]KNCV Nigeria, Technical Programs, Kaduna, Nigeria, [3]KNCV Nigeria, Technical Programs, Kano, Nigeria
e-mail: thevalleylilyo@gmail.com

Background and challenges to implementation: Tuberculosis (TB) is the second leading cause of death globally. In 2022, Nigeria ranked first (1st) in Africa and sixth (6th) worldwide, accounting for about 4.5% of the Global TB burden. Active case-finding (ACF) for TB detection, was one of the WHO-recommended strategies for improved TB notification. KNCV Nigeria in partnership with the National TB programme under the New Tools project introduced Truenat diagnostics across 28 facilities in Nigeria for increased ACF activities.
Primary Health Care Center (PHC), Jaji was one of the beneficiaries of this initiative; however, sample evaluation was sub-optimal due to increasing security challenges in the community where the facility is located.
There was need for a different approach to increase utilization through improved diagnostic access. The study aims to display the increased utilization rate of the Truenat platform due to community ACF engagement.
Intervention or response: Stakeholders in the state were engaged for a seamless transition from facility-based ACF to community ACF. Wellness on Keke (tricycle), a mobile intervention for community ACF (spearheaded by KNCV Nigeria) was coupled with the Truenat machine and taken into surrounding communities. On-the-spot screening and testing was conducted during community ACF. All TB cases diagnosed were linked to facility for TB treatment and care.
Results/Impact: Over a 22-month period (December 2021 - September 2023) at facility ACF implementation, 368 samples were tested with 18 TB cases, with a TB yield of 5% however, within a 15-month period of community ACF implementation (October 2023- December 2024), 1415 samples were tested with 84 TB cases, with a TB yield of 6%.



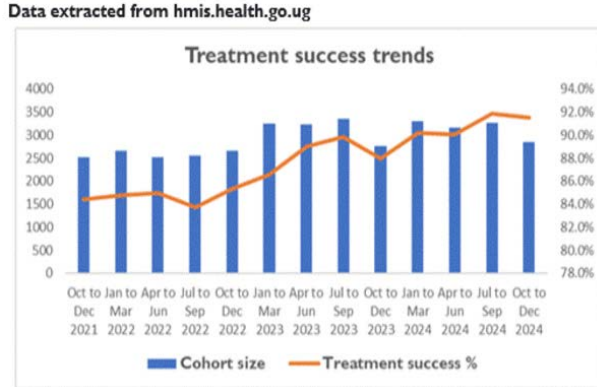
Conclusions: Community ACF efforts contributed to increased diagnostic utilization and TB detection. Decentralized community-centred approaches should be adopted across settings that ensure optimal utilization of TB diagnostics for improved TB notification and maximization of investments.

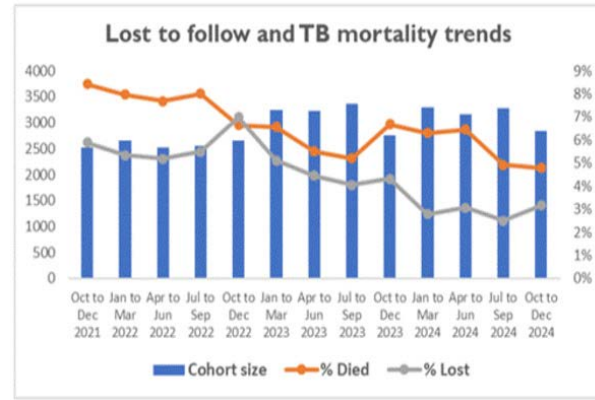
EP42-1106-20 Enhancing TB treatment outcomes in high mobility, densely populated urban hubs: Scalable lessons from targeted interventions

I. Senteza,[1] S. Zawedde-Muyanja,[1] S. C. Mukama,[1] M.G. Nabukenya-Mudiope,[1] H. Luzze,[2] [1]Makerere University College of Health Sciences/Infectious Diseases Institute, USAID Local Partner Health Services-TB Activity, Kampala, Uganda, [2]Ministry of Health, National TB and Leprosy Program, Kampala, Uganda
e-mail: isenteza@idi.co.ug

Background and challenges to implementation: In Uganda, optimizing TB treatment outcomes remains a challenge, particularly in urban areas characterized by high population density and mobility. Factors such as TB-related stigma, unstable housing, financial constraints, and restrictive employment terms negatively impacts TB treatment completion. Male patients, accounting for two-thirds of the TB burden further complicates retention strategies given their poor health-seeking behavior.
We present scalable interventions implemented over three years that improved TB treatment outcomes in the complex urban settings of Kampala, Mukono and Wakiso districts in central-Uganda.
Intervention or response: At project inception, the USAID LPHS TB-Activity conducted root cause analyses to identify TB treatment barriers at the patient and health facility levels. We addressed patient level challenges by engaging civil society organizations to provide a package of customized retention interventions at health facilities accounting for 70% of the TB burden, implemented a community drug delivery program and engaged TB survivors to optimize treatment among hard-to-reach populations.
Institutional modalities focused on proactive review of active cohorts, and corrective actions for treatment interruption and TB related deaths, a hub and spoke to functionalize private facilities as TB treatment points and scaleup of promising interventions to other facilities.
Results/Impact: We compared our performance at project inception in October-December 2021 with the October-December 2024 performance. The treatment success among new and relapse patients with TB improved from 84.4% (2,122/2,514) to 91.4% (2,588/2,832). TB associated mortality reduced from 8.4% (212/2,514) to 4.7% (134/2,832).
Loss to follow while on treatment reduced from 6% (148/2,514) to 3.1% (89/2,832). Both TB-associated mortality and treatment interruption were reduced to below the national threshold of <5%. Other patients either failed or stopped while on treatment due to various reasons.

Data extracted from hmis.health.go.ug





Conclusions: Designing community-led patient centered interventions and strengthening systems to proactively respond to treatment barriers in complex urban settings is pivotal in improving and sustaining TB treatment outcomes.

EP42-1107-20 Role of TB preventive therapy in reduction of incidence of TB disease among health workers in Bungoma County, Kenya

P. Lodi,[1] R. Magomere,[1] [1]Ministry of Health, Department of Health, Bungoma, Kenya
e-mail: paul.lodi2013@gmail.com

Background: Health care workers (HCWs) are at an increased risk of acquiring tuberculosis (TB) disease compared to the general population, due to occupational exposure. In 2020 Kenya rolled out short term TB preventive therapy (TPT) combination of rifapentine and isoniazid for 3 month for all health care workers after TB screening. We aim to determine the role of TPT in reduction of TB incidence in Bungoma County before and after roll out of TPT.

Design/Methods: Health care workers are symptomatically screened for TB using the World Health Organization (WHO) screening tool biannual. Those who screened positive were investigated for TB using a molecular test, those who test positive for TB were initiated on TB treatment, while those who test negative and those who screened negative were initiated on TPT taken once a week for three month.
Results: The results showed that HCW screening was at 0% in 2017 and 100% in 2022. Health care workers initiated on TPT was 0% in 2017 and 37% in 2024. The results revealed that in 2017 when routine screening and TPT initiation was not being implemented, TB notification rate among HCW was 986 per 100,000 after roll out of TPT in 2020 the TB case notification rate was 786 per 100,000 and in 2024 the TB case notification rate dropped drastically to 240 per 100,000. As shown in table 1.

Year	Total No. of HCW	No. of HCW Screened	No. of HCW who developed TB	No. of HCW put on TPT	TB disease Notification rate among HCW/100,000
2017	**1520**	**0 (0%)**	**15**	**0 (0%)**	**986**
2018	**1825**	**609 (33%)**	**15**	**0 (0%)**	**821**
2019	**1850**	**505 (27%)**	**17**	**2 (0%)**	**918**
2020	**2289**	**650 (28%)**	**18**	**5 (0%)**	**786**
2021	**2500**	**700 (28%)**	**20**	**30 (1%)**	**800**
2022	**4259**	**4259 (100%)**	**21**	**241 (6%)**	**493**
2023	**4620**	**4290 (93%)**	**23**	**1600 (35%)**	**497**
2024	**5000**	**4450 (89%)**	**12**	**1850 (37%)**	**240**

Table 1 Tuberculosis notification rate among health care workers in Bungoma County per year.

Conclusions: Bungoma County has demonstrated that screening of health care worker and initiation of TPT among the HCW has shown a decline in TB notification rate. Policy on HCW screening should be adhered to and those who screened negative should be initiated on TPT as this is likely to reduce incidence of TB among HCW which will reduce onwards TB transmission.

EP42-1108-20 Health care workers screening for TB disease over time in relation to TB mortality in Bungoma County, Kenya

P. Lodi,[1] R. Magomere,[1] [1]Ministry of Health, Department of Health, Bungoma, Kenya
e-mail: paul.lodi2013@gmail.com

Background: Tuberculosis (TB) is the leading cause of death from a single infectious agent. Risk of TB disease is higher among health care workers due to close contacts with TB patients. Biannual TB screening is recommended for all health care workers. Those who screened negative are initiated on tuberculosis preventive therapy (TPT). We aimed to assess health care workers screening for tuberculosis disease over time in relation to tuberculosis mortality in Bungoma County.
Design/Methods: This study was carried out in Bungoma County, Kenya. Biannual symptomatic screening of health care workers was done using World Health Organisation (WHO) screening tool. Those who screened negative were initiated on TPT for three month while those who screened positive were evaluated for TB disease by producing sputum for molecular test, those who test positive for TB disease were initiated on TB treatment.
Results: The results showed that in 2017 no HCW was screened for TB, among those who were diagnosed with TB, 53.3% of them died; in 2020 33% of HCW were screened for TB, among those who diagnosed with TB disease 38.9% died. In 2022 100% of HCW were screened for TB, while in 2024 89% of health care workers were screened for TB, non-died while on TB treatment. As shown in table 1.

YEAR	No. of HCW	No. of HCW Screened	No. of HCW put on TPT	No. of HCW who developed TB	No. of HCW who died.	Proportion of HCW who died
2017	1520	0	0	15	8	53.3%
2018	1825	609 (33%)	0	15	10	66.7%
2019	1850	505 (27%)	2	17	7	41.2%
2020	2289	650 (28%)	5	18	7	38.9%
2021	2500	700 (28%)	30	20	6	30%
2022	4259	4259 (100%)	241	21	4	19%
2023	4620	4290 (93%)	1600	23	1	4.3%
2024	5000	4450 (89%)	1850	12	0	0%

Table 1 Screening for TB disease among health care workers in Bungoma County over time.

Conclusions: There was drastic reduction of mortality from tuberculosis among health care workers in Bungoma County with the increase uptake of TB screening. Regular TB screening leads to early identification of TB disease and initiation of treatment leading to favourable treatment outcome and reduce TB transmission. Policy on HCW screening for TB should be followed to the latter.

EP42-1109-20 Strengthening TB detection in high-risk populations: Findings from an intensified screening campaign among Indian mine workers

R. Rao,[1] M. Deka,[2] D. Panchal,[2] S. Malviya,[1] P. Pandey,[3] P. Khan,[3] U. Singh,[1] [1]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [3]Wadhwani AI, National TB Elimination Programme, New Delhi, India
e-mail: dekam@rntcp.org

Background and challenges to implementation: Mine workers in India are vulnerable to tuberculosis (TB) and Silicosis due to excessive exposure to silica dust, poor working conditions, low wages leading to undernutrition and poor living conditions. Emerging evidence links silicosis to an increased risk of multidrug-resistant tuberculosis (MDR-TB). Despite the high risk, TB remains underdiagnosed and underreported due to lack of health seeking behaviour.
This study assesses a targeted TB screening initiative under the Intensified TB Elimination Campaign across key mining regions in India to enhance early detection and care linkage.
Intervention or response: A multi-sectoral, community-based ACF campaign was implemented from December 2024 to March 2025 in partnership with key ministries and local health authorities. Over 83,000 mine workers were screened using symptom screening, digital chest X-ray, and NAAT testing. Mobile diagnostic vans enabled outreach in remote mining areas. Capacity-building of local health personnel and mining-specific IEC/BCC activities were conducted to support community engagement and improve TB detection among these high-risk occupational group.
Results/Impact: During the campaign, among 83,000 mine workers screened, 36,859 presumptive TB cases were identified. Of these, 2,152 were microbiologically confirmed and 2,625 clinically diagnosed with TB, including 86 drug-resistant TB cases. Over 100% of diagnosed patients were initiated on treatment within 24 hours. TPT was started in 414 individuals. The initiative significantly improved TB case detection—more than doubling yield ($P<0.05$)—compared to passive case finding during the same period in the previous year.
Conclusions: Various studies conducted among mine workers depicted the prevalence of TB ranging from 10.7% to about 32%. In the present study, it was also observed that mine workers 9 % prevalence of TB as well as their MDR-TB 4 % may be due to the delay in diagnosis. Scaling up such interventions will be key to reducing the hidden TB burden and advancing India's journey toward TB elimination.

EP43 Diabetes and ageing in TB: Breaking barriers to better care

EP43-1110-20 Prognostic value of the glycation gap in predicting TB treatment outcomes

C.-C. Huang,[1,2] M.C. Becerra,[2] R. Calderon,[3] C.C. Contreras,[4] J. Jimenez,[4] L.W. Lecca,[4,2] M. Mendoza,[4] N.B. Ponce,[4] K. Tintaya,[4] X. Tovar,[2] R.M. Yataco,[4] M.B. Murray,[2,5,1] [1]Brigham and Women's Hospital, Division of Global Health Equity, Boston, United States of America, [2]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States of America, [3]Advanced Research and Health, Advanced Research and Health, Lima, Peru, [4]Socios En Salud, Socios En Salud, Lima, Peru, [5]Harvard T.H. Chan School of Public Health, Department of Epidemiology, Boston, United States of America
e-mail: chuang17@bwh.harvard.edu

Background: Tuberculosis (TB) patients with diabetes mellitus (DM) often experience poorer treatment outcomes than those without DM, prompting interest in glycemic markers as potential predictors. HbA1c reflects average glucose over the past three months, while fructosamine captures a shorter, three-week window. The glycation gap—defined as the difference between observed HbA1c and the HbA1c predicted from fructosamine—has shown promise prognostic value in critical care settings. However, its relevance to TB treatment outcomes remains unexplored.
Design/Methods: We analyzed data from two independent studies conducted in Lima, Peru. The first study was a nested case-control study, comprising 21 TB patients with poor outcomes and 149 with good outcomes. The second was a cohort study including 61 patients with poor outcomes and 1,588 with good outcomes.
We retrospectively measured HbA1c and fructosamine from stored blood samples collected at TB diagnosis. The glycation gap was calculated as the difference between observed and predicted HbA1c calculated by fructosamine levels. We standardized these indicators (z-scores) to enable comparison of effect sizes. In the cohort study, we also assessed prognostic performance of these indicators on treatment outcomes using AUC.
Results: In the case-control study, we found that each unit increase in the standardized baseline glycation gap was associated with increased odds of treatment failure (OR=2.27; 95%CI:1.45–3.56), while neither HbA1c (OR=1.12; 95%CI:0.76–1.65) nor fructosamine (OR = 0.59; 95% CI:0.03–1.34) were significantly associated. In the cohort study, all indicators were associated with treatment outcome: glycation gap (OR=1.92; 95%CI:1.57–2.35), HbA1c (OR=1.24; 95%CI:1.01–1.52), and fructosamine (OR=0.66; 95%CI:0.43–1.00). However, the glycation gap demonstrated superior prognostic value (AUC=0.788) compared to HbA1c (AUC=0.634) and fructosamine (AUC=0.664).

Conclusions: The glycation gap shows greater prognostic value for TB treatment outcomes than HbA1c or fructosamine alone, suggesting its potential role in guiding the clinical management of TB patients.

EP43-1111-20 Investigating the association between TB infection and multimorbidity in people with diabetes

J.K. Peng,[1] Y. Hamada,[1] A. Taliep,[2] L. Barron,[2] R. Goliath,[2] T. Duong,[3] A. Jackson,[2] S. Galant,[2] N. Omar- Davies,[2] R.J. Wilkinson,[2] M.X. Rangaka,[1,3,4] [1]University College London, Institute for Global Health, London, United Kingdom of Great Britain and Northern Ireland, [2]University of Cape Town, Centre for Infectious Diseases Research in Africa, Institute of Infectious Disease and Molecular Medicine, Observatory 7925, South Africa, [3]MRC Clinical Trials Unit at UCL, Institute of Clinical Trials and Methodology, London, United Kingdom of Great Britain and Northern Ireland, [4]University of Cape Town, School of Public Health and Clinical Infectious Disease Research Institute-AFRICA, Observatory 7925, South Africa
e-mail: jiahan.peng.24@ucl.ac.uk

Background: The World Health Organisation has not issued a recommendation for tuberculosis (TB) preventive therapy for people with diabetes because of unclear benefits versus risks. Knowledge gaps exist on the interplay between TB infection (TBI) and multimorbidity in diabetics. People with both diabetes and TBI may have additional comorbidities and risk factors associated with TB, making them particularly vulnerable, yet data on this population is limited.
Design/Methods: We enrolled 673 adults with diabetes attending routine primary care in Khayelitsha, South Africa. We collected data on non-communicable diseases (NCD), TB, and risk factors for both conditions (e.g. smoking and alcohol use). Participants were also tested for TB infection using interferon-gamma release assays. We compared the prevalence of NCD and risk factors by TB infection status, adjusting for age and sex.
Results: The median age was similar between TBI-positive and TBI-negative groups (54 vs 53 years). The prevalence of hypertension was high in both groups (88.6% in TBI-positive and 88.5% in TBI-negative, OR: 1.02, 95% CI 0.57-1,79), as was the prevalence of poor glycaemic control (Hba1c ≥ 7%), which affected 85.9% of TBI-positive and 82.2% of TBI-negative individuals (OR: 1.31, 95% CI 0.82-2.09) (Table). Dyslipidaemia was more prevalent among TBI-positive individuals (OR: 1.46, 95% CI 1.03-1.16).
In TBI-positive and negative groups, 38.9% and 35.6%, respectively, had at least two TB risk factors, and 57.2% and 51.3% had at least two NCD comorbidities. Both the number of TB risk factors and the number of NCD comorbidities were similar between the two groups.

	TBI positive (n=437)	TBI negative (n=202)	Odds ratio (95% CI)[1]
Male (%)	167/437 (38.2)	58/202 (28.7)	NA
Current Smoking (%)	19/412 (4.6)	6/191 (3.1)	1.13 (0.43-3.01)
HbA1c ≥ 7% (%)	354/412 (85.9)	157/191 (82.2)	1.31 (0.82-2.09)
CKD stage 3 or higher (%)	34/412 (8.3)	10/191 (5.2)	1.64 (0.78-3.44)
Hypertension (%)	365/412 (88.6)	169/191 (88.5)	1.02 (0.57-1.79)
Dyslipidaemia (%)	233/412 (56.6)	91/191 (47.6)	1.46 (1.03-2.07)
# of TB risk factors[2]: 0 1 2 or more	31/411 (8.0) 218/411 (53.0) 160/411(38.9)	17/191 (8.9) 106/191 (55.5) 68/191(35.6)	1.05 (0.74-1.48)[4]
# of NCD comorbidities[3]: 0 1 2 or more	20/411 (4.9) 156/411 (38.0) 185/411(57.2)	10/191 (5.2) 83/191 (43.5) 75/191(51.3)	1.27 (0.89-1.80) 4

[1] Adjusted for age and sex; [2] TB risk factors include smoking, alcohol use, HIV, >=HbA1c 7%, low weight, CKD stage 3 or higher, Blood, organ, malignant diseases; [3] NCD comorbidities include CKD stage 3 or higher, hypertension, dyslipidaemia, COPD, cardiovascular diseases, asthma, Blood, organ, malignant diseases; [4] Using ordinal regression

Table. TB risk factors and NCD comorbidities by TBI status.

Conclusions: Participants with both diabetes and TB infection had multiple TB risk factors and concurrent NCD comorbidities beyond diabetes. Although the prevalence was similar regardless of TBI status, the additional vulnerability due to these conditions highlights a need for targeted TB preventive strategies.

EP43-1112-20 Impact of glycemic control on treatment outcomes in rifampicin-resistant people with TB and with diabetes mellitus: Preliminary data from China

Y. Zhang,[1] F. Sun,[1] Y. Li,[1] W. Zhang,[1] [1]Huashan Hospital, Fudan University, Department of Infectious Diseases, Shanghai, China
e-mail: evelyncheung@126.com

Background: Treating rifampicin-resistant tuberculosis (RR-TB) in patients with diabetes mellitus (DM) remains challenging, with a higher risk of poor treatment outcomes.
Design/Methods: Patients aged 16–75 years old with pulmonary RR-TB were prospectively enrolled and received a 9-month oral regimen containing five of the following drugs: bedaquiline, fluoroquinolones, linezolid, cycloserine, clofazimine, and pyrazinamide. DM was diagnosed based on medical history. Poor glycemic control was defined as the presence of a fasting glucose ≥7mmol/L, or a non-fasting glucose ≥10mmol/L, or HbA1c ≥7.0% at more than half of all follow-up points. Definitions of treatment outcome were consistent with the 2022 WHO guidelines. The association between glycemic control and treatment outcomes was analyzed with logistic regression modelling methods. All patients included in the current analysis have completed treatment.

Results: Among 809 RR-TB patients, 109 (13.5%) had diabetes mellitus, with the majority (95/109, 87.2%) diagnosed with type 2 DM. Twenty-nine (26.6%) patients received an antidiabetic therapy including metformin. Poor glycemic control during treatment was observed in 39.4% (43/109) of patients. Baseline demographic characteristics were balanced between those with optimal and poor glycemic control. Treatment success rates were significantly lower in RR-TB patients with poor glycemic control compared to those with optimal control (60.5% vs. 80.8%, P = 0.004), driven by a higher rate of loss to follow-up (25.6%) and treatment failure (14.0%). Multivariate analysis revealed that poor glycemic control during treatment was independently associated with reduced odds of treatment success (adjusted OR = 0.292, 95% CI 0.108–0.792, P = 0.016). However, baseline hyperglycemia (adjusted OR = 0.705, 95% CI 0.157–3.174, P = 0.649) and metformin use (adjusted OR = 2.220, 95% CI 0.666–7.400, P = 0.194) did not have a significant impact on treatment outcomes.

Table 1. Glycemic control and treatment outcome in RR-TB patients

	Optimal glycemic control (N = 66)	Poor glycemic control (N = 43)	P value
Age, Mean ± SD	51.4 ± 11.7	49.3 ± 8.2	0.264
Male — no. (%)	50 (75.6)	38 (88.4)	0.103
BMI — no. (%)			0.539
Underweight	9 (13.6)	4 (9.3)	
Normal weight	44 (66.7)	27 (62.8)	
Overweight	13 (19.7)	12 (27.9)	
Type 2 DM — no. (%)	56 (84.8)	39 (90.7)	0.372
Treatment with metformin — no. (%)	14 (21.2)	15 (34.9)	0.284
Baseline HbA1c, %, Median (range)	9.4 (5.8, 13.8)	10.6 (7.7,19.9)	0.026
Prior TB treatment history — no. (%)	26 (39.4)	19 (44.2)	0.619
Fluoroquinolone resistance — no. (%)	20 (30.3)	8 (18.6)	0.172
Bilateral disease extent — no. (%)	52 (78.8)	37 (86.0)	0.339
Cavitation — no. (%)	58 (87.9)	33 (76.7)	0.126
Positive baseline smear — no. (%)	48 (72.7)	33 (76.7)	0.639
Treatment outcome— no. (%)			0.004
Treatment success	56 (84.8)	26 (60.5)	
Treatment failure	0	6 (14.0)	
Relapse	2 (3.0)	0	
Lost to follow-up	5 (7.6)	11(25.6)	
Death	3 (4.5)	0	

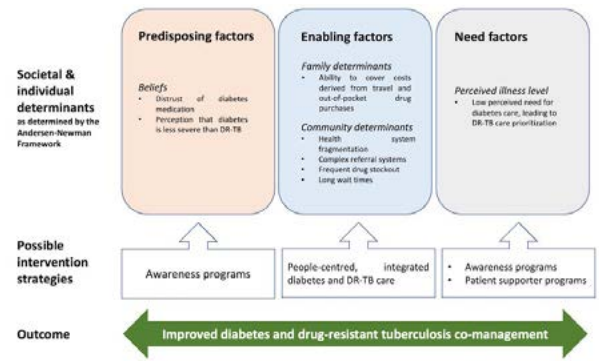
¶ Treatment failure was determined based on symptoms and chest radiography, and participants were switched to longer regimen.

Conclusions: Poor glycemic control during RR-TB treatment significantly reduces treatment success rates, highlighting the need for optimized diabetes management.

EP43-1114-20 Challenges of diabetes mellitus and drug-resistant TB co-management in Indonesia: A qualitative study

A.V. Miranda,[1] S.N. Annisa,[1] H.N. Arafah,[1] N. Hidayat,[1] B.W. Lestari,[2,1] P. Hill,[3] [1]Padjadjaran University, Research Center for Care and Control of Infectious Disease, Bandung, Indonesia, [2]Padjadjaran University, Department of Public Health, Bandung, Indonesia, [3]University of Otago, Center for International Health, Dunedin, New Zealand
e-mail: bony.wiem@unpad.ac.id

Background: Although diabetes mellitus is associated with higher mortality among people with drug-resistant tuberculosis (DR-TB), its care remains underutilized. One reason might be its fragmentation from the Programmatic Management of DR-TB (PMDT). In Indonesia, where the prevalence of diabetes among people with tuberculosis reaches almost 20%, diabetes treatment is mostly provided in primary care settings, while DR-TB management is given in PMDT hospitals.
This research aims to understand the challenges experienced by people with DR-TB in diabetes and DR-TB co-management.
Design/Methods: This qualitative study follows the Andersen-Newman Framework on the societal and individual determinants of healthcare utilization.
The framework divides the determinants into three categories: (a) predisposing factors, (b) enabling factors, and (c) need factors.
From July-October 2024, two researchers interviewed 16 people with DR-TB and diabetes from three PMDT hospitals in Bandung, Indonesia, representing different types of diabetes care: (a) referral to primary care; and (b) 'one-stop shop' approach. Coding and analysis of verbatim transcripts were conducted using Atlas.ti.
Results: Multiple challenges were experienced by people with DR-TB in accessing diabetes care. Predisposing factors include health beliefs, comprising distrust of diabetes medication and the perception that diabetes is less severe than DR-TB. These factors led to the perceived need to prioritize DR-TB management over diabetes care. Healthcare fragmentation led to complex referral systems, additional travel costs, and long wait times, further exacerbating this prioritization. Frequent diabetes drug stockout was also reported, leading to out-of-pocket drug purchases. The' one-stop shop' approach was also reported as challenging, as the model involved visiting two polyclinics, leading to long wait times that discouraged people with DR-TB from accessing diabetes care.



Conclusions: The fragmentation of diabetes care and DR-TB management, coupled with a low understanding of diabetes, caused inoptimal co-management of diabetes and DR-TB. Approaches to reducing this fragmentation should be people-centred, addressing their perceptions, costs and comfort.

EP43-1115-20 Challenges of caregivers of people with TB and diabetes (PwTB-DM) seeking care from the private sector in Chennai - A cross-sectional descriptive study

R. Ananthakrishnan,[1] S. A,[1] R. Thiagesan,[2] S.K. Ramesh,[1] M. T,[1] L. N,[1] S.K. S,[1] [1]Resource Group for Education and Advocacy for Community Healh, Project Implementation, Chennai, India, [2]Resource Group for Education and Advocacy for Community Healh, Research and M&E, Chennai, India
e-mail: ramyardr@reachindia.org.in

Background: Diabetes is a major comorbidity of TB in Tamil Nadu, affecting 26% of people with TB (PwTB). Caregivers play a vital role in supporting PwTB with diabetes (PwTB-DM), yet limited information exists on the challenges they face. Understanding these challenges is essential to engage caregivers meaningfully and improve outcomes among PwTB-DM.
This study aims to explore the roles and responsibilities of caregivers in managing the disease and identify the barriers they encounter while supporting individuals living with both TB and diabetes.
Design/Methods: A cross-sectional study was done among caregivers of PwTB-DM seeking care through the private sector engagement model in Chennai, India. We reached out to 201 caregivers using simple random sampling. A structured questionnaire was used for data collection. Written informed consent was obtained. Data was collected using the EpiCollect application and analyzed using SPSS 22.
Results: Data was collected from 201 caregivers, with 71.6% (n=144) females and 26% in the 31-40 age group. Around 18% (n=37) had diabetes themselves. Caregiver responsibilities included emotional support (61.7%), accompanying to doctor visits (81%), food preparation (68%), and monitoring blood glucose (53%). Perceived challenges of PwTB-DM reported by caregivers included financial constraints (45%), stress (39%), adhering to a healthy diet (52.7%), and medication adherence to both TB & Diabetes (48%). Regarding the impact on caregivers, 49% felt that caregiving led to stress, 41% reported financial strain, 24% experienced physical health effects, and 34% noted that it positively strengthened their relationship with the affected person. The challenges of caregiving are shown in Figure 1.

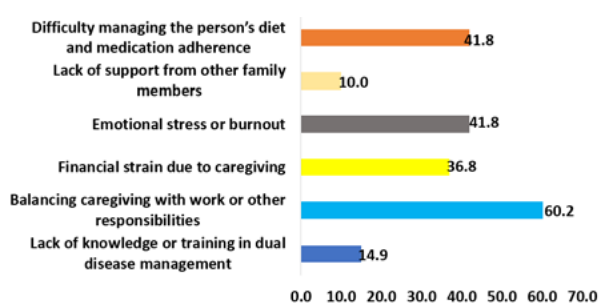


Figure 1. Challenges in caregiver role (n=201).

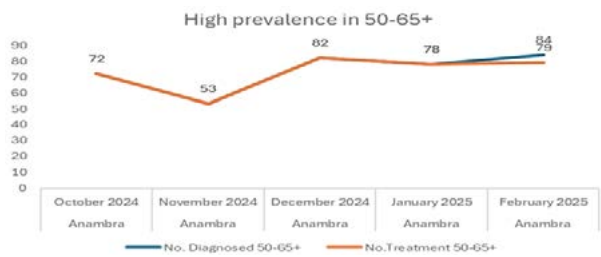
Conclusions: This study is one of its first kind to study the challenges of caregivers of PwTB-DM. It highlights the challenges and burden of caregivers for PwTB-DM, emphasizing their vital role in care. It calls for measures to reduce caregiver burden by family-centric counselling and support.

EP43-1116-20 TB in the elderly: A growing challenge and the need for specialised care in Anambra State

M. Chukwu,[1] A. Galadima,[2] L. Ugochukwu,[1] P. C.Ilueme,[3] M. Sheshi,[4] B. Odume,[5] A. Adekunle,[6] E. Vincent,[7] C. Adesigbin,[8] O. Chijioke-Akaniro,[9] J. Ssekitooleko,[10] A. Reilly,[10] [1]KNCV Nigeria, Strategic Information, Abuja, Nigeria, [2]KNCV Nigeria, Technical, Katsina, Nigeria, [3]KNCV Nigeria, Technical, Anambra, Nigeria, [4]KNCV Nigeria, Programs, Abuja, Nigeria, [5]KNCV Nigeria, Executive Director, Abuja, Nigeria, [6]IHVN, programs, Abuja, Nigeria, [7]IHVN, Programs, Abuja, Nigeria, [8]NTBLCP, NTBLCP, Abuja, Nigeria, [9]NTBLCP, Strategic Information, Abuja, Nigeria, [10]GFCT, GFCT, Switzerland, Switzerland
e-mail: mchukwu@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) among the elderly is becoming a serious public health issue in Anambra State. Older adults are more at risk due to aging, weaker immune systems, and other existing health conditions. TB in this age group often shows unusual symptoms, which can lead to misdiagnosis or delays in treatment, increasing the chances of complications and death. Since TB remains a major infectious disease, there is an urgent need for targeted care and interventions for the elderly. This study explores the prevalence of TB, challenges in diagnosis, and barriers to treatment in older adults in Anambra State.
Intervention or response: A comprehensive review was conducted to identify key limitations in tuberculosis (TB) management among the elderly. This involved the collection and analysis of clinical data from October 2024 to February 2025. Data were gathered from health facility records, and analyzed to identify recurring gaps and challenges.



Results/Impact: Findings indicate that TB in older adults is often underdiagnosed due to overlapping symptoms with other chronic illnesses, leading to delayed or inadequate treatment.

Additionally, polypharmacy, drug interactions, and cognitive decline contribute to poor treatment adherence. Strengthening healthcare provider training and increasing public awareness further mitigate the growing burden of TB in this vulnerable population as shown in the chat below.

Conclusions: Addressing tuberculosis (TB) in the elderly requires a shift toward specialized care models that emphasize early detection, individualized treatment, and comprehensive patient management. The implementation of age-specific diagnostic protocols has significantly improved access to geriatric TB care, leading to earlier diagnoses, better treatment outcomes, and a reduction in mortality rates. Tackling TB among aging populations is not only a medical imperative but also a vital component of global TB control strategies.

EP43-1117-20 TB in older adults (GERIA-TB): Clinical characteristics and outcomes from a low-incidence country

C. Sepulcri,[1] S. Tunesi,[2] M. Mussa,[3] A. Garibbo,[1] L. Crupi,[1] E. Delfino,[4] A. Di Biagio,[4,1] A. Calcagno,[3,5] M. Bassetti,[4,1]
[1]University of Genova, Division of Infectious Diseases, Department of Health Sciences (DISSAL), Genova, Italy, [2]Azienda Ospedaliera-Universitaria SS Antonio e Biagio e C.Arrigo, Infectious Diseases Unit, Alessandria, Italy, [3]Ospedale Amedeo di Savoia, Infectious Diseases Unit, Turin, Italy, [4]IRCCS Ospedale Policlinico San Martino, Infectious Diseases Unit, Genova, Italy, [5]University of Turin, Department of Medical Sciences, Unit of Infectious Diseases, Turin, Italy
e-mail: chiara.sepulcri@gmail.com

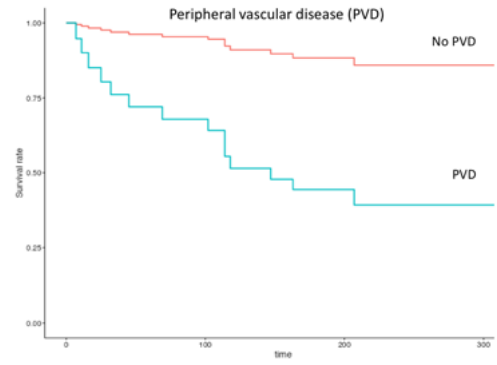
Background: Age is a risk factor for active TB and elderly persons with TB face delayed diagnosis, high rate of adverse events and poor outcomes. However, evidence in this group is scarce. Italy has low TB-incidence (4.4/100.000) and its population is ageing (24.7% ≥ 65 years-old). TB cases in Italy are mainly distributed in two groups: elderly Italian natives and young foreign-born persons from high-incidence countries.

Design/Methods: Retrospective, multicentre study enrolling persons ≥65-years-old diagnosed with TB (2019-2024). We collected data on baseline characteristics, clinical presentation, diagnosis and treatment. Age was classified in: 65-74 (young-old),75-84 (middle-old), ≥85 (old-old).

We considered two outcomes: drug-related adverse events (AE) and death during TB treatment. Cox regressions were used to identify outcome-associated variables.

Results: 81 patients were included (40.7% young-old, 38.3% middle-old, 21% old-old), most (84%) were Italian, males (59.3%) with pulmonary TB (65.4%). All cases were rifampin-sensitive. Median Charlson Comorbidity Index was 4 (IQR 4-6), median of 4 concomitant medications (4-7). 13.8% did not have a clinical suspicion of TB. Diagnosis was made with invasive methods (bronchoscopy, gastric aspirate) in 39/53 (73.6%) of pulmonary TB cases. Median time from symptom onset to TB diagnosis was 42 days (IQR 16-92).

30 patients (37%) experienced at least 1 AE, ≥ grade3 in 12 cases (14.8%). Hepatotoxicity was the most common AE (n=24/30, 80%). Median AE-driven treatment-days loss was 23(IQR 10-30). Pyrazinamide was the drug most frequently permanently interrupted due to AEs. No deaths due to AE were recorded, no variable was associated to AE development. Overall mortality was 21% (n=17), with peripheral vascular diseases and age associated to increased mortality (Figure).



aHR 10.32 (CI 95% 2.23-47.67), p=0.003

aHR: adjusted Hazard Ratio; CI, confidence interval; PVD, peripheral vascular disease

Figure. Adjusted survival curve for the variable peripheral vascular disease (PVD).
The following variables with p<0.1 were included in the multivariable Cox Regression model: age at diagnosis, baseline Chronic Obstructive Pulmonary Disease (COPD), baseline estimated glomerular filtration rate, Charlson Comorbidity Index, number of baseline concomitant medications.
Together with PVD, age at diagnosis was associated with increased mortality:
aHR 1.12 (CI 95% 1.01-1.24, p=0.029)

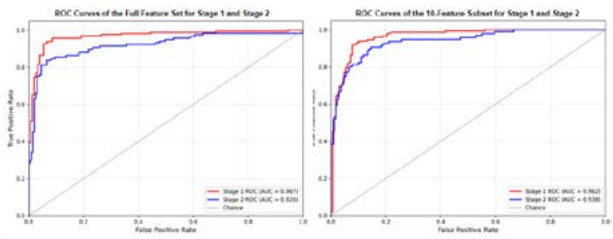
Conclusions: We confirm a high rate of adverse events and mortality in elderly persons with TB. Peripheral vascular disease is a major risk factor for death in our cohort. More evidence can be found expanding the study population.

EP44 Harnessing Innovation: AI, breathomics, and data science for the future of TB detection, prevention and care

EP44-1118-20 Breath analysis using HPPI-TOF-MS and spatial attention convolutional neural networks for latent TB infection screening: A diagnostic accuracy study

L. Fu,[1] Y. Chen,[2] Q. Li,[3,4] M. Sun,[2] G. Deng,[5] [1]Southern University of Science and Technology/Shenzhen Third People's Hospital, Pulmonary Disease Department, Shenzhen, China, [2]Chinese Academy of Medical Sciences & Peking Union Medical College/Institute of Biomedical Engineering, Laser Medicine Laboratory, Tianjin, China, [3]PCAB Research Center of Breath and Metabolism, Breax Laboratory, Beijing, China, [4]Chinese Academy of Sciences/Dalian Institute of Chemical Physics, State Key Laboratory of Medical Proteomics, Dalian, China, [5]Southern University of Science and Technology/Shenzhen Third People's Hospital, Pulmonary Diseases Department, Shenzhen, China
e-mail: flk1981@qq.com

Background: Current screening methods for latent tuberculosis infection (LTBI), including Tuberculin Skin Test (TST) and Interferon-Gamma Release Assay (IGRA), have limitations such as low specificity, high cost, invasive procedures, and complex workflows.
Furthermore, positive LTBI screening requires additional testing to rule out active pulmonary tuberculosis (aPTB), potentially leading to loss-to-follow-up. Breath analysis emerges as a promising non-invasive tool for tuberculosis screening.
Design/Methods: We established a large-scale breath database (>10,000 samples) from patients visiting Shenzhen Third People's Hospital (2019-2024), utilizing High-Pressure Photon Ionization Time-of-Flight Mass Spectrometry (HPPI-TOF-MS). To address instrument drift and high-dimensional data challenges, we proposed a novel method combining global peak alignment and a two-stage convolutional neural network (CNN) with a spatial attention mechanism. In data preprocessing, global peak alignment corrected signal drift. The CNN model included Batch Normalization and Dropout layers to enhance stability and prevent overfitting. Stage one distinguished healthy individuals from LTBI; stage two differentiated LTBI from aPTB. Gradient-based feature selection via signal first derivatives and t-tests identified the top 10 discriminatory features to reduce dimensionality.
Results: We included 316 participants with LTBI, 682 aPTB patients, and 1090 healthy controls. 85% were used as training and 15% as validation. With full feature datasets, training accuracy reached 99.72% (stage 1) and 98.53% (stage 2), with validation accuracy of 91.72% and 87.58%, respectively. After gradient-based feature selection, training set accuracy improved to 99.89% for Stage 1 (sensitivity and specificity both 100%) and 100% for Stage 2 (sensitivity and specificity both 100%). Validation set accuracy after feature selection was 89.17% (sensitivity of 88%, specificity of 90%) in Stage 1, and 85.67% (sensitivity of 75%, specificity of 91%) in Stage 2.



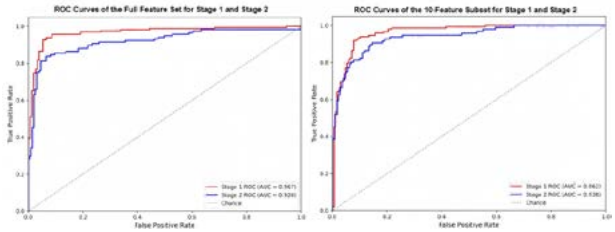
Conclusions: The developed spatial attention CNN effectively addresses data drift, identifies key biomarkers, and accurately classifies TB stages, supporting breath-based LTBI screening. Future validation in community settings is needed to confirm practical applicability.

EP44-1119-20 Construction and preliminary validation of a breath-based diagnostic model for bacteriologically unconfirmed pulmonary TB using deep anomaly detection

L. Fu,[1] Y. Chen,[2] Q. Li,[3,4] M. Sun,[2] G. Deng,[5] [1]Southern University of Science and Technology/Shenzhen Third People's Hospital, Pulmonary Disease Department, Shenzhen, China, [2]Chinese Academy of Medical Sciences & Peking Union Medical College/Institute of Biomedical Engineering, Laser Medicine Laboratory, Tianjin, China, [3]Chinese Academy of Sciences/Dalian Institute of Chemical Physics, State Key Laboratory of Medical Proteomics, Dalian, China, [4]PCAB Research Center of Breath and Metabolism, Breax Laboratory, Beijing, China, [5]Southern University of Science and Technology/Shenzhen Third People's Hospital, Pulmonary Diseases Department, Shenzhen, China
e-mail: 1246948949@qq.com

Background: Diagnosing bacteriologically unconfirmed pulmonary tuberculosis (PTB-U) remains a persistent challenge in clinical settings. Building on our previously developed breathomics-based diagnostic model for bacteriologically confirmed PTB (PTB+), we investigated its generalizability and diagnostic value in identifying PTB-U cases.
Design/Methods: We utilized a large-scale breathomics database (>10,000 samples) established at Shenzhen Third People's Hospital (2019–2024), with data acquired via High-Pressure Photon Ionization Time-of-Flight Mass Spectrometry (HPPI-TOF-MS). Breath spectra from 329 PTB+ patients and 185 patients with non-tuberculous pulmonary diseases were used to train a deep anomaly detection model. This model, based on Convolutional Neural Networks (CNN) integrated with channel and

spatial attention mechanisms, was trained exclusively on PTB+ data using the Deep Support Vector Data Description (Deep SVDD) framework, enhanced by dynamic thresholding and custom data augmentation.
Results: The model demonstrated excellent performance in 5-fold cross-validation, achieving up to 94.55% accuracy, 92.82% sensitivity, and 97.37% specificity in identifying PTB+ cases. When applied to an independent test set consisting of 183 PTB-U cases and 185 non-TB controls, the model achieved 85% sensitivity and 92% specificity, suggesting strong generalizability and shared breathomic features between PTB+ and PTB-U cases.



Conclusions: Our findings support the feasibility of breathomics-based anomaly detection models for identifying PTB-U, indicating potential biological similarity between PTB+ and PTB-U at the molecular signature level. Further validation through large-scale, multicenter studies is warranted to refine and implement this approach in clinical practice.

EP44-1120-20 Transforming TB treatment monitoring with breathomics: A prospective cohort study in drug-susceptible pulmonary TB

L. Fu,[1] Y. Chen,[2] Q. Li,[3,4] M. Sun,[2] G. Deng,[5] [1]Southern University of Science and Technology/Shenzhen Third People's Hospital, Pulmonary Disease Department, Shenzhen, China, [2]Chinese Academy of Medical Sciences & Peking Union Medical College/Institute of Biomedical Engineering, Laser Medicine Laboratory, Tianjin, China, [3]Chinese Academy of Sciences/Dalian Institute of Chemical Physics, State Key Laboratory of Medical Proteomics, Dalian, China, [4]PCAB Research Center of Breath and Metabolism, Breax Laboratory, Beijing, China, [5]Southern University of Science and Technology/Shenzhen Third People's Hospital, Pulmonary Diseases Department, Shenzhen, China
e-mail: flk1981@qq.com

Background: Current methods for monitoring tuberculosis (TB) treatment response rely primarily on sputum culture conversion, radiological changes, and fixed-duration regimens. There is a critical need for new biomarkers. We investigated the use of breathomics and machine learning to dynamically monitor treatment progression and identify individualized stopping points.

Design/Methods: We collected longitudinal breath samples from 100 patients with drug-susceptible pulmonary TB treated with standard HRZE regimen, and analyzed them using HPPI-TOF-MS. Firstly, a Transformer regression model was first trained in a weakly supervised manner, assigning a score of 0 to the first sample and 1 to the final sample, to derive a population-level recovery trajectory f(t) and estimate the earliest timepoints reaching various health score thresholds. Secondly and separately, an MLP classifier was trained to distinguish active TB (≤30 days) from favorable outcome status (FOS; ≥120 days or post-treatment). The classifier was applied to each patient's longitudinal data to determine the proportion reaching the strict FOS threshold (≥1.0) at different timepoints.
Results: The fitted f(t) curve derived from the Transformer model showed a consistent upward trend throughout treatment. Median stopping times for f(t) reaching 0.90, 0.95, and 1.00 were 149, 166, and 192 days, respectively (Figure 1). Separately, FOS similarity scores from the MLP classifier also increased over time. The mean transition time to a FOS-like state was 111.3 days (SD: 61.0), with a median of 62 days (IQR: 31–160). By day 60, 48.9% of patients reached the threshold; by day 90, 56.7%; by day 120, 64.4%; and by day 180, 78.9%.

Conclusions: Our dual-model framework, integrating breath-based Transformer and MLP models, enables non-invasive tracking of TB recovery and identifies patients likely to achieve favorable outcomes before 6 months. These findings support the potential of breathomics-guided tools for individualized treatment shortening, warranting prospective clinical validation in real-world settings.

EP44-1121-20 Streamlined 4-zone point-of-care ultrasound (POCUS) exam for pulmonary TB

L. Nakiyingi,[1] N. Wycliff,[1] R. Dhamdere,[2] E. Jovanovska Janeva,[3] E. Lwanga,[1] R. Shankman,[3] K. Guevarra,[4] E. Nabawanuka,[5] T. Sridhar,[3] J. Ellner,[3] A. Madabhushi,[2] Y.L. Xie,[3] [1]Makerere University, Infectious Diseases Institute, Kampala, Uganda, [2]Emory University School of Medicine, Department of Radiology and Imaging Sciences, Atlanta, Georgia, [3]Rutgers University, NJMS-Department of Medicine, Division of Infectious Diseases, Newark, United States of America, [4]Rutgers University, Rutgers Health Cardiovascular & Pulmonary Diseases, Newark, United States of America, [5]Makerere University, Department of Radiology, Kampala, Uganda
e-mail: lydiakiyingi@gmail.com

Background: Point-of-care ultrasound (POCUS) is a promising, radiation-free triage tool for tuberculosis (TB), but lacks standardized acquisition protocols. We applied machine learning to streamline the POCUS protocol in order to aid in discrimination of pulmonary TB from normal lungs and other respiratory conditions.
Design/Methods: In a prospective study in Uganda, we enrolled individuals aged ≥13 years, including TB index cases, household contacts, and symptomatic clinic evaluees diagnosed with non-TB respiratory conditions.
Participants had sputum GeneXpert Ultra ± TB culture and an 18-zone POCUS exam (12 lung, 6 FASH), performed and interpreted for pathologic findings by ultrasonographers blinded to TB status.
The 18-zone exam was simplified into anatomically-symmetric 2- to 8-zone protocols most predictive of TB status, using Random Forest classifiers trained on 70% of the dataset and tested on the remaining 30%.
Results:

Protocol	Zones	AUC ROC [95% CI] for TB detection	Sensitivity @ 70% Specificity (WHO target for Triage test = minimum 90% sensitivity, 70% specificity)
2-zone	R3_L3	0.68 [0.55 - 0.80]	Sens = 61% Spec= 70%
4-zone	R3_L3_L5_R5	0.82 [0.73 - 0.91]	Sens = 77% Spec= 70%
6-zone	R1_R2_L1_L2_L5_R5	0.79 [0.69 - 0.90]	Sens = 77% Spec= 70%
8-zone	R1_R4_L1_L4_L5_R5_FASH1_FASH6	0.80 [0.69 - 0.91]	Sens = 77% Spec= 70%
12-zone (lung)	R1_R2_R3_R4_L1_L2_L3_L4_L6_R6_L5_R5	0.81 [0.70 - 0.93]	Sens = 77% Spec= 70%
18-zone (Lung+FASH)	Lung + FASH zones	0.76 [0.64 - 0.87]	Sens = 71% Spec= 70%

Table 1. Performance of streamlined 2-, 4-, 6-, 8- zone versus comprehensive 12- and 18- zone POCUS exams.

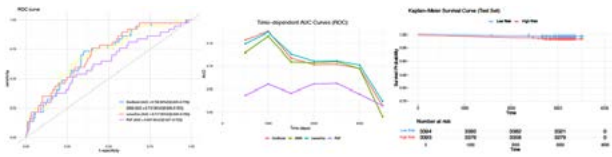
Among 315 participants, 104 were sputum TB-positive (63% male; 2% cough only vs 98% with multiple TB symptoms); 211 were TB-negative, 102 of whom had a non-TB respiratory diagnosis, including 42 with other community-acquired pneumonia.
Simplified 4-, 6-, and 8-zone lung exams performed comparably to the full 12-zone (AUC=0.81) and 18-zone lung+FASH (AUC=0.76) protocols, with AUCs ranging from 0.79–0.82 (see Table 1). At the WHO triage test specificity threshold of 70%, the 4-zone protocol achieved ≥77% sensitivity. Key findings predictive of TB included lung consolidation, air bronchograms, and pleural irregularity.
Conclusions: A simplified 4-zone lung POCUS protocol detected TB with similar accuracy to an 18-zone exam, supporting its potential as a practical triage tool. Though performance in this manually-interpreted, modest-sized dataset did not reach WHO triage test targets, it shows promise with further model development. Results highlight the need for additional training and validation datasets, and ongoing development of a POCUS computed-aided diagnosis (CAD) tool to scale-up TB case findings.

EP44-1122-20 Prediction of TB risk in the elderly population of Eastern China: Development and validation of multiple machine learning models

P. Lu,[1] Q. Liu,[2] H. Ding,[2] J. Wang,[1] [1]Nanjing Medical University, School of Public Health, Nanjing, China, [2]Jiangsu Provincial Center for Disease Control and Prevention, Department of Chronic Communicable Disease, Nanjing, China
e-mail: lpjscdc@163.com

Background: Tuberculosis (TB) poses a significant public health challenge in China, particularly among older adults. This study aimed to develop and validate machine learning models to predict TB risk in the elderly using selected predictors.
Design/Methods: A cohort study of 33,935 participants aged ≥60 years was conducted in Eastern China from January to December 2016, with prospective follow-up to document TB incidence. Lasso regression identified key predictors, and models including CoxBoost, Generalized Boosted Models (GBM), LassoCox, and Random Survival Forests (RSF) were developed. A nomogram was constructed, and performance was assessed using AUC, Brier score, and C-index.
Results: Over a follow-up period exceeding 8 years, 387 participants developed TB (incidence rate: 134.5 per 100,000 person-years, 95% CI: 121.1, 147.9). Lasso regression identified critical predictors, including Drinking, sex, diet, BMI, and Motor function. Among the models, LassoCox demonstrated the highest discriminatory ability with an AUC of 0.717 (95%CI: 0.692–0.742), followed

by GBM (AUC: 0.712, 95% CI: 0.687–0.737), CoxBoost (AUC: 0.708, 95% CI: 0.683–0.733), and RSF (AUC: 0.637, 95% CI: 0.611–0.663). Calibration was reasonable, with Brier scores of 0.338 (95% CI: 0.321–0.355) for LassoCox, 0.346 (95% CI: 0.329–0.363) for RSF, 0.356 (95% CI: 0.339–0.373) for GBM, and 0.326 (95% CI: 0.309–0.343) for CoxBoost.
Time-dependent AUC curves further confirmed the models' predictive stability across the follow-up period. However, Kaplan-Meier survival curves for low- and high-risk groups exhibited limited separation, despite a statistically significant difference (log-rank P < 0.001).



Conclusions: This study successfully developed and validated multiple machine learning models to predict TB risk in the elderly of Eastern China. The LassoCox model showed moderate predictive accuracy for TB risk in the elderly. However, limited survival curve separation suggests the need for additional predictors, higher event rates, and advanced modeling to enhance risk stratification and clinical utility.

EP44-1123-20 Identification of large TB transmission clusters using machine learning models in Taiwan, Kaohsiung

Y.-H. Chen,[1] C.-Y. Wu,[1] H.-H. Lin,[1] [1]National Taiwan University, Institute of Epidemiology and Preventive Medicine, Taipei, Taiwan
e-mail: r12849002@ntu.edu.tw

Background: Tuberculosis (TB) remains a global health challenge, with over 10.8 million new cases and 1.25 million deaths in 2023. Active case finding, particularly through targeted screening of high-risk populations, is crucial for TB control, especially in low-incidence countries striving for elimination. This study aims to explore factors driving TB transmission cluster growth by analyzing Whole Genome Sequencing (WGS) data from Kaohsiung, Taiwan (2019-2023).
By investigating individual and cluster-level characteristics, we aim to identify early predictive features that can improve outbreak prevention and optimize resource use for more effective TB control.
Design/Methods: This study uses data from the Kaohsiung Department of Health, including culture-confirmed TB cases from 2019 to 2023. Clusters are defined by a SNP distance less than 12, with the outcome being the development of transmission clusters with more than 5 individuals. Various machine learning models are employed to identify genetic and epidemiological factors that predict TB transmission and outbreaks.
Results: In this study, we analyze data from 4168 patients, with 1200 in transmission clusters. Clusters with a size ≥5 include 512 patients, while clusters with a size <5 include 688 patients. Using a random forest model in the preliminary analysis, we found several key predictors of large TB transmission clusters: lineage, age, the proximity of reporting date between cases, and geographic proximity. These factors show good predictive value for identifying TB transmission clusters.
Conclusions: This study examines factors that drive TB transmission cluster growth in Taiwan. We will employ various models and quantification methods to identify the most effective prediction approach, ultimately enhancing proactive interventions and public health strategies for TB prevention.

EP44-1124-20 Predicting loss to follow-up among people with TB in Karamoja, Northern Uganda: A machine learning approach

H. Akatwijuka,[1] C.W. Favor,[2] W. Kasozi,[3] A. Etwom,[4] T. Nsubuga,[5] B. Picho,[6] S. Zawedde Mayanja,[7] [1]Infectious Diseases Institute College of Health Sciences Makerere University, Research, Karamoja, Uganda, [2]Infectious Diseases Institute College of Health Sicence Makerere University, Research, Kampala, Uganda, [3]Makerere University college of Health Sciences Infectious Diseases Institute, Research, Karamoja, Uganda, [4]Infectious Diseases Institute, College of Health Sciences, Makerere University, Research, Kampala, Uganda, [5]infectious Diseases Infectious College of Health Sciences Makerere University, Research, Kampala, Uganda, [6]Infectious Diseases Institute College of Health Sciences Makerere University, Research, Kampala, Uganda, [7]Infectious Diseases Institute, College of Health Sciences, Makerere University, research, Kampala, Uganda
e-mail: hakatwijuka@idi.co.ug

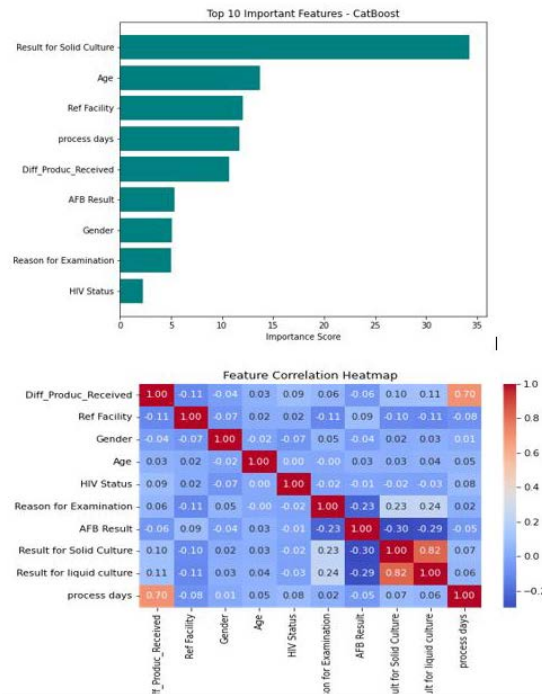
Background: Loss to follow-up (LTFU) while on TB treatment is a key programmatic outcome that may lead to further adverse effects of TB e.g., treatment failure or development of drug resistance. Early identification of individuals at risk of loss to follow-up could enable timely and focused interventions to improve retention and overall program performance. Using machine learning, we developed a predictive model to identify patients most likely to experience loss to follow-up in the Karamoja subregion, north-eastern Uganda.
Design/Methods: We conducted a retrospective study using routinely collected TB treatment data from health facilities in the Karamoja subregion for the period 2019-2022. We defined loss to follow-up as missing eight or more consecutive months of TB treatment. We extracted

data on sociodemographic, clinical, and laboratory variables. We developed a predictive model for LTFU using multiple machine learning algorithms including random forest, light gradient boosting, and decision tree classifier. We split the dataset into training and test sets (80/20) and assessed model performance using the area under the receiver operating curve (AUROC), F1Score, and Cohen Kappa. Feature importance was evaluated to identify key predictors.
Results: Our dataset had 9816 patients, and 13.07% were lost to follow-up. The light gradient boosting model was the best-performing model with an AUROC equal to 0.96, an F1 core of 0.9, and a Cohen Kappa of 0.8. The most significant predictors of loss to follow-up were age>60years, HIV- status, distance > 5 KM from the health facility, referral to another healthy facility during TB treatment, patient belonging to a high-risk group, patient having been previously treated for TB, patient type, PBC disease classification category.
Conclusions: Machine learning models can effectively identify TB patients at risk of loss to follow-up in resource-limited settings, offering an opportunity for targeted support and interventions for those most at risk.

EP44-1125-20 Predicting TB culture contamination using machine learning: The role of sputum transit time and clinical features

T.T. Eliya,[1] B. Emmana,[1] N. Zoakah,[1] L. Shehu,[2] O. Okaniro,[2] J. Bimba,[1] [1]Bingham University Karu, Nigeria, Zankli Research Center, Karu, Nigeria, [2]National Tuberculosis Leprosy and Buruli Ulcer Conrol Programme (NTBCLP), Public Health, Abuja, Nigeria
e-mail: iliya.taryuta@binghamuni.edu.ng

Background: Tuberculosis (TB) culture contamination poses a significant challenge to the timely and accurate diagnosis of TB, particularly in high-burden settings where delays in sample transport and inconsistent laboratory workflows can compromise diagnostic quality.
This study investigates the potential of machine learning (ML) models to predict contamination in Mycobacterium tuberculosis liquid cultures, with a focus on the impact of sputum transit time and related clinical variables.
Design/Methods: Using a dataset comprising routine clinical and laboratory records, a retrospective observational approach was used to evaluate the influence of factors such as sputum transit time, HIV status, AFB smear results, and referring facility on TB culture outcomes. Twelve classification algorithms were tested for predictive performance. Models were assessed using accuracy, F1 score, precision, recall, and ROC AUC metrics.
Results: Logistic Regression, CatBoost, ExtraTrees, and RandomForest classifiers achieved the highest performance, each reaching an accuracy of up to 93.9% and strong ROC AUC scores (up to 0.94). Feature's analysis confirmed that sputum transit time was a key predictor of contamination, alongside AFB results and HIV status.



Conclusions: This study demonstrates the utility of machine learning in enhancing TB diagnostic workflows by accurately identifying specimens at high risk of culture contamination. Integrating such predictive tools into laboratory systems could support targeted interventions, reduce diagnostic delays, and improve the overall quality of TB culture-based testing.

EP44-1126-20 Data visualisation using Microreact dashboards to connect next-generation sequencing analysis, comprehensive test result data and demographics of people with M. tuberculosis in New York state

K. Musser,[1] P. Lapierre,[2] M. Dickinson,[1] J. Shea,[1] B. Lamothe,[3] D. Akerley,[3] J. Levin,[3] Q. Brady,[3] C. MacGowan,[3] N. Dagata,[4] V. Escuyer,[1] [1]Wadsworth Center, NYSDOH, Infectious Disease, Albany, United States of America, [2]Wadsworth Center, NYSDOH, Bioinformatics, Albany, United States of America, [3]Wadsworth Center, NYSDOH, Information Technology, Albany, United States of America, [4]University of Oxford, Centre for Genomic Surveillance, San Diego, United States of America
e-mail: kimberlee.musser@health.ny.gov

Background: Visualization of next-generation sequencing (NGS) data in combination with other clinical test data and patient demographics is often challenging especially for the comprehensive information available for a

Mycobacterium tuberculosis complex (MTBC) case. NGS data are not typically integrated into laboratory information management systems (LIMS) and clinical LIMS often lack the capabilities for visualizations to track trends in real time.

Design/Methods: We have performed clinical whole-genome sequencing (WGS) and targeted NGS (tNGS) on > 6000 MTBC-positive patients with bioinformatic analysis which confirms mycobacterial species, typing (e.g., MTBC lineage and spoligotype), and identifies predictors of antimicrobial resistance (AR; i.e., mutations). The pipelines are run weekly on all MTBC isolates and respiratory specimens that undergo WGS and tNGS. This dashboard creation for MTBC utilizes Data-flo and Microreact software beneath our firewall.

Results: These Microreact dashboards provide user-friendly interactive views of real-time trends in data outputs. The software tools transform, summarize, and visualize the data to enhance data exploration and streamline interpretation. We have web views that allows for visualization over time. We also use mapping by MTBC species, lineage, spoligotype, AR mutation, specimen type and other patient demographic and laboratory testing data.

Conclusions: Visualization of outputs of NGS pipelines in combination with existing data from systems such as LIMS with Microreact dashboards is providing an efficient way to summarize and view that data in real-time. Collaboration with our LIMS and Information Technology (IT) teams, bioinformaticians, and epidemiology partners demonstrates a path forward for comprehensive integration of NGS data into public health workflows.

We strive to expand the utilization of NGS data through providing informative dashboards that can be shared regularly with partners and monitored for trends that may be missed and ultimately hope to demonstrate clinical and public health impact.

EP45 Innovating multi-sectoral engagement to improve TB care

EP45-1127-20 Association between geographic accessibility and use of the private sector among people with TB in Lima, Peru

A. Millones,[1] J. Jimenez,[1] A. Condeso,[1] H. Campos,[1] C. Vargas,[1] L. Lecca,[1] H. Jenkins,[2] C. Yuen,[3] [1]Socios En Salud Sucursal Perú, Lima, Lima, Peru, [2]Department of Biostatistics, Boston University School of Public Health, Boston, MA, USA, Massachusetts, Boston, United States of America, [3]Division of Global Health Equity, Brigham and Women's Hospital, Boston, MA, USA, Massachusetts, Boston, United States of America
e-mail: amillones_ses@pih.org

Background: In Peru, the private sector diagnoses TB but does not deliver TB treatment, and there are no formal referral systems between sectors. We sought to understand why people with TB seek care first in the private sector and whether doing so delays TB treatment.

Design/Methods: We administered questionnaires asking people with TB about their access to health services, including comparative opinions of services in the public and private sector. We calculated relative risk for the association between each opinion and initial care-seeking in the private sector, and used t-tests to assess whether care-seeking in the private sector was associated with delayed treatment. We included people ≥15 years old in their first month of TB treatment from a stratified random sample of 30 health facilities in Lima during 2024-2025.

Results: Of 388 participants, 38% first sought care in the private sector. Participants reported a median of 4 (IQR 3-6) visits before TB diagnosis and a median of 49 days (IQR 27-100) between symptom onset and treatment initiation. While average visits and days until treatment were greater for people who went first to the private sector, differences were not significant (p=0.236, p=0.186, respectively). The most prevalent opinions were that the private sector offers faster attention and more convenient hours, the public sector offers better geographic accessibility and affordability, and the two offer equivalent respectfulness and quality of care (Table).

Surveyed opinions comparing the private and public sectors with regard to accessing TB services and association with initial care-seeking in private sector (N=388)	Public sector is better, n (%)	Private sector is better, n (%)	Two sectors are equivalent, n (%)	Association between believing private sector is better and initial care-seeking in private sector, relative risk (95% CI)
Speed of attention	47 (12)	239 (62)	102 (26)	1.04 (0.80-1.34)
Convenience of hours	62 (16)	181 (47)	145 (37)	1.10 (0.85-1.41)
Geographic accessibility	277 (71)	44 (11)	67 (17)	1.65 (1.24-2.20)
Affordability	382 (98)	1 (1)	5 (1)	Undefined
Respectful treatment	63 (16)	64 (16)	261 (67)	0.97 (0.69-1.37)
Quality of service	60 (15)	126 (32)	202 (52)	0.79 (0.59-1.01)

The only opinion associated with seeking care first in the private sector was that the private sector was more geographically accessible (relative risk 1.65, 95% CI 1.24-2.20).

Conclusions: Many people with TB seek care first in the private sector, possibly when private clinics are more conveniently located. However, this choice is not associated with significant delays in treatment. Public-private partnerships prioritizing private clinics serving communities far from public services could help further reduce time to treatment.

EP45-1128-20 Barriers and best practices in TB treatment initiation across public and private providers in Indonesia: A multi-stakeholder qualitative study

A. Fitriangga,[1] IW.G.A. Eka Putra,[2] G. Archangela Alexandra,[3] A. Alex,[1] [1]Universitas Tanjungpura, Community Medicine, Pontianak, Indonesia, [2]Universitas Udayana, Public health, Denpasar, Indonesia, [3]Indonesia Tuberculosis Research Network, Community Research, Jakarta, Indonesia
e-mail: afitriangga@medical.untan.ac.id

Background: Timely diagnosis and treatment initiation are critical to controlling tuberculosis (TB), yet significant delays persist in Indonesia. Fragmented service delivery, limited patient awareness, and gaps in referral systems contribute to treatment interruption and poor outcomes. This study aimed to explore the barriers and facilitators to TB treatment initiation across different healthcare settings and stakeholders in Indonesia to inform patient-centered and system-level improvements.

Design/Methods: A qualitative study was conducted across six sites in Indonesia: Pontianak (West Kalimantan), Manado (North Sulawesi), Mataram (West Nusa Tenggara), Bogor (West Java), Serang (Banten) and Pringsewu (Lampung). Data were collected through in-depth interviews and focus group discussions with TB patients, health cadres, and healthcare providers in both public and private facilities. Thematic analysis was performed and triangulated with findings from a national TB referral system survey.

Results: Barriers to treatment initiation included limited TB literacy, stigma, fear of medication side effects, economic hardship, reliance on traditional medicine, and geographical inaccessibility. Health cadres highlighted issues such as patient denial, time constraints, and mistrust of healthcare providers. Systemic and provider-level barriers included fragmented referral pathways, poor coordination between facilities, staff shortages, stockouts, and limited engagement of private sector providers. However, promising practices—such as peer support, visual counseling using X-rays, treatment incentives, and community-based follow-up—helped improve treatment uptake and adherence.

Conclusions: This study identifies critical multi-level barriers and locally grounded best practices for TB treatment initiation in Indonesia. Strengthening referral coordination, engaging private providers, and reducing stigma through patient-centered and community-driven approaches are essential to accelerate progress toward TB elimination.

EP45-1129-20 Enhancing TB care in private sector in India: Role of innovative private sector engagement model under programmatic settings

S. Gupta,[1] R. Rao,[2] K. Soundappan,[3] K. Mehta,[4] A. Ranjan,[5] S. Shanmugasundaram,[6] A. Mathur,[2] H. Verma,[7] [1]Solidarity and Action Against The HIV Infection in India (SAATHII), TB Project, New Delhi, India, [2]Ministry of Health and Family welfare, Government of India, Central TB Division, New Delhi, India, [3]Postgraduate Institute of Medical Education and Research (PGIMER), Department of Community Medicine and School of Public Health, Chandigarh, India, [4]GMERS Medical College, Gotri, Vadodara, Gujarat, Department of Community Medicine, Vadodara, India, [5]Government Medical College, Shahdol, Madhya Pradesh, Department of Community Medicine, Shahdol, India, [6]ICMR- National Institute of Epidemiology (ICMR-NIE), Department of Health Research, Chennai, India, [7]National Health Mission, Haryana, State TB Elimination Programme, Ambala, India
e-mail: dr.sandhyagupta@live.com

Background: India's private sector plays a crucial role in the country's tuberculosis (TB) healthcare landscape, with 50% of patients seeking care from private providers. Recognizing this critical role, National Tuberculosis Elimination Program (NTEP) scaled up an innovative private sector engagement model of Patient Provider Support Agency (PPSA) in over 200 districts of country in 2023 to improve TB care in private sector.

Design/Methods: A cross- sectional study was conducted to assess the role of PPSA in improving TB care services among private-sector patients during 2023. We compared district with PPSA and without PPSA for their TB notification, care services and treatment outcomes from private sector at India level. Data for private sector notification from *Ni-kshay* (TB health management information system) was analyzed.

Results: In 2023, districts supported by PPSA (n=204) recorded an average private sector TB notification rate of 106 per 0.1 million and achieved 99.7% of the set target, compared to 530 districts without PPSA, which reported notification rate of 45 per 0.1 million and reached only 80% of the target nationwide.

There was lower pretreatment loss to follow up (LFU) of 2% vs 4% and treatment initiation delay for >7 days (5% vs 10%) in districts with PPSA. They also had improved TB care cascade services- HIV & diabetes testing, bank

detail linkage with *Ni-kshay* for accessing nutrition incentives and treatment success with PPSA support (Figure1). While coverage for rifampicin susceptibility testing, upfront nucleic acid amplification test and uptake of government drugs was lower in PPSA districts compared to non-PPSA districts.

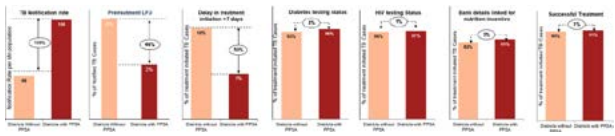


Figure 1. Comparison of private sector TB notification, care cascade services and treatment outcome in districts with and without PPSA during Jan-Dec 2023, India.

Conclusions: The innovative PPSA model demonstrated significant impact in enhancing private-sector TB care in India, achieving higher notification rates, reduced pretreatment LFU, and improved treatment initiation and success rates. Its comprehensive approach to care cascade services underscores its potential for scalability and effectiveness in achieving national TB elimination targets.

EP45-1130-20 Leveraging corporate social responsibility to enhance molecular diagnosis of TB in Uttar Pradesh

P. Shukla,[1] B. Karunakar Shetty,[1] Y. Kharkwal,[1] R. Patil,[1] S. Shrivastava,[1] R. Washington,[2] [1]India Health Action Trust, Tuberculosis, Lucknow, India, [2]India Health Action Trust, Tuberculosis, Bangalore, India
e-mail: bharatesh.shetty@ihat.in

Background and challenges to implementation: A persistent gap in the TB care cascade in Uttar Pradesh, India, is the limited access to WHO-recommended rapid molecular diagnostics (mWRD) for bacteriological confirmation of those diagnosed with active TB. The availability of mWRD is low, particularly within 79 blocks in 8 aspirational districts in UP. Aspirational districts are high-focus areas with poor socio-economic and health indicators, requiring focused attention for TB elimination due to limited infrastructure and higher disease burden.
Intervention or response: In 2023, the Central TB Division and State TB Cell leveraged 61 Truenat machines (Molbio®) from the Indian Oil Corporation Limited (IOCL) under their Corporate Social Responsibility (CSR). 43 of 61 machines were deployed within blocks of 8 aspirational districts, thus increasing availability of machines from 54% to 90%. To optimize utilization state-deployed human resources, India Health Action Trust implemented Diagnostic Network Optimization supported by the Gates Foundation with monitoring for assessment of utilization against capacity and advocacy to ensure a regular supply of test kits and consumables from the State TB Cell.
Results/Impact: Following the deployment of IOCL's Truenat machines, the proportion of microbiologically confirmed TB cases using mWRD in the eight aspirational districts significantly increased from 50% in 2023 to 77% in 2024 and further to 83% in the initial months of 2025. Test utilization against available capacity surged from 40% (8,569 tests conducted out of a 21,500 test capacity in Jan–Feb 2024) to 180% (38,787 tests conducted in the same period of 2025).
This sharp increase was particularly notable during the 100-day Intensified TB Campaign, highlighting the substantial impact of CSR on expanding diagnostic reach in resource-limited settings.
Conclusions: Meaningful partnerships with CSR of large industries can leverage TB diagnostics and contribute to improving availability and utilization of mWRD for bacteriological confirmation of diagnosed active TB.

EP45-1131-20 Is private sector challenging to engage on addressing TB? Situation analysis in Bangladesh

M.F. Wahid,[1] R.S. Banu,[2] S. Islam,[3] S. Yeasmin,[2] [1]USAID LEAP Global, National Tuberculosis Control Programme, Dhaka, Bangladesh, [2]National Tuberculosis Control Program (NTP), Tuberculosis, Dhaka, Bangladesh, [3]BRAC, BRAC Health Programme, Dhaka, Bangladesh
e-mail: dr.rupalisisir298@gmail.com

Background and challenges to implementation: In Bangladesh, nearly 84% of people seek initial care from private healthcare providers, yet these providers contribute only 24% of TB case notifications and 22% of estimated incidence. This underrepresentation reflects critical gaps in collaboration, standardization, and mandatory notification. While the 2014 TB notification policy exists, 37% of private providers remain unaware. Fragmentation, limited diagnostic capacity, and lack of incentives have further hindered systematic engagement.
Intervention or response: To address these challenges, the National Tuberculosis Control Programme (NTP), with partners like BRAC and icddr,b, implemented a comprehensive Public-Private Mix (PPM) model. Interventions included engaging 25,000 Graduate Private Providers (GPPs) and 50,000 Non-Graduate Providers (NGPPs), establishing DOTS corners in 71 hospitals, and launching digital tools such as the JANAO App and eTB Manager for real-time notification and treatment tracking. Diagnostic centers and mobile screening units were deployed in urban hotspots, factories, and workplaces. The PPM Strategic Plan 2023–2026 targets increasing private sector referral contribution from 25% in 2021 to 35% by 2026, improving diagnostic quality, and introducing strategic purchasing and social contracting to sustain engagement. NTP also has a MAF (Multisectoral Account-

ability Framework) strategy for effective engagement of all stakeholders to address TB leveraging domestic resources along with foreign aids and guidance.
Results/Impact: Referrals from GPPs (18%) and private hospitals (4%) have contributed to improved detection. Despite limited incentives, private participation helped maintain a 95% treatment success rate. However, diagnostic quality issues and inconsistent reporting remain prevalent. Increased digital integration and targeted training are beginning to address these challenges.
Conclusions: While the private sector is pivotal in TB care, sustained engagement remains complex due to systemic, operational, and financial barriers. Strengthening governance, incentivizing notification, and integrating digital tools can unlock the sector's potential—supporting Bangladesh's goal to reduce TB incidence from 221 to 135 per 100,000 by 2030.

EP45-1132-20 Disparities in drug-resistant TB detection: A comparative analysis of private healthcare settings and community-based case finding in Katsina State, Nigeria

M. Sheshi,[1] I. Lawrence,[2] A. Okoh,[1] M. Bajehson,[3] S. Useni,[1] N. Nwokoye,[1] B. Odume,[1] [1]KNCV Nigeria, Programs, Abuja, Nigeria, [2]KNCV Nigeria, Programs, Katsina, Nigeria, [3]KNCV Nigeria, Programs, Kano, Nigeria
e-mail: msheshi@kncvnigeria.org

Background: Nigeria has made significant progress in TB treatment coverage in the past 5-years, primarily due to the scale up of community and private sector involvement in TB control. It has however been noted that the identification of DRTB cases remains disproportionately higher from private healthcare settings compared to the community. This raises concerns about the effectiveness of current community strategies in detecting DRTB. The study aimed to compare DRTB detection rates between PPM and community approaches and evaluate the use of GeneXpert diagnostics across both settings in Katsina State, Nigeria.
Design/Methods: A retrospective cross-sectional analysis was conducted using programmatic data from January to December 2024. TB notification data and laboratory reports were reviewed across all private facilities and community campaigns in Katsina. Key variables included the number of TB diagnosed, proportion tested with GeneXpert, and numbers of confirmed DRTB cases. Descriptive statistics summarized trends, while Chi-square tests assessed differences in proportions between settings, with statistical significance set at $p<0.05$.
Results: A total of 15,648 TB cases were diagnosed during the study period; 5,612 (35.9%) through private and 10,036 (64.1%) through community outreaches. Among these, 106 DRTB cases were detected. The DRTB detection rate was significantly higher in private settings: 1.3% versus 0.3% in ACF ($p < 0.001$). GeneXpert was used for 87% of TB cases in private settings compared to 63% in community settings, also statistically significant ($p <0.001$). This indicates that although community case finding contributed a greater share of overall TB case detection, its yield for DRTB remained low, likely due to reduced access to molecular diagnostics.
Conclusions: The study demonstrates a significant disparity in DRTB detection between privateand community-based settings in Katsina state, with private facilities showing higher diagnostic coverage and better utilization of GeneXpert technology. This highlights the need to scale up molecular testing capacity for community intervention.

EP45-1133-20 Institutionalising multi-ministerial accountability for TB prevention adn care: High-level advocacy and subnational monitoring to enhance commitment, TB funding and detection in Indonesia

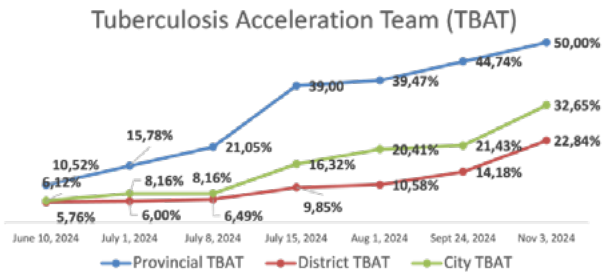
I.A. Isturini,[1] T.T. Pakasi,[2] S.N. Rahma,[2] F.A. Nabila,[3] D.A. Rakhmawulan,[3] A.B. Wicaksono,[4] F. Yunita,[4] [1]Ministry of Health of Republic of Indonesia, Communicable Disease Control Department, South Jakarta, Indonesia, [2]Ministry of Health of Republic of Indonesia, National Tuberculosis Program, South Jakarta, Indonesia, [3]Ministry of Health of Republic of Indonesia, National Tuberculosis Program, Central Jakarta, Indonesia, [4]USAID Long Term Exceptional Technical Assistance Project (LEAP), Technical Department, South Jakarta, Indonesia

Background and challenges to implementation: Indonesia has the world's second-highest tuberculosis (TB) burden (GTB, 2024). Despite committing to reduce TB incidence by 65 per 100,000 population and eliminate the disease by 2030, a $494 million funding deficit persists (NSP, 2024). While the 2021 Presidential Decree on Tuberculosis mandates multi-sectoral collaboration at national and subnational levels, TB remains deprioritized across ministries and stakeholders, hindering progress toward elimination targets.
Intervention or response: In 2024, Indonesia's Ministry of Health, in collaboration with the Coordinating Ministry for Human Development and Cultural Affairs and the Ministry of Internal Affairs, launched a structured virtual monitoring system to strengthen subnational tuberculosis (TB) program governance.
The initiative implemented a two-tiered accountability framework:
1. Ministerial-level reviews with governors and mayors, and;
2. Deputy Minister-level technical meetings with provincial and district health offices.

Key performance indicators—TB case notification, treatment enrollment, contact investigation coverage, and district acceleration team establishment—were tracked monthly. To institutionalize action, the Ministry of Internal Affairs mandated district-level TB acceleration teams and action plans via ministerial decree. Data collection was supported by the NTP and Stop TB Partnership Indonesia.

Results/Impact: By December 2024, 127 districts across 19 provinces established tuberculosis (TB) acceleration teams, reflecting a 3.2-fold increase from June 2024 (30 districts). This expansion enhanced multi-stakeholder collaboration and governance for district-level TB programs.

Concurrently, a landmark financial commitment of IDR 8 trillion (~USD 500 million) was announced by Indonesia's newly elected President in January 2025, signaling high-level prioritization of national TB elimination efforts.



Conclusions: Indonesia's multi-ministerial accountability framework catalyzed district-level TB program governance, evidenced by a 3.2-fold surge in acceleration teams (30 to 127 districts) and a landmark USD 500 million presidential funding commitment. This model demonstrates that structured subnational monitoring and high-level advocacy bridge funding gaps, align priorities, and accelerate progress toward national TB elimination targets.

EP45-1134-20 Accelerating TB elimination in Uganda: A multisectoral accountability framework approach

M. Mwesige,[1,2,3] H. Luzze,[1] N. Modi,[1] M.G. Nabukenya Mudiope,[2] E. Mbabazi,[4] A. Mulindwa,[1] S. Muchuro,[2] [1]Ministry of Health, National TB and Leprosy Program, Kampala, Uganda, [2]Infectious Diseases Institute, Makerere University, Kampala, Uganda, Health Systems Strengthening, Kampala, Uganda, [3]Makerere University, School of Public Health, School of Public Health, Kampala, Uganda, [4]Office of the Prime Minister Prime, Minister's Delivery Unit (PMDU), Kampala, Uganda
e-mail: mathiusmwesige1@gmail.com

Background and challenges to implementation: Uganda faces a significant burden of tuberculosis (TB) due to socioeconomic factors and limited access to healthcare. It ranks among the 30 high-burden TB-HIV countries. To achieve TB elimination by 2030, a multisectoral approach is necessary, addressing financial constraints, geographical barriers, low health literacy, and a limited understanding of TB signs and symptoms.

Intervention or response: Uganda adopted the WHO's MAF-TB to tackle these challenges in controlling TB. The National TB and Leprosy Programme (NTLP) collaborated with the Office of the Prime Minister (OPM) to integrate TB prevention and control into various sectors, thereby fostering a cohesive national strategy. OPM established structures, including policy coordination and implementation committees, to facilitate effective collaboration among Ministries, Departments, and Agencies (MDAs).

Through collaboration with the WHO, Global Fund, and USAID, NTLP provided technical support and resources for capacity building across multiple sectors, including promoting TB awareness and implementing screening initiatives in workplaces.

Results/Impact: The Prime Minister became a Tuberculosis Champion and promoted the implementation of MAF-TB, which led to increased funding and resource allocation within MDAs. 13 MDAs have integrated tuberculosis into their PIAPs and budgets and allocated over UGX 1.8 billion to support workplace tuberculosis screening, treatment linkage, transport, and nutritional support for TB patients. Ministry of Health expanded tuberculosis services closer to the public through workplace

and community screening and testing. 17,357 individuals were screened at 29 workplaces using mobile clinic outreach, and 192 were identified as positive for Tuberculosis.

An integrated national policy on HIV and TB in the workplace has been developed. 7 MDAs incorporated tuberculosis into their HIV workplace policies.

Conclusions: MAF-TB initiative showcases the effectiveness of multisectoral collaboration in addressing tuberculosis. It underscores the need to integrate TB control within broader societal frameworks and address health determinants. Political commitment and dedicated leadership are crucial in mobilising resources and overcoming challenges.

EP45-1135-20 Accelerating Uganda's fight achieving UNHLM targets to end

A. Mulindwa,[1] E. Quinto,[1] M. Mwesige,[2] G. Amanya,[1] D. Rutazaana,[3] S. Turyahabwe,[4] H. Luzze,[1] [1]Ministry of Health, National Tuberculosis & Leprosy Program (NTLP), Kampala, Uganda, [2]Infectious Diseases Institute, Makerere University, Local Partner Health Services – TB Activity (LPHS-TBA), Kampala, Uganda, [3]Ministry of Health, Global Fund, Kampala, Uganda, [4]Ministry of Health, Communicable Disease Prevention & Control, Kampala, Uganda
e-mail: mulindwaalex@gmail.com

Background and challenges to implementation: Uganda demonstrated its commitment to tuberculosis (TB) elimination by reaffirming global targets at the 2nd UN High-Level Meeting (UNHLM) on TB in 2023. Despite prioritizing equitable access to prevention, diagnosis, treatment, and social protection services, systemic barriers persist. These include limited funding, uneven access to diagnostics, workforce shortages, low notification rates for pediatric and drug-resistant TB (DR-TB) cases, stigma, and inadequate social protection. Such challenges slow progress by impacting timely diagnosis, adherence, and overall service delivery.

Intervention or response: To accelerate progress, Uganda implemented a multi-sectoral strategy targeting systemic gaps. Key interventions involved scaling domestic and donor funding, integrating TB screening into community health campaigns through initiatives like CAST+, and expanding rapid diagnostic tools such as GeneXpert in high-burden areas.

Comprehensive social protection packages were provided to enhance adherence and reduce financial burdens on TB patients. Innovative tools—including mobile diagnostic units, digital health platforms, and community health worker networks—extended services to underserved regions. Regular monitoring of key performance indicators (KPIs) informed adjustments and guided decision-making to optimize outcomes.

Results/Impact: Uganda made notable strides toward achieving UNHLM TB targets. TPT coverage exceeded expectations, reaching 539% for contacts over 5 years and 239% for children under 5 years in 2023, with similarly high results in 2024. Notifications rose to 86,498 cases in 2023 (89.9% of the target) and 82% of the 2024 target. DR-TB notifications improved to 78.8% (2023) and 71.5% (2024). However, challenges persist, particularly in pediatric TB notifications, which achieved only 51% of the 2024 target.

Indicator	Target 2023	Achievement (%) 2023	Target 2024	Achievement (%) 2024	Target 2025	Target 2026	Target 2027	Total 2023–2027	Cummulative Performance, 2 Years
Notification - All TB	96,265	89.9	107,767	82	98,971	95,000	87,000	475,236	175,365
TB children (<15 years)	15,925	74.8	19,841	51	14,654	14,000	12,000	72,409	22,037
Notification DR-TB	839	78.8	1,119	71.5	1,233	1,566	1,369	5,948	1,461
TB-TPT. Number of TB contacts, >5 years started on TPT	36,978	539	46,374	469	50,390	58,308	60,879	252,930	417,014
TB-TPT. Number of TB contacts, <5 years started on TPT	20,348	239	26,277	193	26,393	29,805	30,374	133,196	99,380
TPT PLHIV	105,724	105.2	134,044	78	139,452	142,622	145,257	667,099	215,774

Table. Tabulated data for UNHLM Targets 2023–2027 and 2024 Performance.

Conclusions: Uganda's multi-sectoral strategy has significantly advanced its fight against TB, offering a replicable model for TB-endemic countries. Sustained investments, diagnostic expansion, and community-centered interventions remain essential to achieving End TB targets by 2027 and bridging remaining gaps in TB prevention and care or ending TB.

EP45-1136-20 Bridging the gap in drug-sensitive TB treatment initiation in Indonesia: Insights from a national assessment and pathways for public-private collaboration

IW.G. Artawan Eka Putra,[1,2] G.A. Alexandra,[2] A. Fitriangga,[3,2]
[1]Faculty of Medicine, Universitas Udayana, Public Health and Preventive Medicine, Denpasar, Indonesia, [2]The Indonesia Tuberculosis Research Network, Community Research, Jakarta, Indonesia, [3]Faculty of Medicine, Universitas Tanjungpura, Public Health and Preventive Medicine, Pontianak, Indonesia
e-mail: gedeartawan@unud.ac.id

Background: Indonesia remains a high-burden tuberculosis (TB) country, with an estimated 385 cases per 100,000 population in 2023. Despite progress in case notification (77% of estimated cases), treatment enrollment gaps persist, particularly for drug-sensitive TB (DS-TB), with enrollment rates declining from 90.8% (2021) to 88.3% (2023). Disparities exist across healthcare facilities, with private clinics (72–82%) and practitioners (76–82%) underperforming compared to public centers.
This assessment aimed to identify factors to DS-TB treatment initiation and propose actionable solutions.
Design/Methods: This assessment is a national level TB Information System (SITB) data analysis that including 1.195.174 people with DS-TB notified in 2023–2024. the association of subject characteristics, diagnostic procedures, comorbidity status and type of health facility with treatment initiation were analysed using cross tabulation and logistic regression.
Secondary data from the 2023–2024 TB Inventory Study (IVS) were incorporated to evaluate under-reporting factors influencing enrollment.
Results: Key findings revealed lower enrollment among elderly (84.4% for ≥60 years vs. 93.7% for <15 years) and males (87.7% vs. females' 89.1%). Standardized diagnostics (92.9% enrollment) and chest X-ray utilization (92%) improved enrollment rates, while delayed molecular test results (>3 days) reduced enrollment by 10–12%.
Private clinics and practitioners faced systemic challenges, including referral inefficiencies, financial barriers under national insurance (JKN), and under-reporting (77.2% unreported cases in private practices). The IVS identified 15.6% national under-reporting, skewing enrollment rates.
Logistic regression confirmed higher enrollment in facilities integrating comorbidities screening (DM with AOR:21.3; 95%CI:20.3-22.2 and HIV with AOR: 20.6; 95%CI:19.7-21.6), public health centers (AOR:2.14; 95%CI:2.05-2.24).
Conclusions: Strengthening referral systems, standardizing diagnostics, and enhancing private-sector engagement through policy mandates (e.g., MoUs, JKN incentives) are vital. Addressing socio-economic barriers, improving data synchronization, and expanding patient-centered care are recommended. Prioritizing these interventions will bridge enrollment gaps, align with Indonesia's TB elimination targets, and serve as a model for high-burden settings globally.

ABSTRACT PRESENTATIONS FRIDAY 21 NOVEMBER 2025

ORAL ABSTRACT SESSION (OA)

OA25 Enhancing TB detection and diagnostics in public and private settings

OA25-337-21 Acceptability and feasibility of an AI-powered care co-ordination tool in TB management in Patient Provide Supporter Agency (PPSA) service implementation model in India: Qualitative insights

P. Birajdar,[1] M. Pardeshi,[2] [1]Network of Maharashtra By People Living with HIV/AIDS, TB, HIV, Pune, India, [2]Network of Maharashtra By People Living with HIV/AIDS, TB, HIV/STI and Hepatitis, Pune, India
e-mail: prashant.birajdar@nmpplus.org

Background and challenges to implementation: The Network of Maharashtra People with HIV (NMP+) functions as a Patient Provider Support Agency (PPSA) service implementation model under India's National TB Elimination Program (NTEP), supporting Tuberculosis (TB) detection by operationalizing specimen transport, laboratory coordination, and longitudinal follow-up across private healthcare providers.
Intervention or response: An Artificial Intelligence (AI)-enabled digital platform (qTrack) was deployed across ten private healthcare facilities in Pune, India, to support TB surveillance and streamline care coordination. The platform facilitated real-time tracking of TB presumptive patients, sputum collection status, automated alerts for timely follow-up, and intra-facility report sharing.
A mixed-methods qualitative study was purposively conducted among 10 regular users (9 NMP+ field staff and 1 project officer) of the platform. In-depth, semi-structured questionnaires with open-ended questions were used to assess the acceptability and feasibility of the platform.
The responses were then analyzed using Visual Anthropac 4.9 to identify key themes, categories, and salience scores (an indicator of frequency and cognitive importance of a participant response) regarding barriers and facilitators in TB workflow integration.
Results/Impact: Thematic analysis of open-ended responses confirmed the platform's utility in patient tracking and data collation, with high frequency (70–80%) and salience score (0.5–0.8), well above the relevance threshold of 0.087. 90% participants suggested that the real-time notification feature is highly useful to track TB presumptive patients. Participants also noted that the AI tool enabled a real-time surveillance system, enhancing sputum collection tracking through immediate access to patient data.
Additionally, 70% found data management easier, 60% reported improved care coordination, 60% reported simplified patient tracking, and 30% noted a reduction in errors. Satisfaction with AI training and usability was uniformly positive.

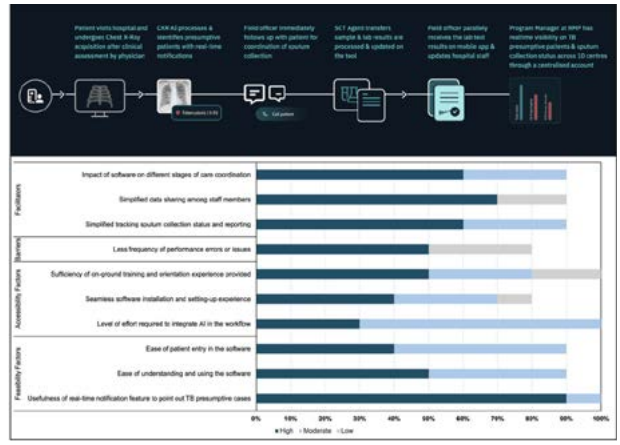


Figure 1. The clinical workflow is represented along with the quantitative representation of the survey results on acceptability, feasibility, barriers and facilitators.

Conclusions: AI-enabled tools strengthen TB surveillance and patient management by optimizing existing workflows, improving real-time care coordination, and operational efficiency across PPSA agencies and the NTEP, without requiring additional infrastructure investments.

OA25-338-21 Utility of symptom-agnostic chest X-ray for facility-based TB screening in Viet Nam: Secondary analysis of a large-scale public-private mix intervention

L.N.Q. Vo,[1,2] A. Codlin,[3,2] T. Garg,[4] R. Forse,[3,2] L.V. Dinh,[5] H.B. Nguyen,[5] T.D. Nguyen,[6] T. Wingfield,[7,8] K.S. Annerstedt,[9] J. Shedrawy,[10] K. Lönnroth,[9,11] J. Creswell,[4] [1]Friends for International TB Relief (FIT), Management, Ha Noi, Viet Nam, [2]WHO Collaboration Centre on Tuberculosis and Social Medicine, Karolinska Institutet, Department of Global Public Health, Solna, Sweden, [3]Friends for International TB Relief (FIT), Management, Ho Chi Minh City, Viet Nam, [4]Stop TB Partnership, Innovations & Grants, Geneva, Switzerland, [5]Viet Nam National Lung Hospital, Management, Ha Noi, Viet Nam, [6]Viet Nam National Lung Hospital, Steering Department, Ha Noi, Viet Nam, [7]Liverpool School of Tropical Medicine, Clinical Sciences and International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland, [8]Liverpool University Hospital NHS Foundation Trust, Tropical and Infectious Diseases Unit, Liverpool, United Kingdom of Great Britain and Northern Ireland, [9]Karolinska Institutet, Department of Global Public Health, Solna, Sweden, [10]The Swedish Institute for Health Economics, Research, Stockholm, Sweden, [11]Government of Åland, Department of Health, Åland Islands, Finland
e-mail: luan.vo@tbhelp.org

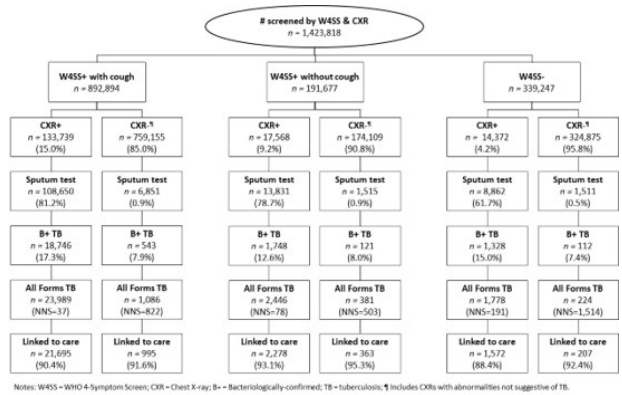
Background: Many people with tuberculosis (TB) report no symptoms and are only detected by chest X-ray (CXR). Since 2020, Viet Nam's guidelines recommend the 'Double-X' algorithm using CXR screening irrespective of symptoms followed by Xpert testing. Few studies have documented verbal and CXR screening for TB at health facilities at a representative scale, both in Viet Nam and globally.

Design/Methods: This was a secondary analysis of case-level data from health-seeking adults at 796 public and private healthcare providers in 15 provinces of Viet Nam in 2020-2023. The dataset encompassed demographic and clinical covariates; WHO 4-symptom screen (W4SS), CXR and sputum test results; and treatment linkage.

Data were analyzed using TB care cascades disaggregated by positive W4SS screens (W4SS+) with cough, W4SS+ without cough and asymptomatic presentation, and by CXR result. Bacteriologic-confirmation was the primary endpoint.

Primary outcomes included yield, number needed to screen (NNS), positivity and proportion of all bacteriologically-confirmed TB in the sample missed by CXR versus W4SS.

Results: Screening 1,423,818 individuals resulted in detecting 22,598 persons with bacteriologically-confirmed TB. Disaggregated by cohort, the yield was 2.2% (19,289/892,894; NNS=46) among persons with W4SS+ with cough, 1.0% (1,869/191,677; NNS=103) among persons with W4SS+ without cough and 0.4% (1,440/339,247; NNS=236) among asymptomatic persons. TB positivity in persons with abnormal CXR was between 4.6-9.4 percentage points higher than with a normal CXR result, so that relying on W4SS only would have required 5.4-6.5x more diagnostic tests. CXR missed 776 (3.4%) of symptomatic persons with bacteriologically-confirmed TB compared to W4SS missing 1,440 (6.4%) persons with asymptomatic TB.



Conclusions: Chest radiography can enable detection of asymptomatic TB, improving pre-test probability, and reducing testing of symptomatic individuals for TB.

OA25-339-21 Impact of private sector involvement in TB case finding: Results from 16 newly-included states in Nigeria

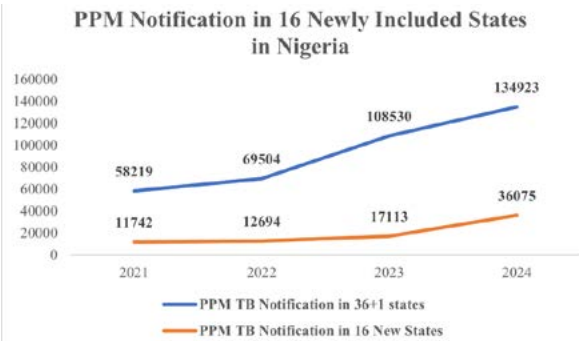
K. Nzeadibe,[1] P. Egbetusi,[1] H. Bello,[1] T. Adetiba,[1] U. Atoi,[1] O. Olupitan,[1] C. Mensah,[2] P. Dakum,[3] S. Makpu,[4] O. Chijioke- Akaniro,[4] J. Ssekitooleko,[5] M. Zamzu,[5] Global Fund NTHRIP Team [1]Institute of Human Virology Nigeria (IHVN), Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria, [2]Institute of Human Virology Nigeria (IHVN), Office of the COO, Abuja, Nigeria, [3]Institute of Human Virology Nigeria (IHVN), Office of the CEO, Abuja, Nigeria, [4]National Tuberculosis, Leprosy and Buruli Ulcer Control, Public Health Department,, Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Nigerian Country Team, Geneva, Switzerland
e-mail: knzeadibe@ihvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge in Nigeria, with a significant number of cases going undiagnosed. Although the private sector serves as the initial point of care for many individuals, its contribution to TB case detection has historically been underutilized. The Global Fund (GF), through the Institute of Human Virology Nigeria (IHVN), initially supported private provider engagement in 21 states. In 2024, this initiative was expanded to the remaining 16 states, achieving full nationwide private sector coverage.

Intervention or response: The engagement strategy targeted diverse private sector providers, including private health facilities, community pharmacies, patent medicine

vendors, traditional birth attendants/healers, and laboratories. A comprehensive approach was adopted, beginning with facility assessments and mapping using a hub-and-spoke model to ensure effective referrals and reduce cascade leakages. Providers received training on TB and HIV service delivery, including the use of the Mobile Application for Tuberculosis Screening (MATS) to support accurate identification of presumptive TB cases. Continuous supervision and mentorship were provided, and performance-based incentives were introduced to boost provider motivation and improve service delivery.

Results/Impact: By the end of 2024, data from the 16 newly engaged states showed a substantial improvement in TB case notifications, with 36,075 new cases reported from the private sector. This represents a 111% increase compared to 2023 and a 184% increase over 2022 levels, giving rise to the total national PPM notification from 108,530 in 2023 to 134,923 TB cases in 2024.



Conclusions: The expansion of private sector engagement to 16 additional states in 2024 significantly improved TB case detection, addressing a major gap in Nigeria's TB response. The results highlight the effectiveness of a structured, incentivized, and tech-enabled approach in mobilizing private providers. Sustaining and scaling this model can enhance early diagnosis, improve linkage to care, and contribute meaningfully to national TB elimination goals.

OA25-340-21 Strengthening public-private mix (PPM) for TB case finding: Expanding the role of private healthcare providers in Nigeria

Q. Ogbuji,[1] B. Nwaogu,[1] A. Uwajeh,[1] O. Onitiju,[1] A. Afolayan,[1] O. Olupitan,[2] T. Adetiba,[2] E. Ubochioma,[3] O. Akaniro,[4] M. Zamzu,[5] J. Ssekitooleko,[5] [1]Association for Reproductive and Family Health, TB & HIV, Abuja, Nigeria, [2]Institute of Human Virology, Nigeria (IHVN), Abuja, Nigeria, Global Fund N-THRIP, Abuja, Nigeria, [3]National TB and Leprosy and Buruli Ulcer Control Programme, Global Fund Program Management Unit, Abuja, Nigeria, [4]National TB and Leprosy and Buruli Ulcer Control Programme, FMOH, Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Grant Management Division, Geneva, Switzerland
e-mail: nwaogu.b@arfh-ng.org

Background and challenges to implementation: Nigeria has a high TB burden, with an estimated incidence rate of 219 cases per 100,000 people. Despite 67% of Nigerians seeking care from private providers, TB case notification from the private sector was only 15% in 2019. Barriers such as limited diagnostic capacity and weak referral systems have hindered TB detection. The Global Fund GC7 TB/HIV Integrated Project introduced a structured Public-Private Mix (PPM) approach to expand case detection across six states: Ekiti, FCT, Kogi, Kwara, Nasarawa, and Rivers.

Intervention or response: The project implemented a Hub-and-Spoke model, engaging 2,472 private facilities, including 580 Private-for-Profit (PFP) hospitals and 53 Faith-Based Organizations (FBOs) as hubs, alongside 964 Patent Medicine Vendors (PMVs), 78 Community Pharmacies (CPs), 35 Standalone Laboratories (SALs), and 762 Traditional Birth Attendants (TBAs) as spokes. Providers were trained. Linkage Coordinators facilitated sample transport and ensured treatment linkage. Screening Officers conducted systematic screening at OPDs, while the Mobile Application for Tuberculosis Screening (MATS) tracked presumptive and positive cases. Financial incentives supported provider engagement.

Results/Impact: In 2024, the GC7 PPM model contributed 11,462 TB cases, with hubs detecting 7,233 (63%), PMVs 3,857 (34%), CPs 139 (1.2%), SALs 22 (0.2%), and TBAs 211 (1.8%). Rivers (4,956) and Nasarawa (3,638) led in notifications. PMVs contributed 69% of cases in Rivers, while Nasarawa had the highest from CPs (136) and TBAs (208). The structured referral system and digital tools improved case identification and treatment linkage.

Conclusions: A structured PPM model effectively increased TB case detection. Key achievements include improved sample referral, expanded diagnostics, and enhanced provider engagement. Sustaining incentives, expanding molecular diagnostics, and strengthening policy integration are critical for long-term success. Collaboration between government and private providers remains essential to achieving Nigeria's TB detection targets.

OA25-341-21 Turning the tide: Five years of enhanced TB detection in Southwestern Nigeria (FY20–FY25)

O. Daniel,[1] A. Agbaje,[2] C. Mensah,[3] P. Dakum,[3] M. Pedro,[4] B. Olaniyi,[1] C. Uzoigwe,[1] R. Eneogu,[5] D. Nongo,[5] A. Alege,[6] S. Labaran,[7] O. Akaniro,[7] [1]Institute of Human Virology Nigeria, Prevention Care and Treatment, Ikeja, Nigeria, [2]Institute of Human Virology Nigeria, Office of the CEO, Ikeja, Nigeria, [3]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [4]Institute of Human Virology Nigeria, Strategic Information, Ikeja, Nigeria, [5]United States Agency for International Development, HIV/AIDS & TB office, Abuja, Nigeria, [6]Society for Family Health, Community, Ikeja, Nigeria, [7]National Tuberculosis, Leprosy and Buruli Ulcer Control Program, Public Health, Abuja, Nigeria
e-mail: odaniel@ihvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains a leading cause of morbidity and mortality globally and in Nigeria. According to the WHO Global TB Report 2023, Nigeria ranks first in Africa and sixth globally among high TB burden countries, with an estimated 467,000 cases in 2022 and a case detection rate of 62%. To address gaps in TB detection and care, the Government of Nigeria, with donor support, implemented multiple interventions including intensified case finding (ICF), expansion of diagnostic tools, and community-level TB surveillance and Contact Investigation.
Intervention or response: Between FY20 and FY25, the USAID TB-LON 3 project implemented in Lagos, Ogun, Osun, and Oyo states introduced critical interventions: scale up of TB services to over 1900 public and private health facilities, deployment of molecular diagnostic platforms, active community TB ICF, and engagement trained contact investigation team. Regular supportive supervision, data-driven reviews, and health system integration further strengthened service delivery.
Results/Impact: A review of quarterly TB notification data showed significant improvement in case detection. From FY20 Q3 to FY25 Q1, TB notifications increased from 972 to 12,024 cases across the four states. Notable peaks occurred in FY24 Q2 (11,942) and Q3 (12,024), demonstrating the impact of targeted community outreach and diagnostic expansion. A total of 111,259 TB cases were notified across the four states, reflecting the success of intensified Case finding and private sector engagement. The consistent upward trend in notifications underscores the effectiveness of integrated interventions, especially in high-burden communities and underserved areas.
Conclusions: Targeted interventions significantly improved TB case detection across the four states. Sustaining these gains requires continuous investment in diagnostics, community engagement, and private sector collaboration. Scaling this model nationally could accelerate Nigeria's progress toward ending TB as a public health threat. Stakeholders are encouraged to support uninterrupted program funding, strengthen health systems, and maintain innovations that bridge existing gaps.

OA25-342-21 Wheels of change: Strengthening TB sample referral and diagnosis through public-private collaboration Meru County experience (2022-2023)

W. Tole,[1] J. Magiri,[2] P. Kirimi,[1] [1]Meru Teaching and Refferal Hospital, Laboratory, Nairobi, Kenya, [2]Ministry of health- Meru Teaching and Referral Hospital-, Laboratory, Nairobi, Kenya
e-mail: winlints@yahoo.com

Background and challenges to implementation: Meru County is among the top 5 high burden counties for Drug Susceptible Tuberculosis and Drug Resistant TB in Kenya,thus requires efficient diagnostic systems to improve case detection and treatment outcomes.Weak specimen referral systems, logistical bottlenecks, and fragmented service delivery often delayed diagnosis and treatment initiation. In response, innovative public-private collaboration models were explored to improve TB diagnostic networks. This study is to evaluate the impact of public-private collaboration on strengthening the diagnostic capacity through an integrated transport and communication framework.
Intervention or response: A collaborative model involving the Ministry of Health Meru County AMREF, KCCB, RESOK and Jamii tekelezi, private courier services, and diagnostic laboratories was implemented Key interventions included deployment of a coordinated hub-and-spoke specimen referral system using motorbike riders, standardized training of healthcare workers on sample packaging and referral protocols, and digital tracking of specimens via mobile reporting tools. Data on turnaround time, number of samples referred, and TB case detection were collected pre- and post-intervention.
Results/Impact: A total of 24,419 specimen were processed in the laboratories out of which 5635 ((23%) were referral specimen.
The collaboration led to an increase in the volume of samples referred for TB testing from 7,333 in 2022 to 18,086 in 2023 and a positivity of 1,127(15.3%) in 2022 to

4,255(24%) in 2023,The system increased the number of TB case detection by 3098 samples(12.6%) A reduction in average turnaround time for GeneXpert results reduced from 14 days to 24 hours ensuring up to 94% of specimen reaching the hubs within the established target transport time, with sustainability, operational efficiency, and geographical reach, particularly in underserved rural and peri-urban areas.
Conclusions: The „Wheels of Change" illustrates the transformative potential of public-private partnerships in overcoming logistical barriers in TB diagnosis. Scaling such models nationally could significantly accelerate TB case detection and treatment initiation, contributing to End TB goals.

OA25-343-21 Enhancing TB detection using innovative screening technologies: Programmatic impact of mobile application for TB screening integration in private healthcare sector in Katsina State, Nigeria

I.T. Lawrence,[1] A.Y. Galadima,[2] R. Abi,[2] M. Sheshi,[3] A. Okoh,[3] B. Odume,[4] O. Olupitan,[5] T. Adetiba,[5] E. Vincent,[5]
[1]KNCV Nigeria, Programmes, Katsina, Nigeria, [2]KNCV Nigeria, Technical, Katsina, Nigeria, [3]KNCV Nigeria, Programmes, Abuja, Nigeria, [4]KNCV Nigeria, Executive Management, Abuja, Nigeria, [5]IHVN, Programmes, Abuja, Nigeria
e-mail: ilawrence@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge in Nigeria, with significant underreporting in the private health sector, where a large proportion of patients seek care. Traditional paper-based TB screening systems often lead to suboptimal identification of presumptive cases, delayed referrals, and incomplete data reporting. In Katsina State, the absence of standardized digital tools for TB screening at private facilities has hindered early TB case detection. Addressing these challenges required a scalable, real-time, and user-friendly digital solution to enhance systematic screening and timely diagnosis.
Intervention or response: The Mobile Application for Tuberculosis Screening (MATs App) was integrated into routine TB screening in private health facilities under the Global Fund Community Public-Private Mix (GF-CPPM) project by KNCV Nigeria in Katsina State. This intervention enabled systematic symptom-based screening, with presumptive cases referred for molecular diagnosis. TB case detection data from pre-implementation (Q1 2024) and post-implementation (Q2 2024) periods were compared to assess impact.
Results/Impact: Between January and June 2024, 295,008 individuals were screened across private facilities in Katsina State. In Q1 (pre-implementation), 95,626 individuals were screened, detecting 736 drug susceptible tuberculosis (DS-TB) (0.8%) and 5 drug resistant tuberculosis (DR-TB) cases. In Q2 (post-implementation), 199,382 were screened, yielding 2,174 DS-TB (1.1%) and 9 DR-TB cases—representing 195% and 80% increases, respectively. The digital platform also improved the completeness and timeliness of case reporting and facilitated better linkage to diagnostic services.
Conclusions: The integration of the MATs App into private-sector TB screening demonstrated substantial gains in TB case detection. This digital intervention enabled efficient identification of presumptive cases, improved diagnostic referrals, and strengthened surveillance within an underutilized care sector.
These findings support the scale-up of digital tools like MATs App to optimize TB case finding in private health settings and underscore their value in accelerating progress toward national TB control targets.

OA25-344-21 Driving efficiency in TB notification: The impact of DHIS2 in Pakistan's private sector

A. Latif,[1] N. Nawaz,[1] A. Ayub,[1] F. Ali,[1] W. Malik,[1] R. Zareen,[1] [1]Mercy Corps, Digital Systems to Engage Private Providers (DEPP-TB), Islamabad, Pakistan
e-mail: ablatif@mercycorps.org

Background and challenges to implementation: Tuberculosis (TB) prevention in Pakistan has been hindered by delays in diagnosis, largely due to a paper-based reporting system—especially in the private sector, which serves over 86% of the population. While the Public-Private Mix (PPM) model enhanced collaboration and TB case notifications, manual processes slowed patient registration, follow-up, and data aggregation, affecting timely TB management.
Intervention or response: To address these delays, Mercy Corps Pakistan implemented a digital, case-based notification system using DHIS2. This transition enabled real-time registration, treatment monitoring, contact screening, and follow-up. With digital integration, bottlenecks from manual reporting were removed, leading to faster decision-making and more efficient program responses. DHIS2 is now operational across all 111 districts supported by Mercy Corps, ensuring streamlined TB surveillance.
Results/Impact: The DHIS2 system has registered 171,927 TB cases, marking a 580% increase from the 25,289 cases recorded during early implementation—demonstrating significant improvements in coverage and performance. Patient follow-up delays dropped from 89% to 53%, and follow-up test availability rose from 49% to 69%. Data completeness also improved, with missing contact numbers reduced from 81% to 49% and national ID gaps from 59% to 35%. In terms of time efficiency, 578 data entry

staff across 111 reporting districts brought down the average reporting time to 14.2 days post-quarter (ending 31 March 2025), compared to 45 days pre-DHIS2—marking a 68.4% improvement. Reports were submitted between 1 and 20 April 2025, reflecting enhanced speed and system responsiveness.

Indicator	Before DHIS2	After DHIS2	Remarks
Patient Follow-up Delays	89%	53%	Improved timeliness in follow-up
Follow-up Test Availability	49%	69%	Better outcome tracking
Missing Contact Numbers	81%	49%	Improved data completeness
Missing National ID Numbers	59%	35%	Improved data accuracy
Reporting Time Post-Quarter	45 days	14.2 days	68.4% faster reporting

DHIS2 Performance and Time Efficiency Overview.

Conclusions: The successful implementation of DHIS2 under the PPM-1 model has significantly improved TB case registration, data quality, and reporting efficiency. With proven impact across 111 districts, this digital model will now be expanded to PPM-2 and PPM-3, further strengthening TB surveillance and private sector integration in Pakistan.

OA25-345-21 Building TB diagnostic infrastructure in Uttarakhand State in India: A joint effort by government and corporate social responsibility

A.K. Nagarkar,[1] B. Bishnu,[2] J.S. Negi,[1] S. Lohakare,[2] Y. Malhotra,[2] S. Chandra,[2] A.K. Bhardwaj,[3] N. Kumar,[4] U. Singh,[4]
[1]Department of Health and Family Welfare, Government of Uttarakhand, Tuberculosis, Dehradun, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [3]National Task Force, National Tuberculosis Elimination Program, New Delhi, India, [4]Ministry of Health and Family Welfare, Government of India, Tuberculosis, New Delhi, India
e-mail: bsinha008@gmail.com

Background and challenges to implementation: In early 2023, Uttarakhand state conducted a Diagnostic Network Optimisation exercise to assess the accessibility and upfront use of Nucleic Acid Amplification Test (NAAT) machines, for Tuberculosis (TB) diagnosis and Rifampicin resistance detection.
Analysis revealed that only 24% of people in hilly regions had access to NAAT laboratories, primarily located in district and sub-divisional hospitals, leading to diagnostic delays and patient drop-offs during referrals. In response, state adopted a decentralization strategy to improve accessibility and timely diagnosis.
This study evaluates the effectiveness of that strategy, focusing on its impact on diagnostic access and patient retention in Uttarakhand's mountainous areas.

Intervention or response: To improve access, the state first redistributed centrally located NAAT machines to peripheral health facilities. Additionally, corporate partners donated 40 more machines as part of their Corporate Social Responsibility (CSR) initiatives. Supply chain systems were streamlined, and regular state-level monitoring was undertaken on a roster basis.
Key performance indicators monitored included:
i. NAAT turnaround time,
ii. Presumptive sample testing rates,
iii. Use of upfront NAAT tests.
Analysis was done using data from Ni-kshay, India's digital TB surveillance platform, covering the 2022-2024 period.
Results/Impact: Number of functional NAAT laboratories rose by 73% in 2024 compared to 2022, leading to accessibility of these laboratories to 79% more people within 30 minutes' travel time. Presumptive TB testing increased by 77% (960 to 1697/100,000; p<0.0001).
Turnaround time for NAAT testing dropped significantly by 73% and proportion of individuals with TB diagnosed using upfront NAAT increased by 93%. Correspondingly, TB notification rates per 100,000 population moved from 228 to 239 (p<0.0001).

Parameters	2022	2023	2024	% change from 2022 to 2024
Population (X 100,000)	119	120	123	
Number of NAAT sites	78	89	135	73%
Population accessing NAAT laboratories within 30 minutes travel (%)	24	33	43	79%
Presumptive TB Examination Rate (per 100,000 population)	960	1316	1697	77%
Turnaround Time for NAAT testing (in days)	15	10	4	-73%
Individuals with TB subjected to upfront NAAT (%)	29	32	56	93%
TB Notification (per 100,000 population)	228	219	239	5%

Table 1: TB program indicators before and after intervention for improving access to diagnostic services with Government effort and CSR contributions in Uttarakhand state, India.

Conclusions: Enabling availability and accessibility of NAAT at peripheral centres, strengthened TB diagnostics, reduced delays, and improved access in underserved areas. This collaborative effort has enhanced early detection and created a more efficient and sustainable approach to TB elimination in hard-to-reach regions.

OA25-346-21 Intensified TB case finding in private hospitals in India: Transforming the incidental screening pathway with computer-aided detection

P. Birajdar,[1] M. Pardeshi,[2] A. Shinde,[3] R. Patil,[4] A. Nair,[5] S. Pawar,[6] P. S Krishnan,[7] A. Agrawal,[6] N. Patil,[6] [1]Network of Maharshtra People with HIV (NMP+), TB, HIV, Pune, India, [2]Network of Maharshtra People with HIV (NMP+), TB, HIV/STI and Hepatitis, Pune, India, [3]Network of Maharshtra People with HIV (NMP+), Health Department - NTEP, Pune, India, [4]Network of Maharshtra People with HIV (NMP+), TB, Pune, India, [5]Qure.ai, Clinical Research, Banglore, India, [6]Qure.ai, Operations, Mumbai, India, [7]Qure.ai, Operations, Banglore, India
e-mail: Saniya.Pawar@qure.ai

Background and challenges to implementation: Public-private partnership is pivotal to Tuberculosis (TB) care delivery and management. In 2023, India reported 2.55 million cases of TB, of which 33% were notified by the private sector. NMP+ (Network of Maharashtra People with HIV), a community-based organization, implements the patient provider support agency (PPSA) initiative in alignment with the National Tuberculosis Elimination Programme (NTEP), engaging private-sector doctors for effective TB care delivery. However, chest X-rays taken at such facilities remain underutilized for TB detection due to resource constraints.

Intervention or response: All routine chest X-rays taken at the six, private, multi-speciality hospitals within the PPSA network were systemically screened for radiological TB signs, regardless of clinical symptoms, using CAD software (qXR v4 and qTrack, Qure.ai) from December 2024 to March 2025. The TB presumptive patients identified by CAD with a TB probability score (range: 0-1; threshold: 0.5) above the threshold, were promptly referred for confirmatory testing as per NTEP protocols.

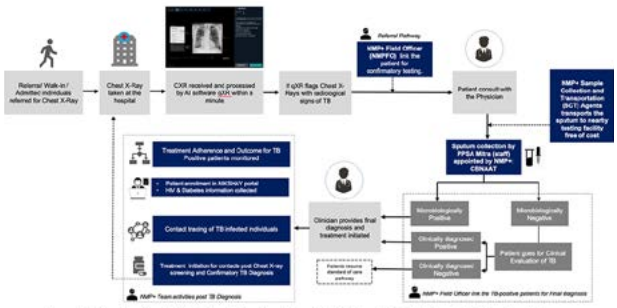


Figure: Workflow involving CAD for Chest X-Ray based Intensified TB Case Finding in Private Healthcare facilities

Results/Impact: Out of the 4522 chest X-rays screened at all the hospitals, 542 (11.9%) were identified as TB presumptive by CAD. 308(56.8%) cases were tested further and 34 (11.03%, 95%CI: 7.77%- 15.08%) were confirmed with tuberculosis over 4 months. The distribution of CAD probability scores for confirmed TB patients (age range: 23-80 years; 61.8% male) was found to be 0.908±0.12 (mean ± standard deviation). Compared to a historical baseline (December 2023 to March 2024), an increase of over 400% was observed in total TB case notifications from these 6 hospitals at the end of the intervention period.

Conclusions: CAD was integrated within the PPSA initiative to facilitate intensified TB case finding in private hospitals using Chest X-rays. A significant increase in TB notifications was observed from these facilities at the end of the intervention period, thus showing promise for scale up of this approach at national level to improve yield and patient outcomes.

OA26 Advancing TB care: Innovations in drugs, vaccines, diagnostics and treatment

OA26-347-21 Early bactericidal activity of oral Sanfetrinem cilexetil against pulmonary TB

M. Murphy,[1] S. Simelane,[1] U. Simonsson,[2] L. Mockeliunas,[2] S. Tiberi,[3] S. Penman,[4] T. Mabuka,[5] A. Diacon,[1] [1]TASK Applied Science, Science Office, Cape Town, South Africa, [2]Uppsala University, Department of Pharmaceutical Biosciences, Uppsala, Sweden, [3]GSK, Global Health R&D Medicines, London, United Kingdom of Great Britain and Northern Ireland, [4]GSK, Global Clinical Science & Delivery, London, United Kingdom of Great Britain and Northern Ireland, [5]TASK Applied Science, Data management, Cape Town, South Africa
e-mail: dr.melissa.m@task.org.za

Background: Sanfetrinem cilexetil is an orally active β-lactam prodrug that inhibits *Mycobacterium tuberculosis* cell wall synthesis. We report findings from a Phase 2A randomized, open-label study (NCT05388448) that evaluated the early bactericidal activity (EBA), pharmacokinetics, safety and tolerability of oral Sanfetrinem cilexetil.
Design/Methods: We randomised 53 adult participants (79% male, mean age: 35 years, mean weight: 54kg) with newly diagnosed, pan-susceptible pulmonary tuberculosis (TB) to receive 14 days of Sanfetrinem cilexetil 1600mg BID (Sanf1600, n=19), Sanfetrinem cilexetil 2400mg BID (Sanf2400, n=17), or Rifampicin 35mg/kg (Rif35, n=17) as microbiological control. EBA was assessed by the daily decrease in sputum colony-forming unit counts using empirical Bayesian estimates from mixed-effects model, and Bayes estimates from this model were used to predict individual EBA. Plasma concentrations of Sanfetrinem cilexetil were measured on day 13. Adverse events (AEs) were assessed daily.
Results: The median predicted 14-day EBA (log_{10}CFU/mL; 95% prediction interval) was 0.72 (0.46-1.87) for Sanf1600, 0.80 (0.40-1.28) for Sanf2400 and 3.94 (1.61-8.79) for Rif35, all significantly different from zero.
For Sanf1600 and Sanf2400 the mean maximum serum concentrations (Cmax; mg/L) were 3.92 (range: 1.89-5.29) and 3.79 (range: 0.54-6.61), and mean area under the curve ($AUC_{0\text{-}8h}$; h*mg/L) was 12.3 (range: 8.36-16.70) and 13.0 (range: 2.82-18.9), respectively.
Most AEs were mild (74.4%) or moderate (20.0%). Nine participants withdrew from the investigative study arms (Sanf1600: 3, Sanf2400: 6), with two Sanf2400 withdrawals due to drug-related AEs.
The other withdrawals were due to withdrawal of consent, worsening of TB or other reasons considered unrelated to treatment. Gastrointestinal AEs were frequent (Sanf1600: 84.2%, Sanf2400: 100%). No drug-related deaths occurred.
Conclusions: Sanfetrinem cilexetil was tolerated in the Sanf1600 group and both Sanfetrinem cilexetil dosages showed significant EBA over 14 days.
Unexpectedly, both 1600 mg BD and 2400 mg BD dosages exhibited similar bactericidal activity and similar serum exposure.

OA26-348-21 Early efficacy and preliminary safety of a novel 6-month regimen containing contezolid, delamanid, bedaquiline (CODA) and fluoroquinolones for Chinese rifampin-resistant people with TB

W. Nie,[1] F. Sun,[2] Y. Ren,[3] J. Huang,[4] W. Zhang,[2] N. Chu,[1] Inspire-CODA Study Group [1]Beijing Chest Hospital, Tuberculosis Department, Beijing, China, [2]National Medical Center for Infectious Diseases, Huashan Hospital, Shanghai Medical College, Fudan University, Department of Infectious Diseases, Shanghai, China, [3]Shanghai Sci-Tech Inno Center for Infection & Immunity, Clinical Research Departement, Shanghai, China, [4]National Medical Center for Infectious Diseases, Clinical Research Department, Shanghai, China

Background: Contezolid (CZD), a next-generation oxazolidinone with reduced myelotoxicity, could optimize 6-month rifampicin-resistant TB (RR-TB) regimens while mitigating linezolid (LZD)-associated toxicities that impair regimen durability.
Real-world evidence from China—contributing 7.3% of global RR-TB cases—remains critical for regimen adoption.
Design/Methods: The ongoing INSPIRE-CODA trial is a multicenter randomized non-inferiority study comparing 6-month CZD-based therapy (800mg BID + delamanid/bedaquiline/fluoroquinolone/clofazimine) against standard 18-month regimens in RR-TB adults.
Primary endpoint combines WHO-defined favorable outcomes at treatment completion and 24-month follow-up.
This interim analysis evaluates:
1. Time-to-sputum-culture conversion (Kaplan-Meier/Cox models),
2. Month-2 culture negativity (chi-square), and;
3. Safety in modified intent-to-treat (mITT) population.
Results: Among 212 randomized participants (107 CODA vs 105 control), 90 vs 93 reached mITT eligibility with balanced baseline characteristics. CODA arm demonstrated 87.8% dose adherence and 85.6% (77/90) favorable outcomes at treatment completion.
Median time-to-culture-conversion was identical in both mITT (28 days both arms; HR 0.97, 95%CI 0.72-1.32, Figure 1A) and per protocol (PP) populations (28 days both arms; HR 1.13, 95%CI 0.82-1.56, Figure 1B).
Subgroup analyses by FQ susceptibility showed consistent patterns (FQ-sensitive: HR 1.09, 95% CI 0.74–1.60; FQ-resistant: HR 0.87, 95% CI 0.53–1.43, Figure 1C).

Month-2 negativity rates showed no intergroup difference (83.3% vs 81.7%, p=0.93). CODA significantly reduced overall AEs (38.9% vs 67.7%) and LZD-related toxicities: peripheral neuropathy (2.8% vs 17.2%) and myelosuppression (5.6% vs 28.0%). Common CODA AEs included gastrointestinal events (13.5%) and transaminase elevation (9.0%).

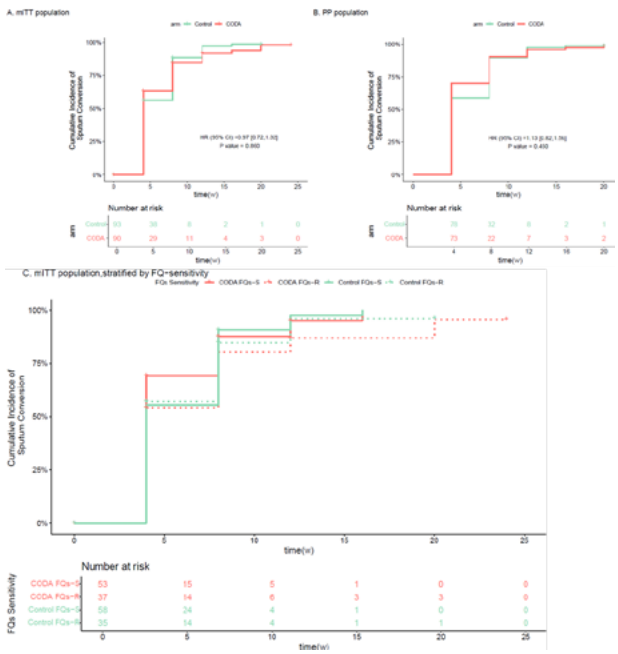

Figure 1: Sputum conversion by cut-off date (Mar. 20, 2025)
mITT: modified intent-to-treat, PP: per protocol, HR: hazard ratio, FQs: fluoroquinolone, FQs-S: fluoroquinolone-sensitive, FQs-R: fluoroquinolone-resistant, w: week.

Conclusions: This first real-world evaluation of 6-month CZD-containing regimens in China demonstrates non-inferior early efficacy versus standard therapy with markedly improved neurological/hematological safety. CZD emerges as a viable LZD alternative for RR-TB optimization, though 24-month follow-up will confirm sustained outcomes.
ClinicalTrials Identifier: NCT06081361

OA26-349-21 Safety and efficacy of TBAJ-876 In combination with pretomanid and linezolid: Week 8 analysis result of NC-009

M. Olugbosi,[1] M. Beumont,[2] L. Lombard,[1] R. Dawson,[3] N. Elias Ntinginya,[4] M. Eristavi,[5] H. Mayanja-Kizza,[6] J. Nedelman,[2] J. Timm,[2] T. Black,[2] D. Hickman,[2] E. Sun,[2]
[1]TB Alliance, Research and Development, Sandton, South Africa, [2]TB Alliance, Research and Development, New York, United States of America, [3]University of Cape Town Lung Institute, Centre for TB Research Innovation, Cape Town, South Africa, [4]National Institute for Medical Research (NIMR), Mbeya Medical Research Center (MMRC), Mbeya, United Republic of Tanzania, [5]National Center for Tuberculosis and Lung Diseases, Research and Development, Tbilisi, Georgia, [6]Georgia Case Western Reserve University, Makerere University, College of Health Sciences, Kampala, Uganda
e-mail: morounfolu.olugbosi@tballiance.org

Background: TBAJ-876 is a second-generation diarylquinoline with greater *in vitro* potency, favorable preclinical safety, and treatment-shortening demonstrated in murine models, relative to bedaquiline. In phase 1 studies, TBAJ-876 was safe and well tolerated. NC-009 study is an ongoing randomized, controlled, phase 2 study evaluating 3 doses of TBAJ-876 in combination with pretomanid and linezolid for 8 weeks, followed by HR, and evaluates both 15- and 26-week total treatment durations.
Design/Methods: 309 participants with newly diagnosed, smear-positive, drug sensitive tuberculosis (TB) were equally randomized to 5 treatment arms: HRZE/HR (8-weeks/18 weeks); BPaL (26-weeks); three doses of TBAJ-876 (25, 50, or 100mg) in combination with Pa-L (8 weeks), followed by HR for 7 or 18 weeks. Primary endpoint is time to stable sputum conversion (SSC) by week 8 based on weekly MGIT.
Participants randomized to TBAJ-876 could stop treatment at week 15 based on negative week 8 MGIT result and resolution of TB symptoms.
Results: The proportions of participants with SSC by week 8 were 31%, 46%, 59%, 45% and 45% for the 25, 50, 100mg TBAJ-876PaL, BPaL and HRZE arms, respectively. Hazard ratios for 100mg TBAJ-876 SSC at week 8 versus BPaL and HRZE were 1.53 (95% CI 0.93, 2.52) and 1.37 (95% CI 0.83, 2.27), respectively. Proportions of TBAJ-876PaL participants who met stopping criteria at week 15 were 28%, 46% and 64% in the 25, 50 and 100mg (p <0.001, vs 25 mg) arms, respectively. TBAJ-876PaL was well-tolerated with comparable safety across doses.
Through 8 weeks, the TBAJ-876PaL and BPaL arms experienced fewer ≥grade 3 treatment-emergent adverse events than the HRZE arm.
Conclusions: TBAJ-876 in combination with Pa-L demonstrated dose-dependent efficacy. The 100mg TBAJ-876PaL arm had higher 8-week sputum conversion than BPaL and HRZE, which were comparable, and a favorable safety profile compared with HRZE.

OA26-350-21 Safety of the novel TB vaccine H107e/CAF®10b in BCGexposed, M.tuberculosis-uninfected adults in Gauteng, South Africa: First in human trial

V. Govender,[1] P. Skallerup,[2] A. Borges,[2] K. Mngadi,[1] T. Beattie,[1,3] E. Nemes,[4] C.L. Arlehamn,[2] S.P. Jochems,[5] S.A. Joostens,[5] R.S. Mortensen,[2] G.J. Churchyard,[1,6,7]

e-mail: vgovender@auruminstitute.org

Background: The H107e protein subunit vaccine consists of eight Mtb-specific antigens not shared with BCG, which eliminates the risk of cross-reactivity to BCG. The safety and reactogenicity of H107e-antigen with liposomal adjuvant CAF®10b was evaluated in BCG-exposed, Mtb-uninfected adults.

Design/Methods: A phase 1a open-label trial (nTB-01) was conducted. Healthy IGRA negative adults aged 18-45 years were sequentially enrolled into one of four study arms to receive two intramuscular injections 28-days apart; H107e-antigen (20mcg) [Arm-1], full-dose CAF®10b adjuvant [Arm-2], H107e/low-dose CAF®10b vaccine [Arm-3] or H107e/full-dose CAF®10b vaccine [Arm-4]. Arm-4 participants received H107e-antigen intranasal mucosal recall 56-days post-injection; Arm-4a (15mcg) and Arm-4b (30mcg). Reactogenicity assessments occurred up to 7-days post-investigational product (IP) administrations with seven months follow-up.

Results: From March to September 2024, 40 healthy adults were enrolled into Arm-1 (n=5), Arm-2 (n=5), Arm-3 (n=15) or Arm-4 (n=15). The median age was 22 (IQR:18-42) years, 52.5% male, 97.5% Black-African, with a median BMI of 23.6 (IQR:18.1-31.7) kg/m². Following two injections, 71 solicited injection site reactions occurred in 35/40 (87.5%) participants. The most frequent local reaction was injection site pain in 35/40 (87.5%) participants. Of 107 post-injection solicited systemic reactions in 29/40 (72.5%) participants, headache was most frequent in 19/40 (47.5%). Similarly, of 18 post-intranasal systemic reactions in 5/15 (33.3%) participants; headache occurred in 4/15 (26.7%). Of 24 post-intranasal local solicited reactions the most frequent were nasal congestion and sneezing in 5/15 (33%) participants each. (Table 1) The majority of adverse events (AEs) were mild to moderate with seven severe events reported post-injection; two laboratory abnormalities not related to IP and five resolved solicited systemic reactions in Arm-4. No serious AEs or AEs of special interest were observed.

	H107e (Arm 1) N (%) E [IR]	CAF10b (Arm 2) N (%) E [IR]	H107e/CAF10b-low adjuvant dose (Arm 3) N (%) E [IR]	H107e/CAF10b-full adjuvant dose (Arm 4) N (%) E [IR]	H107e/CAF10b + low dose mucosal recall (Arm 4a) N (%) E [IR]	H107e/CAF10b + full dose mucosal recall (Arm 4b) N (%) E [IR]
Safety analysis set (N)	5	5	15	5	5	10
Any Adverse events	5 (100.0) 29 [0.90]	4 (80.0) 24 [0.74]	15 (100.0) 94 [0.93]	15 (100.0) 147 [1.51]	5 (100.0) 83 [2.50]	10 (100.0) 64 [1.00]
Any Solicited Adverse events*	4 (80.0) 23 [8.77]	4 (80.0) 13 [4.96]	15 (100.0) 65 [8.26]	15 (100.0) 119 [10.08]	5 (100.0) 69 [17.54]	10 (100.0) 50 [6.35]
Any Solicited systemic reactions	4 (80.0) 19	4 (80.0) 10	10 (66.7) 33	11 (73.3) 45	5 (100.0) 31	6 (60.0) 14
Solicited injection site reactions	3 (60.0) 4	3 (60.0) 3	14 (93.3) 32	15 (100.0) 32	5 (100.0) 12	10 (100.0) 20
Solicited local reactions post mucosal recall					4 (80.0) 16	3 (30.0) 8
Solicited systemic reactions post mucosal recall					2 (40.0) 10	3 (30.0) 8

N: Number of participants, %: Percentage of safety analysis set.
E (IR): Number of events and incidence rate calculated as number of events divided by exposure in months.
* (IR) for solicited adverse events are calculated with collection period of solicited adverse events (up to 7 days after each vaccination).

Table 1: Adverse Events by study arm post injection and post intranasal mucosal recall (nTB01).

Conclusions: H107e-antigen and CAF®10b adjuvant at two doses, individually or in combination, and H107e-antigen intranasally were well tolerated in South African BCG-exposed, Mtb-uninfected adults.

OA26-351-21 Enhancing the acceptability of a phase three TB vaccine trial in the Matlosana sub-district of South Africa: Using the Social Marketing Model

B. Napoleon,[1] [1]The Aurum Institute, Clinical Research Division, Klerksdorp, South Africa
e-mail: BNapoleon@auruminstitute.org

Background and challenges to implementation: The biggest take home from the Covid-19 pandemic; was the vaccine misconceptions when ignored these can spill over to trial participation. It is key for researchers to understand barriers and facilitators of vaccine trial acceptance. When left unaddressed vaccine misconceptions poses a barrier to trial participation. To increase the acceptability of a phase three TB vaccine trial, the social marketing model was utilized to promote the acceptance of the trial.
Intervention or response: Focused on four main components product, promotion, place, price.
1. Product: the phase 3 TB trial
2. Promotion-entails communication and facilitating the acceptability of the trial, this was done through dialogues, education and awareness that addressed the misconceptions
3. Place- the contact point- the CRS this is where the trial is conducted,
4. Price- the counter-performance expected from the "consumer" in this case the potential participants, entailed providing clear and transparent information about the trial and study vaccine.
Five steps followed:
1. situational analysis,
2. identifying and analyzing barriers and facilitators,
3. formulating a marketing plan.
4. implementing the marketing plan, and
5. conducting a program evaluation.
Results/Impact: Identified barriers:
1. Concerns around the safety of the study vaccine,
2. Fears that vaccine causes TB,
3. CRS buys and sells blood of volunteers,
4. Gatekeepers e.g. parents, caregivers and legal guardians of adolescents raised concerns about the safety of the vaccine, facilitators the drive to end TB and stakeholder buy in.
The marketing plan addressed barriers and leveraged on facilitators raised in steps 1 and 2. Using the model had a positive impact on community support which increased participation.
Conclusions: Utilizing the model enhanced recruitment efforts and acceptance of the trial by the broader community, potential participants and the gate keepers. The model has the potential to be used when a novel TB vaccine is introduced to the public to enhance acceptability.

OA26-352-21 Imprecision in TB infection outcomes: Implications for non-inferiority vaccine trials

D. Grint,[1] R. White,[1] G. Churchyard,[2] A. Fiore-Gartland,[3] M. Rangaka,[4] A. Garcia-Basteiro,[5] F. Cobelens,[6]
[1]London School of Hygiene and Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [2]Aurum Institute, n/a, Parktown, South Africa, [3]Fred Hutchinson Cancer Centre, Vaccine and Infectious Disease Division, Seattle, United States of America, [4]UCL, Institute for Global Health, London, United Kingdom of Great Britain and Northern Ireland, [5]ISGlobal, Universitat de Barcelona, Barcelona, Spain, [6]University of Amsterdam, Department of Global Health, Amsterdam, Netherlands
e-mail: daniel.grint@lshtm.ac.uk

Background: Randomised trials comparing new vaccines against tuberculosis for use in neonates and infants, for whom Bacille Calmette-Guérin (BCG) vaccination is established practice, are using tuberculosis infection as the primary endpoint in a non-inferiority design. Markers of tuberculosis infection have imperfect sensitivity and specificity. Flaws in the non-inferiority trial design typically bias towards the null, which may result in falsely declaring non-inferiority.
Design/Methods: We conducted a statistical simulation study to assess the impact of imperfect sensitivity and specificity of tuberculosis infection tests on the interpretation of tuberculosis vaccine trials testing a non-inferiority hypothesis of an infection primary outcome.
Data were generated in three 2-year cumulative risk of tuberculosis infection scenarios (2%, 5%, and 8%). The specificity of tests of tuberculosis infection was assumed to range from 100% to 85%, while the sensitivity was assumed to range from 100% to 64%. Log-binomial regression was used to estimate the relative risk of tuberculosis infection in simulated trials. We assessed the type-I and type-II error implied by these simulated trials.

Test accuracy	Control vaccine		Experimental vaccine		Type-I error (alpha)		
Sensitivity; Specificity	True risk of TB infection	Observed risk of TB infection	True risk of TB infection	Observed risk of TB infection	Expected type-I error	Estimated type-I error	Monte Carlo error
100%; 100%	0.02	0.02	0.025	0.025	2.5%	2.2%	0.3%
100%; 100%	0.05	0.05	0.0625	0.0625	2.5%	2.5%	0.3%
100%; 100%	0.08	0.08	0.10	0.10	2.5%	2.0%	0.3%
95%; 95%	0.02	0.068	0.025	0.073	2.5%	96.8%	0.4%
95%; 95%	0.05	0.095	0.0625	0.106	2.5%	53.2%	1.1%
95%; 95%	0.08	0.122	0.10	0.140	2.5%	27.8%	1.0%

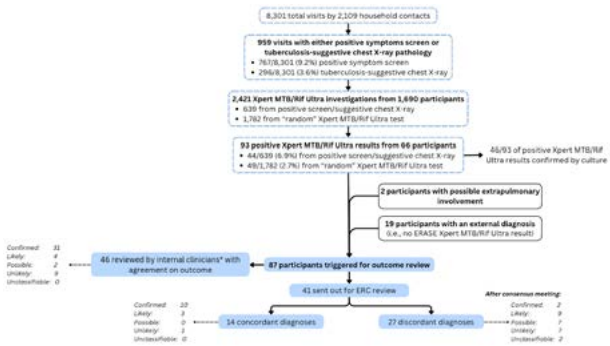
Table shows the simulated observed risk of TB infection for an experimental vaccine for which the true risk of TB infection is 1.25 times higher than the control vaccine and the risk of falsely declaring non-inferiority of the experimental vaccine.
TB: tuberculosis;
Expected type-I error: type-I error (alpha) per the study design parameters.
Estimated type-I error: Probability of falsely declaring non-inferiority when the true risk of TB infection is 1.25 times higher with the experimental vaccine.
Monte Carlo error: standard error of the estmated type-I error due to random variation in the simulation procedure.

Results: With 100% sensitivity and specificity, type-I and type-II error were both approximately equal to the expected values (2.5% and 80%, respectively). With modest deviations from perfect sensitivity and specificity (95% for both), the risk of falsely declaring non-inferiority (type-I error) was 96.8%, 53.2%, and 27.8% in the 2%, 5%, and 8% cumulative tuberculosis risk infection scenarios, respectively (Table).
Conclusions: Tuberculosis vaccine non-inferiority trials using an infection primary outcome must be designed and interpreted accounting for the specificity of the tests used to measure infection, otherwise they risk declaring non-inferiority by default. Until there is a test for TB infection with higher specificity than the interferon-gamma release assay, the use of the non-inferiority trial design for TB vaccine prevention of infection outcomes is not recommended.

OA26-353-21 Refining research outcomes: Lessons from the setup of an endpoint review committee in TB observational diagnostic studies

L. Larsson,[1] C. Calderwood,[2,3] E. Marambire,[3,1] D. Banze,[4] A. Mfinanga,[5] K. Held,[1,6] C. Khosa,[4] T. Minja,[5] J. Mutsvangwa,[7] N. Heinrich,[1,6] K. Kranzer,[8,3,1] ERASE-TB consortium
[1]LMU University Hospital, Institute of Infectious Diseases and Tropical Medicine, Munich, Germany, [2]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom of Great Britain and Northern Ireland, [3]Biomedical Research and Training Institute, The Health Research Unit Zimbabwe, Harare, Zimbabwe, [4]Instituto Nacional de Saúde, Instituto Nacional de Saúde, Maracuene, Mozambique, [5]National Institute for Medical Research, Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, [6]German Center for Infection Research, Partner Site Munich, Munich, Germany, [7]Biomedical Research and Training Institute, Biomedical Research and Training Institute, Harare, Zimbabwe, [8]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom of Great Britain and Northern Ireland
e-mail: llarsson3@outlook.com

Background: Diagnosing tuberculosis remains challenging and limitations of current diagnostic tools. ERASE-TB, a longitudinal cohort study conducted across three high-burden countries, aimed to validate novel diagnostics for early detection of tuberculosis. To ensure high-fidelity outcomes, an Endpoint Review Committee (ERC) was convened.
Design/Methods: ERASE-TB enrolled 2,109 household contacts, who were followed up every 6 months for a maximum of 24 months, with comprehensive clinical, microbiological, and radiological assessments at each visit. Clinical presentation, radiological and microbiological results were summarised for participants who underwent in-depth tuberculosis investigation due to a suggestive X-ray or positive Xpert MTB/Rif Ultra Two study team clinicians reviewed the clinical summaries, with discordant decisions assessed by the ERC (four members including a programme manager, clinicians, and a radiologists) who classified cases based on predefined definitions (confirmed, likely, possible, unlikely).
A consensus meeting was organised to resolve discordances. Semi-structured interviews with ERC members explored their experiences and challenges in tuberculosis classification.
Results: A total of 87 clinical summaries underwent review, 46 were agreed internally, with the majority being categorised as confirmed tuberculosis (31/46, 67.4%). Among the remaining 41, the ERC reviewers agreed on only 14 (34.1%) classifications, with the majority being classified as confirmed tuberculosis (10/14, 71.4%).
Following the consensus meeting for the discordant 27, most were classified as likely (9/27, 33.3%), followed by possible and unlikely (both 7/27, 25.9%). Discordances between reviewers were associated with their professional background. Qualitative interviews highlighted the complexity of tuberculosis diagnosis, value of longitudinal measurements and the tension between academic and clinical pursuits as the prospective clinical judgement would have likely been different to this retrospective academic analysis.



Conclusions: Standardized tuberculosis classification frameworks and real-time expert review can improve diagnostic accuracy and comparability across studies. Future research should integrate ERC processes prospectively to refine tuberculosis case definitions and ensure robust clinical and research outcomes.

OA26-354-21 TRIDORE: Intensive-phase-throughout regimen is safer and more efficacious than triple-dose regimen for retreatment of rifampicin-susceptible TB

M.B. Souleymane,[1] A. Piubello,[2] S. Kadri,[3] A. Soumana,[4] M. Gumusboga,[5] A. Tsoumanis,[6] N. Herssens,[6] H. Landuyt,[6] B. de Jong,[5] L. Lynen,[6] T. Decroo,[6] [1]Damien Foundation Niger, Damien Foundation Niger, Niamey, Niger, [2]Damien Foundation, Brussels, Belgium, Damien Foundation, Brussels, Belgium, Brussels, Italy, [3]Centre Hospitalier Regional de Niamey, Centre Hospitalier Regional de Niamey, Niamey, Niger, [4]Programme National de Lutte contre la Tuberculose, Programme National de Lutte contre la Tuberculose, Niamey, Niger, [5]Institute of Tropical Medicine Antwerp, Biomedical Sciences, Antwerp, Belgium, [6]Institute of Tropical Medicine Antwerp, Clinical Sciences, Antwerp, Belgium
e-mail: bachirsoul@gmail.com

Background: High-dose rifampicin and isoniazid are known to be safe but were not yet combined in a single regimen.
TRIDORE (TRIple-DOse RE-treatment, Clinicaltrials.Gov=NCT04260477) is a pragmatic open-label randomized clinical trial in nine Niger National Tuberculosis Program clinics supported by Damien Foundation.
In previously treated patients with rifampicin-susceptible recurrent tuberculosis (TB), we compared a 6-month first-line regimen, including triple-dose of both rifampicin and isoniazid, with a 6-month intensive-phase-throughout regimen. We assessed non-inferiority (10% margin) for safety and compared efficacy.
Design/Methods: Pragmatic open-label randomized clinical trial. Consenting participants were randomly assigned to either the intervention arm ($6R^3H^3ZE$, with pyridoxin; R^3: 30 mg rifampicin/kg, H^3: 15 mg isoniazid/kg; Z: pyrazinamide; E: ethambutol) or the control arm (6RHZE). Routine monitoring and liver function tests (ALT) were performed at fixed intervals. The primary safety endpoint was the occurrence of any TB drug-related grade 3-5 adverse event (AE).
Non-inferiority was assessed with a 95%CI around the difference (10% non-inferiority margin). The efficacy endpoint was treatment success versus unfavorable outcomes, with correction for re-infection.
Results: Between March 2021 and February 2022, 129 patients were enrolled: 65 and 64 were treated with $6R^3H^3ZE$ and 6RHZE, respectively (Table 1).
For the primary safety endpoint $6R^3H^3ZE$ was not non-inferior to 6RHZE (difference 7.7%: 7.7% vs 0.0%; p=0.02; 95%CI:1.2,14.1; with upper bound above 10%), and was associated with significantly more serious adverse events (16.9% vs 4.7%, p=0.04).
Moreover, $6R^3H^3ZE$ was less efficacious than 6RHZE (86.2% vs 96.8% success, p=0.03).

	Total	$6R^3H^3ZE$		6HRZE	
Total safety analysis	**129**	**65**		**64**	
Any grade 3-5 AE $	5	5	7.7%	0	0.0%
Serious AE	14	11	16.9%	3	4.7%
Hepatotoxicity #	4	4	6.2%	0	0.0%
Total efficacy analysis µ	**128**	**65**		**63**	
Success	**117**	**56**	**86.2%**	**61**	**96.8%**
Cure	114	55	84.6%	59	93.7%

Unfavourable outcome	**11**	**9**	**13.8%**	**2**	**3.2%**
Failure - same strain	0	0	0.0%	0	0.0%
Died	7	5	7.7%	2	3.2%
LTFU	1	1	1.5%	0	0.0%
Discontinued £	3	3	4.6%	0	0.0%

$ Assessed as probably or definitively related
# Grade 3 or higher increase of ALT, or grade 2 increase with jaundice
µ One patients excluded from the efficacy analysis
£ Patient's decision
AE: adverse event

Table 1. Safety and treatment outcomes in patients treated in the TRIDORE trial, randomised to either a triple-dose or intensive-phase throughout first-line re-treatment regimen.

Conclusions: In patients in need of retreatment for rifampicin-susceptible TB, the TRIDORE trial showed that a triple-dose regimen was not non-inferior compared to an intensive-phase-throughout regimen in terms of safety. The triple-dose regimen was associated with both the occurrence of unfavorable safety and treatment outcomes. We propose the intensive-phase-throughout regimen for the retreatment of rifampicin-susceptible TB.

OA26-355-21 Multi-method monitoring of response to individualised all-oral drug-resistant TB therapy reveals rapid conversion to negative in three high burden countries

W. Sabiiti,[1] B. Mtafya,[2] S. Georghiou,[3] E. Okpokoro,[4] G. Seid,[5] A. Meaza,[5] E. Tiermersma,[6] S. Hermans,[7] A. Naidoo,[8] A. Abimiku,[4] N.E. Ntinginya,[9] K. Naidoo,[8] TriAD Consortium [1]University of St Andrews, School of Medicine, St Andrews, United Kingdom of Great Britain and Northern Ireland, [2]National Institute for Medical Research, Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, [3]FIND, Global Health Campus, Geneva, United States of America, [4]Institute of Human Virology Nigeria, International Research Centre of Excellence, Abuja, Nigeria, [5]Ethiopia Public Health Institute, National TB Reference Lab, Addis Ababa, Ethiopia, [6]KNCV TBPlus, KNCV, Hague, Netherlands, [7]Amsterdam Institute of Global Health and Development, Global Health, Amsterdam, Netherlands, [8]Centre for the AIDS Programme of Research in South Africa (CAPRISA), TB Research, Durban, South Africa, [9]National Institute for Medical Research, Directorate of Research, Dar es Salaam, United Republic of Tanzania
e-mail: ws31@st-andrews.ac.uk

Background: The global scale-up of all-oral regimens for drug-resistant tuberculosis (DR-TB) demands reliable tools to monitor treatment response. Conventional bacteriological methods are slow or insensitive. This study

evaluated the molecular bacterial load assay (TB-MBLA), Mycobacteria Growth Indicator Tube (MGIT) culture and smear microscopy (SM) to monitor DR-TB treatment response.

Design/Methods: In Cohort 1 of the TRiAD study, participants with rifampicin-resistant TB (RR-TB) in Ethiopia, Nigeria and South Africa were tested using the Xpert XDR assay to determine resistance to first- and second-line drugs and were prescribed individualized, all-oral regimens accordingly. TB-MBLA (in a subset), MGIT, and SM were used longitudinally to assess treatment response. Outcomes included changes in bacterial load (log_{10}CFU/mL), MGIT time-to-positivity (TTP), and smear grade (SG). Scanty SG was quantified as +0.25 for analysis purposes. Analysis focused on early response (month 2) and sustained response (month 9).

Results: Overall, 845 participants were enrolled with 401 receiving pre-treatment TB-MBLA test of whom 276 were positive and included in longitudinal treatment response analysis. By month two, >80% had converted to negative across all three methods. At month 9, positivity fell to 0.7% (SM), 1.5% (MGIT), and 0.0% (TB-MBLA) (Figure 1A). Rate of TB-MBLA-measured bacterial load clearance was consistent with increasing MGIT TTP, median bacterial load dropped from 4.4(3.1-5.3) to 0.0(0.0-0.0) log_{10}CFU/mL and correspondingly, TTP increased from 13(8.3-25.8) to 42(33-42) days by month-2 of treatment, and remained so throughout the treatment follow-up period. The median SG dropped from +1(0.3-2) to +0.3(0.3-0.3) by month-9 of treatment but had the lowest consistency due to many missed measurements post-month-2 of treatment. High pre-treatment bacterial load was correlated with short TTP, and high SG (Figure 1B).

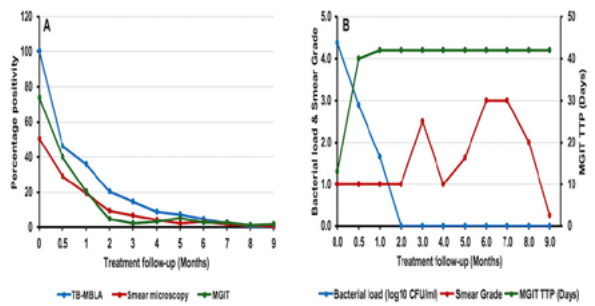

Figure 1: Treatment response measured by tuberculosis Molecular Bacterial Load Assay (TB-MBLA-blue curve), Mycobacteria Growth Indicator Tube (MGIT-green curve) and Smear Microscopy (SM-red curve). A) Decreasing proportion of participants that were TB positive by TB-MBLA, MGIT and SM across 9 months of treatment follow-up. B) The median bacterial load, time-to-positivity (TTP) and Smear grade by TB-MBLA, MGIT and SM across the treatment follow-up period. Higher bacillary load corresponded to shorter MGIT TTP. Fewer data points post month-2 made median smear grade results inconsistent to TB-MBLA and MGIT.

Conclusions: Individualised DR-TB treatment achieves faster rate of conversion-to-negative. The 4h-to-result TB-MBLA test enables early, culture-free monitoring of treatment response, its integration could strengthen clinical management and accelerate programmatic decision-making in high-burden settings.

OA26-356-21 Nebulised bronchodilator-enhanced sputum induction in presumed smear-negative pulmonary TB: A randomised controlled trial (NeB-TB)

P. Mingchay,[1] K. Kawkitinarong,[2] P. Torvorapanit,[1] G. Suwanpimolkul,[1] [1]Chulalongkorn University, Division of Infectious Diseases, Department of Medicine, Faculty of Medicine, Bangkok, Thailand, [2]Chulalongkorn University, Division of Pulmonary Medicine and Pulmonary Critical Care, Department of Medicine, Faculty of Medicine, Bangkok, Thailand
e-mail: m.pichanon@gmail.com

Background: Delayed diagnosis of pulmonary tuberculosis (TB), especially in settings with limited bronchoscopy resources, worsens clinical outcomes and increases transmission risks. Sputum induction is a non-invasive and effective alternative, but improvements in the induction method could further enhance TB diagnostic yield.

We investigated whether adding nebulized bronchodilators could enhance sputum induction effectiveness in patients with clinically presumed smear-negative pulmonary TB.

Design/Methods: In this randomized controlled trial conducted at King Chulalongkorn Memorial Hospital, Thailand, 204 adults with clinically presumed pulmonary TB and negative Xpert MTB/RIF Ultra results or insufficient sputum production were enrolled between June and September 2024.

Participants were randomly assigned to either conventional sputum induction using 3% hypertonic saline alone (n=101), or the novel sputum induction using nebulized bronchodilator combined with 3% hypertonic saline (n=103).

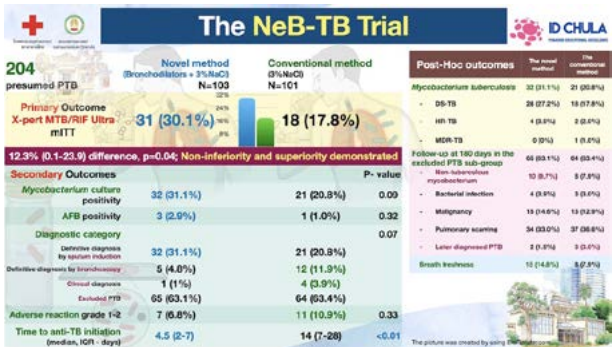
The primary outcome was the proportion of confirmed TB diagnoses via Xpert MTB/RIF assay.

(*Clinical Trials Registration:* TCTR20240709001)

Results: TB diagnosis rates by Xpert MTB/RIF were significantly higher in the novel group (30.1%; number needed to diagnose [NND]=4) compared to the conventional group (17.8%; NND=6), with a difference of 12.3% (95% CI: 0.1–23.9%, p=0.04). The novel sputum induction method increased mycobacterial culture positivity (31.1% vs. 20.8%) and reduced the need for bronchoscopy (4.8% vs. 11.9%).

Participants in the novel group reported fewer adverse reactions, greater comfort, required fewer induction rounds, and initiated TB treatment significantly sooner (4.5 vs. 14 days; p<0.01).

The method was particularly beneficial for outpatients (p=0.04) and showed promising trends in patients with chronic obstructive pulmonary disease.



Conclusions: The novel sputum induction using nebulized bronchodilators demonstrated superiority over conventional induction, resulting in higher diagnostic yield, improved patient comfort, reduced need for invasive procedures, and accelerated initiation of TB treatment. This safe, cost-effective, and patient-friendly method could transform TB diagnostics, especially in resource-limited settings.

OA26-357-21 UNITE4TB – DECISION: A BTZ-043 phase IIB dose-ranging trial in combination with bedaquiline and delamanid

M. Hoelscher,[1,2,3,4] B. Aldana,[5] E. Basson,[1,2] F. Ryklief,[6] L. Botha,[7] F. Saluzzo,[8] K. Jeremiah,[9] L.T. Minja,[10] [1]Tropical Institute at LMU University Hospital, Munich, Germany, [2]German Center for Infection Research (DZIF), Munich partner site, Munich, Germany, [3]Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Immunology, Infection, and Pandemic Research, Munich, Germany, [4]Helmholtz Center Munich, German Research Center for Environmental Health, Munich, Germany, [5]UCSF Center for Tuberculosis, University of California San Francisco, San Francisco, United States of America, [6]TASK, Cape Town, South Africa, [7]TASK EDEN, Eden, South Africa, [8]Vita Salute San Raffaele University, Milan, Italy, [9]National Institute for Medical Research (NIMR), Mwanza, United Republic of Tanzania, [10]National Institute for Medical Research (NIMR), Mbeya, United Republic of Tanzania
e-mail: hoelscher@lrz.uni-muenchen.de

Background: BTZ-043, a DprE1-inhibitor with proven bactericidal activity in phase IIA trials is one of six novel drug candidates currently under evaluation in phase II trials within UNITE4TB, a large European-led TB clinical trials network.

Design/Methods: UNITE4TB-DECISION is a Phase IIB, Open-Label, Randomized Controlled dose-ranging trial to define the safety, tolerability, pharmacokinetics, and exposure-response relationship of three doses of BTZ-043 (T) in combination with Bedaquiline (B) and Delamanid (D).

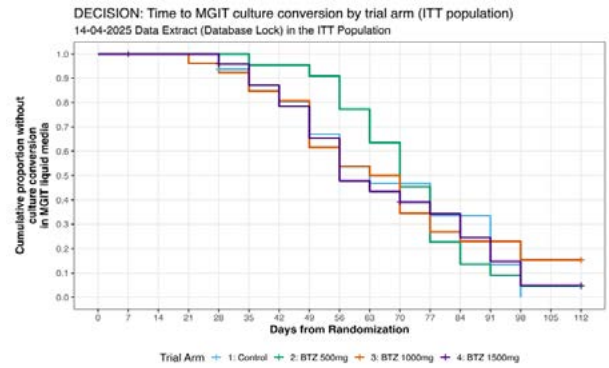
In Tanzania and South Africa, adults participant with newly diagnosed drug-sensitive pulmonary tuberculosis were randomized into one of four treatment arms: BTZ-043 500mg (BDT_{500mg}), 1000mg (BDT_{1000mg}),1500mg (BDT_{1500mg}), or Moxifloxacin 400mg (BDM) each added to bedaquiline and delamanid for 16 weeks. Sputum samples were taken weekly to measure the change in bacterial load by time to positivity (TTP) using the mycobacterial growth indicator tube system (MGIT™). Safety was assessed through weekly electrocardiography, safety blood tests, vision testing, and physical and neurological examinations. Pharmacokinetic measurements were done at week 4 and 8.

Results: Between September 2023 and July 2024 183 individuals were screened for eligibility. 92 were enrolled and assigned to BDT_{500mg} (n=22), BDT_{1000mg} (n=28), BDT_{1500mg} (n=26) and BDM (n=16).

81.5% of participants were male, 90.2% were HIV negative.

64.1% had baseline grade 3+ smear results, and 77.2% had cavities. Three participants (one in each BTZ-043 arm) experienced serious adverse events: increased liver enzymes, hepatotoxicity and brief psychiatric disorder. Nine participants experienced grade 3 events.

No grade 4 events occurred. The slope of increase of TTP over time was comparable between BDT_{1000mg}, BDT_{1500mg} and BDM; the slope for BDT_{500mg} was lower than BDM, p = 0.005. Time to culture conversion showed consistent results (Figure).



Conclusions: Pending the final PK-PD model, we conclude that BTZ-043 1000mg is the appropriate dose based on tolerability, efficacy, and tablet burden for further clinical development in UNITE4TB.

OA27 Institutional hotspots: Addressing TB transmission in hospitals and prisons

OA27-358-21 Spatial distribution of TB among healthcare workers in Brazil: High-density areas and occupational risk (2013-2023)

F.A. Dias e Sanches,[1,2] M.G.d.M. Sérgio,[3] K.d.S. Rodrigues,[4] L.d.C. Cezarino,[3] T.C. Gatto,[3] R.F. da Silva,[5] G.S.d. Carvalho,[3] F.L. Romero Vega,[6] M. Yamamura,[3] [1]Federal University of Rio de Janeiro, Tuberculosis Research Center, Rio de Janeiro, Brazil, [2]Piquet Carneiro University Policlinic, Governance and Compliace and Infection Prevention and Control comission, Rio de Janeiro, Brazil, [3]Federal University of São Carlos, Nursing School, São Carlos, Brazil, [4]Federal University of São Carlos, Social Science School, São Carlos, Brazil, [5]FIOCRUZ / Ministry of Health, National Institute of Infectious Diseases, Rio de Janeiro, Brazil, [6]Ministry of Health, Brazil, National Tuberculosis Program, Brasília, Brazil
e-mail: sanches@hucff.ufrj.br

Background: Certain occupational categories face significantly higher risk of tuberculosis infection compared to the general population. The main risk groups include nursing professionals (3-20 times higher risk), clinical pathologists (6-11 times), bacteriology laboratory technicians (2-9 times), pulmonologists (6 times), and students of Medicine, Nursing, and Physiotherapy (4-8 times).
This study aimed to identify the clinical forms, years, and regions with the highest TB case density among healthcare professionals in Brazil.
Design/Methods: This ecological exploratory study analyzed all 27 Brazilian federative units. The population comprised TB cases among healthcare professionals (2013-2023), using data from DATASUS and IBGE. Researchers conducted descriptive analyses, geospatial analysis, and spatial variation analysis using kernel density estimation with QGIS 3.35.15.
Results: The study identified 10,247 TB cases among healthcare professionals. Pulmonary form accounted for 70% of cases, extrapulmonary 26.2%, and 3.8% presented both forms. 2018 and 2020 had the highest notifications, while 2022-2023 showed increases totaling 1,188 cases. Kernel density analysis identified hotspots in São Paulo, Rio de Janeiro, Espírito Santo, and Minas Gerais.
Conclusions: Brazil continues to show high TB occurrence among healthcare professionals. Only two states with highest case density in this population coincide with states having highest TB incidence generally.
This highlights how urban density impacts occupational exposure. Specific protective actions needed include periodic TB screening, integrated notification systems, and continuous monitoring of work environments.

OA27-359-21 Beyond the workplace: A qualitative study of the impact of TB-related stigma on the private lives of healthcare workers in Indonesia

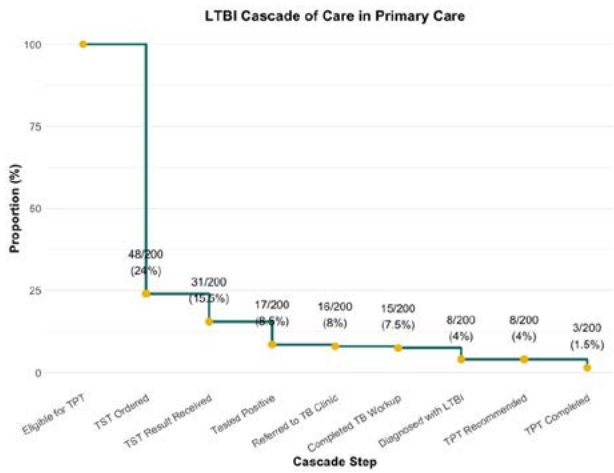
A. Fitriangga,[1] A. Alex,[1] [1]Universitas TanjungPura, Community Medicine, Pontianak, Indonesia
e-mail: afitriangga@medical.untan.ac.id

Background: Tuberculosis (TB)-related stigma affects not only patients but also healthcare workers (HCWs) involved in TB care. While previous research has focused on workplace discrimination, limited studies explore how stigma influences HCWs‘ private lives. This study examines the **social, familial, and psychological impact** of TB stigma on HCWs.
Design/Methods: A qualitative study was conducted using semi-structured in-depth interviews with 30 HCWs across West Kalimantan Province, West Sumatra Province, and South Sulawesi Province, Indonesia. Participants were purposively sampled from hospitals, primary healthcare centers, and TB treatment units. Interviews were transcribed, coded, and thematically analyzed using Braun and Clarke's framework.
Results: Healthcare workers reported experiencing TB-related stigma that significantly impacted their personal lives. Social exclusion was common, with participants describing instances of avoidance, rejection, and discriminatory behavior from neighbors and community members who feared transmission. Within their families, several HCWs encountered emotional distance and mistrust, as spouses and relatives expressed concerns about infection, leading to strained relationships and feelings of isolation.
This contributed to considerable psychological distress, including anxiety, emotional exhaustion, and a sense of being misunderstood or devalued. Many HCWs also engaged in self-isolation and actively avoided disclosing their professional roles, particularly in social settings, to protect themselves from further stigma.
Finally, participants highlighted a lack of institutional support, noting the absence of formal mechanisms to address stigma or provide mental health assistance. In response, they relied on individual coping strategies, such as self-motivation, spirituality, or peer support, to manage the emotional burden.
Conclusions: TB-related stigma extends beyond the workplace, affecting HCWs‘ personal relationships and mental health. Addressing this issue requires community education to dispel TB misconceptions, family-based interventions to foster support, institutional policies to create stigma-free workplaces, and mental health services to protect HCWs‘ well-being. Multi-level interventions are essential to reducing HCW stigma and strengthening TB control efforts in Indonesia.

OA27-360-21 The uptake of TB preventive therapy among primary healthcare practitioners: A retrospective cohort study from Montreal

M. Azimi,[1,2] A. de Pokomandy,[1] L. MacLaren,[1] R. Menzies,[3,2] [1]McGill University, Department of Family Medicine, Montreal, Canada, [2]Research Institute of the McGill University Health Centre, Respiratory Epidemiology and Clinical Research Unit, Centre for Outcomes Research and Evaluation, Montreal, Canada, [3]McGill University, Department of Medicine, Montreal, Canada
e-mail: mojdeh.azimi@mail.mcgill.ca

Background: Tuberculosis (TB) remains an important public health problem in Canada, with foreign-born individuals in Canada being disproportionately affected(1).
Since 5–10% of individuals with TB infection (TBI) progress to active disease, TB preventive therapy (TPT) is crucial for reducing the disease burden(2).
Despite established guidelines, significant drop-offs occur in the TBI care cascade(3). Primary care settings are promising for improving TPT uptake due to strong patient-provider relationships(4).
This study aims to assess primary care's performance in the cascade of TBI care.
Design/Methods: This retrospective chart review was conducted at a primary care clinic in Parc Extension serving predominantly immigrants and refugees. Electronic medical records were used to recreate the cascade of care for TBI. Bivariate logistic regression was used to study the association between patient characteristics and the probability of being tested in primary care.



Results: We reviewed 677 charts to identify 200 patients eligible for TBI testing, whose mean age was 36.1 years (± 17.2), and 70% were females. Only 48/200 (24%) had a TST ordered, representing the most significant point of attrition in the cascade of care. 48 patients (24%) were tested, 31(15.5%) received their test results, and 17 (54% of the tested) were TST-positive. 16 (8%) were referred to TB clinic for evaluation of TB disease, 15(7.5%) completed evaluation to exclude TB disease, 8 (4%) were diagnosed with LTBI, and all had the recommendation to start TPT. Only 3 (1.5%) completed the treatment. Having the first contact with primary care for perinatal care was significantly associated with lower odds of LTBI testing among women (OR = 0.063; 95% CI: 0.014–0.281; $p < 0.001$).
Conclusions: The cascade of care of TBI in this primary care setting was very low. Identifying opportunities to support primary care providers in testing for TB infection and follow-up on TPT could meaningfully improve completion rates.

OA27-361-21 Lessons from occupational screening for TB disease using chest radiography in health workers in South Africa

A. van der Westhuizen,[1] L. MacIntyre,[2] S. Minnies,[1] H. Kotzé,[3] B. Jali-Gola,[1] J.C. Fortuin,[1] B. Allwood,[4] J. Taljaard,[5] C. Ackermann,[3] J. Meintjes,[6] G. Theron,[1] R. Nathavitharana,[7] [1]Stellenbosch University, Division of Molecular Biology and Human Genetics, Cape Town, South Africa, [2]Beth Israel Deaconess Medical Center, Division of Infectious Diseases, Boston, United States of America, [3]Stellenbosch University & Tygerberg Hospital, Division of Radiodiagnosis, Cape Town, South Africa, [4]Stellenbosch University & Tygerberg Hospital, Division of Pulmonology, Cape Town, South Africa, [5]Stellenbosch University & Tygerberg Hospital, Division of Infectious Diseases, Cape Town, South Africa, [6]Stellenbosch University & Tygerberg Hospital, Division of Occupational Medicine, Cape Town, South Africa, [7]Beth Israel Deaconess Medical Center & Harvard Medical School, Division of Infectious Diseases, Boston, United States of America
e-mail: drananjavdw@gmail.com

Background and challenges to implementation: Despite recommendations for occupational health worker (HW) screening for tuberculosis (TB) disease, implementation remains limited. Given high population-level rates of asymptomatic TB, symptom-based screening alone is insufficient. Furthermore, better understanding of HW perspectives is needed to address screening implementation barriers.
Intervention or response: Nested within a study on TB infection in HWs, we implemented an occupational TB disease screening programme among 149 HWs (120 females, median age 27 years, median clinical experience 2 years) at two tertiary hospitals in Cape Town, South Africa. HWs included doctors (n=56), nurses (n=50), allied health and support staff (n=43) without a prior TB history who underwent symptom screening and chest radiography (CXR). A subset (n=12) participated in semi-structured interviews, analysed using the Constrains, Actions, Risks, and Desires (CARD) framework.

Results/Impact: 125 HWs completed baseline CXR screening, with 12 CXRs (10%) reported as abnormal, of which 6 were lung-related and 6 non-pulmonary (Figure). None were diagnosed with TB by sputum Xpert or culture. Abnormal CXRs were reviewed and repeated or referred. HWs acknowledged TB exposure as part of their work environment but did not consistently use protective measures like N95 respirators. They highlighted common delays in diagnosing patients with TB related to systemic constraints that increased HW risk. While not all HWs were able to complete baseline CXR screening, others found doing it at their place of work was a facilitator. HWs appreciated occupational TB screening, while recognising budget constraints for such programmes.

Chest radiography in occupational TB screening: results and HW experiences

Abnormal chest radiographs: 12/125	
Lung abnormalities	**Other abnormalities**
Hilar lymphadenopathy[1]	Increased cardiothoracic ratio[1]
Patchy airspace opacification[1]	Incidental hiatus hernia[1]
Small pleural effusion with atelectasis[1]	Breast nodule[2]
Coarse peribronchovascular markings[1]	Supraclavicular soft tissue abnormality[1]
Right middle lobe opacification[2]	Diaphragmatic nodule[1]
Small airways disease[3]	Rib notching (concern for coarctation)[2]
[1]Sputum Xpert Ultra negative *[2]Resolution on repeat Xray* *[3]Referred to pulmonologist*	*[1]Reviewed and not thought to be significant* *[2]Referred for medical evaluation*

Health workers' views on occupational TB screening	
C ♣ Constraint	*[should occupational screening for TB be available to health workers?] Yes, if it's within a budget that is feasible for our country.* *I think the chest X-ray has been the thing I've struggled most with, to actually it get done.*
A ♦ Action	*In the acute admissions ward, the patients come in with anything and everything, so the probability of TB is there, but it was never such a cause for anxiety that I thought of wearing a N95 mask.* *I didn't know what to expect when I saw the result of the chest x-ray, obviously I don't know how to read it, so I rely a lot on the report.*
R ♠ Risk	*I've come into contact with so many TB patients. They weren't supposed to have TB, but they ended up having TB. They came in for shortness of breath or for asthma. Turns out they had TB.* *I do think it [TB screening] made me more aware of the fact that I am at risk for TB. The fact that I was continuously screened did bring that to the front of my mind that listen, I am at risk, I could be infected at any point.*
D ♥ Desire	*It was nice that it [occupational TB screening] was available, the CXR and then also the GeneXpert. Because we are exposed everyday.* *…because you work here, it's a lot easier to just pop in when you have an hour at lunch, you just quickly do your X-ray.*

Conclusions: Occupational TB screening using CXR was feasible in our setting. Despite the low yield of TB disease, 10% had abnormal CXRs requiring review, highlighting the potential benefits and challenges of screening asymptomatic HWs. Occupational health services must be equipped to interpret and manage these findings, with clear referral pathways.

This study provides practical insights into the design and resourcing needs for scaling up occupational TB screening.

OA27-362-21 Evaluating TB treatment outcomes among healthcare workers in Zambia (2018–2022): A key strategy for enhancing healthcare workers' safety

C.C. Kasapo,[1] J.M. Chama,[1] E. Sinkamba,[1] Z. Mvula,[1] J. Mzyece,[1] A. Mubanga,[1] K. Mushota,[1] R. Chimzizi,[1] P. Saili Lungu,[1] [1]Ministry of Health, Public Health, Lusaka, Zambia
e-mail: mpunduj@gmail.com

Background and challenges to implementation: Healthcare workers (HCWs) face a heightened risk of contracting tuberculosis (TB) compared to the general public, primarily due to increased exposure and inadequate infection control measures. Prompt identification and treatment of TB among HCWs not only safeguard their quality of life but also prevent adverse outcomes, including mortality. In 2018, Zambia launched a nation-wide bi-annual TB screening programme for HCWs, which included symptom and X-ray screening and sputum examinations utilizing GeneXpert and other rapid diagnostic tools. We assessed the TB treatment outcomes in HCWs diagnosed with TB over five years from 2018 to 2022.

Intervention or response: An evaluation of the TB treatment outcomes of HCWs diagnosed with TB from 2018 to 2022 was conducted using a structured cohort analysis approach. Potential factors affecting successful TB treatment were identified through a comprehensive review of treatment records, analysis of routine programme data, and consultation with healthcare workers. Root cause analysis used structured interviews and field observations to explore factors contributing to treatment outcomes.

Results/Impact: 594 HCWs were enrolled in TB treatment over five years, achieving a treatment success rate of 95% (566/594). Among those successfully treated, 35% were declared cured, while 60.4% (360/565) completed their treatment.

Unfavorable outcomes occurred in 5% (28/594) of cases, with 79% (23/30) of these resulting in death before treatment completion. Although patients had known physical addresses, follow-up was hindered by stigma and privacy concerns, leading to some cases being lost to follow-up (LTFU) or not evaluated.

Conclusions: Although the overall treatment success rate among HCWs was high, the findings highlight the need to address gaps in care, particularly about mortality and LTFU. To address gaps, targeted strategies are needed to enhance treatment adherence, TB Preventive Treatment (TPT), and robust workplace infection prevention and control measures.

Additionally, understanding the extent of stigma and discrimination among HCWs requires further study.

OA27-363-21 TB preventive treatment among health workers in Pakistan: Cross-country comparison of outcomes and gaps

K.U. Eman,[1] U.R. Lodhi,[1] T. Asif,[1] B. Kirubi,[2] J. Creswell,[2] S. Tahseen,[1] [1]Dopasi Foundation, Programs, Islamabad, Pakistan, [2]Stop TB Partnership, TB Reach, Geneva, Switzerland
e-mail: kinza_kz@yahoo.com

Background: Health care workers (HCWs) are at significantly higher risk of tuberculosis (TB) infection due to their frequent and prolonged exposure to TB patients, especially in settings with inadequate infection prevention and control (IPC) measures. While global guidelines strongly recommend TB preventive treatment (TPT) for HCWs, studies consistently report low uptake and poor adherence.
Design/Methods: An interventional study titled "Prevent TB to End TB Project", under the TB REACH initiative, was implemented across 61 health facilities in nine districts of Pakistan. HCW, along with other high-risk groups, were screened using symptom assessment and chest radiography.
After ruling out active TB, eligible HCWs were offered rifapentine-based short-course TPT regimens. Data were analyzed to assess TPT initiation and completion rates among HCWs.
In addition, a literature review was conducted to compare uptake and programmatic outcomes from similar interventions in other countries.

Country	Period	Uptake	Completion	Regimen	Key Barriers
Pakistan	2023-24	63%	98%	3HP	Moderate hesitancy, logistical gaps, side effect concerns
India	2022-23	0.9%	Not Mentioned	3HP	Low awareness, side effect concerns
China	2022	Low	Not Mentioned	6H	Attitude–action gap, side effect concerns
Indonesia	2022	Not reported	Not Mentioned	6H	Limited TPT data despite high LTBI burden
Russia	N/a	Not reported	Not Mentioned	Not Mentioned	Risk desensitization among HCWs, Low awareness,
South Africa	2021-22 (Eswatini)	21%	Not Mentioned	6H	Role ambiguity, weak accountability mechanisms, Low awareness,
Phillipines	2018-20	2%	Not Mentioned	6H	Systemic implementation bottlenecks, Low awareness,
Kenya	2022	Does not mention how many in total were offered - Initiated in 14,948 HCWs	80%	6H	Delayed outcome tracking, adverse events

Table.

Results: Out of 1,101 eligible HCW screened in Pakistan, 63% initiated TPT, and among these 98% successfully completed treatment. High treatment-compliance was attributed to short course, close follow up and digital tracking systems.
In contrast, comparative data from India, China, Indonesia, Russia, South Africa, the Philippines, and Kenya revealed significantly lower TPT uptake among HCWs or limited programmatic reporting.
Common barriers identified across these settings included limited awareness, unclear implementation responsibilities, the use of longer-duration regimens, and weak follow-up mechanisms.
Conclusions: TPT implementation for HCWs in Pakistan demonstrates high adherence and feasibility in resource-limited settings. However, the suboptimal-uptake highlights persistent challenges, including risk perception, hesitancy due to uncertainty about TPT effectiveness amid ongoing-exposure, and logistic constraints.
Comparative insights from Kenya, where national TPT scale-up also achieved high completion-rates, further underscore the importance of simplified regimens and robust follow-up systems. For broader impact, TPT should be integrated into occupational-health programs, backed by policy frameworks and targeted education to ensure the protection of frontline health workers.

OA27-364-21 Feasibility and acceptability of chest X-ray with computer aided detection (CAD) among health care workers

P.B. Adogo,[1] J. Bimba,[1] M.O. Iwakun,[1] D. Atuwo,[1] G.O. Adamu,[1] R.I. Balami,[1] C. Adesigbin,[2] O. Chijoke-Akaniro,[2] S. Ovye,[3] D. Bello,[4] V. Iem,[5] B. Squire,[5] [1]Bingham University, Zankli Research Centre, Karu, Nigeria, [2]National Tuberculosis Leprosy and Buruli Ulcer Control Programme (NTBCLP), Public Health, Abuja, Nigeria, [3]Nasarawa State Tuberculosis Leprosy and Buruli Ulcer Control (STBLCP), Public Health, Lafia, Nigeria, [4]FCT Tuberculosis Leprosy and Buruli Ulcer Control Programme (FCT TBLCP), Health, Abuja, Nigeria, [5]Liverpool School of Tropical Medicine (LSTM), Clinical Science, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: adogo.paul@yahoo.com

Background: Tuberculosis (TB) is a significant global health threat, with 10.6 million cases and 1.3 million deaths in 2022. Computer-aided detection (CAD) software can interpret chest X-rays (CXR) with accuracy equal to or greater than human readers, offering an opportunity to improve TB detection and treatment. This study assessed the feasibility and acceptability of CAD-CXR among healthcare workers in Abuja, Nigeria.
Design/Methods: This study employed a phenomenological qualitative research approach with purposive sampling to gather in-depth insights. Five key informant interviews were conducted with healthcare workers in

Abuja, and one focus group discussion was held with nine participants from the START4ALL project. Participants provided verbal and written informed consent before sharing their experiences through in-depth interviews guided by a structured guide. The emerging themes were organized and presented using the Consolidated Framework for Implementation Research (CFIR). The data was analyzed using thematic analysis to identify patterns and meanings.

Results: Findings from this study revealed a high Feasibility for CAD chest X-ray where most respondents reported that it's a screening tool for TB, gives result in real time and reduces man power but challenges existed for funding. Acceptability was high where most participants reported that it helps to find asymptomatic TB, widely acceptable and reduces cost of molecular diagnosis as it identifies presumptive for TB, but few respondents reported that data privacy should be ensured and a need for second reader.

S/N	Theme	Subtheme	Feasibility	Theme	Subtheme	Acceptability
			It's a screening tool for TB			Helps us to find Asymptomatic TB
						Highly sensitive
1	Intervention characteristics	Perceived value and effectiveness	It gives confidence because it gives result in real time	Affective Attitude	Perceived value	It is needed most especially in children and adults that can't produce sputum due to one health condition or the other
			Revolutionized both screening and not only TB. It can be used to diagnose other lung disease as well as cardiovascular diseases			
						It is widely acceptable
2	Resources	Human and material resources	Reduces manpower, because the AI does not require a radiologist to interpret result.	Burden	Time/ resource demand	Reduces the cost of the use of molecular diagnosis, it trims your presumptive
		Availability of funding	Challenges exist in funding			
3	Contextual fit	Alignment with national health policies	Guideline and SOPs developed	Ethicality	Fairness and appropriateness	Ensure Privacy of Data
					Trust in intervention	High Confidence, gives result in real time.
4	Adaptability	Scalability	Continued Advocacy	Perceived effectiveness	Believe in achieving outcomes	Requires a second reader to reduce error

Conclusions: This study demonstrates the feasibility and acceptability of CAD-CXR among healthcare workers in Abuja, Nigeria. The findings suggest that CAD-CXR has the potential to improve TB detection and treatment outcomes, aligning with the Sustainable Development Goals aimed at eliminating TB by 2030.

OA27-365-21 Standards behind bars: Review of TB policies for incarcerated populations in six countries

A. Sharma,[1] C. Parshall,[1] P. Cordova Rivera,[1] A. Rajkumar,[1] S. Lynch,[1] [1]Georgetown University Law Center, O'Neill Institute for National and Global Health Law, Washington, United States of America
e-mail: sl1903@georgetown.edu

Background: Incarcerated populations face a disproportionately high burden of tuberculosis (TB) due to structural inequalities. Despite global commitments to ending TB, national TB policies within prisons remain inconsistent.

This study examines the state of policy for incarcerated populations in six TB high-burden countries.

Design/Methods: The study analyzed national TB-related policies for incarcerated populations in six high-burden countries: three in Eastern Europe and Central Asia (EECA) (Tajikistan, Moldova, Ukraine) and three in Africa (Nigeria, Zimbabwe, Kenya).

A desktop review of Ministry of Justice and Ministry of Health documents was conducted. Key information was extracted and categorized based on alignment with World Health Organization (WHO) standards for TB care in prisons.

Results: Preliminary results suggest that prison occupancy exceeds 100% in all three African countries, while occupancy in EECA countries remains below capacity. Most countries lack clear TB-related nutrition guidelines, except Moldova and Tajikistan, where food norms vary by health status. In Moldova, nutritional support for TB is provided in line with legal norms.

TB screening practices differ: Zimbabwe, Kenya, and Nigeria rely on symptomatic screening, while Tajikistan, Moldova, and Ukraine conduct routine screening at entry; Moldova and Tajikistan also screen periodically and at release. Moldova uses Mantoux testing where X-rays are unavailable.

Equal standards of care for TB are guaranteed as a matter of policy in Nigeria, Tajikistan, and Moldova, including for pre-trial detainees. Nigeria applies the same TB and TB/HIV co-infection protocols to the incarcerated population as to the general population. Moldova and Ukraine have structured post-release care; Tajikistan, Kenya, Zimbabwe, and Nigeria require medical clearance but lack detailed continuity-of-care plans.

Conclusions: Though the sampled EECA countries demonstrate more comprehensive TB care compared to their African counterparts, suggesting regional disparities between the EECA and African regions, the findings highlight an overall lack of focus on TB care in prison policies.

OA27-366-21 Human rights-based and inmate-led TB prevention and care in prisons

A. Hoejrup,[1] F. Mabele,[2] K. Tyrrell,[3] C. Phiri,[1] G. Samungole,[4]
[1]Development Aid from People to People, Partnerhip team, Lusaka, Zambia, [2]Development Aid from People to People in Zambia, Programs, Lusaka, Zambia, [3]Humana People to People Spain, Partnerships, Madrid, Spain, [4]National Ministry of Health, National TB and Leprosy program, Lusaka, Zambia
e-mail: annedorte@dappzambia.org

Background and challenges to implementation: Tuberculosis (TB) is the main cause of death in Zambian correctional facilities with a prevalence 3.5 times the national estimate (researchgate.net/ publication/354886831). Factors such as extreme over overcrowding, poor ventilation, sanitation and hygiene, lack of isolation cell, high inmate mobility between facilities, and poor nutrition value of food contribute to high TB burden. TB screening, diagnosis and treatment remains inconsistent, largely due to limited TB knowledge among prison staff and lack of health staff.

Therefore, Development Aid from People to People (national NGO) conducted a peer led model supporting the screening, diagnosis, treatment and care for persons with TB (PWTB).

Intervention or response: DAPP piloted a peer-driven, inmate-centered model across four Correctional Facilities. Grounded in a rights-based and person-centered approach, trained inmate peer educators delivered continuous TB education, anti-stigma campaign, supported routine screening including on entry, and promoted drug availability and adherence.

Symptomatic inmates received diagnostic via various testing methods. DOT adherence groups consisting of three inmates on TB treatment enhanced adherence and psychosocial support. Food gardens were established. Infection control included ventilation, PPE use, and sanitation. Weakened inmates got light work duty.

Improved system for inmates on transit and aftercare counseling prepared the inmate family for providing TB adherence support.

Results/Impact: From May 2023 to March 2025 in 4 correctional facilities, 4,443 new entrant inmates were screened for TB, 1,106 (25.0%) TB tested, 832 received TPT and 6.5% (72/1106) inmates received active TB treatment. All four facilities reported no new cases of TB disease at end of project.

In one facility the year before, 73% (11/15) of those on TB treatment had poor adherence.

During the intervention phase, treatment adherence changed to 100%. There was acceptance of the model by correctional facility authorities.

Districts in Eastern province, Zambia	Nyimba	Petauke	Chipata	Katete	Katete & Chipata	TOTAL
Indicators / Period	May 24 - Mar 25	May 24 - Mar 25	May 24 - Jan25	May 24 - Mar 25	May 23 - April 24	May 23 - March 25
# of inmates with active TB	21	2	9	6	51	89
# of new entrant inmates screened for TB at entry-point (within 48 hours)	0	389	1599	611	1844	4443
# of inmates tested for TB from screening process	436	90	0	580	0	1106
# of inmates diagnosed TB who started TB treatment	8	2	8	0	45	63
# of routine TB screenings of inmates were conducted in the reporting period	30	166	721	41	0	958
# of sputum samples collected, taken to lab and got back result to inmate	34	90	0	117	1326	1567
# of inmates on TB prevention (TPT) in the previous reporting period who completed therapy	128	51	0	51	0	230
# of TRIOs (small DOT adherence & support groups) formed	31	4	6	30	24	95

Conclusions: Inmate led model of TB screening and treatment support was found to improve case finding and reduce poor adherence.

OA27-367-21 Enhancing TB prevention and care as well as early diagnosis in Zambia's correctional facilities: The Building Bridges Model

N. Sanjobo,[1] P. Hapeya,[2] C. Mundia,[3] V. Alvarez,[4] M. Drage,[5]
[1]IN BUT FREE, Administration, Kitwe, Zambia, [2]IN BUT FREE, Programmes, Kitwe, Zambia, [3]IN BUT FREE, Monitoring and Evaluation, Kitwe, Zambia, [4]LHL International, Programmes, Oslo, Norway, [5]LHL International, Administration, Oslo, Norway
e-mail: nsanjobo@inbutfree.org.zm

Background and challenges to implementation: Zambia's correctional system is prone to TB transmission, causing a public health crisis affecting inmates and posing a broader risk to community health. Zambian correctional facilities are becoming breeding and incubating grounds for TB due to risk factors like overcrowding, poor ventilation, late case detection, poor nutrition, poor health services, high prevalence of HIV and lack of TB screening.

Intervention or response: IN BUT FREE with support from LHL International has been implementing a TB programme called Building Bridges in 13 Zambian cor-

rectional facilities. The project covers over 10,000 prisoners and 1,336 correctional officers. The main goal of the project is to promote the prevention and control of TB and HIV in Zambian correctional facilities using a partnership of actors.

Activities conducted include advocacy for improved prison health, capacity building for the correctional officers and inmates to respond to TB, HIV, TB screening, nutrition support, cell awareness meetings, development of IEC materials and TB surveillance.

Results/Impact: Between 2021-2024, the intervention established a TB Working Group, trained 1,424 inmates as Peer Educators, 58 Psychosocial Counsellors, 241 officers as TB treatment supporters, hosted 3 advocacy meetings, produced and distributed 1,210 IEC materials, strengthened drama groups to promote TB awareness, 25,152 weekly cell awareness sessions conducted, identified and referred 22,392 presumptive cases, of which 487 (2,17%) inmates were diagnosed with TB and started on treatment and supported throughout treatment.

Provided nutrition support to 6,341 inmates, provided hygiene packs to 3,413 TB patients and peers, supplied basic medical equipment to support patient monitoring, linked 56 discharged inmates on TB treatment to nearest clinics and initiated Infection Prevention and Control committees at each facility.

Conclusions: Building bridges is an innovative intervention which can significantly contribute to improved TB prevention and control practices and ultimately reduce TB transmission in correctional facilities.

OA27-368-21 Effectiveness of latent TB infection treatment among individuals in correctional facilities, Taiwan

P.H. Lee,[1] J.C. Wang,[1] P.C. Chan,[1] J.J. Chen,[1] C.F. Feng,[1] H.Y. Lo,[1] C.C. Lee,[1] [1]Taiwan Centers for Disease Control, Chronic infectious diseases, Taipei, Taiwan
e-mail: leepinhui@cdc.gov.tw

Background: Taiwan has a moderate tuberculosis (TB) burden, with the incidence of 28 cases per 100,000 population in 2023. Since 2015, the WHO has recommended LTBI diagnosis and treatment for priority populations including inmates, to help achieve the End TB target. Since 2019, Taiwan CDC has collaborated with the Agency of Corrections to provide tuberculosis preventive therapy (TPT) in correctional facilities.

Design/Methods: We conducted a retrospective cohort study enrolling inmates and staff in correctional facilities from 2019 to 2024, analyzing TB incidence among LTBI-positive individuals stratified by receiving TPT or not followed up until September 6, 2024. We collected demographic characteristics and used the Cox proportional hazards model to evaluate the effectiveness of TPT.

Results: Among the 3,794 LTBI-positive inmates and staff, 3,182 (83.9%) initiated TPT. Twenty cases of active TB were identified during the median follow-up period of 41.5 months (IQR: 18.4–43.5), with an overall incidence rate was 190.6 per 100,000 person-years. The most common selected initial TPT regimen were 3HP (55.2%), followed by 1HP (26.2%) and 9H (10.0%), with 80.4% of participants who initiated TPT completing treatment. The highest completion rate among the initial TPT regimens was observed in the 1HP group (85.6%).

Multivariate analysis showed that individuals who did not receive TPT had a significantly higher risk of developing active TB disease (aHR=15.34, 95% CI: 5.76-40.89) compared to those who received treatment (*Table 1*).

No significant differences of TB risk were observed based on sex, age group, type of correctional facility, or individual previous TB contact history.

	No. of TB	Person-year	Incidence rate per 100,000	Univariate	Multivariate
				HR (95% CI)	aHR (95% CI)
LTBI Status					
No TPT	14	1449.5	965.9	14.77 (5.67-38.44)	15.34 (5.76-40.89)
Received TPT	6	9045.6	66.3	1	1
Gender					
Male	16	9354.3	171.0	1	1
Female	4	1140.8	350.6	2.12 (0.71-6.34)	3.24(1-10.57)
Age Group					
≤60 yrs	13	8452.7	153.8	1	1
>60 yrs	7	2042.3	342.7	2.25 (0.9-5.65)	1.84 (0.73-4.66)
Facility Type					
Prison	18	9931.3	181.3	1	1
Others	2	563.8	354.7	1.55 (0.34-7.02)	1.57 (0.34-7.2)
Identity					
Inmates	18	9974.9	180.5	1	1
Staff	2	520.2	384.5	2.16 (0.5-9.3)	0.90 (0.19-4.26)
TB Contact History					
Yes	6	2818.9	212.9	1.19 (0.46-3.1	1.36 (0.51-3.64)
No	14	7676.2	182.4	1	1

Abbreviation: HR, hazard ratio; aHR, adjusted hazard ratio; LTBI, latent tuberculosis infection; TPT, tuberculosis preventive therapy

Table 1. Risk of active TB among individuals eligible for TPT in correctional facilities (N=3,794)

Conclusions: TPT significantly reduces TB risk in correctional facilities. Individuals who did not receive TPT had more than a 15-fold increased risk of developing active TB compared to those who underwent treatment, highlighting the critical role of preventive therapy in correctional facilities.

OA28 Lung health in children and adolescents

OA28-369-21 Challenges and stethoscope preferences among healthcare workers in diagnosing paediatric pneumonia: A qualitative study in South Africa

A. Mcinziba,[1] L. Viljoen,[1] L.-M. Laubscher,[1] M.M. Van Der Zalm,[1] M. Van Niekerk,[1] A. Gie,[2] N. Hoekstra,[3,4] B.A. Nonyane,[5] S. Kapoor,[4] C. King,[6] E. McCollum,[1,4] P. Barach,[7] [1]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Cape Town, South Africa, [2]Stellenbosch University, Department of Paediatrics and Child Health, Cape Town, South Africa, [3]University of North Carolina School of Medicine,, Department of Paediatrics, Chapel Hill, United States of America, [4]Johns Hopkins School of Medicine, Global Program in Paediatric Respiratory Sciences, Eudowood Division of Paediatric Respiratory Sciences, Department of Paediatrics, Chapel Hill, United States of America, [5]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States of America, [6]Karolinska Institutet, Department of Global Public Health, Stockholm, Sweden, [7]Thomas Jefferson University, Population Health, Philadelphia, United States of America
e-mail: amcinziba@sun.ac.za

Background: Pneumonia is a leading cause of death in children (<5 years of age) in low- and middle-income countries (LMICs). Lung auscultation using conventional stethoscopes is valuable for diagnosis, however, implementation challenges exist. We explored healthcare workers' experiences of traditional stethoscopes and preferred future designs for paediatric use.
Design/Methods: We conducted in-depth qualitative interviews with 9 HCWs (4 doctors, 2 nurses, and 3 medical interns) from January to February 2025 at a tertiary hospital in Cape Town, South Africa. We also conducted unstructured think-aloud activities where HCWs verbalized their thoughts on workflow and drew preferred stethoscope designs.
We purposively sampled HCWs who routinely use stethoscopes on children by profession, age, and sex. We compiled comprehensive case descriptions with illustrative excerpts from the interview audio-recordings and applied deductive qualitative thematic analysis methods.
Results: The HCWs' experiences with stethoscopes depended on children's reactions, work environment, and medical device features. HCWs stated that while stethoscopes are user-friendly, they require subjective, high-skill interpretation for accurate diagnosis. HCWs noted challenges, including that children were intimidated by chest auscultation, and they struggle to clean stethoscopes between patients. HCWs identified potential solutions to the challenges of conventional stethoscopes, including visually appealing designs with colours, floral patterns, and animations, to help provide distraction and minimize intimidation. HCWs also suggested electronic enhancements more consistent with digital stethoscopes, like automated noise cancellation, artificial intelligence (AI) algorithms for sound interpretation and respiratory rate calculation (*Figure 1*).

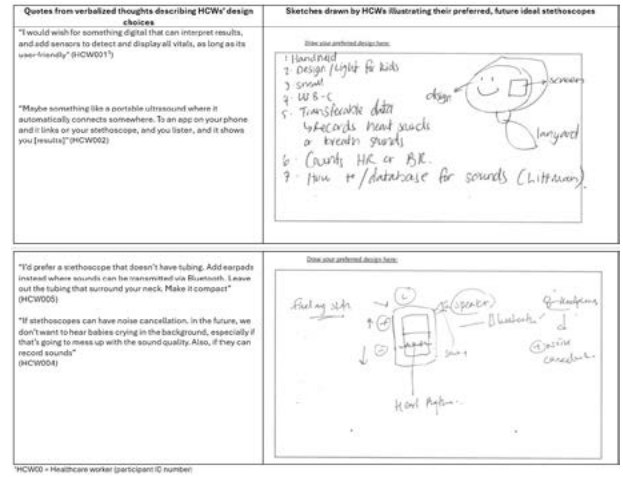


Figure 1. Healthcare workers' recommended stethoscope future designs.

HCWs reported that they would prefer a tubeless design that electronically transmits sounds by Bluetooth to earphones, alleviating the need to carry stethoscopes around their necks.
Conclusions: Future stethoscope designs should be child-friendly, enhance hygiene, and include AI features like auscultation interpretation to aid paediatric respiratory diagnosis.

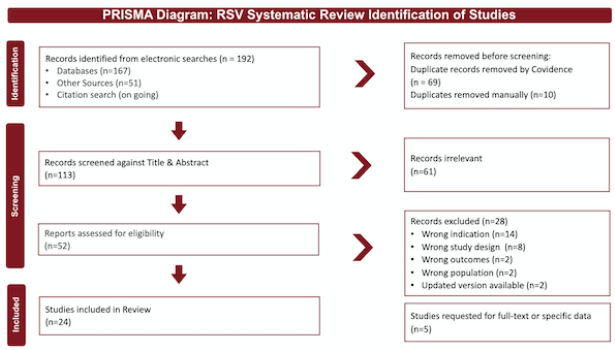
OA28-370-21 Evidence synthesis: RSV burden and the future of respiratory infection surveillance in Pakistan

M. Tariq,[1] H. Ameen,[1] B.A. Usmani,[2] W.Z. Jamal,[2] F. Jehan,[1] M.I. Nisar,[1] MIRNA Pakistan Group [1]Aga Khan University, Paediatrics and Child Health, Karachi, Pakistan, [2]Aga Khan University, Community Health Sciences, Karachi, Pakistan

Background: Respiratory syncytial virus (RSV) has been identified as the leading cause of respiratory infections in South Asian infants, however there is insufficient country-specific evidence to support the introduction of a maternal vaccine to protect children and pregnant women. In this study, we will scope evidence to identify in-country surveillance systems and systematically evaluate literature to quantify RSV disease burden in Pakistan.
Design/Methods: A systematic review to estimate the burden of RSV in pregnant women and children under-5 years from country-specific primary studies would be conducted in accordance with PRISMA guidelines.

Search strategies will be utilised to extract published data and grey literature from electronic databases (PubMed, Web of Science, Cochrane Library, Global Index Medicus, Embase, Medline, Scopus, CINAHL, Pak Medi-net) from inception to December 2024. A scoping review will be undertaken following PRISMA-ScR guidelines to map in-country data sources from peer-review publications, grey literature and expert consultation. Independent reviewers will extract data, and do quality assessments to report pooled prevalence estimates, and conduct meta-analysis. Covidence will be used for data management of all reviews.

Results: Data extraction is currently in-process. For RSV we have shortlisted 24 studies for extraction, all are on children. Only 4 studies report on RSV subtypes, with predominant RSV-A cases. Most studies are short term, have small sample sizes, with insufficient evidence on seasonality. On scoping evidence we have identified that RSV is occasionally tested for as part of influenza-surveillance system, from 8 sentinel sites in Pakistan, however most of the data is not yet publicly accessible.



Conclusions: This combined review estimates RSV disease burden in Pakistan and offers a thorough assessment of surveillance systems.

The findings will provide recommendations for improving monitoring systems and build a case for maternal RSV vaccine introduction in Pakistan.

OA28-371-21 Assessing acute cough in pre-schoolers through TB symptomatic screening: Insights from a five-year retrospective study

Y. Wali,[1] E. Ajumuka,[2] G. Ugochukwu,[3] C. Oke,[4] C. Ogbudebe,[5] O. Chukwuogo,[6] B. Odume,[6]
[1]KNCV Nigeria, Strategic Information, Awka, Nigeria, [2]KNCV Nigeria, Technical/Administration, Asaba, Nigeria, [3]KNCV Nigeria, Technical/Administration, Owerri, Nigeria, [4]KNCV Nigeria, Technical/Administration, Anambra, Nigeria, [5]KNCV Nigeria, Strategic Information, Abuja, Nigeria, [6]KNCV Nigeria, Technical/Administration, Abuja, Nigeria
e-mail: ywali@kncvnigeria.org

Background and challenges to implementation: Globally, tuberculosis (TB) a leading cause of morbidity and mortality among pediatric population with about 30% among persons with TB who died in 2023. Diagnosing and treating TB in children is difficult due to nonspecific symptoms, delaying diagnosis and treatment.

Dubiety among healthcare providers, caregivers, and parents about childhood coughs leads to increased consultations, follow-ups, and antibiotic use, particularly in developing countries like Nigeria.

This study aims to assess acute cough in preschoolers through TB symptomatic screening.

Intervention or response: This retrospective study on KNCV Nigeria's ongoing efforts to enhance early detection of tuberculosis (TB) through active case finding in health facilities across the country.

These activities are carried out by trained medical and healthcare personnel who conduct systematic screening of clients for TB-related symptoms, with particular focus on cough duration. Data from KNCV Nigeria's TBLON project (May 2020-January 2025) in Anambra, Delta, and Imo states.

The study focused on children aged 0-4 years, examining the number screened, cough duration, and TB diagnoses and referred for further evaluation. The analysis was performed using descriptive statistics.

Results/Impact: A total of 363,544 children under the age of five were screened for tuberculosis (TB). Among them, 2,909 children showed signs of a cough lasting less than two weeks—an early symptom that can sometimes be overlooked.

Out of this group, 65 children were diagnosed with TB, highlighting that roughly 1 in every 45 symptomatic children tested positive. This translates to a TB detection rate of 2.23%.

Category	Count	Percentage (%)
Children screened (0–4 years)	363,544	100%
With cough < 2 weeks	2,909	0.8%
Confirmed TB cases in this group	65	2.23% (of 2,909)

Table 1. Data Summary.

Conclusions: A small fraction of the 0–4-year-old cohort (2,909 of 363,544) presented with cough of less than two weeks, the TB detection rate within that group reached approximately 2.23%.
These findings underscore the clinical importance of screening for tuberculosis among young children, even in cases of relatively short-duration cough, to facilitate prompt diagnosis and timely intervention.

OA28-372-21 Assessing lung function impairment in children and adolescents post-TB treatment: Case of Mama Lucy Kibaki Hospital

K. Juliet,[1] [1]Nairobi City County Government, Health, Nairobi City, Kenya
e-mail: kajujujuliet85@gmail.com

Background and challenges to implementation: Post-tuberculosis lung disease (PTLD) is increasingly recognized as a cause of long-term respiratory morbidity, especially in children and adolescents. Patients with PTLD may present with persistence of symptoms or decline in lung function despite successful completion of treatment or cure. Increasing evidence of long-term respiratory complications following TB in a proportion of these patients affecting their quality of life
- Over 60% of patients still have symptoms after completion of TB treatment
- Over 80% have radiological sequalae
- Over 30% have spirometry function test abnormalities and more than 40% have bronchiectasis

Intervention or response: This study assessed lung function outcomes among pediatric TB survivors from 2022 and 2023 using spirometry and the 6-minute walk test (6MWT).
Children and adolescents who had completed pulmonary TB treatment were identified from facility registers, and caregivers were contacted for participation. The healthcare workers including clinicians were sensitized on the study.
Upon obtaining consent, spirometry was performed to assess obstructive and restrictive impairments, while the 6MWT evaluated functional capacity via exertional oxygen desaturation (≥3%).
Results/Impact: There were a total of 55 participants that were enrolled.
Spirometry abnormalities: 18 children (32.7%)
- Obstructive impairment: 9 cases
- Restrictive impairment: 10 cases (slightly more prevalent)

6MWT findings: 35 children (63.6%) showed abnormal desaturation, indicating impaired gas exchange and reduced exercise tolerance despite completing TB treatment.
This supports the presence of lung impairment despite successful TB treatment
Conclusions: A significant proportion of pediatric and adolescents who had successfully completed TB treatment exhibited lung function impairment, highlighting the need for routine monitoring and exercise tolerance assessment in post-TB care in order to improve their quality of life post TB.
Due to limited infrastructure at the health facilities the 6MWT is readily available and is equally important.

OA28-374-21 The TB aftermath: Uncovering the hidden respiratory burden in children

J. Githua,[1] E. Attia,[2] J. Mecha,[1] J. Stern,[3] J. Escudero,[3] J. Mirera,[1] M. Mureithi,[1] E. Maleche-Obimbo,[4] V. Nduba,[1] S. LaCourse,[5] J. Zifodya,[6] [1]Kenya Medical Research Institute, Centre for Respiratory Disease Research, Nairobi, Kenya, [2]University of Washington, Department of Pulmonary, Critical Care and Sleep Medicine, Seattle, Washington, United States of America, [3]University of Washington, Department of Global Health, Seattle, United States of America, [4]University of Nairobi, Department of Pediatrics, Nairobi, Kenya, [5]University of Washington, Department of Medicine, Washington, United States of America, [6]Tulane University, Department of Medicine, New Orleans, Louisiana, United States of America
e-mail: joykgithua@gmail.com

Background: Respiratory sequelae following tuberculosis (TB) in children may persist long-term. However, comprehensive characterization of pediatric post-TB lung disease (PTLD) remains limited.
Design/Methods: We followed children (≤15 years) who received TB treatment, in Kenya. Assessments at 6, 12, and 24 months included clinical evaluation, chest radiography (CXR), spirometry and oscillometry. PTLD was defined as presence of; persistent respiratory symptoms (wheezing, cough, or oxygen saturation <94%), abnormal CXR, or impaired lung function in children receiving TB treatment for ≥5.5 months.
We expanded this definition to include additional pulmonary function parameters: PRISM (Preserved Ratio Impaired Spirometry, (reduced Forced Expiratory Volume in one second (FEV1) or Forced Vital Capacity (FVC) with preserved FEV1/FVC ratio and oscillometry abnormalities. Correlates for PTLD were identified using a generalized linear model at each timepoint.
Results: Among 256 children treated for TB (29 confirmed, 227 unconfirmed), median age was 2.0 years (IQR 0.0-5.0) with 47.6% being male. At 6, 12, and 24 months persistent respiratory symptoms were found in 16 (6.3%), 16 (7.4%), and 6 (4.4%); impaired lung function using spirometry in 1/9 (11.1%), 6/27 (22.2%), and 3/16 (18.8%). Oscillometry abnormalities were detected in 2/3 (66.7%), 4/7 (57.1%), and 18/25 (72.0%) children at the three timepoints (*Table*), with oscillometry identifying small airway dysfunction in 4/32 (12.5%) children with normal spi-

rometry. PRISM identified 13/52 (25.0%) children with abnormal lung function. Structural abnormalities (CXR) were identified in 86 (33.6%), 45 (20.7%), and 14 (10.5%) children at the three assessment points. Overall, 69 (30.0%), 46 (21.2%), and 27 (19.6%) children had at least one post-TB abnormality at the three timepoints (*Table*). At month 12, PTLD was more common in children living with HIV (RR 2.2, p=0.027) and associated with higher weight-for-height z-score (RR 1.2, p=0.045) (*Table*).

Table : Prevalence and Risk Factors for Post-TB Lung Disease at 6, 12, and 24 Months Post-TB Treatment

PTLD prevalence	Month 6: N=69/256 (30.0%)		Month 12: N=46/217 (21.2%)		Month 24: N=27/138 (19.6%)	
	Frequency	%	Frequency	%	Frequency	%
**Respiratory symptoms	16/256	6.3%	16/217	7.4%	6/138	4.4%
**Spirometry abnormalities	1/9	11.1%	6/27	22.2%	3/16	18.8%
**Oscillometry abnormalities	2/3	66.7%	4/7	57.1%	18/25	72.0%
**PRISM abnormalities	3/9	33.3%	8/27	29.6%	2/16	12.5%
**Abnormal CXR	86/256	33.6%	45/217	20.7%	14/138	10.5%
PTLD risk factors	**Median (IQR) or N (%)**	**RR (95% CI), p-value**	**Median (IQR) or N (%)**	**RR (95% CI), p-value**	**Median (IQR) or N (%)**	**RR (95% CI), p-value**
WHZ	-0.1 (-1.4, 0.5)	1.0 (0.9, 1.2) p= 0.485	0.1 (-0.9, 0.8)	¥1.2 (1.0, 1.4) **p=0.045**	0.4 (-0.0, 0.9)	1.2 (0.8, 1.7) p= 0.334
CLHIV	13 (5.1%)	1.3 (0.7, 2.4) p= 0.639	11 (5.1%)	**¥2.2 (1.1, 4.3) p=0.027**	6 (4.3%)	1.8 (0.6, 5.5) p=0.328

Abbreviations: PTLD = Post-TB Lung Disease; RR = Relative Risk; CI = Confidence Interval; IQR = Interquartile Range; WHZ = Weight-for-Height Z-score; CLHIV = Children Living with HIV; CXR = Chest X-ray; PRISM = reduced FEV1 or FVC in the setting of preserved FEV1/FVC ratio; % = Percentage; **Abnormal spirometry:** defined as FEV1, FVC, and FEV1/FVC ratio below the Lower Limit of Normal (< -1.64 Z-score); **Abnormal oscillometry:** included R5 and R20, R5-R20, AX, and resonant frequency considered abnormal when exceeding the Upper Limit of Normal; **PTLD:** defined as any abnormal clinical, radiological, or pulmonary function finding at each assessment timepoint, in children receiving TB treatment for ≥5.5 months; ¥Statistically significant at p<0.05

Conclusions: Respiratory sequelae persist in children post-TB, with oscillometry detecting abnormalities missed by conventional assessment.

OA28-375-21 Bidirectional screening approach for TB and pertussis: Lessons learnt from West Bengal, India

A. Dey,[1] B. Sengupta,[1] S. Chandra,[1] D. Deka,[1] B. Chakladar,[1] S.K. Roy,[2] T.K. Saha,[2] S. Roy,[2] U.B. Singh,[3] B. Roy,[2] R. Mukherjee,[2] [1]Government of India-WHO Country office for India-Technical Support Network, National TB Elimination Program, New Delhi, India, [2]Government of West Bengal, Department of Health and Family Welfare, Kolkata, India, [3]Government of India, Department of Health and Family Welfare, New Delhi, India
e-mail: drabhijitdey@gmail.com

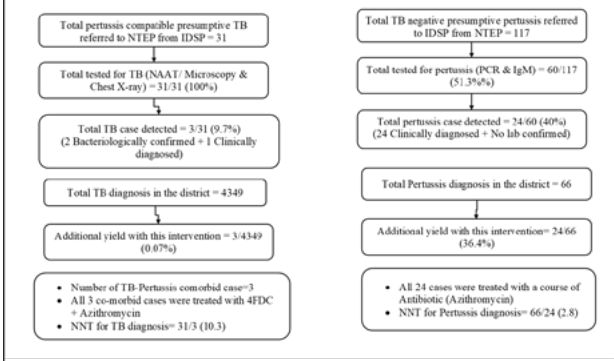
Background and challenges to implementation: Since 2015, the Government of India is conducting pertussis surveillance in the country as a part of Integrated Disease Surveillance Project (IDSP). A person with a cough lasting at least two weeks with at least one of the following symptoms- paroxysms of coughing, inspiratory "whooping", post-tussive vomiting without other apparent cause is considered as a presumptive pertussis and nasopharyngeal swab & blood is collected for laboratory confirmation. On the other hand, under National TB Elimination Program (NTEP), sputum is collected & tested form individuals with ≥2 weeks of cough for TB diagnosis. Over the last decade, both the disease surveillance activities are happening in the health care facilities of West Bengal, but in silo.

Intervention or response: In 2024, South 24 Parganas district of West Bengal devised a cross-referral system of bi-directional screening of TB & pertussis. All those who are presented with cough for ≥2 weeks and sputum is negative for TB, are systematically referred from NTEP to IDSP for pertussis test. On the other hand, all pertussis compatible cases are also sent by IDSP to NTEP for ruling out TB.

Results/Impact: Since January'24 till March'25, total 117 person were referred to IDSP from NTEP. 60 evaluated for pertussis. Though none was laboratory confirmed, 24 were diagnosed as 'Pertussis compatible' followed by the public health actions in the respective households.

On the other hand, total 31 cases were referred to NTEP from IDSP. Total three person with TB diagnosed. All three were TB-Pertussis co-morbid case. **(Fig-1)**

Figure 1: Flowchart depicting the number and percentage of participants at different stages of bidirectional TB-pertussis screening at South 24 Parganas district of West Bengal during Jan'24-Mar'25



Notes: - TB= Tuberculosis, NTEP= National TB Elimination Program; IDSP= Integrated Disease Surveillance Program; NAAT= Nucleic Acid Amplification Test; PCR= Polymerase Chain Reaction; IgM= Immunoglobulin type M (indicated recent infection); 4FDC = Fixed Dose Combination of four 1st line Anti-TB Drugs; NNT= Number needed to Test (to get 1 diagnosed case)

Conclusions: TB pertussis co-exists. Presenting symptom can be very similar. Screening & testing of both the diseases can be arranged in an integrated way. Though the additional yield for NTEP was negligible but for IDSP it was significant. The West Bengal model of bidirectional TB-pertussis screening may be replicated in other endemic areas.

OA28-376-21 The performance of CAD4TB to distinguish radiological TB from not-TB in a paediatric population in South Africa

M. Palmer,[1] H. van Deventer,[1] E. Klinkenberg,[2] H.S. Schaaf,[1] P. Goussard,[3] M. van Niekerk,[1] J. Melendez,[2] K. Murphy,[4] J. Seddon,[1,5] M. van der Zalm,[1] [1]Stellenbosch University, Department of Paediatrics and Child Health, Cape Town, South Africa, [2]Delft Imaging BV, Delft Imaging BV, Delft, Netherlands, [3]Stellenbosch University, Paediatric Pulmonology, Cape Town, South Africa, [4]Radboud University Medical Centre, Radboud Imaging, Nijmegenswed, Netherlands, [5]Imperial College London, Department of Infectious Diseases, London, United Kingdom of Great Britain and Northern Ireland
e-mail: meganpalmer@sun.ac.za

Background: Computer-aided detection (CAD) of chest x-ray (CXR) offers possibility to support access to TB diagnosis in children. However, existing CAD algorithms have been largely trained on adult data and are not recommended for use in those under 15 years by the World Health Organization. Despite this, CAD is being used in children, and it is crucial to understand its performance in paediatric populations. We evaluated the performance of several CAD4TB algorithms to identify radiological TB on paediatric CXRs.
Design/Methods: We used 491 frontal digital CXRs from children aged 0-13 years who were enrolled into a TB diagnostic cohort study with a reference standard of "radiological TB" as classified by consensus between 2 expert human readers. A receiver operating curve (ROC) analysis was performed using output from three CAD4TB software versions: commercially available CAD4TB V6 and V8 and a CAD4pTB (a research model developed by retraining CAD4TB V7 for paediatrics with 445 CXR images from children).

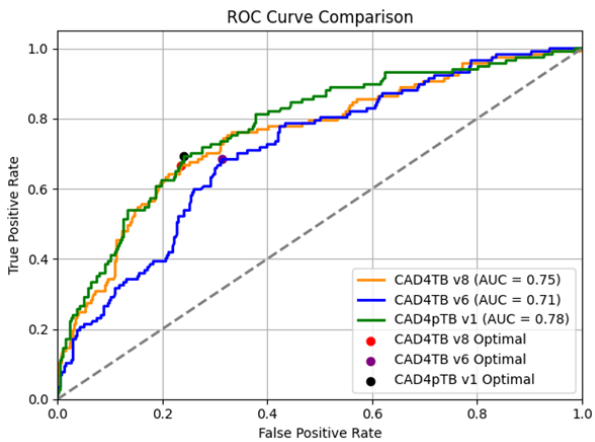


Figure 1. Receiver operating characteristic curves comparing the performance of different CAD4TB models to distinguish between TB and not-TB against the radiological reference standard of a consensus human read chest x-ray.

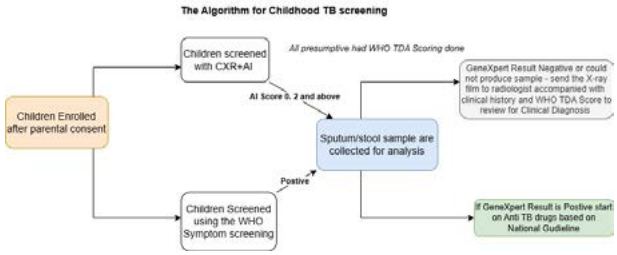
Results: The area under the receiver operating characteristic curve (AUC) of the CAD4TB V6, CAD4TB V8 and CAD4pTB models were 0.71, 0.75 and 0.78 respectively (Fig 1) and, at a fixed specificity of 90% the sensitivity of each was 28%, 33% and 39%.
Conclusions: This analysis provides the first external validation of the CAD4pTB model. The improved performance of the CAD4pTB model compared to the other CAD4TB models, after retraining with a small paediatric CXR set, is promising for the success of future paediatric CAD development.

OA28-377-21 AI-enabled X-ray for childhood TB detection: Early implementation results from school-based TB screening activities in remote rural communities in Nigeria

C. Okoye,[1] J. Ilozumba,[2] O. Akaniro,[3] [1]Catholic Caritas Foundation of Nigeria, TB/HIV, Abak, Nigeria, [2]Catholic Caritas Foundation of Nigeria, TB/HIV, Abuja, Nigeria, [3]National TB and Leprosy Control Program, M&E, Abuja, Nigeria
e-mail: cezeobi@ccfng.org

Background and challenges to implementation: Tuberculosis (TB) remains a global public health challenge, with children under 15 years contributing approximately 12% of the total TB burden. Pediatric TB is frequently underdiagnosed due to non-specific symptoms, difficulty in obtaining sputum, and its paucibacillary nature. These challenges are more pronounced in high-burden countries like Nigeria.
This study presents early findings from school-based TB screening activities using AI-enabled chest X-ray technology to for childhood TB screening in remote Nigerian communities.
Intervention or response: Caritas Nigeria conducted mobile X-ray and AI-assisted active case finding (ACF) in six schools from January to March 2025 across three remote LGAs in Ebonyi State—Ikwo, Ishielu, and Izzi. Using qXR v4.2 (Qure.ai), AI-assisted pediatric chest X-rays, children were screened with parental consent. Those with TB symptoms or AI scores ≥0.2 were referred for GeneXpert testing. WHO treatment Decision Algorithm (TDA) scoring was administered to all identified presumptive TB cases. Q-Track facilitated data capture and care coordination, while children with negative GeneXpert results or unable to provide sputum had their X-rays, clinical history, and TDA scores reviewed by a radiologist for clinical diagnosis.
Results/Impact: A total of 697 children (mean age 9.6 ± 3.18 years; 48% female) were screened across 6 schools. Of these, 664 (95%) underwent dCXR+AI screening; 111 (16%) reported TB symptoms, and 23 (3%) were flagged with AI scores ≥0.2. Sputum or stool samples were obtained from 76 children (11%), of whom 13 (2%) tested positive for TB using GeneXpert. An additional 20 X-rays

with clinical histories and TDA Scores were reviewed by a radiologist, leading to 3 further clinical TB diagnoses. All 16 confirmed TB cases (2%) were initiated on treatment. The number needed to screen (NNS) to detect one TB case was 44



Conclusions: AI-enabled chest X-ray has shown potential in enhancing pediatric TB screening and improving childhood TB detection.

OA28-378-21 Feasibility, tolerability, and yield of nasopharyngeal aspirate and stool samples for molecular TB detection in children with severe pneumonia

M. Coleman,[1,2,3] B. Bhatta,[1] B. Dim,[4] L. Borand,[4,5] R. Moh,[6] C. Khosa,[7] C. Chabala,[8] J. Mwanga-Amumpaire,[9] E. Wobudeya,[10] M. Bonnet,[11] J. Orne-Gliemann,[1] O. Marcy,[1]
[1]University of Bordeaux, National Institute for Health and Medical Research (INSERM) UMR 1219, Research Institute for Sustainable Development (IRD) EMR 271, Bordeaux Population Health Centre, Bordeaux, France, [2]LMU Munich, University Hospital, Division of Infectious Diseases and Tropical Medicine, Munich, Germany, [3]University of Sydney, Sydney Infectious Diseases Institute (Sydney ID), Sydney, Australia, [4]Institut Pasteur du Cambodge, Epidemiology and Public Health Unit, Clinical Research Group, Phnom Penh, Cambodia, [5]Johns Hopkins University School of Medicine, Center for Tuberculosis Research, Division of Infectious Diseases, Baltimore, United States of America, [6]Programme PACCI, Site ANRS, Abidjan, Côte d'Ivoire, [7]Instituto Nacional de Saúde, Centro de Investigação e Treino em Saúde da Polana Caniço, Maputo, Mozambique, [8]University of Zambia, School of Medicine, Department of Paediatrics and Child Health, Lusaka, Zambia, [9]Epicentre, Mbarara Research Centre, Mbarara, Uganda, [10]MUJHU Research Collaboration, MU-JHU Care Limited, Kampala, Uganda, [11]University of Montpellier, Institut de Recherche pour le Développement, INSERM, TRANSVIH MI, Montpellier, France
e-mail: mikaela.coleman@sydney.edu.au

Background: Tuberculosis is common and challenging to diagnose in children with severe pneumonia. Use of nasopharyngeal aspirates (NPA) and stool samples could enhance microbiological diagnosis. We sought to assess their feasibility, safety, yield, and tolerability, amongst children with severe pneumonia.

Design/Methods: This was a nested, cross-sectional substudy within the TB-Speed Pneumonia trial enrolling children admitted with severe pneumonia from 15 hospitals in six countries who underwent systematic tuberculosis screening with NPA and stool collection tested using Xpert MTB/RIF Ultra (Ultra).
Study nurses reported on the feasibility and safety of NPA collection by questionnaire, and assessed tolerability as a before/during NPA discomfort/distress/pain score (/10) using the FLACC (Face/Leg/Activity/Cry/Consolability) scale.
We analysed endpoints using proportions and median (IQR) and examined factors associated with reduced NPA tolerability using uni/multivariable linear regression.
Results: Of 542 children enrolled, 541 (99.8%) and 423 (78.0%) had successful NPA and stool collection, respectively ($p<0.0001$). Nurses reported difficulty in child management or NPA procedure in <5% of children and minor digestive, heart-rate deceleration or dyspnoea in <5% of children; 130 (24%) children had bloody NPA sample.
Valid Ultra results were obtained on 529 (97.6%) NPA and 409 (75.5%) stool samples; 8 (1.5%) children had positive Ultra on any sample, including 8 (1.5%) on NPA, and 3 (0.6%) on stools ($p=0.13$). The median discomfort/distress/pain score increased by 3/10 [IQR 0-4] points during NPA.
Nurse-reported difficulty in NPA procedure was associated with a 0.991 (95%CI 0.068–1.918, $p<0.001$) increase in the discomfort/distress/pain score (poorer tolerability), even after adjusting for institution, child age, sex, nutrition, and HIV status.
Conclusions: NPA and stool are feasible and tolerable microbiological sampling strategies in children with severe pneumonia. NPA had a higher uptake than stool when tested with Ultra, and was associated with a modest, transient discomfort/distress/pain increase for children with minimal adverse events.

OA29 Equity at the doorstep: Community health workers for lung health

OA29-379-21 Strengthening community health workers' engagement in TB prevention and care in Madagascar: Recommendations from the workforce themselves

O.G. Ravololohanitra,[1] H. Razafimanantsoa,[1] E.H. Andriamasy,[1] N. Müller,[2] [1]Doctors for Madagascar, Research, Antananarivo, Madagascar, [2]Charité - Universitätsmedizin, Speciality Network: Infectious Diseases and Respiratory Medicine, Berlin, Germany e-mail: gro@doctorsformadagascar.com

Background: Community health workers (CHWs) play an essential role in tuberculosis (TB) prevention and control in Sub-Saharan Africa, yet their effectiveness remains limited in many countries. In Madagascar, a low-income setting, their engagement is substantially limited due to systemic challenges and a lack of evidence-based prioritization of CHW needs. Direct input from CHWs - main actors at the community level and those directly affected - is an important yet often neglected source of evidence in policy design. This study addresses this gap by presenting recommendations from CHWs themselves on how to strengthen their engagement in TB.
Design/Methods: This qualitative component, part of a larger mixed-methods study, was conducted in two regions (Analamanga and Atsimo-Andrefana) through five focus group discussions with CHWs, purposively sampled from health facilities selected via cluster sampling. Topic guides explored CHW recruitment practices, work environment, perceived roles, motivation, volunteering, incentives, and other factors influencing engagement. Data were collected from September to October 2024 and analyzed using inductive reflexive thematic analysis in NVivo, guided by an evolving codebook.
Results: CHWs' recommendations revealed five key areas to enhance their engagement and effectiveness in TB prevention and control:
1. Consistent financial compensation to cover work-related expenses and sustain motivation;
2. Standardized and strengthened training on TB prevention, case management, and outreach;
3. improved supervision, including performance feedback and opportunities for professional development;
4. Access to essential tools, materials, and transport for community outreach, and;
5. Recognition through formal integration into the national health system.
Background and challenges to implementation: Community health workers (CHWs) play an essential role in tuberculosis (TB) prevention and control in Sub-Saharan Africa, yet their effectiveness remains limited in many countries. In Madagascar, a low-income setting, their engagement is substantially limited due to systemic challenges and a lack of evidence-based prioritization of CHW needs. Direct input from CHWs - main actors at the community level and those directly affected - is an important yet often neglected source of evidence in policy design.
This study addresses this gap by presenting recommendations from CHWs themselves on how to strengthen their engagement in TB.
This qualitative component, part of a larger mixed-methods study, was conducted in two regions (Analamanga and Atsimo-Andrefana) through five focus group discussions with CHWs, purposively sampled from health facilities selected via cluster sampling. Topic guides explored CHW recruitment practices, work environment, perceived roles, motivation, volunteering, incentives, and other factors influencing engagement. Data were collected from September to October 2024 and analyzed using inductive reflexive thematic analysis in NVivo, guided by an evolving codebook.
Conclusions: Addressing CHWs' identified needs can significantly strengthen their role in TB prevention and control. Implementation research is essential to guide, adapt, and evaluate strategies, ensuring they effectively respond to public health needs.

OA29-380-21 Incentivising community action: A results-based approach to TB detection, prevention and care

D.D. Tobaiwa,[1] K. Mutungamiri,[2] [1]Jointed Hands Welfare Organisation, Programs, Gweru, Zimbabwe, [2]Jointed Hands Welfare Organisation, Strategic Information, Gweru, Zimbabwe

Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge, particularly in underserved communities where passive case-finding methods often result in missed cases, delayed diagnosis, and poor treatment outcomes. Jointed Hands Welfare Organization (JHWO), through the USAID-funded Kunda Nqob'iTB (KNTB) project, identified several challenges, including low community engagement, lack of systematic screening, and inconsistent motivation among Community Health Workers (CHWs) affecting case detection efforts.
Intervention or response: To address these barriers, JHWO implemented the Results-Based Community Active Case Finding Model (RBACFM), an incentive-driven, performance-based approach designed to enhance targeted TB screening. CHWs were assigned specific screening targets and provided with performance-based incentives to sustain motivation and accountability.
Geographic hotspot mapping was conducted to direct efforts to high-burden areas, optimizing case detection. Community leaders were actively engaged to foster trust and support screening programs, creating a conducive

environment for CHWs to operate. Routine supervision and capacity-building sessions ensured adherence to screening protocols, improving overall effectiveness.
Results/Impact: The model led to a significant increase in TB case detection. In Gweru district, presumptive TB case referrals from CHWs increased by over 450%, from 367 cases in year one to an average of 2,050 per year by year five. The presumptive TB yield improved from 4% to 21%, and community contributions to overall district TB notifications rose from 5% to 30%. Despite these successes, logistical constraints in remote areas and occasional community reluctance posed challenges, emphasizing the need for stronger supply chain mechanisms and ongoing education efforts.
Conclusions: The RBACFM model has proven effective in improving TB case detection and treatment initiation, offering a scalable approach for high-burden settings. Key recommendations include expanding the model to additional districts, strengthening community education to address TB-related stigma, enhancing CHW training and incentive structures, and leveraging digital tools for real-time monitoring and resource allocation.

OA29-381-21 Boosting TB prevention: The role of community volunteers in increasing uptake of TB preventive treatment among household contacts in Haryana, India

K. Bansal,[1] R. Raju,[2] P. Tanwar,[3] S. Singh,[4] A. Sachdeva,[5] S. Chandra,[6] U.B. Singh,[7] A. Bhardwaj,[8] [1]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Plan, Gurugram, India, [2]Directorate General Health Services, State TB Cell, Panchkula, India, [3]Directorate General Health Services, District TB Cell, Nuh, India, [4]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, Panchkula, India, [5]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, Hisar, India, [6]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [7]Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [8]Maharshi Markandeshwar Medical College, Community Medicine, Solan, India e-mail: bansalk@rntcp.org

Background and challenges to implementation: Tuberculosis Preventive Treatment (TPT) is vital to India's TB elimination strategy, complementing active case finding and infection control. In high-burden settings, prevention is key to reducing transmission. This study explores the impact of engaging Community Volunteers to enhance TPT uptake, adherence and completion among household contacts in Mewat, Haryana—an agriculturally dependent, socio-economically challenged district with limited healthcare access.
Intervention or response: In 2024, the Government of Haryana conducted a prospective comparative study in Mewat district. The study compared TPT uptake, completion, and loss to follow-up (LTFU) rates in HHCs for 2023 and 2024. Data was extracted from Ni-kshay (India's digital TB surveillance portal) and analyzed with SPSS.v.22. Five trained Community Volunteers (one per 0.25 million population) were enrolled to ensure timely initiation, adherence, and completion of TPT, and to update health staff on challenges. As part of the National TB Elimination Program, to recognize the efforts of the community volunteers, an honorarium of $2.90 per HHC was awarded, upon successful treatment completion, depending on regimen and duration.
Results/Impact: In 2024, a total of 4,236 (60%) HHCs out of 7,037 initiated on TPT, compared to 2,061 (34%) out of 6,048 in 2023, as recorded in Ni-kshay. Treatment completion rose significantly from 23% in 2023 to 75% in 2024. Additionally, LTFU was reduced to 5%, highlighting the positive impact of community engagement in improving TPT outcomes.
Conclusions: The intervention clearly demonstrates that engaging trained Community Volunteers significantly improves the uptake, adherence, and completion of TPT among household contacts in high-burden, underserved regions. The remarkable increase in treatment completion from 23% to 75% and the reduction in loss to follow-up to 5% underscore the critical role of community-based support in strengthening TB prevention efforts. This model holds strong potential for replication in other similar high burden resource-limited settings.

OA29-382-21 TB notifications by community-based volunteers in communities serviced by mission health facilities in Zambia: Translating WHO guidance into practice

E. Mwila Bwalya,[1] A. Mubanga,[2] D. Menda,[1] L. Tamba,[1] R. Chilyabanyama,[1] C. Mulikita,[1] K. Sichinga,[1] [1]Churches Health Association of Zambia, Health Programmes, Lusaka, Zambia, [2]Ministry of Health Zambia, NTPL, Lusaka, Zambia

Background and challenges to implementation: Zambia, ranked 21st among the 30 high TB burden countries, reported an estimated 307 TB cases per 100,000 population in 2021. To improve TB management, the country has adopted a decentralized approach, leveraging NGOs and CSOs to bridge care gaps. The Churches Health Association of Zambia (CHAZ), an interdenominational umbrella organization for Church Health Institutions (CHIs), supports community TB services through 162 health facilities, serving 5 million people, primarily in hard-to-reach areas. Key community activities include behavior change communication, presumptive TB case identification, sputum sample collection and transport, and directly observed therapy (DOT). Diagnosis and

treatment initiation occur within CHIs, and a core CHAZ indicator, aligned with WHO guidelines, tracks new TB cases diagnosed and notified through community health worker referrals in each facility's catchment area.

Intervention or response: Aligned with WHO guidance and Global Fund insights, CHAZ has enhanced community-level TB control to accelerate case detection. A differentiated active case finding (ACF) approach, combining quarterly ACF campaigns with TB awareness initiatives led by community-based volunteers (CBVs), has significantly increased TB notifications, as outlined below.

Key investments in CBVs include annual MOH-approved training, quarterly onsite mentorship, transport assistance, and essential supplies for sputum sample transport. From 2018 to 2023, CHAZ supported 559 TB-specific CBVs before transitioning in 2023 to 1,200 polyvalent CBVs, integrating TB, HIV, and Malaria services.

Results/Impact: Regular quarterly reviews have been conducted to assess progress. A key indicator measuring CBVs' contributions to TB notifications has produced the following results.

Conclusions: A decentralized, community-based approach led by CBVs is instrumental in improving early TB detection in underserved populations. This strategy has increased TB notifications by 20% in CHAZ-supported CHIs, aligning with WHO guidance.

Well-trained, motivated, and properly equipped CBVs are essential for effectively implementing and expanding community-based TB activities and referrals.

OA29-383-21 Comparative yields of TB preventive therapy from community contact tracing and facility based contact invitation strategies: Implications for programmatic implementation

S. Mutua,[1] R. Pola,[2] B. Ulo,[1] M. Githiomi,[3] J. Thiga,[1]
[1]Amref Health Africa in Kenya, Global Fund TB Project, Nairobi, Kenya, [2]Respiratory Society of Kenya, Research, Nairobi, Kenya, [3]National Tuberculosis, Leprosy and Lung Disease Program, Public Health, Nairobi, Kenya
e-mail: susan.mutua@amref.org

Background and challenges to implementation: The World Health Organization recommends screening for household members and close contacts of bacteriologically confirmed pulmonary TB (PTB) to prevent Tuberculosis (TB). Facility and community-based contact tracing are key to finding undiagnosed TB and increasing tuberculosis preventive therapy (TPT) uptake for those without active TB. Since 2018, AMREF Health Africa and Kenya's National TB program have implemented both strategies. TPT initiation among eligible contacts of bacteriologically confirmed PTB still remains sub optimal. This abstract directly compares the effectiveness of these two approaches in improving TPT uptake.

Intervention or response: We conducted a retrospective cross-sectional study using routinely collected data covering the period 2023 to 2024 obtained from the national case-based surveillance system in Kenya. In the community-based approach, community health promoters were sensitized to conduct screening of household contacts and referred the eligible individuals to health facilities for further evaluation and initiation of TPT.

In the facility-based approach, healthcare workers contacted household contacts and invited them to visit the health facility for screening and possible TPT initiation. Data were analyzed using R software.

Results/Impact: During the review period, a total of 98,916 individuals eligible for TPT initiation were reported. Of these, 84,875 (84%) were initiated on TPT. Community contact tracing contributed to 59.0% (50,082) of those initiated on TPT while contact invitation accounted for 41.0% (34,793).

Logistic regression analysis suggested that both approaches to contact investigation, screening outcome and outcome of TB evaluation were significant predictors of TPT initiation (p-value < 0.05).

Eligible clients identified through the contact invitation strategy had a higher odds of initiating TPT compared to those reached through contact strategy (OR = 2.02 (95% CI: 1.94 – 2.10, p < 0.001).

Conclusions: The two contact investigation strategies are complementary and when strengthened, have the potential to significantly enhance the overall coverage of TPT.

OA29-384-21 Targeting the golden years: Finding missing people with TB among the elderly through targeted outreaches in Siaya County, Kenya

A. Wanyonyi,[1] G. Onyango,[1] S. Kitui,[1] J. Mungai,[1] M. Wambura,[2] L. Okumu,[3] B. Ulo,[1] [1]Amref Health Africa, Global Fund TB Project, Nairobi, Kenya, [2]Siaya County, Department of Health, Siaya, Kenya, [3]Impact Research Development Organization, GF TB, Siaya, Kenya
e-mail: alice.wanyonyi1@gmail.com

Background and challenges to implementation: Tuberculosis remains a critical health challenge among the elderly population globally. According to the Kenya 2016 Prevalence Survey, TB prevalence was estimated at 426 per 100,000 adult population, doubling the pre-survey estimate of 266 per 100,000, People most affected by TB were of ages ranging from 25-34 years and elderly of 65 years and above. Siaya County is among the ten counties in Kenya with the highest TB burden. While TB diagnosis and treatment are generally accessible, the elderly face specific challenges including delayed TB detection, diagnosis and treatment. Age-related immune decline and high rates of comorbidities increase vulnerability.
Intervention or response: From January to March 2025, Amref in collaboration with IRDO and Siaya County implemented a three-day screening initiative across 3 subcounties with support from Global Fund. The outreach targeted an organized support group for the elderly 60-95 years as 13.2% of people identified with TB were among elderly in 2023. Mobile digital chest X-ray was utilized featuring AI-assisted interpretation and GeneXpert testing. The elderly and their caregivers were mobilized by Adolescent and Young Persons and Community Health Promoters to attend the screening during their routine meetings.
Results/Impact: The outreach targeted 350 elderly individuals, members of an organized group, 270 (77%) were screened, including 111 men and 159 women. Symptomatic screening identified 40(14.8%) people who were presumptive for TB.
Further radiological screening revealed that 23 participants (8.5%) had abnormalities. On testing 13 (4.8%) people were diagnosed with TB, 7 being bacteriologically confirmed through GeneXpert, while 6 cases clinically diagnosed.
Conclusions: This initiative highlights the elderly as a key population for targeted outreach efforts. By combining targeted mobilization, symptomatic and radiological screening and diagnostics, previously undiagnosed TB cases were successfully identified.
These findings emphasize the importance of scaling similar interventions in other regions to enhance early TB detection among the elderly.

OA29-385-21 Enhancement of TB infection prevention through task shifting to community health volunteers (CHVs)

J. Diara,[1] J. Ongbabo,[1] C. Abagwalatu,[1] K. Akaangee,[2] O. Chukwuogo,[3] B. Odume,[4] [1]KNCV Nigeria, Technical, Makurdi, Nigeria, [2]Benue State Tuberculosis, Leprosy and Buruli Ulcer Control Program, Technical, Makurdi, Nigeria, [3]KNCV Nigeria, Technical, Abuja, Nigeria, [4]KNCV Nigeria, Administrative/Technical, Abuja, Nigeria
e-mail: jdiara@kncvnigeria.org

Background and challenges to implementation: The World Health Organization recommends a minimum of 4.45 healthcare workers per 1,000 people to achieve adequate health coverage. In Nigeria, however, this ratio is alarmingly low at just 0.77 healthcare workers per 1,000 people, significantly below the recommended benchmark. Nigeria lacks sufficient DOT Officers in its facilities to also implement contact investigation (CI), which is pivotal to reducing TB infection.
This intervention is aimed to train Community Health Volunteers (CHVs) to take up the task of CI and relieve pressure on the DOT officers.
Intervention or response: The intervention occurred in Benue State, Nigeria, in three phases. The first phase consisted of rigorous training for 31 CHVs, along with pre- and post-tests to evaluate their knowledge and skills both before and after the training. The second phase involved the CHVS implementing the CI under the supervision of DOT officers, while the third phase assessed the implementation outcomes both before and during the process. Data were analyzed using SPSS version 29 and the Wilcoxon signed-rank test at a significance level of 0.05.
Results/Impact: The CHVs' training revealed pre-test scores ranging from 15-50%, (26 CHVs scored between 0-45% and 5 CHVs scored between 50-65%) while the post-test ranged from 30-95%, (1CHV each scored between 0-45% and 50-65%, 23 scored between 70-85%, and 6 scored between 90-100%).
The CI implementation revealed that 1634 index patients were contact-traced, 9679 eligible contacts were identified, and 1289 started TPT from October 2023 to March 2024, while 2538 contacts were traced, 23,567 eligible contacts were identified, and 7576 started TPT from April to September 2024. Both index patients contact traced ($p=0.035$) and TPT enrolment ($p=0.019$) were statistically significant after the intervention.
Conclusions: This study demonstrated not only the enhanced TB infection prevention through CI but also how CHVs can provide a critical link with the health systems in resource-constrained settings.

OA29-387-21 Community-based tobacco cessation intervention among chronic smokers in urban slums: A public health approach

D. S,[1] D.P. D.S,[1] U.R. A,[1] S.K. D,[1] S. N,[1] S. V,[1] [1]Cancer Institute, Resource Centre for Tobacco Control, Chennai, India
e-mail: s.deepika@cancerinstitutewia.org

Background: Tobacco use remains a major public health concern, especially in urban slums. Previous studies have largely focused on clinical or individual-level interventions, highlighting a significant gap in community-oriented approaches. This study aims to assess the effectiveness of a structured community-based intervention to help chronic smokers residing in urban slums.
Design/Methods: Baseline data were collected through surveys to identify, screen, and enroll tobacco users (n=109) from the community. Demographic details and tobacco use history were collected using a case record form. The intervention included tobacco awareness sessions, behavioral counseling, and Nicotine Replacement Therapy (NRT). A follow-up assessment was conducted after six months through in-person visits and phone calls using a structured survey form. Descriptive and inferential statistics were used to analyze the data.

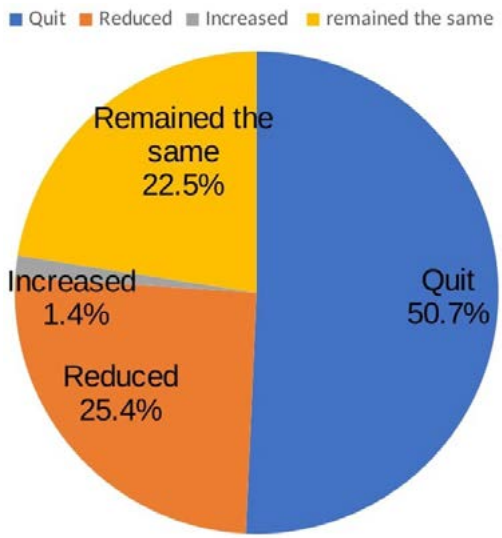


Figure. Current tobacco use after intervention.

Results: Mean age of tobacco users was 53 years, 33.9% completed secondary education, 61.5% were daily-wage workers and 83.5% belonged to low-income group. Majority (88.1%) were smokers, while 11.9% used both forms. Of all, 51.4% initiated tobacco before the age of 18 years and 68.8% were using tobacco for over 30 years. Peer pressure (83.5%) was major reason for initiating tobacco use, and 50.5% continued due to addiction. Of the 71 (65.1%) successfully contacted for post assessment, 15.1% were in precontemplation, 26.8% in contemplation, 7% in preparation, 15.5% in action, and 35.2% were in maintenance stage. Of all, 36 (50.7%) quit and 35 (49.3%) still continue tobacco. Of the current users, 51.4% reported reduced tobacco use and 62.8% attempted to quit tobacco, 77.1% reported motivated to quit following counseling. There is a significant association between reason for initiating and cessation attempts prior intervention.
Conclusions: Behavioral counseling, awareness sessions, and clinical support significantly improved quit and reduction rates among chronic smokers in urban slums. Health concerns and counseling motivated cessation, while addiction remained a key barrier, highlighting the value of community-based interventions.

OA29-388-21 Enhancing TB detection through community-led hybrid contact investigation: A scalable model for hard-to-reach populations

D.D. Tobaiwa,[1] K. Mutungamiri,[2] [1]Jointed Hands Welfare Organisation, Programs, Gweru, Zimbabwe, [2]Jointed Hands Welfare Organisation, Strategic Information, Gweru, Zimbabwe

Background and challenges to implementation: Tuberculosis (TB) contact investigation is crucial in curbing TB transmission, yet traditional methods led by Environmental Health Technicians (EHTs) often missed cases due to accessibility challenges, particularly in remote and hard-to-reach communities. Jointed Hands Welfare Organization (JHWO), under the USAID-funded Kunda Nqob'iTB (KNTB) project, identified key challenges, including low case detection, poor treatment adherence, and high mobility among artisanal and small-scale miners (ASMs), which hindered effective contact tracing.
Intervention or response: To address these barriers, JHWO introduced the TB Hybrid Contact Investigation Model, integrating EHT-led traditional contact tracing with a community-based approach. Community Health Workers (CHWs) were trained in infection prevention, control, and sputum collection, enabling them to support presumptive TB cases at the household level.
The model leveraged digital tools for real-time data collection and strengthened community engagement by involving local leaders and opinion influencers in high-risk populations such as ASMs. These measures facilitated early diagnosis, increased TB Preventive Therapy (TPT) uptake, and reduced stigma associated with seeking healthcare.
Results/Impact: Over a four-and-a-half-year period, the model identified 38,371 contacts, screened 34,537 (90%), and diagnosed 517 (1.5%) TB cases, with 96% initiating treatment. In Mwenezi district, where health facilities are widely dispersed, household-level sputum collection by IPC trained CHW significantly improved case detection. TB notifications from community contributions rose from 5% to 100% at Chingwizi clinic and from 0%

to 43% at Mlelezi clinic. These findings underscore the effectiveness of CHW-led interventions in improving TB case detection and treatment adherence in underserved populations.
Conclusions: The TB Hybrid Contact Investigation Model offers a scalable approach for enhancing TB case detection and treatment adherence, particularly in marginalized communities. Future programs should focus on scaling up CHW training, strengthening community engagement, and integrating digital tools for monitoring and evaluation to optimize TB prevention and control efforts.

OA30 Environmental determinants of lung health: From fossil fuel to filter tips

OA30-389-21 Climate change and TB: An analytical framework

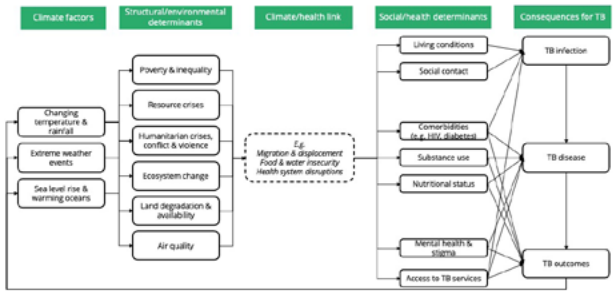
e-mail: msaunder@sgul.ac.uk

Background: Climate change is likely to exacerbate a range of determinants which drive the global tuberculosis epidemic. However, tuberculosis, the world's leading infectious disease killer, is often neglected in wider climate health discussions.
Design/Methods: Commissioned by the World Health Organization (WHO), we developed an analytical framework outlining potential causal relationships between climate change and tuberculosis. We drew on established knowledge and identified tuberculosis determinants which are likely to be sensitive to the effects of climate change, and conceptualised the mechanistic pathways through which this might occur. We collated evidence for these pathways through literature review and narrative synthesis. The resulting framework was presented at a multi-stakeholder consultation organised by WHO on the impact of climate change on tuberculosis and subsequently updated and refined.
Results: The framework (Figure) first maps how changing climate factors (e.g. changing temperature and rainfall) lead to changes in structural and environmental determinants (e.g. land degradation and availability). These are then linked to health via a series of climate/health links, which complete a direct causal pathway through which changes in structural and environmental determinants

drive changes in exposure to social and health determinants. Lastly, social and health determinants are linked to tuberculosis consequences, where they may affect the likelihood of exposure and susceptibility to tuberculosis infection, the risk of progression to tuberculosis disease, and the extent of vulnerability to tuberculosis outcomes.
Our literature reviews summarised evidence on how three priority climate/health links work across these pathways:
i. migration and displacement;
ii. food and water insecurity, and;
iii. health system disruptions.



Conclusions: The available evidence supports the existence of plausible pathways between climate change and tuberculosis, highlighting the need to include tuberculosis in climate risk adaptation and mitigation programmes, and climate-resilient funding and response mechanisms. Further evidence is urgently needed to quantify the effects of climate change on tuberculosis.

OA30-390-21 Tuberculosis and climate emergency: Community analysis on access to TB services during the floods in 2024 in Porto Alegre, Brazil

C. de Almeida,[1] [1]Rede Brasileira de Pesquisas em Tuberculose, REDE-TB, Social Mobilization, Porto Alegre, Brazil
e-mail: carla.lacuriosa@gmail.com

Background and challenges to implementation: Rio Grande do Sul (RS) is the Brazilian state with the highest tuberculosis (TB) epidemic burden. In May 2024, severe flooding struck RS, leading to a health, political, social, and economic crisis that disproportionately affected the most vulnerable populations. To evaluate how this catastrophic event impacted access to TB health services and social policies, the TB social movement conducted a mixed-methods assessment in the metropolitan region of Porto Alegre(RS capital city).
Intervention or response: We carried out a qualitative situational assessment by reviewing government guidelines, conducted in-depth interviews with 09 displaced individuals undergoing treatment for tuberculosis or tuberculosis preventive treatment(TPT), and visited 07 shelters to assess their sanitary conditions and availability of health and social services.
Additionally, a snowball sampling for a quantitative, online, self-administered survey targeting people undergoing treatment for TB or TPT was implemented. The questionnaire included topics on TB prevention, diagnosis, treatment, and access to social policies. Qualitative data were analyzed using content analysis, while descriptive analysis was performed on quantitative data.
Results/Impact: Most of sheltered interviewees (9) reported interruptions in their TB treatment due to lost medications in the floods; feelings of embarrassment and lack of confidential spaces for taking their medication; insufficient information about withdrawal of TB treatment having no documentation or prescription, and experiences of stigma and discrimination.
None of the shelters implemented any TB prevention measures or provided masks. A total of 76 participants completed the survey (51% cis men, 33% cis women, 16% transgender, and 86% PLWHA). Among them, 89% reported treatment interruptions lasting ≥7 days; 97% experienced food insecurity; and 48% described incidents of discrimination.
Conclusions: Strategies deployed by health services to ensure the continuity of treatments were ineffective, highlighting the urgent need for robust, structured contingency plans to mitigate the impacts of climate emergencies on TB and health systems.

OA30-391-21 Asthma and air pollution in Benin: Symptoms' frequency and impact of the harmattan period in adolescents from A4A Project study in Cotonou

A.A. Fiogbé,[1] U. Patinvoh,[1] A.P. Wachinou,[1,2] M. Migan,[3,4] A. Verdin,[3] D. Courcot,[3] F. Bokossa,[5] N. Marilleau,[6] B. Cachon,[4] C. Atindehou,[4] R. Lalou,[7] G. Agodokpessi,[1,2]
[1]Centre Hospitalier et Universitaire de Pneumo-Phtisiologie (CNHUPPC), Service de Pneumologie, Cotonou, Benin, [2]FAculté des Sciences de la santé FSS/ Université d' Abomey-Calavi, UFR de Pneumologie, Cotonou, Benin, [3]Université du Littoral Côte d'Opale (ULCO), Unité de Chimie Environnementale et Interactions sur le Vivant (UCEIV), Dunkerque, France, [4]Faculté des Sciences et Techniques,Université d'Abomey-Calavi, Laboratoire de Biochimie et Biologie Moléculaire, Cotonou, Benin, [5]BLOLAB, Laboratoire de Fabrication Numérique „ Cotonou, Benin, [6]Faculté des Sciences Pharmaceutiques et Biologiques, Université Paris Cité„ Unité Mixte de Modélisation et des Systèmes Complexes (UMISCO), IRD, Paris, France, [7]Faculté des Sciences Pharmaceutiques et Biologiques, Université Paris Cité, UMR 261 – MERIT, IRD, Paris, France
e-mail: afiogbe@yahoo.fr

Background: Air pollution influences gene expression, increasing susceptibility to respiratory diseases such as asthma, and increases also frequency and severity of asthma symptoms. We present here the results from follow-up of asthmatic adolescents icohort study in cotonou. The

main objective was to study the occurrence of respiratory events (acute symptoms or 'attacks'/exacerbations) and to assess the link with exposure to particulate matter (PM), whether collective or personal.
Design/Methods: Among 4,500 adolescents from 6th and 5thclassroom in 25 secondary schools in Cotonou ; we set up a cohort of 730 asthmatic adolesecents. Exposure to PM was measured using of Qameleo® sensors installed in the schools and in adolescent's homes. Levels of gaseous pollutants (NO2, CO, O3, VOCs) were measured by 10 fixed COTON® sensors. Individual exposure was monitored by portable MQair sensors, carried in backpacks.
Results: 604 (84%) asthmatics were regularly followed up over 36 months. During this period, 222 (37%) adolescents reported the occurrence of at least one respiratory event. From 2947 monthly visits, exacerbations occurred in 9.3% of person-months. Adolescents with frequent respiratory events had higher levels of personal exposure to several pollutants. Their mean levels of NO2; PM1; PM2.5; and PM10 was respectively : 11.05(±5.23) µg/m3; 18.85(±11.05) µg/m3; 29.05 (±18.8) µg/m3 and 41.96(±29.24) µg/m3. PM2.5 pollution during the harmattan season is inequaly distributed(Figure 1), and also asthma symptoms occur 2.5 times more during harmattan than outside this period. The triggers were: house dust: 57%; outdoor pollution: 26%; temperature change: 21%; and food allergens: 12%.
Conclusions: In Cotonou, air pollution systematically exceeds WHO thresholds for all pollutants. More than 1/3 of asthmatic adolescents had respiratory events, and the harmattan period contributed 2.5 times to the exacerbations's occurrence. Taking into account information on pollution would help to optimise and personalize asthmatic management in this context.

OA30-392-21 Impact of ambient particulate air pollution on intelligence quotient in 6-8 years children in Odisha, India

K. Dash,[1] P. Jena,[1] [1]School of Public Health, KIIT Deemed to be University, Public Health, Bhubaneswar, India
e-mail: drpratapjena@gmail.com

Background: Ambient air pollution due to particulate matter (particularly PM2.5 and PM10), is a growing public health concern with documented effects on lung and cardiovascular health. Recent evidence suggests particulate matter may also disrupt early cognitive development. In India pollution levels frequently surpass permissible thresholds, but risk remains underexplored. This study examines the association between particulate air pollution and cognitive function in children aged 6 to 8 years in Odisha.
Design/Methods: A comparative analytical study was conducted at two sites, one with high pollution (PM10>60 µg/m³ & PM2.5>40 µg/m³, n=210) and another with low pollution (n=186), from July to December 2022. Children residing for six years within a 1.5 km radius from air quality monitoring stations were assessed using Malin's Intelligence Scale for Indian Children (MISIC). Full-scale intelligence quotient (IQ), including verbal and performance IQ was assessed. Sociodemographic and environmental variables were included in regression model.
Results: Mean full-scale IQ in high-pollution areas was 80.33 ± 6.11 compared to 98.12 ± 6.33 in low-pollution areas ($p < 0.001$). Children from high pollution areas had a verbal IQ of 81.60 ± 5.57, lower than the 99.68 ± 6.60 observed in low pollution areas ($p < 0.001$). Children had a performance IQ of 79.03 ± 8.33 in high-pollution areas, compared to 96.55 ± 8.46 in low-pollution areas ($p < 0.001$). The regression model suggested that full-scale IQ was significantly associated with air pollution exposure, child's age, poor kitchen ventilation, maternal education, child's weight, and family income.
Conclusions: Long-term exposure to air pollution is closely linked to poorer cognitive development in children. This study highlight the importance of considering brain health in lung health strategies and call for immediate efforts to protect young children from ambient air pollution.

OA30-393-21 Effect of food insecurity on TB incidence in climate sensitive Karamoja region of Uganda

B. Joshi,[1] L. Salumu,[1] S. Turyahabwe,[2] L. Thibaut,[1] G. Amanya,[3] R. Migisha,[4] F. Klaassen,[5] M. Savy,[6] F. Cobelens,[5] M. Bonnet,[1] D. Chemtob,[1] [1]Institut de Recherche pour le Développement – IRD, TransVIHMI, Montpellier, France, [2]Ministry of Health, Communicable Disease Prevention and Control, Kampala, Uganda, [3]Ministry of Health, National TB Leprosy Control Program (NTLP), Kampala, Uganda, [4]Mbarara University of Science and Technology, Department of Physiology, Mbarara, Uganda, [5]Amsterdam University Medical Centers, Department of Global Health and Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, [6]Institut de Recherche pour le Développement – IRD, MoISA, Montpellier, France
e-mail: basant.joshi@ird.fr

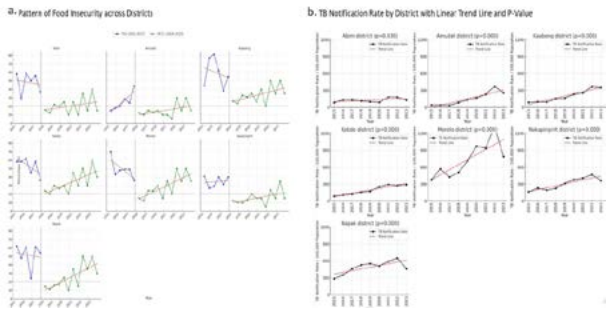
Background: Key risk factors for tuberculosis include food insecurity/undernutrition, both of which may be worsened by the effects of climate change (CC). We conducted an ecological study to investigate the relationship between food insecurity (FI) and TB case notification at population level in Karamoja region (Uganda), that has persistent high levels of FI and tuberculosis incidence, and is highly vulnerable to CC.
Design/Methods: We aggregated secondary biannual data on FI, i.e. the Food Consumption Score (FCS) (from Food Security and Nutrition Assessment Survey (2015-2017) and Integrated Food Security Phase Classification [IPC]) (2018-2023) and on TB notification (from pro-

grammatic records) at district level between 2015-2023. We performed time series analysis using Augmented Dickey-Fuller test, linear regression, and Mann-Kendall tests to assess trends, seasonality and patterns of FI and TB notification. Temporal relationships between FI and TB cases were assessed using Vector Autoregressive (VAR) models and Granger causality test.

Results: We confirmed the chronic burden of FI and TB in Karamoja with high seasonality in FI, identifying Kaabong, Kotido and Moroto as hotspot districts where more than 25% of households experienced FI. In pre-2018 analysis based on FCS (Figure), districts showed stationarity trends of FI except in Amudat and Kotido, indicating relatively stable pattern ($p<0.05$), whereas increase in trends ($p<0.05$) was observed in the majority of districts post-2018.

Overall, TB notification rates increased by 37% annually (*p<0.01*), with the highest increase observed in Moroto district (89% annual increase, *p<0.01*).

Figure: Pattern of Food Insecurity and TB notification in Karamoja Region, Uganda, 2015-23



The VAR model suggested that FI temporally impacted TB case notification, with a lag of 2 years (*p=0.03*). No reciprocal effect of TB notification on FI was found (*p=0.51*).

Conclusions: Our preliminary analysis underscores the seasonal patterns of FI and increasing trend of FI and TB notification rates over time, but potential confounding factors, including programmatic interventions, might have contributed for increase in TB notification rates.

OA30-394-21 Factors contributing to delayed TB diagnosis in Somalia: Survey data identifies poverty, malnutrition, displacement, and low awareness as key factors delaying TB diagnosis in Somalia

A.I. Omar,[1] F. Ngari,[2] A. Hassan,[3] [1]World Vision International, Somalia Program, Garowe, Somalia, [2]World Vision International, Somalia Program, Garowe, Kenya, [3]Ministry of Health Puntland, Public Health, Garowe, Somalia

Background: Delayed tuberculosis (TB) diagnosis is a major barrier to TB control, especially in Somalia. This is as a result of the fragility context of the country which leads to weak health systems, presents a critical case to understand how structural vulnerabilities—poverty, malnutrition, and displacement—contribute to diagnostic delays.

Design/Methods: A nationally representative, cross-sectional TB patient cost survey was conducted in 2024 across 36 TB treatment facilities in Somalia. Of the 1,005 DS-TB patients interviewed, 961 were included in the analysis. Structured questionnaires were used to collect data on care-seeking behavior, socioeconomic status, and awareness of TB services. Data were entered using CSPro and analyzed using STATA version 17. Diagnostic delays were defined as >14 days from symptom onset to treatment initiation and summarized using medians and interquartile ranges.

Results: Among 961 patients, 736 (77%) experienced diagnostic delays >14 days. The median delay was 37 days—30 days patient delay and 7 days system delay. Results indicate that the below factors contributed to delay in diagnosis

- 614 (64%) lived below the international poverty line ($1.90/day).
- 510 (53%) were undernourished.
- 384 (40%) reported moderate to severe food insecurity.
- 213 (22%) were internally displaced (median delay: 45 days vs. 32 days for non-displaced).
- 374 (39%) were aware that TB treatment is free. (services, 2024)

Conclusions: Three-quarters of DS-TB patients (736 of 961) experienced significant diagnostic delays. These delays were driven by poverty, undernutrition, displacement, low awareness of free TB services, and reliance on informal providers. The National TB program together with its stakeholders have begun mitigation measures by developing policy documents e.g. MAF and PPM policy to better guide TB control activities and improve health literacy in the country. These actions are essential to reduce delays and achieve equitable, timely TB care in fragile settings like Somalia

OA30-395-21 Ten-year trends in second hand smoking (SHS) in Europe 2012-2023: A snapshot review

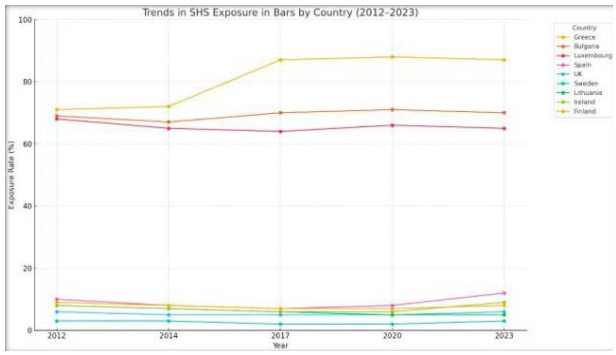
A. Aravind,[1] A. TamilSelvi,[2] S. Rajendra,[1] [1]University of Buckingham, University of Buckingham School of medicine, Buckingham, United Kingdom of Great Britain and Northern Ireland, [2]Countess of Chester Hospital NHSFT, Dept of Medicine, Chester, United Kingdom of Great Britain and Northern Ireland

Background: Nearly one-third of cancers are linked to tobacco, including second-hand smoke (SHS), which raises cancer risk by up to 16% in non-smokers. In December 2024, the EU recommended reducing SHS exposure outdoors. SHS exposure affects 31% of Europeans, varying by country and policy enforcement.We examined trends from 2012 to 2023

Design/Methods: We reviewed various tobacco surveys and collated them mainly from the Eurobarometer surveys done in 2012, 2014, 2017, 2020, and 2023. The data was scrutinised to ascertain the trends of passive smoking with individual country data in Europe.

Results: There is variability in secondhand smoke (SHS) exposure rates among European countries. Greece has consistently high levels of SHS exposure, despite existing regulations. In contrast, Spain, the UK, Sweden, Finland, and Ireland demonstrate low and stable SHS levels, which suggests effective law enforcement and a good public understanding of the risks involved.

Bulgaria and Luxembourg show moderately declining trends in SHS exposure, while Lithuania has experienced a significant reduction since 2012. However, in 2023, some countries like Spain and Ireland are seeing an upward trend in SHS exposure, which may be linked to enforcement fatigue or an increase in social activity.



Conclusions: Second-hand smoke remains a significant public health threat in Europe. Despite some progress, exposure is still growing in some countries, especially in countries with less robust tobacco control policies. Continued legislative action and public support are key to reducing SHS exposure and achieving the EU's 2040 smoke-free goal.

OA30-396-21 A comprehensive bibliometric exploration on the health impact of e-cigarettes

D. Walia,[1] C. Goel,[1] S. Goel,[1] [1]Post Graduate Institute of Medical Education and Research, Chandigarh, Department of Community Medicine and School for Public Health, Chandigarh, India
e-mail: dikshawalia05@gmail.com

Background: E-cigarettes, or vapes, are battery-powered devices that heat a liquid—typically containing nicotine and other chemicals—to produce an aerosol inhaled by the user. Often mistaken for harmless vapor, this aerosol contains fine particles and harmful substances. Their popularity, especially among youth, stems from perceived reduced harm compared to traditional tobacco. In 2021, an estimated 82 million people globally used e-cigarettes. However, growing evidence links their use to respiratory, cardiovascular, neurological, and metabolic comorbidities. This study examines global research trends on the health effects of e-cigarettes.

Design/Methods: A bibliometric analysis was conducted using the Scopus database, applying the Population–Exposure–Outcome Framework to examine global research on e-cigarette-related health effects. Keywords related to e-cigarettes ("electronic cigarette" OR "e-cigarette" OR "vaping") and health outcomes ("disease" OR "health effect" OR "morbidity") were combined using Boolean operators. The search was restricted to English-language publications from 1974 to 2024. Out of 26,018 retrieved documents, 18,038 research articles met the inclusion criteria and were included in the final analysis.

Results: A comprehensive bibliometric analysis of 18,038 articles revealed a 400% rise in annual publications on e-cigarettes between 2015 and 2023, with 65.4% published after 2018. The United States led in output, followed by the UK, China, Germany, Italy, and Canada.

Co-occurrence network analysis highlighted dominant themes such as human demographics, smoking cessation, and electronic nicotine delivery systems. Temporal trends showed a shift from health systems research to behavioral and regulatory themes post-2016.

Word cloud visualization reinforced the prevalence of terms like smoking, vaping, nicotine, and adolescents, indicating growing scholarly focus on health risks and emerging tobacco products.

Conclusions: The growing body of research underscores the association between e-cigarette use and major health risks, particularly respiratory and cardiovascular. Despite increasing output, gaps remain in long-term and policy-oriented studies. Collaborative and longitudinal research is essential to inform evidence-based regulations.

OA30-397-21 Global trends and industry influence in tobacco harm reduction research: A bibliometric analysis (2014–2024)

N. Satpathy,[1] D.K. Satpathy,[2] [1]Siksha,O' Anusandhan Deemed to be University, Community Medicine, Bhubaneswar, India, [2]Birla Institute of Technology and Science, Department of Computer Science & Information Systems, Pilani, India
e-mail: nancysatpathy@soa.ac.in

Background: Tobacco harm reduction (THR) is increasingly promoted as a public health strategy due to the proliferation of electronic nicotine delivery systems (ENDS), heated tobacco products (HTPs), and nicotine pouches. However, concerns persist that the tobacco industry's involvement in THR research may influence the evidence base and shape global policy discussions.
This study aimed to assess global research trends, identify dominant actors and themes, and examine the extent of tobacco industry affiliation in THR literature.
Design/Methods: A bibliometric analysis was conducted on 354 peer-reviewed THR-related publications indexed in Scopus between 2014 and 2024. VOSviewer software was used to perform co-citation analysis, bibliographic coupling, and keyword co-occurrence mapping. Author affiliations were manually screened using institutional data and conflict-of-interest statements to classify studies as tobacco industry-affiliated, tobacco control/public health-affiliated, or unclassified. Descriptive statistics were used to quantify research output, citation trends, and affiliation types.

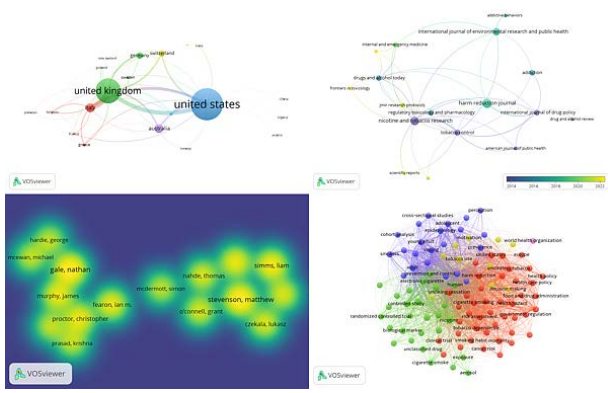


Figure: Visual Mapping of Global THR Research Themes and Networks (2014–2024).

Results: THR publications increased significantly after 2019. The United States and the United Kingdom contributed the most to publication and citation volume. Three core thematic clusters were identified: toxicological research, policy and regulation, and behavioral studies.
Bibliographic coupling revealed two dominant author networks, both linked to transnational tobacco companies such as British American Tobacco and Philip Morris International. Of the 354 studies, 79 were industry-affiliated, 24 were tobacco control-affiliated, and the remainder were initially unclassified. Deeper analysis revealed that many unclassified studies involved authors with undisclosed or indirect industry ties.
Conclusions: The THR research landscape is shaped by a small number of highly networked, industry-linked authors and institutions. This concentration risks distorting the scientific narrative favoring product-based harm reduction strategies. Strengthening independent, public health–driven research and increasing transparency in author disclosures are essential to ensure balanced evidence for global tobacco control policymaking.

OA30-398-21 Heated tobacco product use and tobacco abstinence: A prospective cohort study

T. Ukai,[1] A. Ohkado,[1] [1]Research Institute of Tuberculosis, Department of Epidemiology and Clinical Research, Kiyose, Japan
e-mail: ukai_tomohiko@jata.or.jp

Background: Heated tobacco products (HTPs) have gained popularity in recent years, particularly among individuals seeking to quit smoking conventional cigarettes. Despite their growing use, the effectiveness of HTPs in supporting smoking cessation and achieving tobacco abstinence remains unclear.
This study aimed to examine whether HTP use was associated with abstinence from cigarettes and from all tobacco products in a large, population-based cohort in Japan.
Design/Methods: We conducted a sequential follow-up analysis of a prospective cohort using data from a nationwide, internet-based, self-reported survey conducted annually between 2019 and 2023. The study included 7,501 Japanese adults (aged ≥20 years) who were current cigarette smokers at baseline.
Participants were classified as exclusive cigarette users (n = 4,989) or dual users of cigarettes and HTPs (n = 2,512). Primary outcomes were 1-year abstinence from cigarette use and total tobacco abstinence.
Rate ratios (RRs) and 95% confidence intervals (CIs) were calculated using inverse probability-weighted Poisson generalized estimating equation models, adjusting for sociodemographic variables, use of evidence-based cessation support, smoking dependence, and survey year.
Results: After one year, 19.5% of exclusive cigarette users and 18.2% of dual users reported abstinence from cigarette use (RR, 0.93; 95% CI, 0.83–1.04).
Total tobacco abstinence was achieved by 17.3% of exclusive cigarette users and 8.2% of dual users (RR, 0.49; 95% CI, 0.42–0.58).
Conclusions: Dual users were significantly less likely than exclusive cigarette users to quit all tobacco products. These findings suggest that HTP use, particularly in combination with cigarette use, may not facilitate successful tobacco cessation.

OA31 Informing evidence-based TB policies

OA31-399-21 Power, players and politics: Who are the power brokers of TB control in Pakistan - International donors or national leadership?

S.S. Habib,[1] T. Masoud,[2] H. Bin Hamza,[2] W. Zulfiqar,[2] W. Jadoon,[2] N. Rafiq,[2] Z. Gardeezi,[2] S. Siddiqui,[1]
[1]The Aga Khan University, Community Health Sciences, Karachi, Pakistan, [2]Ministry of National Health Services, Regulations and Coordination, (MoNHSRC), Islamabad, Pakistan
e-mail: shifa.habib@aku.edu

Background: Pakistan is the fifth highest TB burden country, yet only 5.5% of TB financing is domestically resourced (Global-TB report 2024) with heavy reliance on the Global Fund for AIDS, Tuberculosis and Malaria (GFATM). An in-depth strategic review was commissioned by Ministry of National Health Services, Regulation and Coordination, Pakistan, to assess how GFATM's long-term financial assistance has strengthened the TB programme, including an in-depth stakeholder analysis cutting across themes of governance, service delivery and financial sustainability.
Design/Methods: Stakeholder analysis followed a mixed-methods approach embedded within the broader strategic review of GFATM. Stakeholder mapping was informed by a desk-review. In-depth interviews were conducted with a total of 232 key informants from federal and provincial governments, implementing partners, donors, and civil society. Data were analyzed using NVivo. Stakeholder analysis included roles, interest, level of influence, decision-making processes.
Results: Analysis identified concentration of influence among limited key actors. Geneva-based GFATM secretariat remains the key decision-maker and agenda-setter in the country. Country Coordinating Mechanism (CCM), comprising federal and provincial government representatives, has been rendered powerless by the imposition of Additional Safeguard Policy (ASP), allowing GFATM to directly make decisions regarding the primary implementers of TB programme. Mercy Corps, primary recipient for TB in private sector directly reports to GFATM, bypassing the national TB programme. Local Fund Agent (LFA) acts as GFATM's in-country monitor. NTP maintains little oversight function especially across private sector. Provincial TB Control Programs have limited voice in strategic decision-making forums, despite being central to service delivery. Co-ordination among principal recipients, sub-recipients and provinces remains fragmented, and community and civil society participation remains minimal (Figure-1).

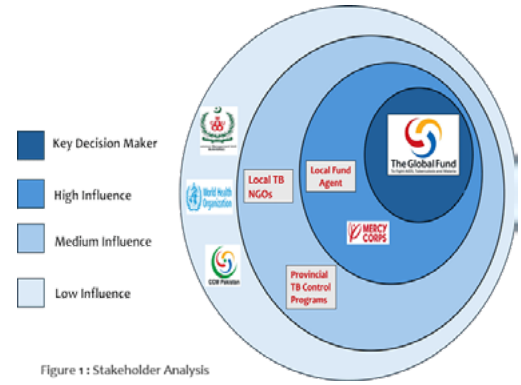

Figure 1: Stakeholder Analysis

Conclusions: TB landscape in Pakistan is dominated by donors for leading strategic decision-making and financing, undermining the national leadership. As the world grapples with abrupt donor freezes and shifting geopolitical priorities, Pakistan must transition to domestic leadership and financing.

OA31-400-21 Comparing the relative epidemiological impact, costs and cost-effectiveness of TB interventions across three countries

K.C. Horton,[1] A. Schwalb,[1] M. Harker,[1] L. Goscé,[1] E. Venero-Garcia,[1] L. O'Brien,[1] A. Gun,[1] T. Sumner,[1] F. Mcquaid,[1] R.A. Clark,[1] R.G. White,[1] R.M.G.J. Houben,[1]
[1]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland
e-mail: katherine.horton@lshtm.ac.uk

Background: While a range of interventions exists for TB - spanning prevention, screening, diagnosis, and treatment - their potential impact and cost-effectiveness are seldom compared across domains and settings with different background TB epidemiology and structural drivers.
Design/Methods: We calibrated a deterministic TB model, including transmission, non-infectious and asymptomatic disease and key structural drivers, to TB epidemiological indicators in South Africa (HIV), Brazil (incarceration) and India (undernutrition).
We implemented a standard set of seven interventions focussing on prevention, diagnosis and treatment of TB (Figure) as well as nutritional supplementation in India and TB screening in prisons in Brazil. To enable comparison between interventions, we standardised scale-up (2025-2030), target coverage (80% of relevant population), and strength of evidence for epidemiological impact (availability of published efficacy data).
We estimated epidemiological impact by 2050 (reduction in prevalence, incidence and deaths) and costs per disability-adjusted life year (DALY).

Results: We found that only three interventions prevented >10% of incident TB episodes by 2050: vaccination (15-28% across countries), community screening (32-38%) and screening in prisons (23%) (*Figure*).
Impact of other interventions was more limited, between 0% (shortened drug-susceptible treatment) to 5% (nutritional intervention). Cost-effectiveness ratios ranged from cost-saving (e.g. shorter drug resistant therapy in Brazil and South Africa) to over 10,000 USD/DALY averted (high-cost community screening in Brazil).
In Brazil and South Africa, all interventions except shortened drug-susceptible treatment and, in Brazil only, high-cost community screening, appear to be cost-effective, while no intervention was below the cost effectiveness threshold in India.

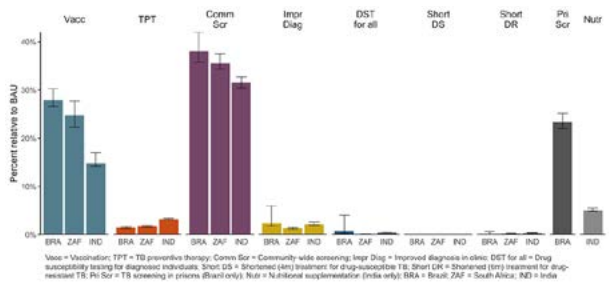

Figure. Incident TB episodes averted grouped by intervention (2025-2050).

Conclusions: By comparing impact and costs across intervention domains and settings with modern evidence, we highlight strong differences between interventions in terms of potential epidemiological impact and their costs-benefit, informing crucial discussions around prioritisation for funding, policy and product development.

OA31-401-21 New drugs, diagnostics and vaccines in India: Their potential impact on TB burden, and priorities for their development

S. Mandal,[1] N. Arinaminpathy,[2] K. Rade,[3] R. Rao,[4] U. Singh,[4]
[1]John Snow India, Data Analytics and Modelling Division, Delhi, India, [2]World Health Organization, TB Monitoring, Evaluation and Strategic Information, Geneva, Switzerland, [3]Stop TB Partnership, Global Health, Geneva, Switzerland, [4]Ministry of Health & Family Welfare, Central TB Division, Delhi, India
e-mail: sandipccmb@gmail.com

Background: Emerging tools, such as new drugs, diagnostics and vaccines, raise key questions for strategic planning in the TB response: what is their potential impact in high-burden settings? Across this range of potential new tools, what are the highest-priority needs, to maximise reductions in TB incidence and mortality?
We aimed to address these questions using mathematical modelling with a focus on India, the country with the world's largest TB burden.

Design/Methods: We developed a novel model of TB transmission dynamics in India, incorporating data on the diagnostic pathway, and from India's recent national prevalence survey. We performed the following analyses: (i) 'Intervention projections': we simulated the potential impact of hypothetical new, more-effective regimens; improved diagnostics in routine TB care; population screening for TB; and a prevention-of-disease vaccine. (ii) 'Strategic priorities': Shifting focus to the TB cascade, rather than specific interventions, we analysed which existing gaps would – if addressed – yield the largest reductions in TB burden in India.
Results: Figure 1 (left panel) shows projected incidence reductions from new tools, acting in successive combination. For example, screening 15% of the population per year with chest X-ray followed by NAAT confirmation would reduce incidence rates in 2040 by an incremental 24% (95% uncertainty intervals 17 – 33%), relative to no intervention. Analysis of strategic priorities (right panel) highlights that in future, the greatest reductions in TB disease burden would result from interventions that can target the pre-careseeking delay, and the risk of developing TB following infection.

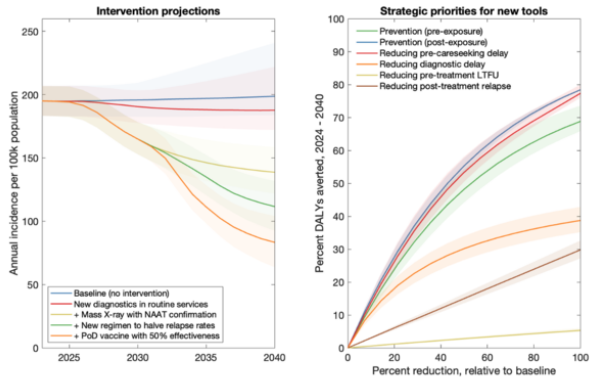

Figure: The potential impact of new tools on TB burden in India. *Left-hand panel*: Projected incidence under different interventions acting in successive combination, with the following assumptions: new diagnostics would facilitate increased microbiological testing for TB at the primary care level. Ultraportable X-ray machines, coupled with high-throughput NAAT, would allow screening of 15% of the population per year (prioritised as needed, amongst high-prevalence groups). From 2030 onwards, a new regimen would be sufficiently shortened and simplified, to promote treatment completion and cut post-treatment relapse by half. Also from 2030, a new vaccine would have 50% effectiveness in reducing the risk of progression to TB, amongst people with infection. *Right-hand panel:* Shifting focus from specific interventions to TB cascade, the potential impact of addressing different gaps in the TB cascade. On the x-axis, the value 0% represents no intervention, while 100% represents a hypothetical scenario where respective gaps are fully closed.

Conclusions: The combined use of new drugs, diagnostics and vaccines could achieve substantial reductions in TB burden. Nonetheless, these findings highlight the critical role of new tools that can facilitate accelerated case-finding (e.g. highly portable X-rays with AI reads) and post-exposure prevention of TB (e.g. a prevention-of-disease vaccine, or nutritional support).

OA31-402-21 Combination strategies to control the TB epidemic in the Karamoja subregion of Uganda: A modelling analysis

S. Zawedde-Muyanja,[1] L. Najjemba,[1] B. Picho,[2] T. Nsubuga,[2] A. Etwom,[2] D. Dowdy,[3] T. Ryckman,[3] [1]The Infectious Diseases Institute, College of Health Sciences, Makerere University, Research, Kampala, Uganda, [2]The Infectious Diseases Institute, College of Health Sciences, Makerere University, Health Systems Strengthening, Kampala, Uganda, [3]Johns Hopkins University, Public Health, Baltimore, United States of America
e-mail: szawedde@idi.co.ug

Background: The Karamoja subregion in north-eastern Uganda is disproportionately affected by TB, with an estimated prevalence more than three times the national average. Although current health systems strengthening interventions have achieved substantial increases in the number of people treated for TB, their impact on TB incidence and mortality is less clear.
We aimed to assess the impact of current and additional interventions, tailored to the context of the TB epidemic in Karamoja, to achieve further reductions in TB incidence and mortality.

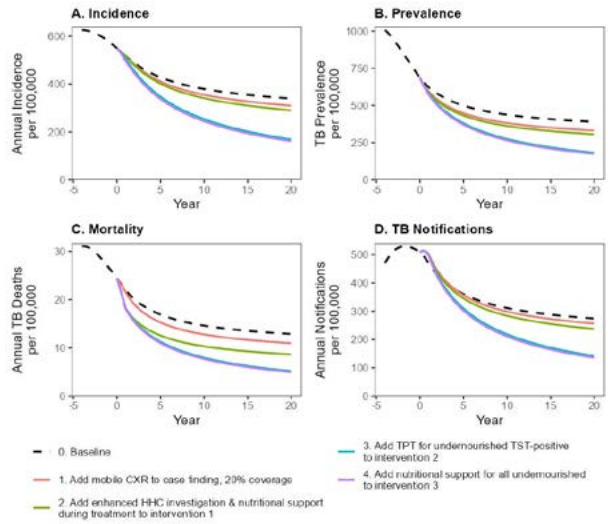

Figure: Projected declines in annual TB incidence (A), prevalence (B), mortality (C) and notifications (D) per 100,000 population following the layered implementation of various interventions. Black dashed lines: current health systems strengthening interventions continued over 20 years. (1) Red lines: Bi-annual community-based active TB case-finding using CXR to screen for TB achieving 20% population coverage. (2) Green lines: Adding to intervention 1 enhanced contact investigation and nutritional support for the undernourished during TB treatment (3) Blue: Adding to intervention 2 provision of TPT to all undernourished TST positive persons found during community based active TB case-finding. (4) Purple: Adding to intervention 3 provision of nutritional support to all undernourished patients found during community-based active TB case finding.

Design/Methods: We developed a dynamic compartmental model calibrated to TB epidemiology in Karamoja (population 1.4 million, 50% children <15 years, 34% undernourished, TB incidence: 670/100,000 and TB prevalence 853/100,000).
In addition to current health systems strengthening interventions, we modelled four layered interventions: community-based active TB case-finding using chest X-ray with computer aided detection covering 20% of the population; increased home-based contact investigation plus nutritional support for undernourished persons with TB disease; community-wide testing and treatment of TB infection; and nutritional support to undernourished persons with TB infection. We estimated the number of tuberculosis disease episodes and deaths that could be averted over 20 years.
Results: Over 20 years, continued implementation of current health systems strengthening interventions would decrease TB incidence by 2.4% per year to 339/100,000 and TB mortality by 3.2% per year to 13/100,000. The implementation of four additional interventions would accelerate declines in TB incidence and mortality bringing TB incidence to 161/100,000 and TB mortality to 5/100,000 at 20 years. This would result in 47,500 (95% CI 18,000-76,600) TB cases and 2,400 (95% CI 1,000-4000) TB deaths averted compared to current interventions.
Conclusions: Combination interventions to reduce undernutrition and find people with TB disease and infection can have substantial epidemiological impact in the Karamoja subregion of Uganda.

OA31-403-21 What will it take to achieve the End TB targets in South Africa?

L. Johnson,[1] M. Kubjane,[2] L. Brown,[3] L. Jamieson,[2] P. Naidoo,[4] G. Tanna,[5] G. Meyer-Rath,[2] [1]University of Cape Town, Centre for Integrated Data and Epidemiological Research, Cape Town, South Africa, [2]University of Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [3]University of Stellenbosch, South African Centre for Epidemiological Modelling and Analysis, Johannesburg, South Africa, [4]Independent consultant, N/A, Cape Town, South Africa, [5]Gates Foundation, N/A, Johannesburg, South Africa
e-mail: Leigh.Johnson@uct.ac.za

Background: The WHO End TB strategy targets an 80% reduction in TB incidence between 2015 and 2030. Recent cuts in donor funding for TB and HIV programmes have prompted renewed focus on the most critical drivers of TB incidence in sub-Saharan Africa. We aimed to assess which factors are likely to be most critical in South Africa, a country with one of the highest TB incidence rates globally.
Design/Methods: We adapted an existing mathematical model of TB and HIV in South Africa (Thembisa). Prior distributions were specified to represent uncertainty ranges for 30 model parameters that were considered to be highly uncertain and potentially important in driving future TB incidence. Latin Hypercube Sampling was used to draw a sample of 1000 parameter combinations from these distributions, and the model was projected to 2040 for each parameter combination. Partial rank correlation coefficients (PRCCs) were calculated between each parameter and the average adult TB incidence rate over the 2025-2040 period.
Results: The adult TB incidence rate in South Africa is projected to decline by 34% by 2030, relative to 2015 levels (95% CI: -13% to 63%). The parameters most strongly associated with future TB incidence are the probability of

microbiological testing when seeking treatment for TB symptoms (PRCC=-0.97), the future diabetes prevalence (PRCC=0.79), the reduction in social contacts post-COVID (PRCC=-0.74), future smoking rates (PRCC=0.58), the efficacy of 3HP in curing TB infection (PRCC=-0.52) and the prevalence of binge drinking (PRCC=0.40; see Figure).

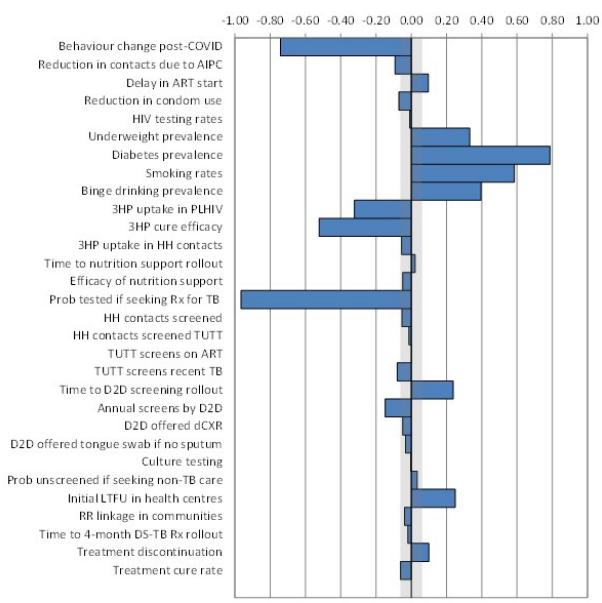

Figure: Partial rank correlation coefficients between 30 parameters and average TB incidence rates in South Africa over 2025-2040
Shaded grey area represents correlation coefficients that are not significantly different from zero. 3HP = 3 months of isoniazid and rifapentine (TB prevention), AIPC = airborne infection prevention and control, ART = antiretroviral treatment, D2D = door-to-door (community-based testing), dCXR = digital chest X-ray, DS-TB Rx = drug-sensitive TB treatment, HH = household, LTFU = loss to follow-up, RR = relative rate, TUTT = targeted universal TB testing.

Conclusions: It is unlikely that the End TB targets will be met in South Africa, given currently available interventions. However, it is possible to achieve substantial reductions in TB incidence with increased microbiological testing in symptomatic individuals and renewed focus on risk factors such as diabetes and smoking. Further analysis is needed to assess which interventions will be most cost-effective.

OA31-404-21 TBMod: A flexible, open-source framework for modelling TB

R. Bakker,[1,2] T. Prys-Jones,[1] R. Clark,[1] T. Sumner,[1] P. Pelzer,[3] D. Jerene,[2] A. Gebhard,[2] R. White,[1] [1]London School of Hygiene & Tropical Medicine, Department of Infectious Disease Epidemiology and Dynamics, London, United Kingdom of Great Britain and Northern Ireland, [2]KNCV Tuberculosis Foundation, Department of Tuberculosis Elimination and Health Systems Innovation, The Hague, Netherlands, [3]IAVI, Epidemiology, Amsterdam, Netherlands
e-mail: roel.bakker@gmail.com

Background: TBMod is a versatile modelling framework to simulate the transmission and progression of tuberculosis (TB), and allows us to project the health and economic impact of interventions. The model has undergone major development during 2024-25, with the latest features highlighted below.
Design/Methods: TBMod is a deterministic model implemented in R that simulates TB transmission using ordinary differential equations. The framework allows users to specify model structure in an XML file, without changing the source code. Users specify 'dimensions' (e.g. TB natural history, age, HIV) and how many strata exist within each dimension (e.g. susceptible, infected). Users can also make parameters defined for one dimension dependent on states in another dimension, e.g. TB progression may depend on HIV status. Previously six dimensions were routinely specified - TB, age, HIV, socioeconomic status, risk and vaccination status. Transmission is determined by the transmission probability per contact and number of contacts per day between age groups specified by contact matrices. The R package deSolve solves the differential equations.
Results: New features:
Expanded Dimensions: Five additional dimensions are included for modelling TB drug resistance, diverse intervention strategies (e.g., treatment, vaccine combinations), and risk factors (e.g., smoking, incarceration, and undernutrition).
Trigger-by-Transition: Changes in one dimension (e.g., ending TB treatment) now prompt adjustments in multiple related dimensions, such as TB state and drug resistance levels.
Diagnostic-Based Treatment: Treatment protocols can be tailored based on a combination of diagnostic test results.
Assortative Mixing in Model States: Particularly in environments like prisons, population mixing is modelled based on incarceration status, with restricted interactions between incarcerated and non-incarcerated groups.
Conclusions: TBMod is a flexible framework with increasing utility from new features. These allow us to better estimate the impact, effectiveness and cost of interventions to identify and counter TB. In turn, we can select an optimal mix of interventions for a given budget.

OA31-405-21 Large notification impact of a multi-component active case finding and person-centered care intervention in urban Viet Nam: The Erase TB case study

L.P. Nguyen,[1,2] H.T.L. Mo,[3] L.N.Q. Vo,[3,4] N.T.T. Nguyen,[5] A.J. Codlin,[6,4] R. Forse,[6,4] T.M.H. Dang,[7] L.H. Nguyen,[7] A.T.T. Pham,[8] D.V. Pham,[8] H.B. Nguyen,[9] L.V. Dinh,[9]
[1]FIT RD Ltd., Program, Ha Noi, Viet Nam, [2]IRD VN Ltd., Program, Ha Noi, Viet Nam, [3]Friends for International TB Relief (FIT), Management, Ha Noi, Viet Nam, [4]Karolinska Institutet, Department of Global Public Health, Solna, Sweden, [5]Friends for International TB Relief (FIT), Program, Ho Chi Minh City, Viet Nam, [6]Friends for International TB Relief (FIT), Management, Ho Chi Minh City, Viet Nam, [7]Pham Ngoc Thach Hospital, Management, Ho Chi Minh City, Viet Nam, [8]Ha Noi Lung Hospital, Steering Department, Ha Noi, Viet Nam, [9]Viet Nam National Lung Hospital, Management, Ha Noi, Viet Nam
e-mail: lan.nguyen@tbhelp.org

Background and challenges to implementation: To end TB, it is necessary to reach all persons with TB, whether asymptomatic, underdiagnosed or under-reported. Further, services have to be patient-centered to increase treatment linkage and retention. To achieve these ambitions, all three pillars of health systems, public, private and community, need to be engaged.
Leveraging those pillars, the Erase TB project employed a tri-factor active case finding (ACF) approach combined with social support to close the treatment coverage gap all along the TB care cascade.
Intervention or response: The 3-year project was implemented jointly with the National TB Program (NTP) from Q2/2020-Q1/2023 in 10 districts of Ha Noi and Ho Chi Minh City, Vietnam, and compared to eight control districts. The project leveraged primary care officers for community engagement and contact investigation, pop-up health screening campaigns for hotspot mass screening and public-private mix (PPM) for facility-based case finding and private treatment notification. The project provided Xpert as a first-line diagnostic test for everyone with TB-abnormalities on chest X-ray (CXR) irrespective of symptoms. Monetary and non-financial social support was provided to enhance treatment linkage and adherence. The notification impact was analyzed based on control-adjusted, pre-/post-intervention trends.
Results/Impact: In total, the project screened 305,412 individuals by CXR, tested 29,647 on Xpert and detected 11,575 persons with all forms of TB. Of these, 96.8% (11,199/11,575) were linked to care, including 75.5% (8,735/11,199) treated in the private sector. About 56.3% (6,303/11,199) of these treatment notifications were additional based on the trend analysis.
Despite the impact of COVID-19 lockdowns, the NTP's average quarterly notification rate in the intervention area increased by 42.5% from 1,232 to 1,756, which was sustained throughout the project.

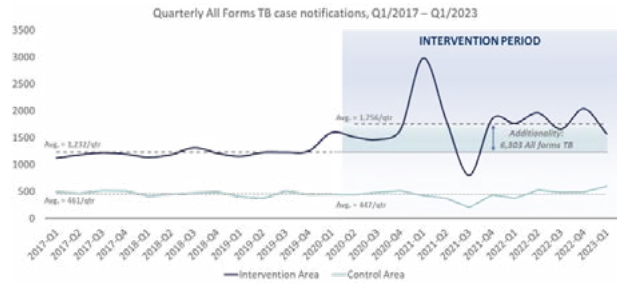

Figure. Quarterly all forms TB case notifications, Q1/2007 - Q1/2023.

Conclusions: A sustained, comprehensive package of ACF interventions complemented by social support can substantially narrow treatment coverage gaps and should be considered for scale-up in order to achieve end TB ambitions.

OA31-406-21 Potential impact, costs, and benefits of population-wide screening interventions for TB in Viet Nam

A. Schwalb,[1,2,3] K. Horton,[1,2] M. Harker,[1,2,4] L. Gosce,[1,2] L. Veeken,[5] T.-A. Nguyen,[6,7,8] F. Cobelens,[9,10] G. Fox,[7,8] D.V. Luong,[11,12] H.B. Nguyen,[11,12] G. Marks,[13,8,14] R. Houben,[2,1]

e-mail: alvaro.schwalb@lshtm.ac.uk

Background: Population-wide screening may accelerate the decline in tuberculosis incidence, but optimal screening algorithms and durations must balance resource considerations.

Design/Methods: We calibrated a deterministic TB transmission model, including non-infectious and asymptomatic disease, to TB epidemiology in Viet Nam. We designed three population-wide screening algorithms from 2025: using sputum nucleic acid amplification test (NAAT, Xpert MTB/RIF Ultra) only; chest radiography (CXR) followed by NAAT; and CXR only (i.e., without microbiological confirmation).

We determined the number of annual screening rounds required to reduce pulmonary TB prevalence below 50 per 100,000 people. Cost-effectiveness was assessed using incremental cost-effectiveness ratios (ICERs), representing the additional costs (in US$) per disability-adjusted life year (DALY) averted compared to business-as-usual by 2050.

We considered the total number treated and the budgetary impact. Additionally, we assessed the impact of reducing the NAAT unit price from US$8 to US$1.

Screening algorithm	BAU	NAAT		CXR+NAAT		CXR
Rounds required to reach the threshold	Not reached	6 annual rounds		8 annual rounds		3 annual rounds
Cumulative TB incidence	2.25m (95%UI: 1.57-3.04)	0.95m (95%UI: 0.63-1.31)		0.93m (95%UI: 0.63-1.29)		0.51m (95%UI: 0.36-0.71)
Cumulative DALYs	8.12m (95%UI: 5.85-10.83)	3.74m (95%UI: 2.64-4.99)		3.85m (95%UI: 2.75-5.13)		2.21m (95%UI: 1.59-3.01)
Unit price of NAAT	N/A	US$8	US$1	US$8	US$1	N/A
Cost of diagnosis and screening	363m (95%UI: 222-578)	2,428m (95%UI: 1,675-3,465)	991m (95%UI: 693-1,360)	1,211m (95%UI: 845-1,719)	962m (95%UI: 679-1,335)	350m (95%UI: 251-474)
Cost of treatment	138m (95%UI: 86-209)	336m (95%UI: 220-511)		253m (95%UI: 152-393)		2,609m (95%UI: 1,552-3,941)
Annual cost of front-loading	N/A	427m (95%UI: 299-599)	190m (95%UI: 138-258)	161m (95%UI: 111-224)	129m (95%UI: 92-174)	949m (95%UI: 606-1,415)
Annual cost savings	N/A	12.3m (95%UI: 6.5-21.4)		12.7m (95%UI: 6.7-21.4)		15.6m (95%UI: 9.2-24.7)
ICER compared with BAU	N/A	516 (95%UI: 233-1,073)	189 (95%UI: 71-426)	225 (95%UI: 85-520)	167 (95%UI: 57-380)	410 (95%UI: 178-929)

Results: NAAT-based algorithms required at least six rounds to reach the prevalence threshold, while CXR-only required three. The NAAT-only algorithm achieved a prevalence reduction consistent with the ACT3 trial after three rounds.

The CXR+NAAT algorithm averted 3.85m DALYs (95%UI:2.75-5.13) at US$225 (95%UI:85-520) per DALY averted compared with business-as-usual. For CXR+NAAT, the front-loaded investment of US$161m (95%UI:111-224) annually during the intervention resulted in average annual cost savings of US$12.7m (95%UI:6.7-21.4) up to 2050 compared to business-as-usual.

In the CXR-only algorithm, screening costs are lower ($350m [95%CI:251-474] vs $1,211m [95%CI:845-1,719] in CXR+NAAT), but treatment costs are much higher ($2,609m [95%CI:1,552-3,941] vs $253m [95%CI:152-393] in CXR+NAAT), due to more treatment initiations in people without TB. Reducing the cost of NAAT led to a 63% and 26% reduction in the estimated ICER for the NAAT-only and CXR+NAAT algorithms, respectively.

Conclusions: In Viet Nam, population-wide screening could achieve ambitious policy goals. Substantial front-loaded investment is followed by persistent cost savings and could be further offset by more affordable NAATs.

OA31-407-21 Community-driven TB elimination in India: Lessons from VHAI's multi-state interventions

B. Mathew,[1] [1]Voluntary Health Association of India, Tobacco Control, Delhi, India

Background and challenges to implementation: India accounts for nearly 27% of the global tuberculosis burden, with the country's National Strategic Plan aiming to eliminate TB by 2025. Despite progress, implementation challenges remain significant — including late diagnosis, stigma, loss to follow-up, and underreporting from the private sector. In tribal and hard-to-reach areas, poor access to health services further hampers early detection and treatment adherence.

The COVID-19 pandemic disrupted essential TB services, leading to delays in diagnosis, treatment interruption, and reduced case notifications.

Intervention or response: VHAI, in collaboration with state and district health departments, implemented community-based TB prevention and care programs. The intervention focused on:

- Community sensitization and awareness through folk media, school programs, and community meetings
- Active case finding and contact tracing in underserved populations, including tribal and migrant communities
- Capacity building of frontline workers (ASHAs, ANMs, and TB Health Visitors)
- Psychosocial support and nutritional counseling to TB and drug-resistant TB (DR-TB) patients
- Strengthening private sector engagement and referral linkages
- Supporting the Nikshay Poshan Yojana by facilitating access to nutritional support

Results/Impact: The interventions led to:

- Over **40,000 individuals** reached through TB awareness & stigma-reduction campaigns
- **Improved treatment adherence**, with over **92% treatment completion rates** reported among patients supported under the program
- Enhanced community participation, with the formation of local TB champions and peer support groups
- Strengthened DOTS services in partnership with state TB cells and improved notification from the private sector by up to 30% in high-burden districts

Conclusions: This highlights the importance of community-driven and decentralized approaches to TB prevention and care. Integration with the health system, local leadership, and trust-building are key to addressing stigma and improving access to services. These successful models from high-burden and marginalized regions can inform state and national strategies as India pushes toward its 2025 TB elimination goal. Sustained investment, cross-sector collaboration, and empowering communities will be vital to end TB.

OA31-408-21 Impact of US government funding cessation on TB prevention and care: An African multicountry survey

K. Koura,[1,2] A.N. Soe,[3] R. Dlodlo,[4] Y. Lin,[5] P. Sinha,[6,7] G. Badoum,[8,9] M. Dogo,[10] H. Charles,[11] A. Harries,[12,13] [1]International Union Against Tuberculosis and Lung Disease, TB Department, Paris, France, [2]Université Paris Cité, IRD, UMR261 MERIT, Paris, France, [3]International Union Against Tuberculosis and Lung Disease, TB Department, Mandalay, Myanmar, [4]International Union Against Tuberculosis and Lung Disease, TB Department, Paris, Zimbabwe, [5]International Union Against Tuberculosis and Lung Disease, TB Department, Paris, China, [6]Boston University Chobaninan and Avedisian School of Medicine, Section of Infectious Diseases, Boston, United States of America, [7]Boston Medical Center, Medical Center, Boston, United States of America, [8]International Union Against Tuberculosis and Lung Disease, TB Department, Paris, Burkina Faso, [9]Université Joseph KI-ZERBO, Unité de Formation et de Recherche en Sciences de la Santé (UFR/SDS), Ouagadougou, Burkina Faso, [10]International Union Against Tuberculosis and Lung Disease, TB Department, Paris, Togo, [11]Boston University Schools of Public Health and Medicine, Departments of Global Health, Epidemiology, Biostatistics and Medicine, Boston, United States of America, [12]International Union Against Tuberculosis and Lung Disease, TB Department, Paris, United Kingdom of Great Britain and Northern Ireland, [13]Faculty of Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, Department of Clinical Research, Londonunited, United Kingdom of Great Britain and Northern Ireland
e-mail: kgkoura@theunion.org

Background: The U.S. government has been a key contributor to global TB elimination through USAID, PEPFAR, and CDC. However, on January 20th, 2025 an executive order freezing foreign aid has led to an abrupt cessation of over 80% of USAID TB programs. This disruption poses serious risks to TB services in resource limited settings, especially in Africa.

Design/Methods: A rapid online survey was conducted in March 2025, targeting 52 National TB Programs (NTPs) in Africa. Seventeen countries (33%) responded. The survey assessed immediate and anticipated effects of U.S. funding cuts on TB care, diagnostics, staffing, implementing partners, and WHO support.

Results: Eleven (65%) countries reported immediate negative impacts, including disruption in funding for case detection, reduced diagnostic capacity, staff layoffs, and limited patient outreach and adherence support. Ten (59%) anticipated further disruption within three months, such as reduced procurement of medical supplies and weakened treatment supervision. Four (24%) countries reported reduced patient access to diagnosis and treatment. Six (35%) experienced interruptions in monitoring, evaluation, and supervision activities. TB-related training was affected in 11 (65%) countries, with refresher courses delayed and training for new staff suspended. Implementing partners in 11 (65%) countries reduced operations, downsized staff, ceased outreach, and scaled back support for decentralized services. WHO technical assistance was affected in 9 (53%) countries, with delayed consultant recruitment, reduced evaluation support, and slowed procurement.

Table 1: Effects of US funding stoppages on TB program services: responses from 17 National TB Programs in March 2025

Question	Response=YES	
	Number	(%)
Has US Government funding stoppage already affected TB care?	11	(65)
Is US Government funding stoppage likely to affect TB care in the next 3 months?	10	(59)
Has procurement of TB treatment medication been negatively affected? *	0	-
Has procurement of TB diagnostic consummables been negatively affected? *	0	-
Is patient access to TB diagnosis and treatment negatively affected?	4	(24)
Is monitoring, evaluation, recording and reporting of TB negatively affected?	6	(35)
Is support supervision of sub-national and peripheral health facilities negatively affected?	6	(35)
Is TB training within the country negatively affected?	11	(65)
Has the functionality of NTP central, provincial and district offices been negatively affected?	5	(29)
Has the NTP had to lay off any staff due to funding stoppages?	7	(41)
Are any supporting NGOs or implementing partners negatively affected by funding stoppages?	11	(65)
Is WHO country support negatively affected?	9	(53)

Footnotes: NTP = National TB Program; NGO=non-governmental organization; WHO=World Health Organization

*One country states that procurement has been partially affected

Countries: Benin, Burkina Faso, Djibouti, Eswatini (former "Swaziland"), Ethiopia, Guinea, Guinea-Bissau, Kenya, Madagascar, Namibia, Niger, Nigeria, Sierra Leone, Somalia, South Africa, Togo, Zimbabwe.

Conclusions: The sudden suspension of U.S. funding is already disrupting TB programs, threatening recent progress and increasing the risk of drug-resistant TB. Urgent action is needed to reinstate funding and protect TB services. These findings underscore the need for sustained and diversified funding to ensure resilience in TB control across Africa.

OA32 Person-centred quality care for all

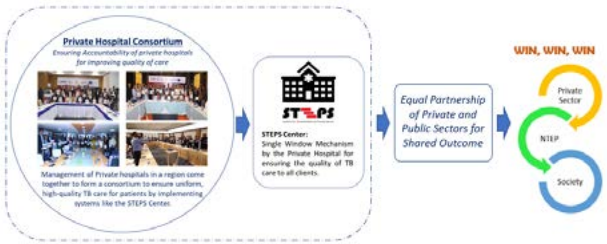
OA32-409-21 Private healthcare sector-led initiative to end TB in India

S.K. Khetarpal,[1] G. J. Gyani,[1] N. Srivastava,[2] M. Rajiv,[2] R. P S,[2] J. Jaju,[2] [1]Association of Healthcare Providers (India), Policy Advocacy, Delhi, India, [2]International Union Against Tuberculosis and Lung Disease (The Union), The Union, Delhi, India

Background and challenges to implementation: In New Delhi, India, over 50% of people with presumed TB seek care from the private sector, where lack of systems for treatment adherence support often lead to sub-optimal quality of care. Limited capacity of the TB program is a challenge in reaching out to the vast number of private hospitals. Efforts to engage the private sector through an outsourced interphase agency could not be sustained throughout due to financial implications.

Intervention or response: Association of Health Care Providers of India (AHPI), a non-profit organization of private hospitals, made itself accountable to End TB. Through official letters, multiple meetings and workshops, AHPI advocated with its member hospitals to ensure standards of TB care to all clients by initiating STEPS centres as a single window system in their hospitals and follow up with their clients regularly over telephone for adherence support, counselling and contact investigations in an 'after-sales care' model. AHPI also organized the private sector in the form of three city consortiums of private hospital managements, which acted as a united front of top management of the private hospital and served as a platform for dialogue between the sectors and reviewing progress.

Figure 1: System for TB Elimination by Private Sector (STEPS) Consortium of Private Hospitals



Results/Impact: Three city consortiums were formed with 34 major hospitals with monthly meetings. 18 private hospitals in Delhi initiated STEPS and two hospitals initiated intensified case finding from OPD. TB Notification from these hospitals increased by 27% in quarter-1, 2025 as compared with the previous quarters.

Over three months, these hospitals actively supported 14,500 people with TB for treatment adherence, counselling and monthly nutritional support. Additional cost for the program per person with TB supported is estimated as 4 USD.

Conclusions: Private sector led sustainable system for ensuring standards of TB care is possible and appears to be a low-cost solution.

OA32-410-21 Longitudinal single patient viewer (SPV) usage, awareness, and training for integrated patient management in South Africa

L. Viljoen,[1] C. October,[1] B.B. Prince,[2] E. Mohr-Holland,[3] N. Berkowitz,[3] K. du Preez,[1] [1]Stellenbosch University, Paediatrics and Child Health, Cape Town, South Africa, [2]The Health Foundation of South Africa, The Health Foundation of South Africa, Cape Town, South Africa, [3]City of Cape Town, Department of Health, Cape Town, South Africa
e-mail: lario@sun.ac.za

Background: The availability of longitudinal and cross-sectional clinical data at patient level is essential for optimal patient tuberculosis (TB)management. The Single Patient Viewer (SPV) platform, a web-based electronic health record and data access portal, offers a user-friendly and accessible platform for use by health workers (HWs).

We report on awareness, usage, uptake, and training of SPV In Cape Town, South Africa, after the implementation of data scaling initiative.

Design/Methods: We report on data from two rounds of questionnaires (2022 – 2024) among HWs from 58 public health facilities. Clinical, management, and support staff using electronic information services completed questions on SPV - Round 1 (R1) n=921; Round 2 (R2) n=871.

HWs completed surveys lasting ~10 minutes on electronic devices or online. Descriptive statistics were employed using the Software, Analytic and Descriptive Statistics Programme (SAS).

Results: SPV is essential for managing TB patient data. In R1, reported SPV awareness (368/921; 39.95%) and usage (181/921; 19.65%) was low, and only 181/368 (49.18%) of HWs aware of SPV, were using SPV. After extensive training and support efforts, in R2, there was a significant increase in SPV awareness (630/871; 72.33%) and usage (437/871; 50.17%).

Of those aware of SPV, (437/630; 69.37%) were using SPV. Users reported consistent high scores for perceived usefulness of SPV, with significant improvements in perceived SPV usefulness for lab results, drawing reports, and reportedly having the needed training t use SPV - Table 1.

Some gaps persist: 268/437 (61.33%) of HWs reported that they were not using SPV to its full capacity and 116/437 (26.54%) did not use their own login details when accessing SPV.

	R1 (%)	R2 (%)	p-value difference
SPV helps manage patients better	174/183 (95.1)	412/437 (94.3)	0.281
SPV is useful for following up on missing lab results	123/184 (66.8)	373/437 (85.4)	<0.001
SPV is useful for getting patient information from other facilities	177/184 (96.2)	422/437 (96.6)	0.616
SPV is useful for drawing reports	123/183 (66.8)	335/437 (76.7)	0.016
SPV is user friendly	146/183 (79.8)	385/437 (88.1)	0,008
Have the training needed to use SPV	85/182 (46.7)	265/437 (60.6)	0,001

Table. SPV usefulness and training: R1 vs R2.

Conclusions: Extended training and support efforts increased HW awareness and usage of SPV, allowing HWs to better use electronic systems to manage TB patients. Targeted efforts are needed to ensure user access and confidence in using this consolidated platform.

OA32-411-21 Development and validation of a TB provider trust scale: A pilot study

S. Law,[1] L. Abou-Chakra,[2] E. Chanamé,[3] C. Pinedo Chuquizuta,[4] C.D. Mitnick,[5] [1]McGill University, Department of Global and Public Health, Montreal, Canada, [2]McGill University, Department of Epidemiology, Biostatistics and Occupational Health, Montreal, Canada, [3]Universidad Peruana Cayetano Heredia, Departamento Académico de Enfermería, Lima, Peru, [4]Socios en Salud Sucursal Perú (SES), Lima, Lima, Peru, [5]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States of America
e-mail: lawsteph@gmail.com

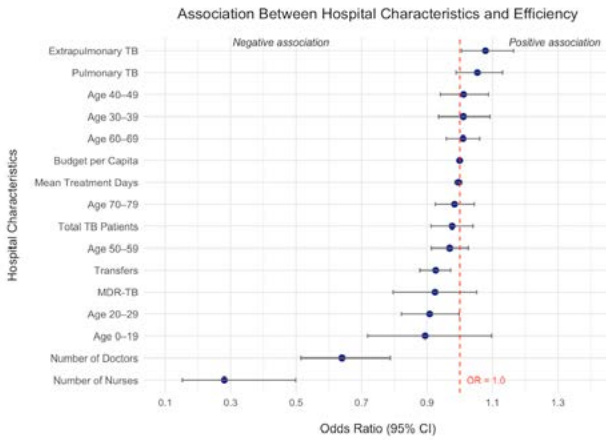
Background: Provider trust towards people with TB is an important element of a positive patient-provider relationship, affects access to treatment-related interventions, and is associated with many patient outcomes, including treatment adherence and satisfaction with care.
However, existing tools that measure provider trust have not been validated for patients with tuberculosis (TB) in resource-limited settings.
Design/Methods: We developed a 28-item survey instrument to measure TB provider trust based on: previous qualitative research on patient-provider trust in Cape Town, South Africa; focus group interviews with 6 TB providers in Lima, Peru; and cognitive interviews with TB providers in Cape Town (n=10), and Lima, Peru (n=10). We pilot tested the survey with 50 TB providers (doctors, nurses, health promoters and nursing assistants) in Lima.
We conducted exploratory factor analysis (EFA) to assess construct validity, and estimated Cronbach's alpha coefficients to assess internal consistency and correlation coefficients to assess external construct validity against the TB stigma scale, perceptions of medication non-adherence, and TB attitudes and practices.
Results: Study participants had varying years of experience working in TB care: 13 (26%) for <1 year, 18 (36%) between 1-5 years, and 19 (38%) for >5 years. General trust towards people affected by TB was high (median of 8 [range, 2-10] on a scale from 1 to 10); 39 providers (78%) believed it is important for TB providers to trust their patients (rating>8). EFA suggested a three-factor model, which we interpreted as "Patient behaviours", "Provider behaviours", and "Systems and guidelines." The questionnaire and each individual question demonstrated excellent internal consistency (Cronbach's $\alpha > 0.80$) and were highly correlated with related scales.
Conclusions: The TB Provider Trust Scale may measure three distinct factors related to provider trust towards people affected by TB. The scale should be further validated in a larger scale study in various resource-limited and high-burden settings.

OA32-412-21 Measuring the efficiency of TB care in Korea's public-private mix project: A data envelopment analysis approach

D. Kim,[1] S. Ju,[1] H. Lee,[1] S. Kim,[1] C. Song,[2] H. Sohn,[1]
[1]Seoul National University, College of Medicine, Department of Preventive Medicine, Seoul, Republic of Korea, [2]Korea Disease Control & Prevention Agency, Division of TB Prevention and Control, Sejong, Republic of Korea
e-mail: donghoon.kim@snu.ac.kr

Background: A public–private mix (PPM) project for TB care was launched in South Korea in 2011 and expanded nationwide, contributing to a reduction in TB incidence from over 80 per 100,000 to 49.4 by 2020. Despite the increasing number of participating hospitals, little is known about how efficiently PPM hospitals use resources.
This study addresses that gap by evaluating institutional-level efficiency using national patient data, providing evidence to inform resource allocation and guide scale-up strategies in South Korea and other countries pursuing similar TB service models.
Design/Methods: We assessed the technical efficiency of hospital-level PPM units for TB care in South Korea from 2019 to 2023 using data from the Korea Disease Control and Prevention Agency's annual TB notification report. Patient-level data (n=113,624) were aggregated into 797 hospital-year units from 172 hospitals. An input-oriented Bootstrap DEA—appropriate in healthcare settings with complex input-output relationships—was applied, followed by logistic regression to examine institutional characteristics associated with higher efficiency based on the best-performing model.
Results: Among 797 PPM units, 29 (top 10%) were classified as efficient (efficiency score ≥ 0.9). Hospitals with more doctors (OR = 0.63, $p < 0.001$), nurses (OR = 0.27, $p < 0.001$), and patient transfers (OR =0.93, p=0.003) were

less likely to be efficient. A higher proportion of younger patients (aged 0–29) and multidrug-resistant TB cases was also associated with lower odds of efficiency. Conversely, efficiency was positively associated with treating more pulmonary/extra-pulmonary TB and serving populations (aged 30–69).



Conclusions: Efficient resource use is critical for strengthening TB care, particularly in low- and middle-income countries scaling public–private approaches. This study highlights how institutional and clinical characteristics shape efficiency, providing actionable evidence to guide resource allocation, performance monitoring, and the optimization of PPM models in Korea and other settings with constrained health system capacity.

OA32-413-21 People-centred care for culturally diverse people with drug-resistant TB in Norway: Healthcare strategies and challenges

E. Storvig,[1,2] I. Harstad,[3,4] B. Ehrnström,[5,2]
[1]Norwegian University of Science and Technology, Department of Mental Health, Trondheim, Norway, [2]St. Olavs University Hospital, Department of Infection, Trondheim, Norway, [3]Norwegian University of Science and Technology, Department of Public Health and Nursing, Trondheim, Norway, [4]St. Olavs University Hospital, Department of Pulmonary Medicine, St. Olavs Hospital, Trondheim, Norway, [5]Norwegian University of Science and Technology, Department of Clinical and Molecular Medicine, Faculty of Medicine and Health Sciences, Trondheim, Norway
e-mail: eline.storvig@stolav.no

Background and challenges to implementation: Strategies to combat tuberculosis emphasize people-centred care, an holistic and respectful approach that addresses mental health and social well-being alongside medical goals. In Norway, most individuals who develop tuberculosis are immigrants, and special attention should be given to their psychosocial needs.

Aim: To explore the perspectives and lived experiences of culturally diverse patients with drug-resistant tuberculosis, as well as healthcare providers in hospitals and municipalities, in relation to people-centred care.
Specifically, this study aims to:
a. Explore the strategies employed to promote people-centred care.
b. Identify the challenges associated with receiving and delivering people-centred care.
Intervention or response: A qualitative study was employed, using semi-structured, individual interviews with 16 former patients with drug resistant tuberculosis and 19 healthcare providers caring for this patient group. The data was analyzed using thematic analysis.
Results/Impact: Several participating healthcare providers highlighted patients' holistic well-being during treatment, implemented strategies to help patients manage treatment and daily lives, and used interpreters to secure communication.
However, the study uncovered communication challenges and inconsistencies in healthcare across participating hospitals, within individual hospitals, and in primary healthcare settings. Some participating patients recounted adverse events, including medication error that undermined their trust in the healthcare system.
The study identified three main themes: Inconsistencies in healthcare - ranging from core components to adverse events; Knowledge and mutual understanding; Motivational strategies and support.
Conclusions: Key strategies include effective communication to foster mutual understanding, structural interventions to address inconsistencies in care, and various forms of support, including peer support.
Recognizing the impact of drug-resistant tuberculosis and an immigrant background on patients' overall well-being is essential. Barriers include poor communication, adverse events, and limited access to psychological care. Under Norwegian law, patients have the right to an interpreter, and this study reinforces the importance of this provision.

OA32-414-21 A mixed-methods evaluation of the acceptability, implementation and effectiveness of a gender-specific TB intervention in Uganda

J. Nidoi,[1,2] T. Wingfield,[2,3,4,5] J. Pulford,[3] R. Thomson,[3] B. Ringwald,[2] W. Muttamba,[1] M. Henrion,[6] S. Ranga,[1] E. Akera,[1] B. Kirenga,[7,1] [1]Makerere University Lung Institute, Research and Innovation, Kampala, Uganda, [2]Liverpool School of Tropical Medicine, Centre for Tuberculosis Research, Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland, [3]Liverpool School of Tropical Medicine, International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland, [4]Liverpool University Hospitals NHS Foundation Trust, Tropical and Infectious Diseases Unit, Liverpool, United Kingdom of Great Britain and Northern Ireland, [5]Karolinska Institutet, WHO Collaborating Centre in TB and Social Medicine, Department of Global Public Health, Stockholm, United Kingdom of Great Britain and Northern Ireland, [6]Malawi Liverpool Wellcome Research Programme, Statistical Support Unit, Blantyre, Malawi, [7]Makerere University, Department of Internal Medicine, Kampala, Uganda
e-mail: Jasper.Nidoi@lstmed.ac.uk

Background: Existing tuberculosis (TB) screening guidelines don't address men's gendered socio-behavioural barriers to TB care. We implemented a gender-specific intervention package, called IGNITE, in public health facilities in Uganda. IGNITE screened for TB using symptom-based checklist stamps, distributed TB educational materials, and introduced male-friendly TB clinics with evening opening hours, health education by male champions in "men's corners", and integrated TB, HIV, diabetes, and hypertension screening.
Design/Methods: We conducted a mixed methods evaluation of the acceptability, implementation and effectiveness of the intervention package. We did process evaluation through in-depth interviews with implementation stakeholders and patients, observations and workshops. Interviews also explored acceptability. To assess effectiveness, we compared TB notification data before (January–June 2023) and after (July–December 2023) IGNITE at intervention (Gombe and Mityana hospitals) and control (Luwero and Kiboga hospitals) sites, applying a quasi-Poisson regression model.
Results: The intervention was deemed acceptable, attributed to improved access to additional screening services and shorter waiting times. The stamps were perceived to simplify TB screening and improve documentation, while educational materials increased inquiries about TB screening services.
Intervention implementation varied, with Gombe achieving higher coverage with the stamp and integrated screening. Mityana had higher coverage with other components. Numbers of people with presumed TB increased in Gombe but declined in Mityana. Gombe's TB notifications rose by 46.3% driven entirely by male notifications (Female 0%, Male 88.4%), while Mityana reported a 36.4% increase across both genders (Female 26.3%, Male 45.1%). Notifications declined in control facilities. The intervention significantly increased TB case notification rates (RR: 1.51, 95% CI: 1.03-2.22), males had a higher notification rate than females (RR: 1.5, 95% CI: 1.23-1.83). Higher proportions of females with TB initiated treatment pre- and post-intervention (97.4%-100%) than men (91.4%-97.7%).

Quote:

I felt good because, some of them, I had never tested before like diabetes and pressure... For HIV I had last tested a year ago. But I was able to get those services at once when I was getting tested for TB. Interviewee 15, patient, male

Table: Quasi-Poisson regression analysis of the association between the intervention, sex and facility on TB case notification rates

Predictor	TB cases notified		TB case notification rate ratio (95% CI)	p-value
	No intervention	Intervention		
(Intercept)			*245.72 (169.65- 355.89)	
Intervention	781	300	**1.51 (1.03- 2.22)**	**0.038**
Female	304	116	Ref	
Male	477	184	**1.50 (1.23- 1.83)**	**< 0.001**
Gombe	82	120	Ref	
Mityana	132	180	0.79 (0.61- 1.01)	0.062
Luwero	279	-	1.10 (0.82- 1.49)	0.519
Kiboga	288	-	1.11 (0.82- 1.5)	0.492
Month	-	-	0.98 (0.95- 1.01)	0.106
♦Intervention:sexMale	-	-	1.02 (0.69- 1.49)	0.925

*Intercept is the baseline TB case notification rate

♦ Interaction term for intervention and male sex to explore how the intervention's effect varied by sex

Conclusions: The gender-specific intervention enhanced TB screening and increased notifications among men without reducing those among women.

OA32-415-21 Gender-specific predictors of TB mortality among adolescents and young adults in Kenya: A national surveillance study

R. Pola,[1] I. Kathure,[2] J. Chakaya,[1] [1]Respiratory Society of Kenya, Public Health and Research, Nairobi, Kenya, [2]Ministry of Health, National TB Program, Nairobi, Kenya
e-mail: rhodapola@gmail.com

Background: Adolescents and young adults (AYA, aged 15–24 years) face unique barriers to timely TB diagnosis and treatment contributing to poor outcomes. They account for 15% of global TB notifications, with males consistently outnumbering females. Gender disparities in TB outcomes remain underexplored. This study identified sex-specific predictors of mortality in this population to inform targeted interventions.
Design/Methods: We conducted a retrospective cohort study using data from the National TB patient management system (TIBU) from 2017 to 2022. Individuals aged 15 –24 years with bacteriologically confirmed TB were included. Mortality predictors were assessed using multivariable logistic regression, stratified by sex with adjusted odds ratios (AORs) and 95% confidence intervals (CIs) calculated.

Results: Among 58,792 individuals initiated on TB treatment, 59% were male. The mortality rate was 1% among males and 2% among females. Among females, mortality was significantly associated with undernutrition (AOR: 1.83, 95% CI: 1.41–2.37, p < 0.00001) and HIV infection (AOR: 8.49, 95% CI: 6.66–10.83, p < 0.0001). Among males, multiple factors were associated with mortality, including extrapulmonary TB (AOR: 3.23, 95% CI: 1.02–10.23, p = 0.0462), previous TB history (AOR: 3.02, 95% CI: 1.50–6.07, p = 0.0019), alcohol use disorder (AOR: 4.91, 95% CI: 1.96–12.30, p = 0.0007), undernutrition (AOR: 2.40, 95% CI: 1.33–4.30, p = 0.0033), HIV infection (AOR: 6.35, 95% CI: 3.68–10.94, p < 0.0001), and treatment at a Level VI facility (AOR: 3.18, 95% CI: 1.33–7.58, p = 0.0091).
Conclusions: These findings highlight sex-specific predictors of TB mortality among young people in Kenya emphasizing the need to promote gender-responsive approaches in TB care and management. By recognizing the differing risk profiles of male and female TB patients, gender specific support systems can be designed to improve TB reduce TB related in this age group.

OA32-416-21 Understanding knowledge gaps challenges access to TB care for gender-diverse individuals in India

A. Shendge,[1] B. Kumar,[2] D. Joseph,[3] A. Aher,[4] A. Shukla,[4]
[1]Global Coalition of TB Advocates, Global Coalition of TB Advocates - Youth, Sonipat, India, [2]Global Coalition of TB Advocates, Management Global Coalition of TB Advocates, Delhi, India, [3]Global Coalition of TB Advocates, Communications, Noida, India, [4]Tweet Foundation, Management, Delhi, India
e-mail: atul.shendge@gctacommunity.org

Background: Tuberculosis continues to be a challenge for public health in India, affecting the most marginalized groups. Although TB affects the transgender population disproportionately, they remain excluded from mainstream efforts, with behavioural, social, and cultural factors contributing to their vulnerability.
Design/Methods: A sequential mixed-methods approach was applied. An online survey collected quantitative data from 419 participants in 17 states on Knowledge, Attitude and Practice, and health-seeking behaviour. The qualitative data was collected through interviews conducted with community leaders and stakeholders.
Results: The findings yield great revelations as regards the TB landscape within the transgender and gender-diverse community:

- TB Awareness: The study suggests a gap in knowledge as out of the survey population, 42.7% (N=179) identified TB as an airborne condition, However, only 29.1% (N=122) correctly said that it was caused by a bacterium.
- Symptoms Awareness: Although the common symptoms reported were cough, fever, weight loss, and night sweats, knowledge of symptoms varied according to gender identity.
- TB Prevalence: Transgender women had the highest prevalence (55.9%) followed by Transgender men (21.2%) within the total sample.
- Treatment Access: Overall 50.1% (N=210) faced barriers to TB services of which Transgender women - 31.3 faced the greatest difficulties.
- Difficulty in Accessing Services: Most challenges included lack of information (26.2%), discrimination (59.4%, N=249) and lack of finance. Highest care access difficulty was reported by transgender women (50.1%, N=210).
- Stigma and Discrimination: More than 60% of transgender women and Hijras were victims of stigma at healthcare facilities.

Conclusions: The community of transgender and gender-diverse persons faces a high burden of TB and also great barriers to care. Thus, community-led interventions are necessary. It would be critical for equitable TB care and the India TB elimination goal to strengthen transgender-led organizations, expand TB preventive treatment, integrate WHO's Community, Rights and Gender framework, and ensure financial support through direct benefit transfers.

OA32-417-21 Navigating dual burdens: Intersectionality of TB and social stigma among transgenders, MSM, female sex workers, and people living with HIV in India: Findings from a qualitative study

A. Sinha,[1] A. Sharma,[1] A. Kowlgi,[2] A. Kar,[2] R.S. Potty,[2] B.J. Sunitha,[3] J.F. Munjattu,[1] J. Malar,[4] K. Kumarasamy,[1]
[1]Karnataka Health Promotion Trust, Tuberculosis, Bengaluru, India, [2]Karnataka Health Promotion Trust, MERL, Bengaluru, India, [3]Karnataka Health Promotion Trust, Grama Panchayat Interventions, Bengaluru, India, [4]STOP TB Partnership, STOP TB Partnership, Geneva, Switzerland
e-mail: atreyee.sinha@khpt.org

Background: Tuberculosis (TB) continues to be a highly stigmatised condition, particularly among already marginalised groups. Transgender persons and men who have sex with men (TG-MSM), female sex workers (FSWs), and persons living with HIV (PLHIV) face dual and intersecting stigmas due to their identities and health status. This study, conducted under the STOP-TB partnership, explores TB-related stigma among these populations groups often excluded from national TB surveillance due to their 'hard-to-reach' status.
Design/Methods: Using an exploratory qualitative design, 24 in-depth interviews were conducted from November 2023 to January 2024 in Bangalore, Karnataka. Participants, recruited through community based and

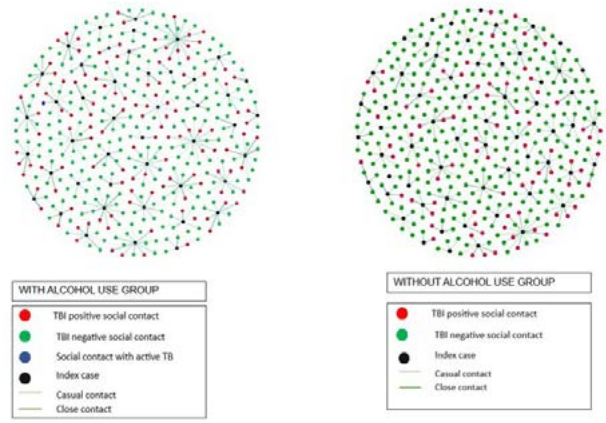
non-governmental organizations, were adults from TG-MSM, FSW, and PLHIV communities, with current or past TB history.
Ethical approval was sought from competent authorities. Data were transcribed, coded using a pre-defined thematic framework, and analyzed deductively.
Results: Stigma among participants manifested in layered and compounding ways—rooted in fear of contagion, myths about transmission, moral judgment, and visible markers of difference (e.g., gender expression).
TG-MSM respondents reported acute discrimination due to high visibility and limited family or community support. Social isolation and internalized stigma led to concealment of illness, delayed care-seeking, and mental health challenges. FSWs linked TB with economic vulnerability—fearing client loss and income disruptions due to physical symptoms.
PLHIVs described stigma from both diseases as mutually reinforcing, amplifying social withdrawal and undermining treatment adherence. Across all groups, stigma limited access to nutrition, emotional support, and timely diagnosis—factors critical for successful TB treatment.
Conclusions: TB stigma among key populations is deeply rooted in socio-cultural perceptions and intersectional identities. Targeted interventions—community-led support systems, tailored IEC campaigns, and legal safeguards—are essential to mitigate stigma and ensure equitable access to TB care and support services.

OA32-418-21 Understanding TB transmission driven by alcohol sharing behaviours and venues: A comparative cross-sectional social network survey in Puducherry, India

C. Retnakumar,[1] S. Sarkar,[1] K. Nagarajan,[2] P. Chinnakali,[1] B. Bharadwaj,[3] [1]JIPMER, Preventive and Social Medicine, Puducherry, India, [2]NIRT, Chennai, Department of Social and Behavioral Research, Chennai, India, [3]JIPMER, Psychiatry, Puducherry, India
e-mail: dr.charutha.r@gmail.com

Background: Over 80% of tuberculosis (TB) transmission occurs in extra-household settings, particularly social-gatherings. The current contact tracing strategies miss to capture community transmissions networks driven by socialisation behaviours. We utilised social network survey methods to investigate the TB infection transmission and to identify individuals and congregation places with high transmission potential in Puducherry, India.
Design/Methods: We conducted a comparative cross-sectional study using egocentric sampling of 106 male pulmonary persons with TB and their social contacts with(n=355) and without alcohol use disorder. (n=358). Data on frequency of socialisation and venues were collected. All contacts were tested for TB infection using the cy-tb skin test, with an induration of ≥5 mm considered positive. Gephi software was used for network visualization and calculation of metrics: Degree Centrality (indicating how well-connected a person is) and Betweenness Centrality (indicating how individuals /venue may facilitate TB spread between groups).
Results: The contact network comprising of persons with alcohol use had 403 nodes and 358 edges, with higher average degree (1.78) and betweenness centrality (4.02), as compared to the non-alcohol network (416 nodes, 355 edges, degree: 1.7, betweenness: 2.6). Networks comprising of the alcohol sharing places showed higher betweenness (35.96) and mean path length (3.66). TB Infection rates increased with group size (16.6%, 22.2%, and 66.6 % in dyads, triads and tetrads respectively), indicating increased infection risk in more connected networks driven by alcohol use.

Figure 1. Contact Network of TB Patients with & without Alcohol Use: TB Infection Among Social Contacts



Conclusions: Social network methods helped in identifying key alcohol sharing venues and sharing individuals with high potential for TB infection transmission. Venue specific targeted screening and interventions beyond household settings could be critical for interrupting tuberculosis spread in communities.

OA33 The future of TB screening: Integrating AI, economic modelling, and community-based approaches

OA33-419-21 Ensuring diagnostic accuracy: Real-time quality control for AI-driven chest X-ray screening in resource-limited settings

A.K. Singh,[1] M. Tadepalli,[1] H. Varatharajan,[2] S. Sridhar,[2] J.A. Chiramal,[3] [1]Qure.ai Technologies Private Limited, R&D, Bengaluru, India, [2]Qure.ai Technologies Private Limited, Product, Bengaluru, India, [3]Qure.ai Technologies Inc., Product, Atlanta, United States of America
e-mail: justy.antony@qure.ai

Background: Tuberculosis (TB) remains a leading cause of mortality in low- and middle-income countries (LMICs), where chest X-rays (CXRs) are widely used for screening. However, suboptimal CXR quality due to poor positioning, exposure errors, or inadequate inspiration is common and can delay diagnosis and compromise interpretation. In LMICs, ultra-portable X-ray machines have expanded access, but the lack of radiologists has accelerated adoption of computer-aided detection (CAD) tools like qXR. Without robust quality control (QC), these AI models may be forced to interpret flawed images, increasing the risk of misdiagnosis. We evaluated the performance of qXR's integrated QC module, designed to automatically detect and flag poor-quality CXR.
Design/Methods: qXR's QC module uses a deep convolutional neural network (EfficientNetB5) to detect four quality issues: clipped anatomy (incomplete lung fields), rotation, poor inspiration, and bad exposure. Trained on 28,503 CXRs, it was evaluated on 2,866 validation images, each possibly carrying multiple quality tags. The QC module runs alongside other qXR models, delivering results in 30–60 seconds.
We report area-under-the-receiver-operating-characteristic-curve (AUROC), sensitivity, specificity, and optimal thresholds for each quality issue, compared with corresponding radiologist assessments.
Results: qXR QC module achieved AU-ROC of 0.967, 0.910, 0.89 and 0.839 against clipped anatomy, rotation, poor inspiration and bad exposure in the validation dataset ensuring robust performance in detecting quality anomalies.

Quality Issue	Test Set Count	AUC	Sensitivity	Specificity	Optimal Threshold
Clipped Anatomy	998	0.967	0.92	0.93	0.184
Rotation	614	0.910	0.94	0.94	0.626
Poor Inspiration	368	0.890	0.90	0.75	0.084
Bad Exposure	886	0.839	0.78	0.76	0.428

Table 1: Performance of qXR-QC module against radiologist report stratified by each quality issue.

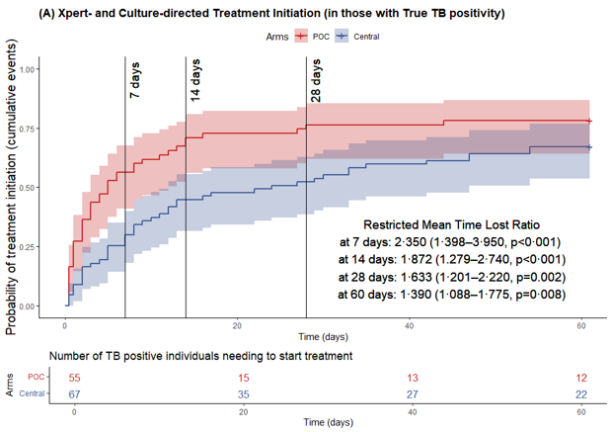
Conclusions: The qXR QC module is a critical safeguard for AI-based CXR interpretation in LMICs. By reliably identifying poor-quality images before CAD analysis, it reduces diagnostic errors, prevents resource waste, and provides real-time feedback for reacquisition. By reducing repeat scans and minimizing human QC reliance, this module enhances workflow efficiency and enables decentralisation of TB screening operations. This quality assurance layer enhances the integrity of automated TB screening and supports responsible AI deployment in resource-constrained settings.

OA33-420-21 Time-to-treatment-initiation studies of a randomised controlled trial in community-based active case-finding for TB

T. Perumal,[1] S. Jaumdally,[1] A. Esmail,[1] A. Chizema,[2] C. Phiri,[3] I. Massango,[4] A.J. Scott,[1] S. Oelofse,[1] B. Meggi,[4] J. Mutsvangwa,[2] H. Ayles,[3,5] K. Dheda,[1,6] [1]University of Cape Town Lung Institute, Medicine, Cape Town, South Africa, [2]Biomedical Research and Training Institute, Research, Harare, Zimbabwe, [3]Zambart, Medicine, Lusaka, Zambia, [4]Instituto Nacional de Saúde, Centro de Investigação e Treino em Saúde da Polana Caniço, Maputo, Mozambique, [5]London School of Hygiene and Tropical Medicine, Clinical Research, London, Zambia, [6]London School of Hygiene and Tropical Medicine, Infection biology, London, South Africa
e-mail: tahlia.perumal@uct.ac.za

Background: Delays in tuberculosis treatment initiation fuel the TB epidemic. Active case-finding is critical to interrupt transmission and reduce burden. Here, we described the time-to-treatment initiation patterns of a randomised controlled trial for active case-finding (XACT-3).
Design/Methods: Data from the XACT-3 study were included. Briefly, participants at risk for TB received Xpert Ultra testing (randomised to Xpert performed point-of-care or centralised laboratory) and TB culture (reference). We investigated time-to-treatment-initiation in those with definite TB (culture-positive or Xpert-positive without previous history of TB) between the arms. Time analysis models adjusted for age, sex, and site were performed. Regression analysis was performed to identify independent predictors.
Results: Of 3288 at-risk individuals (POC arm, n=1643; central arm, n=1645), 122 (3·71%) were classified as definite TB. The Schoenfeld test for proportional assumptions was significant; thus, restricted mean time analyses were performed. POC Xpert was associated with faster treatment initiation within 7,14, 28 and 60 days (restricted mean time lost ratio [95% CI]: 2·350 [1·398–3·950; p<0·001], 1·872 [1·279-2·740, p<0·001]; 1·633 [1·201–2·220, p=0·002]; and 1·390 [1·088–1·775, p=0·008], respectively). POC Xpert was also associated with a shorter

time between confirmed diagnosis and treatment initiation (difference in 60-day restricted mean survival time [dRMST] -11·8 days [95% CI: -3·2 to -20·3 days; p = 0.007]). This was particularly true in those with cough or cavitary disease at baseline (60-day dRMST [95% CI]: -16·482 days [-6.063 to -26·901], p=0.002 and -16·559 days [-1.727 to -31.391], p=0.029; respectively). No clinical factors independently influenced time-to-treatment initiation.



Conclusions: Point-of-care diagnostics significantly accelerate tuberculosis treatment initiation compared to testing performed at a centralised facility, thereby reducing periods of transmissibility. These data support the integration of point-of-care diagnostics in community-based active case-finding strategies.

OA33-421-21 CAD4TB trajectory modelling in a cohort of household contacts and association with socio-demographic and clinical characteristics

L. Larsson,[1] C. Calderwood,[2,3] E. Marambire,[3,1] D. Banze,[4] A. Mfinanga,[5] K. Held,[1,6] C. Khosa,[4] T. Minja,[5] J. Mutsvangwa,[7] N. Heinrich,[1,6] K. Kranzer,[8,3,1]
ERASE-TB consortium [1]LMU University Hospital, Institute of Infectious Diseases and Tropical Medicine, Munich, Germany, [2]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom of Great Britain and Northern Ireland, [3]Biomedical Research and Training Institute, The Health Research Unit Zimbabwe, Harare, Zimbabwe, [4]Instituto Nacional de Saúde, Instituto Nacional de Saúde, Maracuene, Mozambique, [5]National Institute for Medical Research, Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, [6]German Center for Infection Research, Partner Site Munich, Munich, Germany, [7]Biomedical Research and Training Institute, Biomedical Research and Training Institute, Harare, Zimbabwe, [8]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom of Great Britain and Northern Ireland
e-mail: llarsson3@outlook.com

Background: Computer-aided detection (CAD) software, such as CAD4TB, is increasingly used for tuberculosis screening and diagnosis. However, its longitudinal performance in tracking disease progression remains unclear.
This study aimed to evaluate CAD4TB versions 6 (v6) and 8 (v8) over time using growth mixture modelling to identify distinct trajectories of CAD scores among individuals undergoing serial chest X-rays.
Design/Methods: ERASE-TB enrolled 2,109 tuberculosis household contacts from three countries (Zimbabwe, Mozambique, Tanzania) who were followed up 6-monthly for up to 24 months with comprehensive clinical, microbiological, and radiological assessments at each visit. Each chest X-ray was retrospectively analysed using CAD4TB v6 and v8. Growth mixture modelling was applied to identify latent group trajectories for each CAD version and association between latent groups and socio-demographic/clinical characteristics was investigated using chi-squared testing.
Results: For CAD4TB v6, four latent trajectory classes were identified: i) decreasing (median: 42.7, IQR: 36.7-45.0), ii) persistent high (median: 63.0, IQR: 44.3-81.9), iii) persistent medium (median: 42.7, IQR: 28.4-47.3), and iv) persistent low scores (median: 9.1, IQR: 3.2-19.7). In contrast, CAD4TB v8 identified three main trajectory classes: i) high to low (median: 32.9, IQR: 27.4-43.4), ii) low to high (median: 8.2, IQR: 2.8-20.4), and iii) persistent low scores (median: 3.9, IQR: 2.2-7.6). Higher-scoring trajectories for both versions were associated with older age, living with HIV, an incident tuberculosis diagnosis, increased symptom presentation, and previous TB.

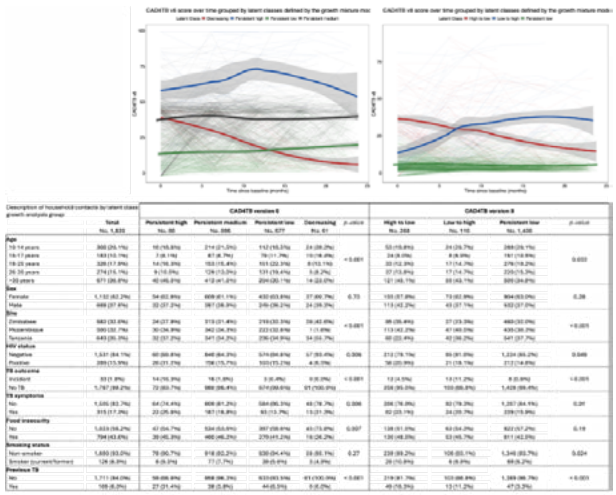


Figure 1: CAD4TB group trajectories (version 6 left and version 8 right) and association with clinical and socio-demographic characteristics.

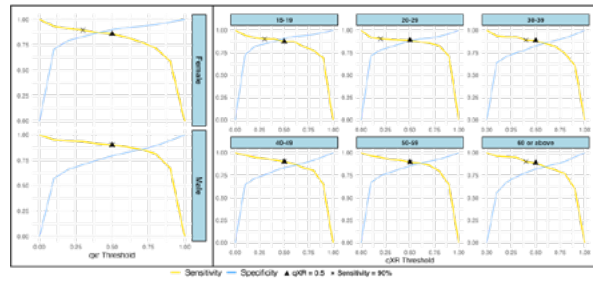
Conclusions: Our findings suggest that CAD4TB scores exhibit distinct longitudinal trajectories, which may provide insights into disease progression.
Trajectory differences between CAD4TB v6 and v8 highlight the impact of underlying deep learning algorithms used for training.

OA33-422-21 Differentiated TB abnormality thresholds for artificial intelligence interpretation of chest X-rays

T. Garg,[1] S. Banu,[2] S. Ahmed,[2] M. Muyoyeta,[3] M. Kagujje,[3] S. John,[4] S. Abdulkarim,[5] A. Codlin,[6] L.N.Q. Vo,[7] N. Murphy-Okpala,[8] J. Creswell,[1] [1]Stop TB Partnership, Innovations and Grants, Geneva, Switzerland, [2]icddr,b, Infectious Diseases Division, Dhaka, Bangladesh, [3]Centre for Infectious Diseases Research in Zambia, Tuberculosis Department, Lusaka, Zambia, [4]Janna Health Foundation, Research, Yola, Nigeria, [5]SUFABEL Community Development Initiative, Research, Gombe, Nigeria, [6]Friends for International TB Relief (FIT), M&E, Ho Chi Minh City, Viet Nam, [7]Friends for International TB Relief (FIT), Management, Ha Noi, Viet Nam, [8]RedAid Nigeria, Tuberculosis Department, Abuja, Nigeria
e-mail: tusharg@stoptb.org

Background: Different abnormality scores are often needed to produce similar screening performance in different populations. Performance of artificial intelligence (AI) to interpret chest x-ray (CXR) may change based on different demographic characteristics and adjusting threshold scores could improve performance.
Design/Methods: We pooled 12,112 records from chest x-ray screening in Bangladesh, Nigeria, Viet Nam, and Zambia with corresponding age, sex, AI abnormality scores for TB (qXR score, qXRv3, Qure.ai), and GeneXpert result to calculate sensitivity and specificity at various qXR thresholds with GeneXpert as the reference standard. Manufacturer-recommended qXR threshold is 0.5.
Results: Overall, 7.6% had positive Xpert, 44.7% were females, and 20-29 years old, 30-39, 40-49, 50-59, and 60+ constituted 15.1%, 16.3%, 17.2%, 19.6%, and 27.4% of the population, respectively.
Most (59.3%) qXR scores were less than 0.1 and 18.6% were above 0.5. At default 0.5 threshold, pooled sensitivity was 0.89 and specificity was 0.84.
Sensitivity and specificity among females were 0.86 and 0.9, and among males 0.9 and 0.79 respectively. WHO Target Product Profile (TPP) of 90% sensitivity was achieved at gender-differentiated qXR thresholds of 0.3 (female) and 0.5 (male) respectively, with a marginal loss in specificity (0.81).
For age, 90% sensitivity was achieved at 0.3 qXR threshold for 15-19 age group, 0.2 for 20-29, 0.4 for 30-39, 0.5 for 40-49 and 50-59, and 0.4 for 60+.
There were no scenarios for sex and age groups where both sensitivity and specificity improved compared to the 0.5 threshold.



Conclusions: While differentiated abnormality threshold scores did not show improvement in both sensitivity and specificity compared to the 0.5 threshold, different thresholds were required to achieve 90% sensitivity for both sex and age groups highlighting the need to adjust thresholds based on context, target population for screening, and testing capacity.

OA33-423-21 Factors affecting the performance of chest X-ray artificial intelligence-based computer-aided diagnosis for TB in a primary health centre

C. Khosa,[1,2] D. Robert,[3] J. Ribeiro,[1] A. Machiana,[1] I. Jani,[1] L. Amzil,[4] C. Cubai,[1] A. Rachow,[5] S. Ross-Howe,[4] S. Chawla,[6] [1]Instituto Nacional de Saúde, Centro de Investigação e Treino em Saúde da Polana Caniço, Maputo, Mozambique, [2]Eduardo Mondlane University, Department of Physiological Science, Clinical Pharmacology, Faculty of Medicine,, Maputo, Mozambique, [3]Qure.ai, Clinical Research, Bangalore, India, [4]Cloud Diagnostics Canada ULC, Research & Development, Kitchener, Canada, [5]Ludwig Maximilian University of Munich (LMU), Division of Infectious Diseases and Tropical Medicine, Munich, Germany, [6]Qure.ai, Global Health Innovation, Mumbai, India
e-mail: celso.khosa@ins.gov.mz

Background: Chest X-ray (CXR)-based diagnosis for tuberculosis (TB) using artificial intelligence (AI) computer-aided detection is being increasingly adopted. We assessed the diagnostic accuracy of one such AI device (qXR) and factors associated with inaccurate results.
Design/Methods: This retrospective study utilized data from people with cough presenting at a Primary Health Center in Maputo, Mozambique, to develop a cough analysis algorithm. Xpert MTB/RIF test results, CXRs, medical history, demographics, body weight and height, and spirometry results at enrollment were included in this analysis. CXRs were processed by AI. Using a microbiological reference standard based on Xpert, we calculated the area under the receiver operating characteristic curve (AUROC), sensitivity and specificity of AI. Subgroup analyses examined people living with HIV (PLHIV), people with a previous TB (PWTH), body mass index (BMI), forced expiratory volume in one second (FEV1), forced vital capacity (FVC) and FEV1: FVC ratio categories. A multivariable logistic regression model assessed factors associated with incorrect (false positive/false negative) AI results.

Group	AUROC (95% CI)	Sensitivity (95% CI)	Specificity (95% CI)
Overall (n=220)	0.92 (0.86–0.97)	92.0% (80.8–97.8)	83.5% (77.1–88.8)
PLHIV (Yes, n=55)	0.93 (0.86–1.00)	100% (71.5–100)	72.7% (57.2–85.0)
PWTH (Yes, n=41)	NA	NA	65.7% (47.8–80.9)
BMI Low (<18.5, n=51)	0.86 (0.75–0.97)	96.2% (80.4–99.9)	44.0% (24.4–65.1)
BMI Normal (n=115)	0.92 (0.82–1.00)	90.5% (69.6–98.8)	91.5% (83.9–96.3)
Low FEV1 (Yes, n=77)	0.92 (0.85–0.99)	96.0% (79.6–99.9)	75.0% (61.1–86.0)
Low FVC (Yes, n=79)	0.92 (0.86–0.98)	96.2% (80.4–99.9)	75.5% (61.7–86.2)
Low FEV1: FVC Ratio (Yes, n=12)	NA	NA	80.0% (44.4–97.5)

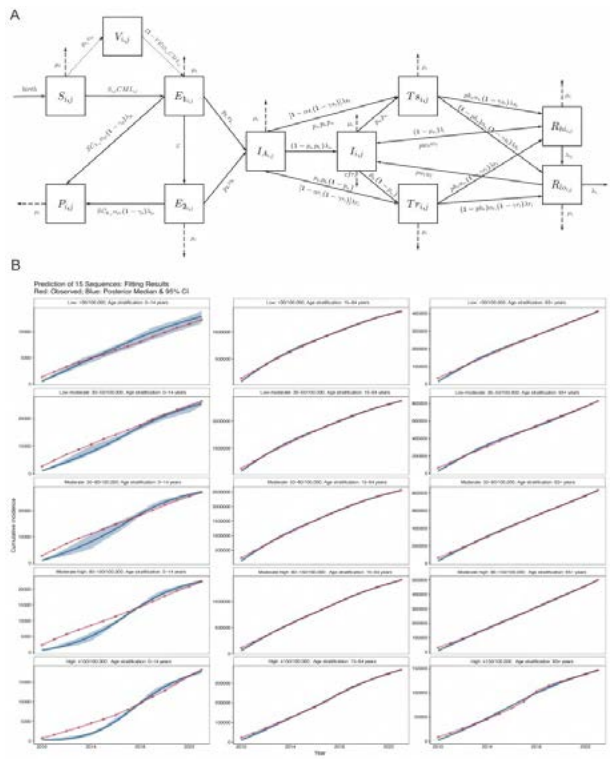
Results: Among 220 participants (mean age+standard-deviation: 39±14.6; 50% female) with available Xpert results, 55 (25%) were PLHIV, 41 (18.6%) PWTH, 51 (23.2%) had low BMI, 12 (5.4%) low FEV1:FVC ratio, and 50 (22.7%) had microbiological confirmed TB. AI performance AUROC: 0.92 (95% CI: 0.86- 0.97), sensitivity: 92% (80.8-97.8), specificity: 83.5% (77.1-88.8) overall. Specificity was relatively lower in PWTH (65.7%), PLHIV (72.7%), and low BMI group (44%).
Logistic regression analysis showed that low BMI, PLHIV and PWTH were independently associated with incorrect AI results ($P < 0.05$), while age, gender, FEV1, FVC and FEV1:FVC ratio did not.
Conclusions: AI met the WHO TPP criteria without threshold calibration. The likelihood of incorrect AI results was higher in those with low BMI, past TB history and HIV. More research is needed to corroborate the findings and to investigate if these subgroups will benefit from focused calibration.

OA33-424-21 Mathematical modelling of TB transmission and intervention effectiveness: Evaluating age-specific control measures across epidemiologically diverse regions in China

Z. Wen,[1] W. Zhou,[1] L. Ma,[1] W. Wang,[1]
[1]Fudan University, School of Public Health, Shanghai, China

Background: Tuberculosis (TB) remains a major public health challenge in China, with 748,000 cases reported in 2022. Despite a 3% annual incidence decline, achieving "End TB Strategy"'s 2030/2035 targets demands optimized strategies. Current interventions inadequately address heterogeneous transmission across epidemiologically stratified regions.
This study employs transmission dynamics modeling to evaluate intervention effectiveness and predict TB incidence trajectories under optimized control measures.
Design/Methods: A compartmental model stratified by 3 age groups and 5 regions categorized by incidence of TB simulated TB natural history from susceptibility to previous-cases' management. Parameters derived from national surveillance, cohort studies, and literature informed transitions between compartments.
Bayesian block-adaptive Markov chain Monte Carlo (MCMC) algorithms calibrated transmission coefficients and progress rates by fitting with the number of notifications from 2010 to 2023. The effectiveness of assumed interventions varied by regions and age groups were evaluated: active cases finding, passive cases finding, patient management and novel vaccine.
Results: The model demonstrated strong concordance with empirical data across all demographic strata, as evidenced by coefficients of determination (R2) exceeding 0.85. While most populations exhibited heterogeneous temporal trajectories with progressive incidence declines post-2020, sustained transmission persisted among children under 14 years in low-to-moderate transmission zones. National projections under baseline conditions re-

vealed a 25.5% reduction in tuberculosis incidence from 40.81 (95% CI: 39.17–43.14) to 30.40 per 100,000 population between 2023 and 2035. Counterfactual analysis estimated that optimized active case-finding strategies could avert 2.40 million TB cases, surpassing passive case finding (0.49 million), patient management (0.57 million), and novel vaccine (0.22 million) at the national level, from 2025 to 2035.



Conclusions: The modeling framework demonstrates epidemiological validity with sustained TB incidence reduction under current policies. Prioritizing active case detection and strengthening pediatric surveillance could accelerate progress toward elimination targets. Continuous refinement of intervention strategies remains imperative for persistent transmission hotspots.

OA33-425-21 A Bayesian cost-effectiveness model of TB screening and diagnosis in seven high TB burden low- and middle-income countries

A. McCoy,[1] T. Garg,[2] T. Wingfield,[3] M.Y.R. Henrion,[1] E. Worrall,[1] on behalf of the Start4All: Start Taking Action for TB Diagnosis consortium [1]Liverpool School of Tropical Medicine, Clinical Sciences, Liverpool, United Kingdom of Great Britain and Northern Ireland, [2]Stop TB Partnership, Innovations and Grants, Geneva, Switzerland, [3]Liverpool School of Tropical Medicine, Clinical Sciences and International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: tusharg@stoptb.org

Background: High costs of diagnostic tests and screening programs remain a major barrier to timely TB identification in resource-limited settings. Evidence on the cost-effectiveness of more sensitive and scalable screening and diagnostic tests is limited. The Start4All consortium is a 7-country Unitaid-funded research project aimed at developing and evaluating TB screening and diagnostic tests and test combinations (algorithms), with the goal of expanding diagnostic coverage to primary healthcare (PHC) and community settings.

Design/Methods: Five screening and diagnostic tests were evaluated: a capillary blood-based assay (C-reactive protein; CRP), sputum-based rapid molecular tests (PCR; individual and pooled), a lateral-flow urine test for lipoarabinomannan (LF-LAM), and digital chest X-rays with AI-based computer-aided detection (CAD-CXR). A microbiological reference standard of culture was used to confirm TB disease.

We compared the cost and effectiveness of concurrent and sequential positive serial algorithms of CRP, CAD-CXR, LF-LAM, and individual and pooled PCR. Performance data were used to calculate sensitivity, specificity, positive and negative predictive values, and proportions of positive results, with Bayesian conditional probability employed to estimate the accuracy of these algorithms.

Cost analysis was conducted from the provider perspective, incorporating commodity and implementation costs.

A decision tree model was developed to assess the cost per TB case detected across all countries. Probabilistic sensitivity analysis (PSA) was performed to account for uncertainty in model parameters.

Results: Preliminary results indicate that at PHC, for all adults and adults living with HIV, the sequential introduction of CAD-CXR or CAD-CXR followed by pooled PCR could reduce commodity costs by up to 66%, with a reduction in TB cases detected of up to 20% compared to algorithm with only individual PCR. PSA showed that the optimal algorithm varies depending on context, specifically decision-makers' willingness-to-pay and willingness-to-accept thresholds.

Conclusions: The scale-up of more cost-effective algorithms could lead to increased TB case detection through broader coverage.

OA33-426-21 Cost-effective diagnostic strategies for targeted mass screening campaigns: Pooled GeneXpert vs. TB-LAMP testing in Ethiopia

H. Terefe,[1] T. Helil,[2] A. Banti,[1] E. Tadesse,[1] T. Assefa,[1] Z. Trife,[3]
[1]REACH Ethiopia, Program Managment, Addis Ababa, Ethiopia, [2]REACH Ethiopia, Program, Awash 7, Ethiopia, [3]REACH Ethiopia, Monitoring, Evaluation and Research, Addis Ababa, Ethiopia
e-mail: tamiru.a@reachet.org.et

Background and challenges to implementation: Mass screening and treatment (MSaT) campaigns are critical in detecting undiagnosed TB cases, particularly in asymptomatic individuals, helping to interrupt transmission and reduce disease burden. However, these campaigns are resource-intensive and logistically complex, especially in high TB burden countries like Ethiopia, where limited resources and the global economic crisis strain health systems.

This operational study compared the cost-effectiveness and diagnostic performance of two TB diagnostic tools—pooled GeneXpert and TB-LAMP testing during community-based screening campaigns in both urban and pastoralist settings.

Intervention or response: A total of 2,055 sputum samples were collected and tested using pooled GeneXpert (4:1 ratio), resulting in 514 pooled tests and 41 deconvolution tests. In parallel, 672 samples were tested using TB-LAMP to compare accuracy, throughput, and cost metrics.

The study considered both direct and indirect costs—including consumables, labor, equipment, and patient time—and calculated the unit cost per test, cost per TB case detected, and the incremental cost-effectiveness ratio (ICER).

Results/Impact: Both methods achieved 100% concordance in TB case detection. The positivity rate was 1.4% for pooled GeneXpert and 2.0% for TB-LAMP. Pooled GeneXpert testing saved 1,500 cartridges—approximately USD $15,000. The unit cost per test was $3.20 for pooled GeneXpert and $4.30 for TB-LAMP. The cost per TB case detected was $136 and $197, respectively. GeneXpert cartridge costs accounted for 47% of total test costs, while TB-LAMP consumables made up 45% of its costs. TB-LAMP demonstrated higher throughput, processing up to 112 samples/day compared to 32/day for a 4-module GeneXpert machine.

Conclusions: Both tests were diagnostically reliable, but pooled GeneXpert offered greater cost savings and efficiency. When paired with high-quality specimens, pooled testing is a novel, scalable solution for resource-limited settings. It enables broader coverage, faster results, and cost-effective TB case detection—key elements for successful MSaT campaigns and advancing toward TB elimination goals.

OA33-427-21 Cost-effectiveness of clinic-based and community-based active case finding in South Africa

S. Sweeney,[1] N. McCreesh,[2] I. Yoon,[1] P. Khan,[3,4] I. Govender,[3,4] M. Sithole,[4] R. White,[2] R. Houben,[2] A. Grant,[4,5] [1]London School of Hygiene & Tropical Medicine, Department of Global Health and Development, London, United Kingdom of Great Britain and Northern Ireland, [2]London School of Hygiene & Tropical Medicine, Department of Infectious Disease Epidemiology and Dynamics, London, United Kingdom of Great Britain and Northern Ireland, [3]London School of Hygiene & Tropical Medicine, Department of Clinical Research, London, United Kingdom of Great Britain and Northern Ireland, [4]Africa Health Research Institute, Health Informatics, Hlabisa, South Africa, [5]London School of Hygiene & Tropical Medicine, Department of Clinical Rsearch, London, United Kingdom of Great Britain and Northern Ireland

Background: South Africa is implementing targeted universal testing for TB (TUTT) in health facilities, however in the context of a global funding crisis, many programs have halted, and countries will need to reconsider the most cost-effective approaches to TB care and prevention.

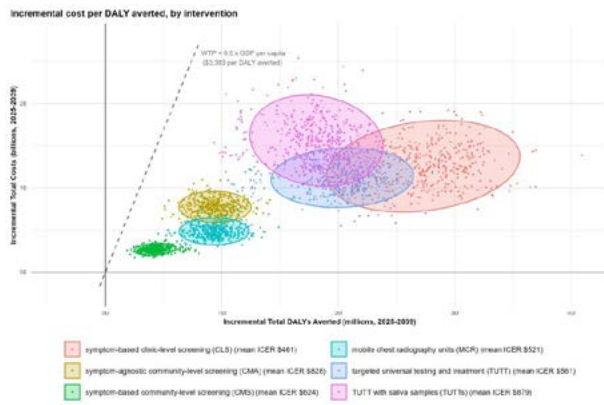
Design/Methods: We estimated the potential cost and cost-effectiveness of six case finding approaches from the provider perspective in South Africa. Scenarios included symptom-based community-level (CMS) and clinic-level (CLS) screening, symptom-agnostic community-level screening (CMA), mobile chest radiography units (MCR), TUTT using only expectorated sputum (TUTT), and TUTT allowing saliva samples (TUTTs).

Clinic-based approaches reached all clinic attendees; community-based approaches were targeted to areas with higher prevalence, reaching 10% of the population. Mtb transmission, disease development, progression, and treatment were simulated in an individual-based model.

We parameterized a cost-effectiveness model using primary and secondary cost data and estimated incremental costs and disability-adjusted life years (DALYs) for each scenario over 15 years, compared with the current standard of care. Incremental cost-effectiveness ratios (ICERs) were compared against a willingness-to-pay (WTP) threshold of $3,383 per DALY averted.

Results: All modeled interventions were under the WTP threshold and therefore likely cost-effective, with ICERs ranging from $466 (CLS) to $907 (TUTTs) per DALY averted (Figure). Targeted community-based approaches

had less coverage and were therefore cheaper but less cost-effective than clinic-based approaches. Reduced targeting would increase coverage but likely reduce cost-effectiveness. CLS and MCR were more cost-effective than TUTT; CLS was more costly and MCR was less effective overall than TUTT. There was some uncertainty in results; this did not affect overall conclusions.



Conclusions: All modeled approaches to case finding were cost-effective, but all will require additional investment. Due to the current turmoil in global aid policy, some TB programs may opt for more cost-saving options in future. This analysis provides policy-makers with a range of ACF options to consider.

OA34 From households to health systems: Innovations, ethics, and integration in TB prevention and contact care

OA34-428-21 Is household contact investigation a missing link for TB care in Chhattisgarh, India? Operational research using programmatic data

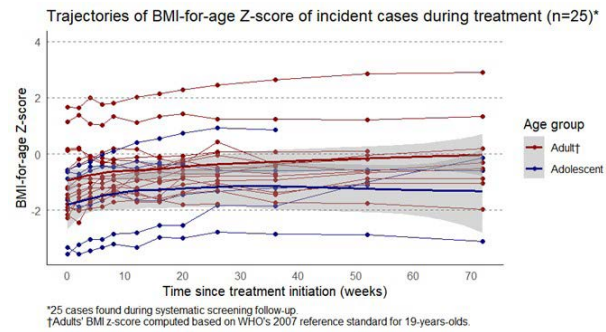
C. Malik,[1] [1]Sangwari- People's Association for Equity and Health, Clinic program, Ambikapur, India
e-mail: drchetanyamalik86@gmail.com

Background: Household contact (HHC) investigation helps early identification of people with tuberculosis (TB) and initiation of TB preventive treatment (TPT) among those at high risk of developing TB. The study uses National TB Elimination Program data from Chhattisgarh, a central Indian state, to assess the coverage of HHC investigation, proportions identified with TB and put on TPT for all age groups and age<5 years. It identified predictors of HHC investigation not done among those notified for TB.
Design/Methods: This is a cross-sectional analytical study of all notified people with bacteriologically confirmed pulmonary TB and their HHCs from October to December 2023. Coverage of HHC investigation, those diagnosed with TB (among HHC) and put on TPT were calculated. Sociodemographic, clinical and health system related factors were used for finding predictors of HHC investigation not done through modified Poisson regression.
Results: Of 4221 people notified with TB, HHC investigation was done for 3177 (75%) cases. Among total11670 contacts screened, TB was diagnosed in 0.9% for all age groups and 0.7% for children<5 years. TPT was initiated in 66% for all age groups and 73% for children<5 years.
Women (adjusted prevalence risk aPR 1.10; 95%CI:1.01-1.19), those notified from non-tribal districts (aPR 1.14; 95%CI:1.01-1.29), current facility being tertiary care (aPR 1.50; 95%CI:1.12-2.00) and private (aPR 1.42; 95%CI:1.08-1.86) facility, diagnosed with test other than sputum microscopy (aPR NAAT 3.19; 95%CI:2.39-4.28;LPA 8.88 95%CI:6.15-12.82; culture 9.69; 95%CI:5.99-15.68) and for whom diabetes (aPR 1.40; 95%CI:1.16-1.70) and HIV screening (aPR 1.55, 95% CI:1.17-2.05) was missing predicted higher risk of HHC investigation not done.
Conclusions: The study highlights need to improve HHC investigation, low yield of TB and TPT initiation. Predictors of HHC investigation not done suggest a need to decentralize it to primary level and improved data-based program monitoring. A statewide capacity building initiative for improving investigation of HHC is the way forward.

OA34-429-21 Severity of TB disease in people diagnosed through systematic screening

C.M. Nguyen,[1] L. Larsson,[1] C. Calderwood,[2,3] E. Marambire,[2] A. Rachow,[1,4,5] D. Banze,[6] A. Mfinanga,[7] K. Held,[1,4,8,5] C. Khoso,[6] L. Minja,[7] N. Heinrich,[1,4] K. Kranzer,[1,2,3]
ERASE-TB Study Group [1]LMU Munich, Institute of Infectious Diseases and Tropical Medicine, LMU University Hospital, Munich, Germany, [2]Biomedical Research and Training Institute, The Health Research Unit, Harare, Zimbabwe, [3]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom of Great Britain and Northern Ireland, [4]German Center for Infection Research (DZIF), Partner site Munich, Munich, Germany, [5]German Research Centre for Environmental Health (HMGU), Unit Global Health, Helmholtz Zentrum München, Neuherberg, Germany, [6]Instituto Nacional de Saúde (INS), Instituto Nacional de Saúde (INS), Maputo, Mozambique, [7]National Institute for Medical Research, Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, [8]Fraunhofer Institute for Translational Medicine and Pharmacology (ITMP), Immunology, Infection and Pandemic Research, Munich, Germany
e-mail: nguyen.minh@campus.lmu.de

Background: Systematic tuberculosis (TB) screening aims to diagnose TB early before extensive lung damage develops and onward transmission occurs. However, there is limited data on the severity of TB among people diagnosed through screening and their recovery during treatment.
Design/Methods: As part of ERASE-TB, a TB household contact (HHC) cohort study conducted in Mozambique, Tanzania, and Zimbabwe (2021 – 2024), HHCs aged 10+ were screened for TB every 6 months for up to 2 years. The screening was chest x-ray (CXR) and symptom-based; confirmatory sputum testing used Xpert MTB/Rif and culture. HHCs with microbiologically confirmed pulmonary TB were initiated on treatment and continued to be followed for 3 years in a substudy.
Results: 35 HHCs in ERASE-TB (21 women, median age 26.6 years) were diagnosed with TB and enrolled in the substudy, 10 at baseline, and 25 during follow-up (incident). Twenty-three cases (65.7%) were symptomatic: two-thirds (n=23) reported cough (median duration 2 (interquartile range [IQR] 1.5–4.3) weeks). Other symptoms reported included weight loss (n=12 (34.3%)), fever/chills (n=12 (34.3%), and night sweats (n=6 (17.1%)). Median CAD4TB(v8) scores at diagnosis were 47.88 (IQR 13.58–86.07). There were 9 (25.7%), 15 (42.9%), and 10 (28.4%) people with semiquantitative Xpert MTB/RIF levels of very low/low, medium, and high/very high, respectively. The median time-to-culture positivity was 12.25 days (IQR 8.82–17.53). At diagnosis, the median BMI z-score was -0.87 (IQR (-1.84) – (-0.21)). BMI z-score increased steadily during treatment until week 26 (median -0.57, IQR (-1.04 – 0.07). The median time-to-resolution of cough symptoms was 4 weeks (IQR 2 - 6).



Conclusions: Most HHCs diagnosed through screening appear to have advanced disease, evidenced by at least medium Xpert MTB/Rif positivity (equivalent to smear-positive TB) and CAD4TB(v8) scores. During treatment, most HHCs saw increased BMI. A limitation of this study is the lack of a comparator group.

OA34-430-21 Breaking the chain: A community-based intervention for screening and TB preventive treatment in household contacts

K.U. Eman,[1] U.R. Lodhi,[1] G.N. Kazi,[1] T. Asif,[1] B. Kirubi,[2] J. Creswell,[2] S. Tahseen,[1] [1]Dopasi Foundation, Programs, Islamabad, Pakistan, [2]Stop TB Partnership, TB Reach, Geneva, Switzerland
e-mail: kinza_kz@yahoo.com

Background: Pakistan continues to bear a high burden of tuberculosis (TB), with household contacts of TB patients identified as a key population for targeted preventive interventions. Tuberculosis preventive treatment (TPT) plays a vital role in reducing the risk of disease progression; however, large-scale implementation remains suboptimal.
An intervention study was undertaken to identify and address operational challenges and inefficiencies affecting the uptake and delivery of TPT within routine programmatic settings.
Design/Methods: The intervention involved screening household contacts of TB patients diagnosed through routine programmatic services at health facilities, as well as those identified via ongoing active case finding (ACF) activities in surrounding areas.
Implemented across 61 health facilities in Pakistan during 2023–2024, the intervention followed national guidelines to determine TPT eligibility. Active TB was excluded through symptom assessment and/or chest X-ray screening. Dedicated paramedics delivered tailored health education and follow-up support.
Data were collected digitally on TPT eligibility, initiation, and completion, and were analyzed by age group to assess trends and gaps in preventive treatment uptake and adherence.

Results: A total of 23,127 household contacts were screened; 87% were eligible for TPT. Uptake was 37% overall, with initiation in 37% of adults, 34% of children aged 5–14, and 43% under five. Among those initiated, 96% completed treatment. Challenges included fear of side effects, limited risk perception, and logistical barriers. High adherence was supported by structured counseling, follow-up, and strong community trust in trained paramedical staff.

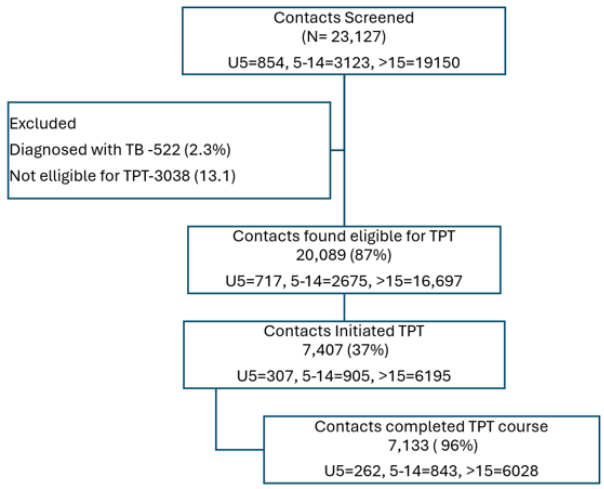


Figure 1: Results of household screening of TB contacts and uptake of TPT and completion rate in Pakistan

Conclusions: TPT delivery among household contacts is feasible with high completion rates. However, low initiation highlights the need for targeted advocacy, trust-building, and trained staff. Strengthening program readiness requires TB infection testing, minimizing out-of-pocket costs, logistical support for transport, access to chest X-rays, and robust follow-up to improve uptake and ensure equitable, sustained implementation.

OA34-431-21 Breaking barriers: Healthcare workers' perspectives on strengthening TB prevention therapy (TPT) implementation in Indonesia and the Philippines

P. Kulkarni,[1] M.D.C. Reñosa,[2] L. Steiner,[3] P. Raichur,[1] C.E. Lamigo,[4] B.J. Sornillo,[4] R.A.B. Hechanova,[5] A.F. Hapsari,[6] A.S. Hasibuan,[6] E. Yunihastuti,[6] J. Golub,[7] C.J. Hoffmann,[3] BEAT TB Study Team [1]Johns Hopkins Centre for Infectious Diseases in India, CIDI, Pune, India, [2]Research Institute for Tropical Medicine, Department of Health, Muntinlupa, Philippines, [3]Johns Hopkins University, Division of Infectious Disease, Baltimore, United States of America, [4]Research Institute for Tropical Medicine, Department of Epidemiology and Biostatistics, Muntinlupa, Philippines, [5]Research Institute for Tropical Medicine, Medical department, Muntinlupa, Philippines, [6]Cipto Mangunkusumo General Hospital, HIV Integrated Unit, Jakarta, Indonesia, [7]Johns Hopkins University, Department of Medicines, Baltimore, United States of America
e-mail: pkulka10@jh.edu

Background: Tuberculosis preventive therapy (TPT) is a cornerstone in global TB control. Despite strong evidence supporting its efficacy, TPT remains sub-optimal across healthcare settings due to systemic, logistical, and socio-behavioral challenges.

This study explores healthcare workers' (HCW) perspectives on the barriers to TPT implementation for people living with HIV and their recommendations for improving uptake in Indonesia and the Philippines–two high TB-HIV burden countries.

Design/Methods: We conducted ten focus group discussions (FGDs; n=52) and four in-depth interviews (IDIs) with HCWs involved in HIV/TB care between June and December 2023.

Data were analyzed using Reflexive Thematic Analysis (RTA), with Normalization Process Theory (NPT) guiding the analysis across four constructs viz. Coherence, collective action, cognitive participation and reflexive monitoring.

Results: Key barriers to TPT implementation included low awareness of recommending the TPT, inconsistent prescription practices, shortage of medicines, and limited human resources.

HCWs also highlighted the need for additional training, structured standard operating procedures (SOPs), uninterrupted TPT supply, and reminder systems to increase prescribing. There was a lack of TPT delivery reporting or other structured feedback mechanisms.

Suggested approaches to increase TPT prescribing included HCWs' training on TPT eligibility, treatment duration, understanding of regimens, side-effect management, improved communication, interdepartmental coordination, and structured patient education.

Increasing staffing and reinforcements and establishing peer support groups were proposed to mitigate operational obstacles. Embedding TPT guidelines into daily

workflows and aligning interventions with site-specific needs were also proposed to improve TPT implementation.

Background and challenges to implementation: Tuberculosis preventive therapy (TPT) is a cornerstone in global TB control. Despite strong evidence supporting its efficacy, TPT remains sub-optimal across healthcare settings due to systemic, logistical, and socio-behavioral challenges.

This study explores healthcare workers' (HCW) perspectives on the barriers to TPT implementation for people living with HIV and their recommendations for improving uptake in Indonesia and the Philippines–two high TB-HIV burden countries.

Intervention or response: We conducted ten focus group discussions (FGDs; n=52) and four in-depth interviews (IDIs) with HCWs involved in HIV/TB care between June and December 2023.

Data were analyzed using Reflexive Thematic Analysis (RTA), with Normalization Process Theory (NPT) guiding the analysis across four constructs viz. coherence, collective action, cognitive participation and reflexive monitoring.

Results/Impact: Key barriers to TPT implementation included low awareness of recommending the TPT, inconsistent prescription practices, shortage of medicines, and limited human resources.

HCWs also highlighted the need for additional training, structured standard operating procedures (SOPs), uninterrupted TPT supply, and reminder systems to increase prescribing. There was a lack of TPT delivery reporting or other structured feedback mechanisms.

Suggested approaches to increase TPT prescribing included HCWs' training on TPT eligibility, treatment duration, understanding of regimens, side-effect management, improved communication, interdepartmental coordination, and structured patient education.

Increasing staffing and reinforcements and establishing peer support groups were proposed to mitigate operational obstacles. Embedding TPT guidelines into daily workflows and aligning interventions with site-specific needs were also proposed to improve TPT implementation.

Conclusions: HCWs recognized the importance of TPT and suggested ways to improve prescribing, while noting issues with the coherence of TPT within their work environment, including inadequate support for training and lack of systematic reflexive monitoring.

Sustained investment in workforce development and inter-departmental coordination is essential for optimizing TPT delivery This highlights potential user-driven strategies for enhancing TPT prescribing.

NPT Constructs	Major themes	Illuminating Quotes	
		Factors affecting implementation	Pathways for improvements
COHERENCE	Perception and Capacity (understanding of the TPT)	"The patient really needs to take that for Tuberculosis prevention, how long is the duration, what are the possible side effects. That's it. That's as far as we were um… trained. But other than that, for example, the issues after you give the medication to the patient. Side effects, how do you explain to the patient the side effects, how it's handled? What is the level of… uh… what are the assurances that we can give the patient that it will… the benefit over their um issues, their concerns. So there, we're kind of lacking in those areas." P3-01-FG01	So far, our consultants are also DPJP [/Physician Responsible for Patients/] and our supervisors are also on standby. So, if we have any confusion, we can immediately consult. FG03-04
COGNITIVE PARTICIPATION	Clinician and Patient buy-in (willingness to engage)	I also think TPT is an important medicine, for example if patients already know its benefits, the more we know about the medicine, the more we can sell it. Drink it, drink it. That's good, you know. That's good, you know. The more we know the product, the more we can sell it – cross talk|| Lots. That's it, right? So how do we want to sell, the salespeople don't even understand the medicine. 02_FGD05_20231207_Nurses2	That means that's enough. The point is education. And if the nurse asks whether this has reached the community health center, this information is still not extensive, because the information has already reached the community health center. But even the medical team doesn't know yet, I see. So the key is understanding the medical team. FG-05-01
COLLECTIVE ACTION	Operationalization of TPT (ability and resources to deliver it)	No special training. But we have discussions – cross talk|| Discussing topics like that has been a program of our education, right? So, maybe even if there weren't any, there would be a patient every time we have authority over us, above that there is a doctor in charge. So, every time we get a case, we discuss it. Doc, there is a TPT candidate, we have discussed it too. Yes, according to this theory, what are the benefits? But for proper training –cross talk|| formal, certification has never been done. FG03-06	It can be overcome by every time after that all the doctors' type and then keep writing again that this patient has received TPT. The only thing is that there is no SOP for us to write that. Second, that is also the problem, we have a rotation system here, people change again, change again, change again, change again (talk quickly) so you can't mean as long as it's not required, you can't expect that everyone will write –cross talk|| So there is a risk that if it is a year later, the next doctor who accepts this patient will not know whether this patient has received TPT or not. FG03-01
REFLEXIVE MONITORING	Evaluating outcomes and cost-effectiveness (ability to appraise or amend) participants' reflections on the impact and effectiveness of TPT, including strategies for improvement	We just ask the patient. We do not have a paper or a card… to… for monitoring of it. Ahh, none… but, upon follow-up, we just ask.. 01-FG03-P03	Apart from cadre formation, there is also an approach to the patient's community. Actually, in my opinion, there are two of them, because they will be more than just listening to the doctor, but testimonials from other people or survivors too... in my opinion, they are also more effective to see than those that are practiced daily. So I think the collaboration is between primary health care and fellow SIDA communities too. This is also something that should be approached if you want to improve or speed up and complete this TPT program. FG03-06 (02_FGD03_20231205_Specialists)

e-mail: edson.marambire@lrz.uni-muenchen.de

Background: Households affected by TB face amplified vulnerabilities due to high prevalence of co-morbidities including HIV. HIV testing of TB household contacts is recommended by the WHO however implementing this is challenging.
Design/Methods: We conducted a cross-sectional analysis of 822 people with pulmonary TB (PWTB) and 2,108 household contacts across Mozambique, Tanzania, and Zimbabwe. TB was microbiologically confirmed. Data included HIV status, ART use, and spousal relationships. HIV sero-discordance between the PWTB and their spouse was assessed.
Results: Among 822 PWTB, 30% (244/822) were people living with HIV, of whom 34% (82/244) were diagnosed with HIV at the time of their TB diagnosis. Household contacts included 373 (17.7%) spouses of PWTB.
Among the spousal pairs, HIV status was as follows: both negative (219, 59%), one living with HIV the other not (53, 14%), both living with HIV (76, 20%).
In pairs where at least one person was living with HIV, more than a quarter (53/213, 24.9%) had a partner without HIV. The PWTB was more likely to be the one living with HIV (30/106, 28%).
Of the spouses living with HIV 13 (12.1%) were diagnosed during TB contact investigations. HIV testing yield was 13.2% among spouses of PWTB with newly diagnosed HIV, 4.4% among spouses of PWTB on ART and 1.2% among spouses of HIV negative PWTB. Notably, 13.4% of PWTB not on ART had prior household TB exposure, underscoring opportunities for earlier intervention.

		HIV status of people with TB				
		Negative	Positive, on ART	Positive, not on ART	Unknown	Total
HIV status of the spouse	Negative	219 (90.5%)	20 (29.4%)	10 (26.3%)	17 (68.0%)	266 (71.3%)
	Known Positive	20 (8.3%)	45 (66.2%)	23 (60.5%)	6 (24.0%)	94 (25.2%)
	Newly Positive	3 (1.2%)	3 (4.4%)	5 (13.2%)	2 (8.0%)	13 (3.5%)
	Total	242 (100%)	68 (100%)	38 (100%)	25 (100%)	373 (100%)

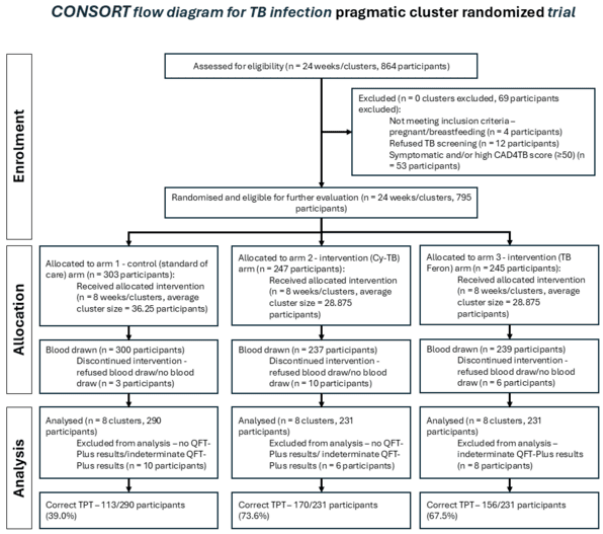
Conclusions: TB diagnosis exposes systemic gaps in access to HIV care. Among spouses of ART-naive PWTB delayed diagnosis and treatment may contribute to HIV transmission. The high sero-discordance rates and HIV prevalence in these households demand urgent integration of HIV testing and prevention into TB contact investigation. Strengthening integration of TB and HIV programmes is critical to closing these gaps in high TB/HIV-burden settings.

OA34-433-21 Diagnostic performance of novel TB infection skin tests and interferon-γ release assays (IGRAs) to detect TB infection in Ndola, Zambia: A pragmatic cluster randomised trial

R. Mwape,[1] A. Schaap,[1] B. Tapisha,[1] M. Cheeba,[1] L. Mwenge,[1] A. Mubanga,[2] N. Kasanda,[3] M. Simwinga,[1] H. Ayles,[1] K. Shanaube,[1] Ubumi Bwandi Study Team
[1]Zambart, Research Directorate, Lusaka, Zambia, [2]Ministry of Health, Zambia, National Tuberculosis and Leprosy Programme, Lusaka, Zambia, [3]Ministry of Health, Zambia, Ndola District Health Office, Ndola, Zambia
e-mail: richard@zambart.org.zm

Background: TB infection (TBI) testing remains a big challenge for low-resource and high TB-burden countries such as Zambia. Recently novel TBI tests have been developed, however, more data is needed on their clinical performance, costs and effectiveness in specific populations.
Design/Methods: We conducted a three-arm pragmatic cluster-randomized trial between May-November 2024 at a primary care facility in Ndola, Zambia to determine whether novel tests for TBI would increase the proportion of individuals receiving TPT correctly. All participants were randomized to one of three arms weekly and had blood collected for QuantiFERON-TB Gold Plus (QFT-Plus) as a reference standard.
Arm one was the current Zambian standard of care where TPT is offered without TBI testing (control). TBI was ascertained using Cy-Tb™ skin test and STANDARD™ F TB-Feron FIA (IFN-gamma) test in arms two and three respectively(intervention) and TPT was offered to participants who tested positive.

We defined "correct TPT" as individuals who met national guidelines for TPT, screened negative for TB, and (1) had a positive QFT-Plus and received TPT or (2) had a negative QFT-Plus and did not receive TPT.
The primary outcome was the proportion of individuals who were managed with "correct TPT".
Results: 39.0% (32.7-45.2 95%CI) correctly started TPT in the control arm,73.6% (70.1-77.1 95%CI) in the Cy-TB arm, and 67.5% (55.2-79.9 95%CI) in the TB-Feron arm (figure). The adjusted RR for correct TPT was 1.73 (1.37–2.17 95%CI) and 1.62 (1.23–2.14 95%CI) for Cy-TB and TB-Feron arms respectively. Compared to the QFT-Plus, TB-Feron had a better clinical performance than Cy-TB at diagnosing TBI with 82% sensitivity and 86% specificity versus 65% sensitivity and 93% specificity.



Conclusions: Our study showed that the use of either Cy-TB or TB-Feron increased the chances of receiving correct TPT and reduced inappropriate TPT. This demonstrates the potential use of TB-Feron or Cy-TB as routine TBI tests.

OA34-434-21 Feasibility and acceptability of integrating TB-specific skin testing into home-based household contact investigation for TB infection in Uganda

A. Kityamuwesi,[1] M. Musoke,[1] A. Nakate,[1] L. Kunihira Tinka,[1] S. Bamushaye,[1] S. Muchuro,[2] S. Turyahabwe,[2] H. Luzze,[2] L.J. Davis,[3,4] S. Zawedde-Muyanja,[1,5] A. Cattamanchi,[6,7,8] A. Katamba,[1,9] [1]Uganda Tuberculosis Implementation Research Consortium, WALIMU, Research, Kampala, Uganda, [2]Ministry of Health, National TB and Leprosy Division, Kampala, Uganda, [3]Uganda Tuberculosis Implementation Research Consortium, WALIMU, Research, New Haven, United States of America, [4]Yale School of Public Health and Yale School of Medicine, Epidemiology of Microbial Diseases & Pulmonary, Critical Care, and Sleep Medicine, New Haven, United States of America, [5]Infectious Diseases Institute, Research, Kampala, Uganda, [6]Uganda Tuberculosis Implementation Research Consortium, WALIMU, Research, Irvine, United States of America, [7]Division of Pulmonary and Critical Care Medicine, San Francisco General Hospital, University of California San Francisco, San Francisco, United States of America, [8]Division of Pulmonary Diseases and Critical Care Medicine, University of California Irvine, Orange, United States of America, [9]Makerere University College of Health Sciences, School Of Medicine, Kampala, Uganda
e-mail: akityamuwesi95@gmail.com

Background: The 2018 WHO and 2021 Uganda National Guidelines recommend expanding tuberculosis preventive therapy (TPT) eligibility to HIV-negative household contacts aged 5 years and above with confirmed TB infection. We assessed the acceptability and feasibility of integrating TB-specific skin testing (TBST) into home-based household contact investigation in Uganda.

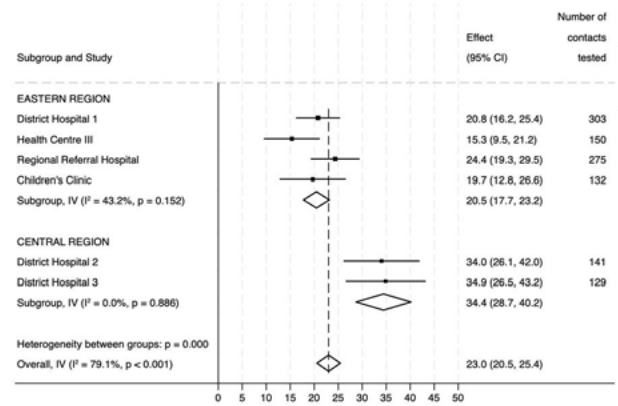


Figure 1. Forest Plot showing prevalence of TB infection by health facility.

Of 1,255 eligible contacts screened, median age was 23 years (IQR: 14–35), 58.2% (n=671) were female and most (95.2%) were household contacts. 1,153 (92%) accepted testing. Those who declined TBST (n=102) cited fear of injections (n=35), lack of symptoms (n=27), skepticism of TB infection (n=17), and concerns about skin reactions

(n=16). Only 24 contacts (2%) were unavailable for the 48–72-hour reading. Of the 1,129 contacts who completed testing, 272 (24.1%) tested positive for TB infection. The prevalence of TB infection varied regionally (ranging from 20.8% in Eastern Uganda to 34.4% in Central Uganda) and by age (ranging from 14% among children aged 8–14 to 40% among adults ≥40).

Conclusions: Integrating home-based TB-specific skin testing into routine home-based household contact investigation is both feasible and highly acceptable in Uganda. Effective scale-up will require addressing misconceptions about TB infection and fears about TST procedures to further increase acceptance.

OA34-435-21 mTST: An AI-based approach for quality assurance and measurement of tuberculin skin test administration and reading

A. Lopes,[1,2] Z. Tian,[2] M. Bastos,[3] M. Logel,[1,2] C. Valiquette,[1,2] D. Menzies,[1,2] [1]Research Institute of the McGill University Health Centre, Respiratory Epidemiology and Clinical Research Unit, Montreal, Canada, [2]McGill University, McGill International TB Centre, Montreal, Canada, [3]University of Manitoba, Department of Family Medicine, Winnipeg, Canada
e-mail: aariana.lopes@mail.mcgill.ca

Background: Tuberculin skin tests (TSTs) have important limitations related to errors in administration and reading, and the need for return visits after 48-72 hours for reading. We developed an AI-based mobile application using smartphone images to measure TST administration blebs, and induration after 48-72 hours. This may enhance training and quality assurance for TST administration and reading, and reduce patient burden related to in-person TST reading.

Design/Methods: In the first phase, 86 images from a smartphone camera were used to train an AI-based mobile application, to optimize lighting, angle, distance and focus to enhance quality of image capture.

In the second phase, the app captured 20 images of injection blebs in volunteers who received varying quantities of saline injections (0.02 mL, 0.05 mL or 0.10 mL) to create small (≤7mm) or adequately sized (>7mm) injection blebs with the injection syringe in the picture.

A 4-step deterministic algorithm was used to analyze RGB channels (values of red, blue and green light) at the pixel level of the image to identify the injection bleb and edges.

Using the known SI unit dimensions of the syringe and principles of optical physics, the size of the injection site bleb was determined, and compared to manual measurement (reference value).

Results: In preliminary results the initial algorithm correctly identified 8 of 10 (80%) photos of adequate injections, and 10 of 10 (100%) photos of inadequate. The quality standardized smartphone pictures contained all the information necessary for adequate measurement of injection blebs. In the next phase of development, our algorithm will be trained to measure TST indurations to provide numerical (in mm) and categorical (significant/non-significant) results.

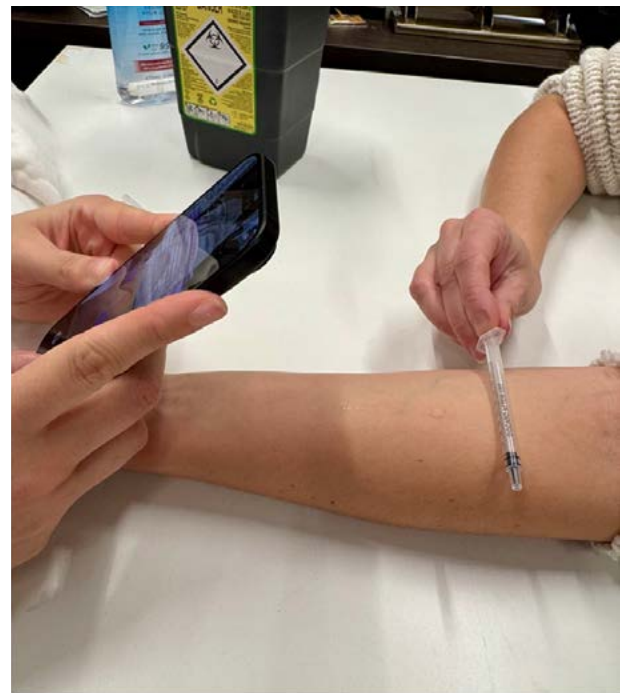

Figure 1. Image capture of injection blebs using a smartphone camera.

Conclusions: This AI-based mobile application may offer a promising solution, with the potential for global application, to reduce errors in TST administration, and minimize the need for in-person TST reading.

OA34-436-21 Beyond specificity: A bioethical frameworks essay on the ethical imperatives in choosing between PPD Rt23 and recombinant tuberculin tests

F.A. Dias e Sanches,[1,2] [1]Federal University of Rio de Janeiro, Tuberculosis Research Center, Rio de Janeiro, Brazil, [2]Piquet Carneiro University Policlinic, Governance and Compliace and Infection Prevention and Control comission, Rio de Janeiro, Brazil
e-mail: sanches@hucff.ufrj.br

Background: Tuberculosis (TB) remains a significant global health challenge, particularly in high-burden countries. Two major diagnostic approaches—PPD Rt23 and newer recombinant tuberculosis tests (Diaskintest/EC tests)—differ in specificity among BCG-vaccinated populations. This choice carries implications beyond technical considerations, necessitating analysis across bioethical,

philosophical, social, and geopolitical dimensions. Civil society engagement is crucial for implementing ethical diagnostic strategies that respect community values and enhance program acceptance, particularly where historical mistrust of medical interventions exists.

Design/Methods: We conducted a structured ethical analysis examining TB diagnostic strategies through multiple frameworks: (1) Principlism (autonomy, beneficence, non-maleficence, justice); (2) Capabilities approach; (3) Social justice theories; (4) Limitarian justice; and (5) Contextual analysis. Literature review synthesized evidence on biological efficacy, while systematic application of theoretical frameworks enabled evaluation of ethical implications. Community perspectives were integrated through content analysis of advocacy documents and interviews with civil society representatives from high-burden TB countries.

Results: Recombinant tests demonstrate higher specificity (92-99%) than PPD Rt23 (59-68%) in BCG-vaccinated populations while maintaining comparable sensitivity. This biological advantage aligns with ethical principles by reducing unnecessary treatment, enhancing autonomy through accurate information, and promoting justice through efficient resource utilization. The capabilities approach reveals how false positives restrict substantive freedoms, while social justice perspectives highlight community engagement as essential for implementation. Civil society participation strengthens diagnostic strategies by ensuring contextual appropriateness, mitigating stigma, and fostering community ownership—improving both ethical practice and program effectiveness.

Conclusions: Technical advantages of newer TB diagnostic tests cannot be separated from broader ethical, social, and political contexts. TB control programs should adopt integrated approaches that prioritize tests minimizing false positives, meaningfully engage civil society, contextualize strategies within local realities, apply ethical frameworks consistently, and promote health as a fundamental right. This integration guides development of TB control strategies that are technically effective, ethically robust, and socially embedded through authentic community participation.

OA35 Tiny-people, big challenges: Emerging diagnostics for paediatric TB

OA35-437-21 Chest X-ray artificial intelligence for detection of paediatric pulmonary TB: A multi-site retrospective diagnostic accuracy study from rural and peri-urban India

A. Singh,[1] D. Robert,[2] A. Divya S,[3] S. Beryl,[4] S. Mane,[5] S. Pawar,[6] P. S Krishnan,[7] M. Tadepalli,[8] J.A. Chiramal,[9]
[1]Chinchpada Christian Hospital, Emmanuel Hospital Association, Medicine, Chinchpada, Nandurbar, India, [2]Qure.ai, Clinical Research, Banglore, India, [3]Nav Jivan Hospital, Emmanuel Hospital Association, Pediatrics, Palamau, India, [4]Baptist Christian Hospital Tezpur, Pediatrics, Tezpur, India, [5]Dr. D.Y Patil Medical College, Hospital and Research Centre Pimpri Pune, Pediatrics, Pune, India, [6]Qure.ai, Operations, Mumbai, India, [7]Qure.ai, Operations, Banglore, India, [8]Qure.ai, Research and Development, Banglore, India, [9]Qure.ai, Products, Atlanta, United States of America
e-mail: Saniya.Pawar@qure.ai

Background: Chest X-ray (CXR) screening for adult pulmonary tuberculosis (PTB) using artificial intelligence (AI) devices is increasingly being adopted, but evidence in children is limited. We assessed the diagnostic accuracy of an AI device (qXR) trained on paediatric as well as adult CXRs.

Design/Methods: We retrospectively collected data from historical records of consecutive children with presumed PTB aged 6 to 15 years from four Indian facilities. Children with available data of demographics, CXRs taken within 10 days of diagnosis date and PTB diagnosis (positive/negative) were included. AI probability scores for the likelihood of PTB were obtained from each CXR.

Two reference standards were used;

1. A composite reference standard (CRS) –positive if confirmed microbiologically based on sputum-smear/Xpert/culture (confirmed PTB) or clinically (unconfirmed PTB) and negative otherwise;
2. A microbiological reference standard (MRS) -positive if microbiologically confirmed and negative otherwise.

Area-under-the-receiver-operating-characteristics-curve (AUROC), sensitivity and specificity of AI are reported along with threshold calibration analysis. A multivariable logistic regression model assessed if age, gender, contact history and previous TB history (PTBH) were associated with inaccurate AI results.

Results: Data from 367 children (mean age±standard-deviation: 10.6 ± 3.0 years; 205 (55.8%) males) was analysed. Nine (2.4%) had positive PTBH, 20 (5.4%) had contact history, 51 (13.9%) were confirmed TB and 24 (6.5%) were unconfirmed TB cases. AUROC was 0.85 (95% CI: 0.79-0.91) and 0.88 (0.82-0.94), respectively, using CRS and MRS. At 70% specificity, the sensitivity was 82.7%

(72.2-90.4) and 86.3% (73.7-94.3), using CRS and MRS, respectively. Age, gender and contact history did not affect AI accuracy, but positive PTBH was associated with inaccurate results ($P < .01$).

Table: Diagnostic accuracy results of AI in detection of paediatric pulmonary TB

Reference standard	AUROC	Sensitivity at optimal threshold [$]	Specificity at optimal threshold [$]	Sensitivity at 70% specificity	Specificity at 90% sensitivity
CRS	0.85 (0.79-0.91)	72.0% (60.4-81.8)	88.4% (84.1-91.8)	82.7% (72.2-90.4)	56.2% (50.3-61.9)
MRS	0.88 (0.82-0.94)	84.3% (71.4-93.0)	85.8% (81.4-89.4)	86.3% (73.7-94.3)	65.5% (60.0-70.7)

AI: Artificial intelligence; AUROC: Area under the receiver operating characteristics curve
CRS: Composite reference standard; MRS: Microbiological reference standard.
All numbers in parentheses indicate 95% confidence intervals (DeLong's for AUROC and exact binomial for others)
[$]Optimal threshold was determined based on Youden's index maximizing sensitivity and specificity. The optimal threshold was found to be 0.4275 for both MRS and CRS-based analysis.

Conclusions: AI had good accuracy in detecting confirmed and unconfirmed paediatric PTB using CXRs. CXRs from children with previous history of TB were more prone to have inaccurate AI results. Accuracy was not affected by age, gender and contact history.

OA35-438-21 Generation of paediatric chest X-rays with TB-related findings using deep generative models

García-Basteiro,[6,11,12] B. Santiago-García,[13,6] E. López-Varela,[11,12] M.J. Ledesma-Carbayo,[1,2] Spanish Network for the Study of Pediatric Tuberculosis (pTBred) [1]Universidad Politécnica de Madrid, Biomedical Image Technologies, Madrid, Spain, [2]Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red de Bioingeniería, Biomateriales y Nanomedicina (CIBER-BBN), Madrid, Spain, [3]Children's National Hospital, Department of Radiology, Washington, United States of America, [4]George Washington University, School of Medicine and Health Sciences, Washington, United States of America, [5]Gregorio Marañón University Hospital, Pediatric Infectious Diseases Department & Gregorio Marañón Research Health Institute (IiSGM), Madrid, Spain, [6]Instituto de Salud Carlos III, Centro de Investigación Biomédica en Red de Enfermedades Infecciosas (CIBERINFEC), Madrid, Spain, [7]RITIP Translational Research Network in Pediatric Infectious Diseases, RITIP Translational Research Network in Pediatric Infectious Diseases, Madrid, Spain, [8]Stellenbosch University, Desmond Tutu TB Centre, Department of Pediatrics and Child Health, Cape Town, South Africa, [9]Hospital Materno Infantil Gregorio Marañón, Radiología Pediátrica, Madrid, Spain, [10]HM Hospitales, Radiología Pediátrica, Madrid, Spain, [11]Centro de Investigação em Saúde de Manhiça, Centro de Investigação em Saúde de Manhiça, Manhiça, Mozambique, [12]Hospital Clínic, Universitat de Barcelona, ISGlobal, Barcelona, Spain, [13]Gregorio Marañón University Hospital, Pediatric Infectious Diseases Department, Madrid, Spain
e-mail: daniel.capellan@upm.es

Background: The diagnosis of pediatric tuberculosis (TB) remains a significant global challenge due to non-specific symptoms, less specific radiological signs compared to adults, and limited annotated data. While chest X-rays (CXRs) are widely used to diagnose TB, interpretation is hindered by variable presentations and low inter-reader agreement. The lack of large, diverse pediatric CXR datasets limits the development of effective AI-based tools.

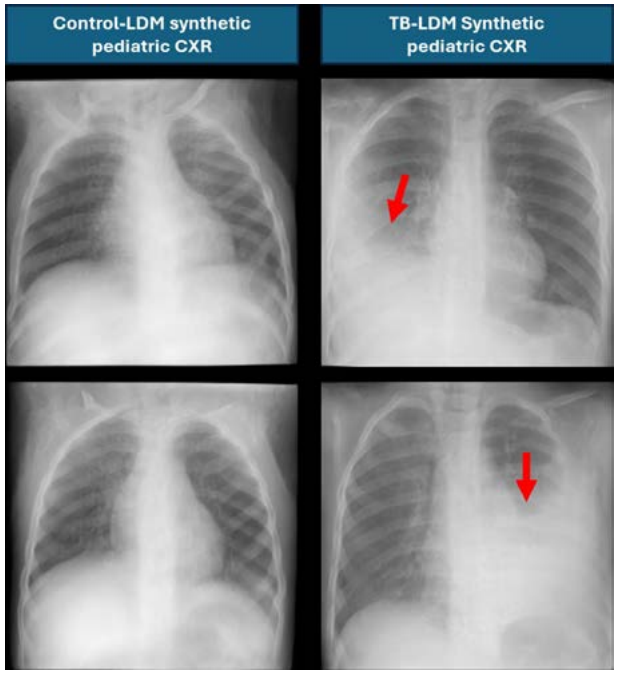
This study explores the use of deep generative models to generate realistic pediatric CXRs with TB-related findings and their impact on deep learning-based TB detection.

Design/Methods: A latent diffusion model (LDM) was trained using 592 anterior-posterior (AP) and posterior-anterior (PA) CXR images sourced from two pediatric TB cohorts: the Manhiça Health Research Center (CISM, Mozambique) and the Spanish Network of Pediatric Tuberculosis (pTBred, Spain).

We evaluated image quality using quantitative metrics such as Fréchet inception distance (FID). We then used the generated data to pre-train a convolutional neural net-

work (DenseNet121) and assessed whether the synthetic images could help improve TB detection performance on pediatric CXRs.

Results: Our approach successfully generated high-resolution (256x256) pediatric CXR images, both with TB-related findings (TB-LDM) and without (Control-LDM). Main generated findings include pleural effusion and consolidation (see figure). Quantitative evaluation showed favorable image quality, with TB-LDM scoring an FID of 143.30 when compared to adult data and an FID of 93.28 when compared to pediatric data. Pre-training a DenseNet121 on synthetic data (N=2,000) led to a 2.47% increase in area under the curve (AUC), from 0.8097 (95% CI: [0.7434, 0.8760]) to 0.8344 (95% CI: [0.7680, 0.9007]), compared to its non-pre-trained version.



Conclusions: Latent diffusion models can generate coherent pediatric CXRs with TB-related findings. These synthetic images can enhance AI model performance when used for pre-training. This approach holds promise for addressing data scarcity in pediatric TB imaging and supporting the development of more accurate diagnostic tools.

OA35-439-21 Diagnostic performance of *an optimised computer-aided diagnosis (CAD) for TB algorithm* on chest radiographs from an exclusively paediatric population in The Gambia

V.F. Edem,[1,2] S.C. Agbla,[3] E. Nkereuwem,[1,4] N. Mohammed,[1] S.A. Owusu,[1,4,5] A.K. Sillah,[1] B. Saidy,[1] U. Egere,[6] B. Kampmann,[1,4,7] T. Togun,[1,4,8] [1]Medical Research Council The Gambia at London School of Hygiene and Tropical Medicine, Vaccine and Immunity Theme, Fajara, Gambia (Republic of The), [2]University of Ibadan, Department of Immunology, Ibadan, Nigeria, [3]University of Liverpool, Department of Health Data Science, Liverpool, United Kingdom of Great Britain and Northern Ireland, [4]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Disease, London, United Kingdom of Great Britain and Northern Ireland, [5]University of Development Studies, Department of Paediatrics and Child Health, Tamale, Ghana, [6]Liverpool School of Tropical Medicine, International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland, [7]Institute of International Health, Charité Centre for Global Health, Berlin, Germany, [8]London School of Hygiene and Tropical Medicine, TB Centre, London, United Kingdom of Great Britain and Northern Ireland
e-mail: edem-victory.fabian@lshtm.ac.uk

Background: Diagnosis of tuberculosis in children is mostly based on clinical evaluation and chest x-ray findings. Computer-aided diagnosis (CAD) of tuberculosis algorithms have shown promise in adults but require further optimization for use in children. We assessed the diagnostic accuracy of the qXR CAD algorithm (Qure.ai) which has been further trained with dCXR images of children.

Design/Methods: We conducted a retrospective diagnostic accuracy study using dCXRs from well-characterised cohorts of Gambian children aged < 15 years with presumed pulmonary tuberculosis. The children were consecutively recruited between 2012 and 2024. We measured performance of qXR against a microbiological reference standard (MRS) and clinical reference standard (ClRS; unconfirmed-TB versus unlikely-TB), and also used Bayesian latent class analysis (LCA) to address the inherent limitations of MRS and ClRS in children. Diagnostic performance was assessed using the area under the receiver operating characteristic curve (AUROC) and point estimates of sensitivity and specificity.

Results: A total of 932 children were included in the analysis, with confirmed tuberculosis in 80 (9%), unconfirmed tuberculosis in 163 (17%), and unlikely tuberculosis in 689 (74%). Using MRS, qXR showed an AUROC of 0.68 (95%CI 0.61-0.75), with sensitivity and specificity of 54% (95%CI 43-64%) and 82% (95%CI 79-84%), respectively. Against ClRS, qXR showed an AUROC of 0.73 (95%CI 0.69-0.77), with sensitivity and specificity of 41% (95%CI 34-49%) and 87% (95%CI 84-89%), respectively.

Applying Bayesian LCA, with assumption of conditional independence between tests, qXR sensitivity and specificity were 79% (95%CrI 66-90%) and 82% (95%CrI 79-85%), respectively. Assuming conditional dependence between culture and Xpert, qXR demonstrated sensitivity and specificity of 87% (95%CrI 71-98%) and 83% (95%CrI 80-86%), respectively.

Conclusions: The optimized qXR CAD system could enhance the diagnosis of tuberculosis in children < 15 years, including those missed by conventional microbiological tests, particularly in resource-limited settings where expert radiological interpretation is scarce.

OA35-440-21 Evaluating the performance of CAD4TB software using photographs of digital chest X-rays in children with pulmonary TB

H. Van Deventer,[1] C. Hulsman,[1] M. Van Niekerk,[1] I.I. Decuyper,[2] J. Oliwa,[3,4] T. Decroo,[2] P. Goussard,[5] H.S. Schaaf,[1] E. Klinkenberg,[6] M. Palmer,[1] M.M. Van der Zalm,[1] [1]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Cape Town, South Africa, [2]Institute of Tropical Medicine, Unit of Tuberculosis, Department of Clinical Sciences, Antwerp, Belgium, [3]Institute of Tropical Medicine, Department of Public Health, Antwerp, Belgium, [4]Health Services Unit, KEMRI-Wellcome Trust Research Programme, Nairobi, Kenya, [5]Stellenbosch University, Paediatric Pulmonology, Department of Paediatrics and Child Health, Cape Town, South Africa, [6]Delft Imaging BV, Technical Medicine, Den Haag, Netherlands
e-mail: heidivd@sun.ac.za

Background: Efforts are underway to optimise computer-aided detection (CAD) models for paediatric tuberculosis (TB) diagnosis using chest X-rays (CXRs).

To support point-of-care use, we evaluated the performance of CAD4TB on photographs of digital paediatric CXRs, compared to original digital images, and explored whether image quality and artefacts affect model performance.

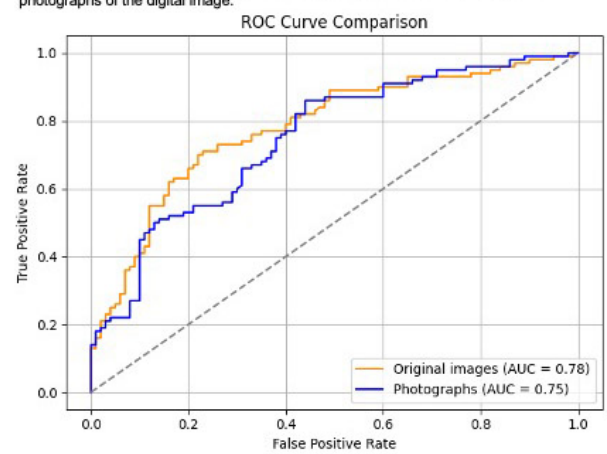
Design/Methods: We analysed 200 CXRs from children aged 0–13 years enrolled in a TB diagnostic study in Cape Town, South Africa—100 radiologically positive and 100 negative for TB, based on human radiological classification by two blinded TB experts with consensus resolution. CXR images were processed by the CAD4TBv7 modified for paediatrics (CAD4TBpTBv1) software as 1) original digital CXR image (TIFF) and subsequently as 2) photograph (JPEG) of the digital CXR on a screen using a Samsung A54 phone (camera 50 megapixels).

We generated receiver operator curves (ROC) and compared the area under the curve (AUC) between the two approaches against the same reference (human radiological classification of CXR), with significance tested via the DeLong method.

Results: The median CAD score for radiological TB images was 41.9 (interquartile range [IQR] 23.7-70.8) for the original images versus 60.6 (IQR 35.6-76.2) for the photographs of the images. For the radiological negative images the median CAD score was 14.3 (IQR 7.5-27.8) for the original images versus 29.8 (IQR 16.5-49.9) for the photographs. The AUC of the original digital CXR images was 0.78, compared to an AUC of 0.75 of the photographs (p=0.12, Figure 1).

Original images of the CXR at a set sensitivity of 90% had a specificity of 41%, compared to 40% specificity for the photographs of the images.

Figure 1. CAD4pTB comparison between original digital chest X-ray image and photographs of the digital image.



Legend: ROC curves of the original and the photographs of images using CAD4pTB software and radiological human read as reference standard. ROC= receiver-operator-curve, AUC= area under the curve.

Conclusions: The performance of paediatric adapted CAD4TBv7 was similar between photographs of digital CXRs and the original digital CXRs, supporting its potential for point-of-care use. Further model training is expected to optimise performance.

OA35-441-21 The comparison of Roche Cobas and Xpert Ultra on induced sputum to detect childhood pulmonary TB

J. Luiz,[1,2] C.B. Baard,[1] L.J. Workman,[1] K. Van As,[1,2] Y. Hlombe,[1,2] H. Poore,[3] D. Jaganath,[4,5] A. Cattamanchi,[3,5] M.P. Nicol,[6,7] H.J. Zar,[1] [1]University of Cape Town, South African Medical Research Council (SAMRC) Unit on Child and Adolescent Health, Department of Paediatrics and Child Health, Red Cross War Memorial Children's Hospital, Cape Town, South Africa, [2]Dora Nginza Hospital, Department of Paediatrics, Gqeberha, South Africa, [3]University of California Irvine, Division of Pulmonary Diseases and Critical Care Medicine, Irvine, United States of America, [4]University of California San Francisco, Division of Pediatric Infectious Diseases, San Francisco, United States of America, [5]Institute for Global Health Sciences, University of California San Francisco, Center for Tuberculosis, San Francisco, United States of America, [6]University of Cape Town, Division of Medical Microbiology and Institute for Infectious Diseases and Molecular Medicine, Cape Town, South Africa, [7]University of Western Australia, Marshall Centre, School of Biomedical Sciences, Perth, Australia
e-mail: juaneta@gmail.com

Background: Cobas MTB (Roche) is a moderate complexity Nucleic Acid Amplification Test (NAAT) conditionally recommended for the diagnosis of pulmonary tuberculosis (PTB). However, there are limited studies on its diagnostic accuracy, and no studies to date in children.
Design/Methods: We prospectively enrolled children (under 15 years) being investigated for PTB at Dora Nginza Hospital (Eastern Cape, South Africa) between January 2024 and February 2025. Induced sputum (IS) samples were tested with liquid culture, and either Xpert MTB/RIF Ultra (Ultra) or Cobas MTB. Children were categorised as having 'confirmed' (including Ultra trace positive), 'unconfirmed', or 'unlikely tuberculosis (TB)', according to NIH consensus definitions.
We calculated the diagnostic accuracy of Cobas MTB and Ultra in reference to a microbiological (culture-based) reference standard and a composite reference standard (CRS; TB defined as Confirmed on IS culture, or Unconfirmed TB).
Results: Of 170 children with valid culture results included, the median age was 24.2 months (IQR 12.2-47.8 months), 85 (50.0%) children were under two years old, 18 (10.6%) were living with HIV, 65/166 (39.2%) were under-weight-for-age, and 11 (6.5%) had culture-confirmed TB. Against culture, the sensitivity of Cobas MTB was similar to Ultra (66.7%; 95% CI 22.3-95.7 vs. 60.0%; 95% CI 14.7-94.7).
However, Ultra had a significantly higher yield (14/93; 15.1%) when compared to culture (11/93; 11.8%) and detected 11/93 (6.5%) additional children with culture-negative Unconfirmed TB. In comparison, Cobas MTB detected fewer cases (4/77; 5.2%) than culture (5/77; 6.5%). Against the CRS, Cobas MTB was less sensitive than Ultra (8.0%; 95% CI 2.2-19.2 vs. 23.3%; 95% CI 13.4-36.0) while specificity was 100% for both tests.
Conclusions: Cobas MTB had a lower yield and was less sensitive than Xpert Ultra for detecting culture-negative PTB in children.

OA35-442-21 Point-of-care ultrasound to support the new WHO treatment decision algorithms in the diagnosis of TB in children

L. Moretó Planas,[1] L. Fidelle Nyikayo,[2] B Yiech Lual,[2] E. Briskin,[3] B. Tut Chol,[4] P Joseph Panyuan,[5] L.C. Ruby,[6] S. Bélard,[6] A. Arias-Rodríguez,[7] H. Huerga,[7] [1]MSF, Medical Department, Barcelona, Spain, [2]MSF, Malakal Project, Malakal, South Sudan, [3]Epicentre, Medical Department, Paris, France, [4]MSF, Coordination, Juba, South Sudan, [5]Ministry of Health, National TB Program, Juba, South Sudan, [6]University of Tübingen, Pediatric, Tubingen, Germany, [7]Epicentre, Medical Department, Brussels, Belgium
e-mail: msfe-malakal-research@barcelona.msf.org

Background: Point-of-care ultrasound (POCUS) could support WHO-recommended treatment-decision algorithm (TDA) for pulmonary tuberculosis (PTB) in children in the absence of chest X-ray. We assessed the utility of POCUS to support the TDA for diagnosis of TB in children in a context with no access to chest X-ray.
Design/Methods: This cross-sectional study took place at Malakal (South Sudan), from January to December 2024. Children <10 years old with presumptive PTB were assessed with TDA and underwent blinded clinician-performed and interpreted POCUS to assess for subpleural nodules, lung consolidation, pleural and pericardial effusion, abdominal lymphadenopathy, splenic and hepatic micro-abscesses and ascites. A POCUS positive result was defined as the presence of any of these signs. Highly suggestive of TB POCUS was defined as presence of pericardial effusion, splenic micro-abscesses or abdominal lymph nodes. POCUS was not used for treatment decision or for the final TB classification of children as per the reference standard.
Results: Of 216 children enrolled (48.1% females, median age 0.9 years), 203(94.0%) were malnourished and 12(5.6%) living with HIV. The TDAs were indicative of TB treatment in 95(44.0%) children. Most common POCUS signs in patients with TB were splenic micro-abscesses (7;6.7%), lung consolidation (6;5.7%) and pleural effusion (6;5.7%). POCUS was positive in 41(19.0%) and highly suggestive of TB in 17(7.9%) children and respectively would have led to additional 14(11.6%) and 7(5.8%) children started on TB treatment among 121 children with TDA not indicative of TB. As per the reference standard, among 66 children with unlikely TB, POCUS was negative in 58(87.9%) and not highly suggestive of TB in 64(97.0%).

Conclusions: The systematic use of POCUS in addition to TDAs would lead to an increase of TB cases. Using POCUS signs highly suggestive of TB would diagnose a lower additional number of children with TB but with lower risk of overdiagnosis.

OA35-443-21 Evaluating the diagnostic accuracy of the TAM-TB assay for paediatric TB in the RaPaed-TB study

M. I.M. Ahmed,[1,2] A. Razid,[1,2] Z. Franckling-Smith,[3] H. J Zar,[3] A. Mfinanga,[4] D. Banze,[5] R. Semphere,[6] V. P Verghese,[7] J. Sarojini Michael,[8] K. Held,[1,2,9] C. Geldmacher,[1,2] L. Olbrich,[1,2,9,10] [1]LMU University Hospital, Institute of Infectious Diseases and Tropical Medicine, Münich, Germany, [2]German Center for Infection Research (DZIF), partner site Munich, Munich, Germany, [3]University of Cape Town, Department of Paediatrics & Child Health, SA-MRC Unit on Child & Adolescent Health, Cape Town, South Africa, [4]National Institute for Medical Research, Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, [5]Instituto Nacional de Saúde, Instituto Nacional de Saúde, Marracuene, Mozambique, [6]Kamuzu University of Health Sciences, Helse Nord Tuberculosis Initiative, Blantyre, Malawi, [7]Christian Medical College, Department of Pediatrics, Vellore, India, [8]Christian Medical College, Department of Clinical Microbiology, Vellore, India, [9]Fraunhofer Institute ITMP, Immunology, Infection and Pandemic Research, Munich, Germany, [10]University of Oxford, Department of Paediatrics, and the NIHR Oxford Biomedical Research Centre, Oxford, United Kingdom of Great Britain and Northern Ireland
e-mail: Alia.Razid@med.uni-muenchen.de

Background: Diagnosing pediatric tuberculosis (TB) is challenging due to the paucibacillary nature of the disease and limited sensitivity of sputum-based diagnostic assays. The T cell activation marker (TAM)-TB assay, a sputum-independent blood test, measures Mycobacterium tuberculosis (MTB)-specific T-cell activation using flow cytometry and has shown diagnostic potential in previous studies.
Design/Methods: As part of the prospective study, RaPaed-TB, we evaluated a simplified TAM-TB assay using ESAT6/CFP10 peptides and CD38 assessment in children and adolescents with suspected TB under 15 years of age across five low-and-middle-income countries. Whole blood samples were collected at baseline (n=975) and up to six months post-treatment initiation. Participants were classified as confirmed TB, unconfirmed TB, or unlikely TB based on NIH guidelines.
Results: Among children with valid TAM-TB results (n=678), 25.4% (n=172) had confirmed TB, 26.8% (n=287) unconfirmed TB, and 47.8% (n=219) unlikely TB. 136 samples had invalid controls and 48 had indeterminate results. The assay demonstrated a sensitivity of 63.7% (CI: 53.6-73) using only culture-confirmed TB as a reference standard. The sensitivity dropped to 50% (CI 42.2-57.8) when using culture and/or Xpert ULTRA to confirm active TB diagnosis. The assay specificity was 95.0% (CI: 91.1-97.4 reference standard: unlikely TB). Notably, 26.1% of unconfirmed TB cases exhibited an active TAM-TB profile. TB treatment led to a significant decline in MTB-specific T cell activation ($p<0.0001$), likely reflecting reduced bacterial burden, with median CD38 expression on $IFN\gamma^+$ $CD4^+$ T-cells decreasing from 75.4% at baseline to 22.1% at Visit 4 in the confirmed TB group. 27% of confirmed TB cases remained TAM-TB positive six months post-treatment initiation.
Conclusions: These findings demonstrate high specificity of the TAM-TB assay and emphasizes its ability to detect TB, including when microbiological confirmation is negative, in a large African-Asian pediatric cohort. However, its technical complexity and the number of invalid results suggest the need for further assay refinement.

OA35-444-21 Urine lipoarabinomannan concentrations among children living with and without HIV with clinically diagnosed TB disease in KwaZulu-Natal, South Africa

M. Fajans,[1] D. Wilson,[2,3] Y. Naidoo,[4] L. Lillis,[5] M. Perez,[5] D. Boyle,[5] J. Cantera,[6] B. Grant,[6] R. Dalmat,[7] P. Drain,[8,1,7] PROVE-TB Study Group [1]University of Washington, Epidemiology, Seattle, United States of America, [2]Umkhuseli Research and Innovation Management, N/A, Pietermaritzburg, South Africa, [3]University of KwaZulu-Natal, Internal Medicine, Pietermaritzbug, South Africa, [4]University of KwaZulu-Natal, Pediatrics, Pietermaritzbug, South Africa, [5]PATH, Global Diagnostics, Seattle, United States of America, [6]Global Health Labs, Diagnostics, Bellevue, United States of America, [7]University of Washington, Global Health, Seattle, United States of America, [8]University of Washington, Medicine, Seattle, United States of America
e-mail: mfajans@uw.edu

Background: Urinary LAM (uLAM) is an appealing biomarker for TB diagnosis in children because sputum collection is challenging. While testing is approved in children living with HIV (CLHIV) with a CD4 count of <200 cells/mm^3, its potential as a diagnostic for children without severe HIV (the majority of the global TB burden) has not been well characterized. Our objective was to evaluate uLAM's clinical diagnostic accuracy in children with clinical TB symptoms using highly sensitive electrochemiluminescent immunoassays (ECL-LAM) and the most accurate known LAM antibodies.
Design/Methods: We conducted a prospective longitudinal cohort study of children with clinical TB symptoms, aged 1-12 years at Harry Gwala Regional Hospital in KwaZulu-Natal, South Africa between October 2020 and May 2022, enrolling both HIV-negative children and CLHIV with a CD4 count >200 cells/mm^3. We measured uLAM concentrations using two LAM capture:detection anti-

body pairs , FIND 28:A194-01 (F/A) and S4-20:A1194-01 (S/A), and compared them to a clinical reference standard (CRS) for clinical TB diagnosis.

Results: Among the 97 children, 59.8% were female, with median age 2.6 years (IQR: 1.6-4.8). HIV prevalence was greater in CRS-positive (CRS+) children (17.6% vs 3.2%, p=0.0207). Four children had confirmed TB and thirty diagnosed clinically. F/A had a higher sensitivity compared to S/A (52.4% vs. 9.3%, p<0.0001) in CRS+ children (61.8% vs 8.8%, p<0.0001) and in children with only a clinical diagnosis (63.3% vs 6.7%, p=0.0001), but a lower specificity (49.2% vs. 94.2%, p<0.0001). The difference in median concentrations when stratified by CRS or HIV status was not significant.

		Positive by reference standard		Negative by reference standard			
Sample Type - Ab Pair (Reference Standard)	N	TP/ TP+FN	Sensitivity, % (95% CI)	TN/ TN+FP	Specificity, % (95% CI)	Positive Likelihood Ratio (95% CI)	AUC (95% CI)
Urine – F/A (Clinical Diagnosis – Primary Reference Standard[1])	97	21/34	61.8 (43.6, 77.8)	32/63	49.2 (36.4, 62.1)	1.22 (0.85, 1.74)	0.56 (0.45 – 0.66)
Urine – S/A (Clinical Diagnosis– Primary Reference Standard)	97	3/34	8.8 (1.9, 23.7)	57/63	90.5 (80.4, 96.4)	0.93 (0.25, 3.47)	0.50 (0.44 – 0.56)
AlereLAM (Clinical Diagnosis– Primary Reference Standard)	97	17/34	50.0 (32.4, 67.6)	34/63	54.0 (40.9, 66.6)	1.09 (0.71, 1.67)	0.52 (0.41-0.63)
Urine- F/A (Confirmed + Unconfirmed)[2]	97	26/45	57.8 (42.2, 0.723)	27/52	48.1 (34.0, 62.4)	1.11 (0.78, 1.60)	0.53 (0.43 – 0.63)
Urine- S/A (Confirmed + Unconfirmed)	97	6/45	13.3 (5.1, 26.8)	49/52	94.2 (84.1, 98.8)	2.31 (0.61, 8.71)	0.54 (0.48 – 0.60
AlereLAM (Confirmed + Unconfirmed	97	23/45	51.1 (35.8, 66.3)	29/52	55.8 (41.3, 69.5)	1.16 (0.76, 1.76)	0.53 (0.43 – 0.64)

[1] CRS-positive is defined as either having confirmed TB (Xpert Ultra or MGIT liquid culture positive), being clinically diagnosed by a pediatrician or initiated on TB treatment within 2 months of baseline evaluation

[2] Graham et al. (2015)'s clinical case definitions for pediatric intrathoracic tuberculosis used as secondary reference standard. These case definitions are used to standardize reporting of TB diagnostic evaluations in children.

Table 1. Diagnostic performance of the ECL-LAM F/A and S/A compared to AlereLAM performance as compared to clinical diagnosis and clinical case definition reference standards.

Conclusions: In a predominantly HIV-negative cohort of children, the diagnostic performance of ECL-LAM fell below WHO target thresholds even for a non-sputum, point-of-care test (65% sensitivity and 98% specificity). While urine may be an attractive specimen for pediatric TB diagnosis, current antibodies used for uLAM may have limited value in HIV-negative children.

SHORT ORAL ABSTRACT SESSION (SOA)

SOA14 A taste for something new: Innovative sampling for mycobacterial testing

SOA14-655-21 Evaluation of a novel tongue swab specimen for molecular TB testing on the point-of-care LumiraDx platform

R. Dalmat,[1] E. Budiawan,[1] M. Ngwane,[2] S. Bosman,[3] A. van Heerden,[4] Z. Magcaba,[5] N. Ngcobo,[5] S. Aucock,[5] A. Deisher,[1] E. Rechkina,[1] D. Wilson,[6] P. Drain,[1]
[1]University of Washington, Global Health, Seattle, United States of America, [2]Umkhuseli Innovation and Research Management, Molecular Laboratory, Pietermaritzburg, South Africa, [3]Human Sciences Research Council, Centre for Community Based Research, Pietermaritzburg, South Africa, [4]University of the Witwatersrand, Wits Health Consortium, Pietermaritzburg, South Africa, [5]Umkhuseli Innovation and Research Management, Clinical Research, Pietermaritzburg, South Africa, [6]Harry Gwala Regional Hospital, Department of Internal Medicine, Pietermaritzburg, South Africa
e-mail: ronita@uw.edu

Background: Tongue swabs tested for TB on a portable rapid point-of-care (POC) molecular platform offer faster, more accessible diagnostic testing. The LumiraDx platform includes a swab preparation device and Mycobacterium tuberculosis complex test strip that provides results in <30 minutes.
We assessed whether LumiraDx MTB STAR MDx assay meets the WHO target product profile (TPP) accuracy thresholds for a non-sputum POC diagnostic (≥65% sensitivity and ≥98% specificity).
Design/Methods: Between August 2024-March 2025, we enrolled adults presenting to clinics in Pietermaritzburg, South Africa with signs or symptoms of TB disease. Tongue swabs obtained from each participant were processed, without freezing, on a LumiraDx lysis device and tested using the LumiraDx MTB and Xpert Ultra assays. Concordance between the assays (Cohen's Kappa) and diagnostic accuracy of each against sputum Ultra and MTB culture were assessed.
Results: Among 274 participants enrolled to date (65% living with HIV; 51% female; median age 38y), 15% were sputum Ultra positive (semiquantitative: 51% high/medium; 39% low/very low; 10% Trace). Compared to sputum Ultra, LumiraDx sensitivity was 61.1% [95% CI: 43.5-76.9%] and specificity 99.0% [95% CI 96.3-99.9%], with 8.8% invalid [*Table*].
Results against a microbiologic reference standard were similar. Compared to sputum culture, LumiraDx sensitivity was 64.7% [95% CI: 46.5-80.3%] and specificity 100% [95%CI: 96.8-100%], with 2.7% invalid. Differences in performance among people living with and without HIV were not significant, but performance trended by sputum Ultra semiquantitative result: >90% for 'High' to '0%' for 'Very low'. Concordance between tongue swab testing on Ultra vs. LumiraDx was almost perfect [Kappa=0.85 (95% CI: 0.74-0.97)].

Reference	Swab test	N*	Valid	n/N*	Sensitivity	n/N*	Specificity
Culture – Sputum	LumiraDx – Microbrush swab	150	146/150 (97.3%)	22/34	0.647 (0.465, 0.803)	112/112	1 (0.968, 1)
Culture – Sputum	Xpert Ultra – Copan swab	163	150/163 (92.0%)	25/35	0.714 (0.537, 0.854)	115/115	1 (0.968, 1)
Xpert Ultra – Sputum	LumiraDx – Microbrush swab	251	229/251 (91.2%)	22/36	0.611 (0.435, 0.769)	191/193	0.990 (0.963, 0.999)
	Xpert Ultra semiquantitative value		High	10/11	0.909		
			Medium	4/6	0.667		
			Low	7/11	0.636		
			Very low	0/4	0		
			Trace	1/4	0.250		
Xpert Ultra – Sputum	Xpert Ultra – Copan swab	266	248/266 (93.2%)	26/39	0.667 (0.49, 0.814)	209/209	1 (0.983, 1)
	Xpert Ultra semiquantitative value		High	11/12	0.917		
			Medium	8/9	0.889		
			Low	6/10	0.600		
			Very low	0/4	0		
			Trace	1/4	0.250		

Differences in denominators across categories of each assay are due to slight variations in population due to later start date for LumiraDx vs. Xpert Ultra tongue swab collection; delay in return of culture results, and invalid tongue swab assay results.

Conclusions: This first clinical evaluation suggests tongue swab testing on the LumiraDx platform may meet TPP thresholds for a non-sputum molecular POC test. Larger clinical validation and implementation studies are warranted to improve precision of accuracy estimates and assess impact on patient outcomes.

SOA14-656-21 Positive progress: Development of *M. tuberculosis* proficiency products for tongue swab testing protocols

M. Craven,[1] C. Connors,[1] C. Jedeszko,[2] D. Emsweller,[1] G. Styba,[2] L. Turnbull,[1] [1]Quantigen, Global Public Health Research, Fishers, United States of America, [2]Fortis Life Sciences, IPOC, Boston, United States of America
e-mail: lindsey.turnbull@quantigen.com

Background: Proficiency products are critical for ensuring diagnostic accuracy of *Mycobacterium tuberculosis* (MTB) detection. Universal standardizations of diagnostic evaluations will benefit from device-agnostic, thermostable, and non-infectious proficiency products. Performance verification at clinical sites will also require standardization of protocols for clinical samples and controls. A thermostable tongue swab control that provides effective performance on multiple devices and workflows would set a new standard in TB diagnostics for how devices are evaluated in the field and by the manufacturer.
Design/Methods: Cultured H37Ra MTB strain was quantified, heat-inactivated, and spiked onto dry swabs containing 30ng/swab of RNaseP and lyophilized for stability. These swabs were packaged and stored at ambient temperature for two months.
Five lyophilized control swabs were tested across devices at clinically relevant colony-forming units (CFU) per swab as follows: 500, 250, 100, 50, and 25, on four tongue

swab compatible diagnostic platforms: qPCR (25µL reactions), Xpert Ultra (Ultra), Molbio TrueNAT (Molbio), and Co-Diagnostics PCR Pro (Co-Dx).

Results: qPCR and Co-Dx detected 100% of control swabs at all tested concentrations. Ultra and Molbio detected 100% of swabs with a concentration of 50CFU/swab and higher, and 80% at 25CFU/swab. For both Ultra and Molbio, there was one invalid result at 25CFU/swab, rather than negative.

Conclusions: Lyophilized swab controls containing MTB demonstrate stable detection across a range of low concentrations on four devices following storage for two months at ambient temperatures.

Continued development of device-agnostic, shelf-stable proficiency products will enable central laboratories and point-of-care settings to share a standardized toolbox for more equivalent evaluations.

SOA14-657-21 Non-Invasive diagnosis of pulmonary TB using face mask sampling: A prospective study in adults from Moldova

D. Woelk,[1,2] L. Meiwes,[1,2,3] V. Crudu,[4] N. Ciobanu,[4] A.-M. Comanac,[5] S. Kulcitkaia,[5] A. Vasiliu,[6] A.M. Mandalakas,[1,2,6] C. Lange,[1,2,3] T.T. Brehm,[1,2,7] D. Chesov,[1,2,5] [1]Research Center Borstel, Leibniz Lung Center, Clinical Infectious Diseases, Borstel, Germany, [2]German Center for Infection Research (DZIF), Clinical Tuberculosis Unit, Hamburg-Lübeck-Borstel-Riems, Germany, [3]University of Lübeck, Respiratory Medicine and International Health, Lübeck, Germany, [4]Chiril Draganiuc Institute of Pneumology, Department of Pneumology, Chisinau, Republic of Moldova, [5]Nicolae Testemitanu State University of Medicine and Pharmacy, Discipline of Pneumology and Allergology, Chisinau, Republic of Moldova, [6]Baylor College of Medicine, Global TB Program, Department of Pediatrics, Houston, United States of America, [7]University Medical Center Hamburg-Eppendorf, Division of Infectious Diseases, I. Department of Medicine, Hamburg, Germany
e-mail: dariusz.woelk@gmail.com

Background: Sputum-based diagnostic methods for pulmonary tuberculosis (PTB), including culture and Xpert MTB/RIF Ultra, offer high sensitivity and specificity. However, they depend on the patients' ability to expectorate sputum and may require invasive procedures such as bronchoscopy when sputum is unavailable. Therefore, we evaluated the diagnostic accuracy of face mask sampling (FMS) as a non-invasive alternative.

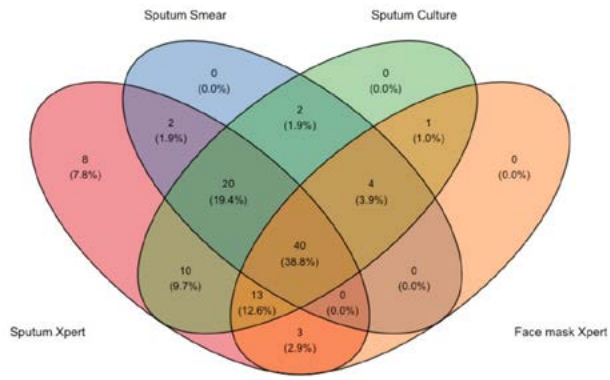
Design/Methods: In this prospective study, adult patients with suspected or recently confirmed PTB who had received less than 3 days of anti-TB treatment were recruited in Chisinau, Moldova.

Every participant received three face masks fitted with polyvinyl alcohol strips and wore each mask for 30 minutes. Samples were then analysed on site using Xpert MTB/RIF Ultra. Results were compared with those obtained from sputum microscopy, Xpert MTB/RIF Ultra, and culture.

Results: From April 2024 to February 2025, a total of 117 patients were enrolled in the study. Of these, 103 (88%) were diagnosed with PTB by sputum culture and/or Xpert MTB/RIF Ultra, with 90 testing positive by sputum culture. The sensitivity of FMS, using sputum culture as the gold standard, was 64% (95% CI: 54–74%).

Notably, among the 90 patients with a positive sputum culture, 5 cases (6%) were detected by FMS but not by Xpert MTB/RIF Ultra. Of these five FMS-positive, Xpert-negative cases, three (60%) were trace positive and two (40%) were low positive by FMS.

Among 35 (34%) patients with rifampicin resistance (RR) detected in sputum Xpert MTB/RIF Ultra, 13 (37%) also had RR detected in at least one of their face mask samples.



Conclusions: Although FMS demonstrated limited sensitivity for diagnosing PTB, it detected *M. tuberculosis* DNA in 6% of culture-positive patients who tested negative by sputum Xpert MTB/RIF Ultra.

This finding suggests that, in resource-equipped settings, FMS may serve as a valuable complementary tool for the rapid diagnosis of PTB.

SOA14-658-21 Diagnostic yield of tongue swab- compared to sputum-based molecular testing in four high-burden countries

S. Muzazu,[1] A.J. Barrameda,[2] R. Crowder,[3] H. Le,[4] R. Kabuleta Luswata,[5] C. Moe,[3,6] A. Andama,[7] C. Denkinger,[8,9] H. Phan,[4,10] C. Yu,[2] A. Cattamanchi,[11,6] TSwaY Study Group [1]Centre for Infectious Disease Research in Zambia, Tuberculosis, Lusaka, Zambia, [2]De la Salle Medical and Health Sciences Institute, Research Services, Dasmariñas, Philippines, [3]University of California San Francisco, Center for Tuberculosis, San Francisco, United States of America, [4]Center for Promotion of Advancement of Society, Center for Promotion of Advancement of Society, Hanoi, Viet Nam, [5]World Alliance for Lung and Intensive Care Medicine in Uganda, World Alliance for Lung and Intensive Care Medicine in Uganda, Kampala, Uganda, [6]University of California Irvine, Division of Pulmonary Diseases and Critical Care Medicine, Irvine, United States of America, [7]Makerere University College of Health Sciences, Department of Medicine, Kampala, Uganda, [8]Heidelberg University Hospital, Department of Infectious Disease and Tropical Medicine, Heidelberg, Germany, [9]German Centre for infection Research (DZIF), partner site Heidelberg University Hospital, Heidelberg, Germany, [10]UCSF - VNTP Research Collaboration Unit, UCSF - VNTP Research Collaboration Unit, Hanoi, Viet Nam, [11]University of California San Francisco, San Francisco, Center for Tuberculosis, San Francisco, United States of America
e-mail: Seke.Muzazu@cidrz.org

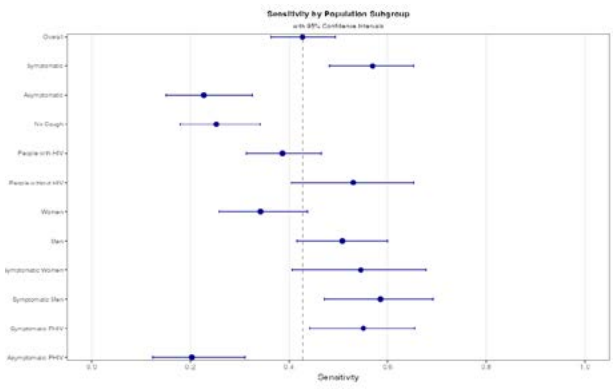
Background: Tongue swab-based molecular testing is emerging as a promising non-sputum option for tuberculosis (TB) diagnosis. Studies to date confirm high specificity (>98%) but lower sensitivity than for sputum-based molecular tests. We investigated whether lower sensitivity could be offset by increased sample availability, resulting in similar diagnostic yield.
Design/Methods: Between Sept 2024-Jan 2025, we screened and enrolled consecutive people with presumptive TB at clinics in the Philippines, Vietnam, Uganda, and Zambia. We offered tongue swab collection followed by routine sputum collection and TB testing (per national guidelines in each country, but primarily sputum tested with Xpert MTB/RIF Ultra [Xpert; Cepheid, USA]). Tongue swabs were tested using the novel MiniDock MTB Test (Guangzhou Pluslife Biotech, China). We compared difference in yield, defined as a positive test result, between tongue swab and sputum molecular testing using McNemar's test of paired proportions with a pre-specified margin of non-inferiority of +/- 3%.
Results: Of 1639 participants enrolled, 851 (51.9%) were female, 415 (25.3%) were living with HIV and 132 (8.1%) were children <5 years old. Overall, 1418 (86.5%) provided sputum and 38 (2.3%) provided stool for Xpert testing, while 1639 (100%) provided tongue swabs for MiniDock MTB testing. Yield was similar for tongue swabs (64/1639, 3.9%) and sputum (66/1639, 4.0%), and within the pre-specified margin of non-inferiority (difference -0.1%, 95% CI -1.0 to +0.8). Results were similar across countries. The yield of combined tongue swab and sputum testing was higher (88/1639; 5.4%) than either specimen alone.
Conclusions: TB diagnostic yield was non-inferior with tongue swab- vs. sputum-based molecular testing. Tongue swab-based molecular platforms may have an added value to enhance existing molecular diagnostic strategies, and may be considered for rapid TB testing in settings where sputum-based molecular platforms are not feasible due to cost, challenges with sputum collection, and/or infrastructure requirements.

SOA14-659-21 Test performance of tongue swabs subjected to Xpert MTB/RIF Ultra, collected from high-risk South African adult primary healthcare clinic attendees (TUTTPlus Study)

R. Berhanu,[1] A. David,[2] L. Genade,[3] A. Hesseling,[4] S. Nzama,[5] N. Mncube,[3] T. Seiphetlo,[3] N. Pillay,[3] M. Mohlamonyane,[3] N. Martinson,[3] L. Scott,[2] L. Lebina,[5] TUTT-Plus Study Gropu [1]Vanderbilt University Medical Center, Department of Medicine, Division of Infectious Diseases, Nashville, TN USA, South Africa, [2]University of the Witwatersrand, Wits Diagnostics Innovation Hub, Health Sciences Research Office, Faculty of Health Sciences, Johannesburg, South Africa, [3]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa, [4]Stellenbosch University, Department of Pediatrics and Child Health, Desmond Tutu TB Centre, Stellenbosch, South Africa, [5]Africa Health Research Institute, Tuberculosis, Durban, South Africa
e-mail: rebecca.h.berhanu@vumc.org

Background: Tongue swabs' ease of collection and lower nosocomial transmission risk make them an attractive tool, especially for testing sputum-scarce individuals. We report test characteristics of tongue swabs (Xpert Ultra) compared to routinely collected sputum analyzed on a molecular platform (Xpert-Ultra, MAX MDR-TB, or Cobas MTB). We recruited adults attending clinics with risk factors for TB (HIV, prior TB, close TB contact) and tested those with and without symptoms of TB.
Design/Methods: Adults with ≥1 risk factor for TB (people living with HIV, prior TB, household contact) with and without TB symptoms were tested at 10 clinics in three South African provinces with tongue swabs and sputum. We report sensitivity, specificity, positive (PPV) and negative predictive value (NPV) of tongue swabs subjected to Xpert MTB/RIF Ultra (Ultra) relative to single sputum subjected to molecular testing (Xpert-Ultra, MAX MDR-TB, or Cobas MTB).
Results: In 6568 participants with both tongue swabs and sputum results, 20% reported symptoms of TB, 70% were women, and 77% were PLWH. A single tongue swab

identified 100/238 participants with sputum-positive TB; overall sensitivity, specificity, PPV, and NPV was 43% (95% CI: 36%-49%), 99% (95% CI: 99%-100%), 82% (95% CI: 75%-88%), and 98% (95% CI: 97%-98%), respectively. Sensitivity in those with TB symptoms vs asymptomatic was 57% vs 23% (p<0.001), in men vs women was 51% vs 34% (p=0.015), and in PLWH vs without HIV was 39% vs 53% (p=0.5) (Figure).



Conclusions: Tongue swab testing demonstrated sub-optimal sensitivity and excellent specificity relative to sputum molecular testing for TB in this largely asymptomatic population of primary healthcare clinic attendees. Sensitivity was highest in men, particularly symptomatic men without HIV. Globally, men face a higher risk for TB yet lower diagnosis rates. Using a targeted testing strategy with tongue swab testing could facilitate TB detection in men, particularly in community settings outside health facilities.

SOA14-660-21 Testing tongue swab samples by Cepheid Xpert MTB/RIF Ultra: Comparison of two protocols applied to samples from people with low-bacillary load TB

R.C. Wood,[1] S. Goodgion,[1] A.M. Olson,[1] A.K. Luabeya,[2] M. Hatherill,[2] G.A. Cangelosi,[1]
[1]University of Washington, Department of Environmental & Occupational Health Sciences, Seattle, United States of America, [2]University of Cape Town, South African Tuberculosis Vaccine Initiative, Cape Town, South Africa
e-mail: woodr8@uw.edu

Background: Tongue swabs (TS) are an important non-sputum diagnostic specimen for TB that studies have shown to be preferred by patients and providers. While swab-specific manual extractions and qPCR protocols have yielded higher sensitivities than testing swabs by Xpert Ultra, Xpert remains desirable due to its widespread use and familiarity among providers and technicians. This project evaluated an easy-to-use protocol for analyzing TS by Xpert Ultra by using already-available reagents and no additional equipment.

Design/Methods: TS samples from symptomatic South African patients (N=313) were previously collected and tested by Xpert Ultra by a published protocol that involves heating to 100°C and addition of TE buffer. Replicate, paired samples from a subset of the same patients were tested by a new method that uses Xpert Sample Reagent (SR) diluted with PBS.
The two methods were compared to each other, and testing a single sample was compared to testing serial samples. Samples from patients with low bacillary loads were prioritized.
Results: There were 108 low-bacillary load participants for whom two TS samples were tested, one by the heating and TE method and one by the diluted SR method; 88 were TB-positive by sputum MRS and 20 were TB-negative. The heating and TE method was 42.5% (38/88; 95CI 33-54%) sensitive, while the diluted SR method was 52.3% (46/88; 95CI 41-63%) sensitive relative to sputum MRS. Both methods were 100% (20/20; 95% CI 83-100%) specific. A single sample tested by the heating and TE method was 75.5% (182/241; 95CI 70-81%) sensitive overall. Serial samples, where a TS-positive by either method was deemed positive, was 81.3% (196/241; 95CI 76-86%) sensitive relative to sputum MRS.
Conclusions: This study supports the diluted SR method for testing TS by Xpert Ultra. It is logistically advantageous and has no disadvantages in diagnostic accuracy. When feasible, serial sampling may help boost diagnostic accuracy.

SOA14-661-21 Multicentre evaluation of tongue swabs using a new molecular point-of-care assay for TB diagnosis in China

J. Cui,[1] C. Guo,[1] Y. Gao,[1] Z. Li,[1] [1]The First Affiliated Hospital of Xinxiang Medical University, Department of Tuberculosis, Xinxiang, China
e-mail: 49993803@qq.com

Background: Global tuberculosis (TB) elimination efforts remain hindered by diagnostic delays. Rapid molecular point-of-care testing (POCT) offers critical advantages over conventional methods. Previous studies have shown that tongue swabs can emerge as a viable non-invasive alternative.
Therefore, combining POCT with tongue swabs may be of great value in optimizing diagnostic pathways and improving the detection rate of tuberculosis.
This multicenter study evaluates a novel molecular POCT using tongue swabs and sputum specimens in China.
Design/Methods: A total of 547 patients presenting with tuberculosis-related symptoms were recruited from four clinical sites in China. Tongue swab specimens were collected and tested using Genewise-MTBC, a rapid and fully automated POCT diagnostic system paired with microfluidic-based assay kits (Figure B).

Sputum specimens underwent smear microscopy, liquid culture, and molecular testing (Genewise-MTBC and Xpert MTB/RIF). Diagnostic performance of the tongue swab was compared with sputum microbiological reference standard (MRS) (Figure A).

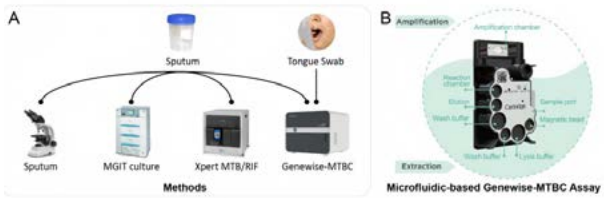
Results: Among the enrolled patients, elderly people (≥ 65 years old) accounted for 36.4%, and males accounted for 72.6%. According to the clinical diagnosis, 283 of 547 patients were diagnosed as confirmed pulmonary TB (PTB) cases.

Compared with conventional methods, sputum-based Genewise-MTBC showed superior sensitivity (94.35% vs. Xpert MTB/RIF: 88.69%, culture: 57.24%, smear: 42.05%) (Figure C).

For tongue swab specimens, the Genewise-MTBC demonstrated enhanced performance, achieving 80.85% sensitivity while retaining 100% specificity compared to MRS (Figure D).

Compared to sputum Xpert MTB/RIF, the Genewise-MTBC for tongue swabs also showed high agreement (86.85%), with sensitivity and specificity of 86.85% and 96.62%.

In addition, among the 73 smear-negative and culture-positive TB patients, the positive rate of tongue swab reached 75.3%.



C Detection results of different methods based on sputum samples

Sputum		MRS-positive		Sensitivity (95%CI)	Specificity (95%CI)	Concordance (95%CI)
		TB	Other diseases			
Smear	Positive (+)	119	3	42.05% 36.44%-47.87%	98.86% (96.71-99.61)	69.47% 65.49%-73.18%
	Negative (-)	164	261			
MGIT 960 culture	Positive (+)	162	0	57.24% 51.42%-62.87%	100.00% (98.57-100.00)	77.88% 74.21%-81.16%
	Negative (-)	121	264			
Genewise-MTBC	Positive (+)	267	0	94.35% 91.01%-96.49%	100.00% (98.57%-100.00%)	97.07% (95.30%-98.19%)
	Negative (-)	16	264			
Xpert MTB/RIF	Positive (+)	251	0	88.69% (84.47%-91.88%)	100% (98.57%-100.00%)	94.15% (91.86%-95.83%)
	Negative (-)	32	264			

D Diagnostic accuracy of tongue swabs compared with sputum MRS

Tongue Swab	Sputum MRS		Total	Sensitivity (95%CI)	Specificity (95%CI)	Concordance (95%CI)	Kappa	*P* value
	Positive (+)	Negative (-)						
Positive (+)	228	0	228					
Negative (-)	54	265	319	80.85% (75.86%-85.02%)	100% (98.57%-100%)	90.13% (87.34%-92.35%)	0.804	<0.001
Total	282	265	547					

Conclusions: Using tongue swabs and sputum specimens on Genewise-MTBC can exhibit non-inferior performance to Xpert MTB/RIF and enable decentralized implementation.

SOA14-662-21 Feasibility and diagnostic performance of tongue swab-based qPCR testing for TB in programmatic settings in Vietnam

V. Vatsyayan,[1] D.V. Luong,[2] D.N.B. Hoa,[2] D.D. Thu Ha,[3] N. Thi Kim Thanh,[3] M. Trinh,[4] M. Duong,[4] G. Nguyen,[4] D. Ngo,[5] M. Campbell,[6] S. Khan,[6] [1]Clinton Health Access Initiative, Infectious Disease - Global TB, Hanoi, Viet Nam, [2]National Lung Hospital, Vietnam National Tuberculosis Program, Hanoi, Viet Nam, [3]National Lung Hospital, Department of Microbiology and National Reference Laboratory, Hanoi, Viet Nam, [4]Clinton Health Access Initiative, Country Programs- Vietnam, Hanoi, Viet Nam, [5]Clinton Health Access Initiative, CHAI Leadership, Hanoi, Viet Nam, [6]Clinton Health Access Initiative, Infectious Disease - Global TB, Boston, United States of America
e-mail: nguyenbinhhoatb@yahoo.com

Background: Despite Vietnam's progress in tuberculosis case detection through its 2X strategy—chest X-ray plus Xpert Mycobacterium tuberculosis/Rifampicin—diagnostic gaps remain, especially among asymptomatic individuals and those unable to produce sputum. The high cost of scaling this strategy (~$32 million, 4.4 times the national budget) highlights the need for low-cost, non-invasive diagnostics.

This study evaluates the feasibility and diagnostic performance of tongue swab-based quantitative polymerase chain reaction testing, using individual and pooled approaches, as a complementary screening tool for TB in Vietnam.

Design/Methods: We conducted a cross-sectional study at the National Lung Hospital, Hanoi, enrolling 1,025 participants aged ≥5 years with presumptive TB.

Individuals on TB treatment or unable to provide sputum were excluded. Sputum samples were tested using Xpert MTB/RIF Ultra; tongue swabs were collected using sterile nylon-flocked swabs, processed via direct lysis, and analyzed via qPCR targeting MTB-specific genes.

We assessed sensitivity, specificity, reproducibility, and feasibility of single swab and 4-sample pooling. Assay costs were compared with Xpert.

Results: Tongue swab qPCR achieved 51% sensitivity, and 96% specificity compared to sputum Xpert, with 85.5% overall concordance.

Sensitivity was highest among high bacterial load cases (91%). Reproducibility was moderate, with 58% of positives consistent across replicates, largely due to manual processing variability.

Pooled swab testing (size 4) performed comparably to individual testing. At $5 per assay (≈$1.25 with pooling), the approach offers a significantly lower-cost alternative to Xpert ($23.46/ test).

Sensitivity	**51% (42.95%- 59.05%)**	**95% Confidence Interval**			
Specificity	**96% (94.67%- 97.33%)**	**95% Confidence Interval**			
MTB Level (Xpert MTB/RIF Ultra)	Number of samples	Percentage agreement with tongue swab tested using qPCR	95% CI	Average Ct	Average standard deviation (SD)
High	35	91%	(81.5% – 100.5%)	30.75	0.37
Medium	21	62%	(41.2% – 82.8%)	32.13	0.4
Low	60	40%	(27.6% – 52.4%)	35.04	0.67
Very Low	16	6%	(-5.6% – 17.6%)	38.03	0.76
Trace	16	31%	(8.3% – 53.7%)	37.42	1.07
Negative	798	92%	(90.1% – 93.9%)		
Overall Concordance	946	86%	(83.3% – 87.8%)		

Conclusions: Tongue swab qPCR is a feasible, low-cost TB diagnostic tool with high specificity. While improved processing is needed to boost sensitivity and consistency, early evidence supports its use—especially pooled testing for community-based screening and active case finding. As one of the first programmatic evaluations of swab on an open-PCR platform, this study highlights the potential of swab-based diagnostics to complement existing strategies and expand equitable access to TB testing.

SOA14-663-21 An ultra-high throughput tongue swab molecular testing platform (NEXAR) for mass TB screening

L. Noble,[1] D. Gast,[1] A. David,[1] R. Latiff,[2] D. Emsweller,[3] C. Connors,[3] L. Turnbull,[4] W. Stevens,[1,5] N. Martinson,[2] L. Scott,[1] [1]University of the Witwatersrand, WITS Diagnostic Innovation Hub, Health Sciences Research Office, Faculty of Health Sciences, Johannesburg, South Africa, [2]University of the Witwatersrand, Perinatal HIV Research Unit, Faculty of Health Sciences, Johannesburg, South Africa, [3]Quantigen LLC, Research and Development, Fishers, United States of America, [4]Quantigen LLC, Global Public Health Research, Fishers, United States of America, [5]National Health Laboratory Services, National Priority Programmes, Johannesburg, South Africa
e-mail: lesley.scott@wits.ac.za

Background: Breaking the *Mycobacterium tuberculosis* complex (MTBC) transmission cycle is critical, and one approach is identifying asymptomatic individuals in the community. Mass non-invasive tongue-swab (TS) collection matched with high-throughput molecular testing may provide a solution for community-based screening.
We describe a novel molecular MTBC assay developed for the ultrahigh-throughput, open-PCR NEXAR (LGC) platform.
Design/Methods: The TS lyse-to-PCR uses vortex bead-beating of TS in 400µl buffer, followed by 5µl-reaction assembly in proprietary NEXAR ArrayTape™, water-bath-based (altitude-limited to 92°C) PCR-cycling to amplify insertion sequences 6110 and 1081 and RNase P (endogenous internal control), and standardised endpoint fluorescence threshold gating. Dry TS from 992 individuals, primarily MTBC negative or with low bacillary loads by TS Xpert MTB/RIF Ultra (Ultra, Cepheid) to simulate an asymptomatic cohort, were retrieved from -80°C storage for NEXAR testing. NEXAR results were compared to TS collected dry with same-day Ultra processing (66%-diluted SR method).
Results: Reproducibility testing of control swabs (Quantigen) showed robust detection to 25CFU/swab. By Ultra TS, 877 specimens were MTBC-negative and 115 MTBC-positive, with >87% of the latter reporting Ultra semi-quantitation of low, very low or trace. HIV status was available for 379 participants (47.0% positivity). NEXAR generated 71.3% (95%CI: 61.8-79.2) positive percentage agreement (PPA) and 98.5% (95%CI: 97.4-99.2) negative percentage agreement (NPA) against Ultra TS. Stratified by HIV status, PPA increased to 81.3% (95%CI: 54.4-96.0) in HIV-negative individuals and decreased to 52.9% (95%CI: 27.8-77.0) amongst HIV-positive individuals; NPA remained >95%. Table 1 highlights increased PPA in high mycobacterial load specimens and NEXAR detection including semi-quantitative trace.

Table 1: NEXAR positivity stratified by TS Ultra semi-quantitative result

All valid results (error rate: 1.3%)			With HIV result	
Ultra TS semi-quantification	Number	NEXAR Positive n (%)	HIV positive n_{NEXAR}/n_{Ultra} (%)	HIV negative n_{NEXAR}/n_{Ultra} (%)
MTB detected high	3	3 (100%)	-	-
MTB detected medium	11	9 (81.8%)	0/1 (0.0%)	-
MTB detected low	58	50 (86.2%)	4/5 (80.0%)	8/8 (100.0%)
MTB detected very low	31	18 (58.1%)	5/9 (55.6%)	3/4 (75.0%)
MTB detected trace	12	2 (16.7%)	0/3 (0.0%)	2/4 (50.0%)
MTB not detected	877	21 (2.4%)	150/160 (93.8%)	175/185 (95.0%)

Conclusions: NEXAR testing is highly centralized and currently limited by manual front-end TS processing, but automated testing targeting 5000 tests/day is feasible. NEXAR PCR does not reach diagnostic performance of Ultra TS, but optimization (e.g. front-end sonication, alternative PCR reagents, lower altitude) may align this technology for high-throughput community screening.

SOA14-664-21 qPCR batch-processed tongue swabs as screening tool for large-scale community-based case-finding of TB

S.L. Olifant,[1] A. Medina-Marino,[2] K. Fiphaza,[2] N. Sibanda,[2] R.P.H. Peters,[1] PB. Fourie,[1] TB-HOME Study Advisors: Maria Pieruccini (Brown Univ., USA), Adam Penn-Nicolson (FIND), Morten Ruhwald (FIND) [1]University of Pretoria, Department of Medical Microbiology and Centre for Tuberculosis Research, Pretoria, South Africa, [2]University of Cape Town, Desmond Tutu Health Foundation, East London, South Africa

Background: Tuberculosis (TB) case-finding and treatment-initiation with strong public-health impact can only be achieved at scale if efficient triaging for presumptive TB in large populations is feasible, fast-paced, and afford-

able. Currently, high-throughput molecular systems allow for as many as 320 tests/8 hours (e.g., Xpert Infinity-80, Cepheid), but are generally employed for processing sputum samples in high-capacity laboratories at significant cost. This study evaluated test outcomes from tongue swab samples collected from persons with known exposure to TB, transported and stored at ambient temperature, and centrally batch-processed by manual quantitative PCR (qPCR).

Design/Methods: Tongue swabs, transferred into individual 5 ml leak-free tubes containing 1.5 ml PrimeStore® Molecular Transport Medium (PS-MTM), were collected from household members exposed to persons with confirmed pulmonary TB (Xpert Ultra/culture) in Buffalo City (East London), South Africa, and airfreighted non-refrigerated in batches to Pretoria (1200 km away) once per week. Swab samples for qPCR were prepared without an extraction pre-step and analysed in triplicates using multiplex PrimeMix® MTB targeting the multi-copy IS6110 and IS1081 genes of *Mycobacterium tuberculosis* (*Mtb*). Paired sputum specimens were processed in-home by Xpert Ultra (single cartridge Omni/Edge).

Results: 98% (900/914) of eligible subjects accepted swab collection; only 32% (292/914) could provide a matching sputum sample. Invalid assay results from swab or sputum (7,9% and 8,6%, respectively) were excluded from analysis. *Mtb* was detected in 10.9% of sputums and 4.9% of tongue swabs, overall (n=269). Swab sensitivity vs. sputum (trace=negative) was 56,5% and specificity 96,7%. Importantly, an 83% concordance of swab-positive with sputum-based Xpert Ultra Medium/High results was shown (Table 1). Amongst 622 individuals without sputum samples, 3,4% were swab positive.

Tongue swab: qPCR	Sputum: GeneXpert Ultra category						Total
	High	Medium	Low	Very low	Trace	Negative	
Positive	8	2	3	0	2	6	21
Negative	1	1	6	2	6	232	246
Total	9	3	9	2	8	238	267

• Sensitivity* 56,5% (13/23); Specificity* 96,7% (238/246) [* Ultra „Trace" counted as negative]

• McNemar test on paired proportions: P = 0.8145; Difference: 0.74%; 95CI: -2.35% to 3.83%

• Concordance swab qPCR positive to sputum Ultra High/Medium positive: 83,3% (10/12)

Table 1. Results from paired sputum and tongue swab samples in PrimeStoreÒ, respectively processed by GeneXpert Ultra MTB/RIF and qPCR (PrimeMixMTB®), in household contacts of patients with confirmed pulmonary tuberculosis.

Conclusions: Tongue swabs collected in PS-MTM, shipped non-refrigerated and batch-processed centrally by affordable qPCR protocols allow for large-scale community-based case-finding that reduces time and cost associated with processing sputum and non-sputum samples individually.

SOA14-665-21 Diagnostic accuracy and feasibility of the AveloMask for non-invasive detection of pulmonary TB via breath aerosol sampling

P. Risch,[1] T. Broger,[1] Z. Booi,[2] K. Tiseo,[1] H. Santhosh Kumar,[1,3] P. Sander,[3,4] A. Cattamanchi,[5,6] C. Denkinger,[7,8] G. Theron,[2] C. Fialová,[9] C. Adlhart,[9] R. Venter,[2] [1]Avelo Inc, Rütistrasse 16, Schlieren, Switzerland, [2]Stellenbosch University, DSI-NRF Centre of Excellence for Biomedical Tuberculosis Research, South African Medical Research Council Centre for Tuberculosis Research, Division of Molecular Biology and Human Genetics, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [3]University of Zurich, Institute of Medical Microbiology, Zurich, Switzerland, [4]National Reference Laboratory for Mycobacteria, National Reference Laboratory for Mycobacteria, Zurich, Switzerland, [5]University of California San Francisco, Center for Tuberculosis, San Francisco, United States of America, [6]University of California Irvine, Department of Medicine, Division of Pulmonary Diseases and Critical Care Medicine, Irvineuni, United States of America, [7]Heidelberg University Hospital, Department of Infectious Diseases and Tropical Medicine, Heidelberg, Germany, [8]Heidelberg University Hospital, Heidelberg, German Center for Infection Research (DZIF), partner site, Heidelberggermg, Germany, [9]Zurich University of Applied Sciences, School of Life Sciences and Facility Management, Institute of Chemistry and Biotechnology, Wädenswil, Switzerland
e-mail: rouxjeane@sun.ac.za

Background: Sputum-based diagnostics often miss tuberculosis (TB) cases due to sample collection challenges. Breath aerosols, a primary route of *Mycobacterium tuberculosis* (MTB) transmission, offer a promising, non-invasive alternative. We evaluated the diagnostic performance and usability of the AveloMask—a novel, point-of-care breath aerosol collection kit—for PCR-based detection of active pulmonary TB.

Design/Methods: We conducted a retrospective diagnostic accuracy study among symptomatic participants at primary healthcare facilities in Cape Town, South Africa. Participants wore the AveloMask for 45 minutes, with instructed deep coughing at the start and end. Aerosols were captured on a fiber-filter, stabilized in buffer, biobanked, and later tested via qPCR targeting *IS6110*. Reference standards included sputum Xpert Ultra (SXRS) alone and a composite microbiological reference standard (MRS, including culture). Usability was assessed through structured questionnaires.

Results: A total of 58/61 (95%) enrolled participants provided evaluable breath samples, of which 59% (34/58) had confirmed TB. Against SXRS, sensitivity was 71.0% (95% CI: 53.4–83.9%) and specificity 92.3% (95% CI: 75.9–97.9%). Against MRS, sensitivity was 64.7% (95% CI: 47.9–78.5%) and specificity 91.7% (95% CI: 74.2–97.7%). Sensitivity increased with sputum bacterial load, reaching 100% among those with high MTB concentrations. *IS6110* copy numbers ranged from 4–2147 (mean: 175),

indicating likely incomplete DNA-extraction. Usability feedback indicated mask and collection procedures were easy and acceptable.

Conclusions: The AveloMask demonstrated promising diagnostic accuracy for active TB, especially among individuals with higher bacterial loads, and was well-tolerated. These findings support further optimization of sample processing and validation in larger, more diverse populations and settings.

SOA15 Zero deaths? Hope dims with funding cuts

SOA15-666-21 The potential impact of reductions in international donor funding on TB incidence and mortality in low- and middle-income countries

R.A. Clark,[1] C.F. Mcquaid,[1] A.S. Richards,[2] R.M.G.J. Houben,[1] R.G. White,[1] K. Horton,[1] [1]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [2]University of Glasgow, School of Health and Wellbeing, Glasgow, United Kingdom of Great Britain and Northern Ireland
e-mail: rebecca.clark@lshtm.ac.uk

Background: Tuberculosis (TB) prevention, diagnostic, and treatment services in many settings rely heavily on international donor funding. In 2025, the United States Agency for International Development (USAID) was dismantled, eliminating a major source of funding to many national TB programmes. Other countries have also announced cuts to overseas development assistance.

We quantified the potential epidemiological impacts attributable to these reductions in international donor funding.

Design/Methods: We calibrated a deterministic TB model to epidemiological indicators in low- and middle-income countries.

We projected three potential future TB scenarios assuming:

a. Levels of funding in 2024 continue,

b. Termination of USAID funding from 2025, and;

c. Additional reductions in funding through The Global Fund in line with current donor announcements from 2025.

We assumed a reduction in TB treatment initiation rates proportional to budget reductions for each scenario by country, and we estimated cumulative excess incident episodes of symptomatic TB and TB deaths.

Donor	Change in funding	Excess symptomatic tuberculosis episodes		Excess tuberculosis deaths	
		median (95% UI)	% (95% UI)	median (95% UI)	% (95% UI)
Termination of funding via USAID					
United States	-100%	1 390 900 (1 113 500, 1 675 000)	1·3% (1·0, 1·7)	420 500 (335 800, 558 000)	3·8% (3·0, 4·9)
Expected change in funding via The Global Fund					
United States	-93%	2 841 700 (2 135 800, 3652 700)	2·6% (1·9, 3·6)	699 200 (505 600, 869 200)	6·0% (4·5, 7·7)
France	-37%	260 200 (196 500, 329 100)	0·2% (0·2, 0·3)	63 100 (46 200, 77 900)	0·6% (0·4, 0·7)
Germany	-24%	125 800 (95 000, 159 100)	0·1% (0·1, 0·2)	30 500 (22 400, 37 700)	0·3% (0·2, 0·3)
United Kingdom	-40%	207 900 (157 000, 263 000)	0·2% (0·1, 0·3)	50 500 (36 900, 62 300)	0·4% (0·3, 0·6)
Japan	+17%	-79 700 (-100 700, -60 200)	-0·1% (-0·1, -0·1)	-19 400 (-23 900, -14 200)	-0·2% (-0·2, -0·1)
Canada	-26%	103 300 (78 000, 130 600)	0·1% (0·1, 0·1)	25 100 (18 400, 30 900)	0·2% (0·2, 0·3)
European Commission	-35%	109 200 (82 500, 138 100)	0·1% (0·1, 0·1)	26 500 (19 400, 32 700)	0·2% (0·2, 0·3)
Sweden	-10%	12 000 (9 000, 15 100)	0·0% (0·0, 0·0)	2 900 (2 100, 3 600)	0·0% (0·0, 0·0)
Norway	-12%	10 100 (7 600, 12 800)	0·0% (0·0, 0·0)	2 500 (1 800, 3 000)	0·0% (0·0, 0·0)
Italy	+15%	-12 000 (-15 200, -9 100)	0·0% (0·0, 0·0)	-2 900 (-3 6, -2 1)	0·0% (0·0, 0·0)
Netherlands	-29%	22 700 (17 100, 28 600)	0·0% (0·0, 0·0)	5 500 (4 000, 6 800)	0·0% (0·0, 0·1)
Australia	-3%	2 300 (1 800, 2 900)	0·0% (0·0, 0·0)	600 (400, 700)	0·0% (0·0, 0·0)

Results: We modelled 79 countries, representing 91% of global TB incidence and 90% of global TB mortality in 2023. Our modelling suggested that the termination of USAID funding may lead to 420 500 excess TB deaths by 2035. Further reductions in funding through The Global Fund in line with current announcements by the United States, France, the United Kingdom, and Germany may lead to an additional 699 200, 63 100, 50 500, and 30 500 TB deaths, respectively. Excess deaths are projected to be greatest in the African region and in low-income countries.
Conclusions: We estimate substantial impacts on TB morbidity and mortality due to reductions in international donor funding. Expanded support from domestic and international donors is essential to address immediate gaps in prevention, diagnosis, and treatment.

SOA15-667-21 Why are people with TB dying?

N.N. Jason,[1] N. Ruswa,[1] K. Kalukambe,[1]
[1]Ministry of Health and Social Services, Directorate of Special Programme, Windhoek, Namibia
e-mail: NDAPEWAJASON15@gmail.com

Background and challenges to implementation: Namibia has a high TB burden, ranked under top 10 globally. Despite standard TB patient management, the country continues to report high TB deaths, with a current 7.2% TB fatality rate among treated patients, exceeding the national target. To address this, an Quality Improvement initiative was introduced to investigate factors, situations, or conditions that may have contributed to each TB death. Early findings on the causes of TB mortality in Namibia are reported here.
Intervention or response: A multidisciplinary team conducted TB mortality audits at the district level for every TB death from 2022 to 2023. These included facility-based mortality assessments and community-based death reviews, with teams discussing causes and proposing remedial interventions. Data were recorded electronically.
Results/Impact: Of the 496 of the TB deaths audited, 309 (62%) were males. Mean age was 48 years (range <1 year to 103 years).
The majority of 450 (91%) patients had drug-susceptible TB and 379 (76%) were new cases. A significant number (192; 39%) were clinically diagnosed, of which 99 were pulmonary. There was an equal number of HIV infected and uninfected at 238 (48%) and 20 (4%) with an unknown HIV status.
Of those with HIV, majority (166; 70%) were receiving antiretroviral therapy (ART), 26 had interrupted, 39 had no ART at all and 7 had unknown ART status.
The primary cause of death was deemed to be non-TB in 145 (29%) patients, with HIV-related immunosuppression, old age, kidney injury, liver disease, and accidental deaths topping the list. For direct TB deaths, the key contributors were late presentation, HIV-related immunosuppression, and complicated extrapulmonary disease.
Conclusions: Mortality audits are essential in pinpointing preventable and systemic factors that lead to TB deaths, offering a chance to enhance systems and progress towards the End TB goals. We propose integrating mortality audits into TB program service delivery.

SOA15-668-21 TB associated mortality rate and case fatality ratio in India: A scoping review

A. Bhaskar,[1] M. Muniyandi,[2] J. Joseph,[3] R. Jajal,[3] S. A,[4] S. Pandey,[5] B. Watson,[1] S.u. Hadi,[6] R. Goyal,[3] N. Arinaminpathy,[7] R. Rao,[8] S. Swaminathan,[9]
[1]ICMR-National Institute for Research in Tuberculosis, Statistics, Chennai, India, [2]ICMR-National Institute for Research in Tuberculosis, Health Economics, Chennai, India, [3]International Aids Vaccine Initiative (IAVI), Global Access Research, New Delhi, India, [4]International Aids Vaccine Initiative (IAVI), Global Access Research, Chennai, India, [5]BL Pandey Foundation for Social Initiatives, NA, New Delhi, India, [6]International Aids Vaccine Initiative (IAVI), Accesss, New Delhi, India, [7]WHO, TB Monitoring, Evaluation & Strategic Information, Geniva, Switzerland, [8]Central TB Division, Central TB Division, New Delhi, India, [9]M S Swaminathan Research Foundation, M S Swaminathan Research Foundation, Chennai, India
e-mail: adhinb6001@gmail.com

Background: TB is the deadliest infectious disease, killing more than malaria and HIV combined. India is the country with the highest burden of TB, accounting for around 30% of global new TB patients and 5,00,000 deaths annually. To strengthen estimates of the burden of mortality due to TB in India, we sought to collate all of the available evidence available from country-specific studies.
Design/Methods: We performed a scoping review of articles published since 2006 in PubMed and included data from cohort (prospective or retrospective) and cross-sectional studies including, but not limited to, studies of treatment cohorts.
The pooled estimates for mortality rate and case fatality ratio were obtained using random effect modelling. For estimating the case fatality ratio, the data reported in India TB report is also used.
Results: We included four studies reporting TB mortality rate and five studies reporting case fatality ratio. The population of selected studies were inclusive of general, rural and tribal population and private sector with varying age limits.
There was substantial heterogeneity between the studies, indicated by I^2>95% for both mortality rate and case fatality ratio, underscoring the variability in TB epidemiology across regions and populations. We did not do a subgroup analysis for TB mortality as the number of studies

included were small. The mortality rate was estimated as 69.6 (95% CI: 22, 213) per 100,000 population. The overall case fatality ratio was estimated as 4.8% (95% CI: 4% – 5.6%).
However, the subgroup analysis showed higher case fatality ratio (>7%) in patients under retreatment which include relapse, failure and treatment after default.
Conclusions: The high mortality and case fatality rates indicate the need for further strengthening of surveillance and conducting more well-designed studies to provide deeper insights into the dynamics of TB mortality, to support in designing tailored interventions to reduce the disease burden in India.

SOA15-669-21 Sex differences in risk factors for unsuccessful TB treatment outcomes: A retrospective cohort study of six Eastern European countries, 2020-2022

O. Skouvig Pedersen,[1] T. Butova,[2] M. Kuzhko,[3] S. Niemann,[4,5] A. Rosenthal,[6] A. Grinev,[6] C. Wejse,[7] A. Fløe,[1] V.N. Dahl,[7] D. Butov,[8,4] on behalf of the TB Portals group [1]Aarhus University Hospital, Department of Respiratory Diseases and Allergy, Aarhus, Denmark, [2]Merefa Central District Hospital, Outpatient Department, Merefa, Ukraine, [3]National Scientific Center of Phthisiatry, Pulmonology and Allergology named after F. G. Yanovskyi, Chemoresistant Tuberculosis, Kiev, Ukraine, [4]Leibniz Lung Center, Research Center Borstel, Molecular and Experimental Mycobacteriology Group, Borstel, Germany, [5]German Center for Infection Research (DZIF), Partner Site Hamburg-Lübeck-Borstel-Riems, Borstel, Germany, [6]U.S. National Institute of Allergy and Infectious Diseases, Office of Cyber Infrastructure and Computational Biology, Rockville, United States of America, [7]Aarhus University Hospital, Department of Infectious Diseases, Aarhus, Denmark, [8]Kharkiv National University, Department of Infectious diseases, Childhood Infections and Phthisiology, Kharkiv, Ukraine
e-mail: olebella@gmail.com

Background: Addressing sex differences in health and disease is essential for achieving universal health coverage. However, studies on the association between sex and unsuccessful tuberculosis treatment outcomes have shown conflicting results. This study examines this association and analyses sex-stratified risk factors associated with unsuccessful outcomes.
Design/Methods: This retrospective, observational cohort study analysed prospectively collected data from six Eastern European countries from 2020-2022. The data used were obtained from the 'TB Portals' database maintained by the National Institute of Allergy and Infectious Diseases. Treatment outcomes were defined using World Health Organization criteria.
Uni- and multivariable logistic regression models were used to assess the association between sex and unsuccessful outcomes ('treatment failure', 'lost to follow-up', 'died', or any of these). After propensity score matching females and males, the multivariable analysis was repeated. Risk factors were analysed separately for each sex and compared using interaction terms.
Results: Among 1,490 females, 19% (95%CI: 18, 22) achieved an unsuccessful treatment outcome, compared with 30% (95%CI: 29, 31) among 4,553 males. In the multivariable analyses, female sex was associated with 32% lower odds of any unsuccessful outcome (adjusted odds ratio [aOR] 0.68, 95%CI: 0.58, 0.80), 36% lower odds of dying (aOR 0.6, 95%CI: 0.5, 0.8), and 37% lower odds of treatment failure (aOR 0.6, 95%CI: 0.5, 0.9). The association between sex and being 'lost to follow-up' was not significant. In the propensity score-matched cohort, sex was not associated with unsuccessful outcomes. Risk factors for unsuccessful outcomes were similar for females and males, except that in females aged > 65 years, where the odds of death were 2.2 times higher (95%CI: 1.1, 4.4).
Conclusions: Male sex was associated with worse outcomes but adjusting for clinical and socio-demographic factors attenuated the association, suggesting behavioural rather than biological drivers. Prospective studies are needed to confirm these findings.

SOA15-670-21 Key determinants of loss to follow-up and mortality among people with multi-drug-resistant TB in Papua New Guinea: A multi-province analysis

R. Yasi,[1] H. Nindil,[2] C. Ruda,[3] [1]National Department of Health, Public Health, Port Moresby, Papua New Guinea, [2]National Department of Health, NTP, Port Moresby, Papua New Guinea, [3]World Health ORganization, Communicable Diseases, Port Moresby, Papua New Guinea
e-mail: yasirob@gmail.com

Background and challenges to implementation: Multidrug-resistant tuberculosis (MDR-TB) patients in Papua New Guinea (PNG) experience unacceptably high rates of loss to follow-up (LTFU) and mortality, particularly in provinces with limited programmatic support. Identifying contributing factors is critical to inform targeted interventions.
Intervention or response: With the aim of assessing key demographic, clinical, and programmatic determinants of LTFU and mortality among MDR-TB patients across selected provinces in PNG, we conducted a retrospective review of 303 MDR-TB patient records from eight conveniently selected provincial TB management units (TBMUs), comprising both Global Fund (GF)-supported and non-GF-supported provinces. Of these, 171 were LTFU and 132 died during treatment in 2022. Variables analyzed included age, sex, residence, HIV status, site of disease, timing of adverse outcome, and type of treatment support. Statistical significance was assessed using chi-square tests ($p<0.05$).

Results/Impact: Most LTFU (72%) and deaths (70%) occurred among patients aged 15–45 years (p=0.006). Rural village residence was strongly associated with adverse outcomes (LTFU: 84%, deaths: 66%, p=0.00035). LTFU was most frequent in the first two months (32%) and after four months (33%) of treatment (p=0.0026). Absence of treatment support was a critical factor: 21% of LTFU and 59% of deaths had no support (p<0.00001).
Patients in non-GF-supported provinces—without community treatment supporters (CTS), transport or food support—accounted for the highest adverse outcome rates. HIV positivity was significantly associated with mortality (20% of deaths, p=0.0000065). Sex and site of TB disease were not statistically significant predictors.
Conclusions: Rural residence, lack of treatment support, younger adult age, and HIV-positive status are key determinants of adverse outcomes among MDR-TB patients. Urgent investment is needed in community-based support, patient enablers, and targeted interventions in under-resourced provinces to improve treatment outcomes.

SOA15-671-21 Treatment outcomes and post-treatment mortality among adults with drug-resistant TB in Sierra Leone: A national prospective cohort study

F. Greenwood,[1] R. Kamara,[2] M. Saunders,[3] T. Wingfield,[4]
[1]Liverpool School of Tropical Medicine, Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland, [2]Ministry of Health and Sanitation Sierra Leone, Disease Prevention and Control, Freetown, Sierra Leone, [3]St George's University, Institute for Infection and Immunity, London, United Kingdom of Great Britain and Northern Ireland, [4]Liverpool School of Tropical Medicine, Clinical Sciences and International Public Health, Liverpool, United Kingdom of Great Britain and Northern Ireland
e-mail: Tom.Wingfield@lstmed.ac.uk

Background: Multidrug-/rifampicin-resistant tuberculosis (MDR/RR-TB) is a global health threat. We evaluated programmatic outcomes and mortality post-treatment success among people with MDR/RR-TB in Sierra Leone, investigating factors associated with adverse outcomes.
Design/Methods: A prospective cohort study of individuals with microbiologically-confirmed MDR/RR-TB managed in Lakka Hospital, Freetown from 2017 to 2022 was undertaken. Treatment predominantly mirrored the World Health Organization (WHO) 2019 short (9-11 months) or long (18-24 months) or the all-oral regimens. Routinely collected data characterised baseline demographic and social, health, and disease-related factors, and treatment outcomes.
Participants were followed 12-months post-treatment completion to ascertain long-term mortality. A directed acyclic graph informed logistic regression, calculating adjusted odds ratios (aOR) and 95% confidence intervals (95%CI) to explore factors associated with adverse programmatic outcomes (National Leprosy and TB Control Program registered death before/during treatment, or loss to follow-up "LTFU") and post-treatment mortality.
Results: 739 people with MDR/RR-TB were included with a median age of 34-years (IQR: 25-45), 70% (517/739) male, 22% (160/734) HIV-positive and 60% (439/729) underweight. Overall, 78% (578/739) achieved programmatic success, 18% (134/739) died, and 3.7% (27/739) LTFU.
Demographic and social factors associated with adverse programmatic outcomes were ≥45-years (aOR=1.9;95% CI=1.1-3.2) and unemployment (aOR=2.9;95% CI=1.8-4.8). Health-related factors were HIV-positive (aOR=1.8;95% CI=1.1-2.7), chronic lung disease (aOR=1.7;95% CI:1.0-2.9), renal impairment (aOR=4.8;95% CI=1.8-12.9) and other co-morbidities (aOR=2.8;95% CI=1.2-6.8). Disease-related factors were underweight (aOR=1.6;95% CI=1.1-2.4), long treatment regimen (aOR=2.0;95% CI:1.3-3.2) and pneumothorax, effusion, or consolidation on chest radiograph.
Among people with programmatic success, 9.9% (57/578) were known to have died during 12-month follow-up. Post-treatment mortality was associated with smoking (aOR=2.7;95% CI=1.3-5.5), HIV-positive (aOR=2.0;95% CI:1.0-3.9), chronic lung disease (aOR=2.2;95% CI:1.1-4.7), previous TB episode LTFU (aOR=3.1;95% CI=1.1-8.7), and severe radiological disease (aOR=2.4;95% CI=1.2-4.5).
Conclusions: Despite effective treatment provision our results indicate high adverse outcomes among people with MDR/RR-TB in Sierra Leone underscoring the urgent need for holistic, person-centred interventions extending beyond active TB treatment, and providing an evidence base for their design.

SOA15-672-21 Unmasking the impact of COVID-19 on TB mortality in Brazil: A Bayesian structural time series analysis with implications for future health crises

R.B.V. Tavares,[1] D. Gomes,[2] Y.M. Alves,[1] N. Zini,[1] A.F. Tártaro,[1] T.Z. Berra,[1] M.E.P. Pelodan,[1] D.d.M. Pinheiro,[1] A.A. Monroe,[1] J.G.d.A. Ballestero,[1] P.F. Palha,[1] R.A. Arcêncio,[1]
[1]Ribeirão Preto College of Nursing at University of São Paulo, Maternal-infant and Public Health Nursing, Ribeirão Preto, Brazil, [2]School of Science and Technology at University of Évora, Mathematics, Evora, Portugal
e-mail: reginaldobazon@usp.br

Background: The COVID-19 pandemic disrupted tuberculosis (TB) control, particularly in high-burden, socially unequal settings such as Brazil. Service interruptions and reduced healthcare access likely affected mortality trends. This study assessed the causal impact of the pandemic on TB mortality across Brazilian macroregions using Bayesian structural time series modeling.

Design/Methods: An Ecological time series study conducted using national mortality data from the Mortality Information System (SIM) from January 2012 to December 2022. TB deaths were analyzed at national and regional levels. A Bayesian Structural Time Series (BSTS) model, in combination with ARIMA models, was used to estimate counterfactual TB mortality rates for pandemic period (2020–2022), allowing inference of the causal impact of COVID-19 on TB mortality.

Results: There were 51,809 TB deaths recorded during 2012-2022 in Brazil. The model predicted a national TB mortality rate of 0.18 per 100,000 (95% CI: 0.18–0.19) during the pandemic period, while the observed mean rate was 0.20, indicating a cumulative excess mortality of 9.9% (95% CI: 8.8%–11%). Midwest region showed the greatest relative increase, with a 30% rise in TB mortality (95% CI: 25%–35%). The probability of a causal impact was high across all regions: Brazil (99.90%), Midwest (99.90%), Southeast (99.90%), South (99.90%), Northeast (96.77%), and North (99.58%), indicating a significant and widespread effect of the pandemic on TB mortality (Figure 1).

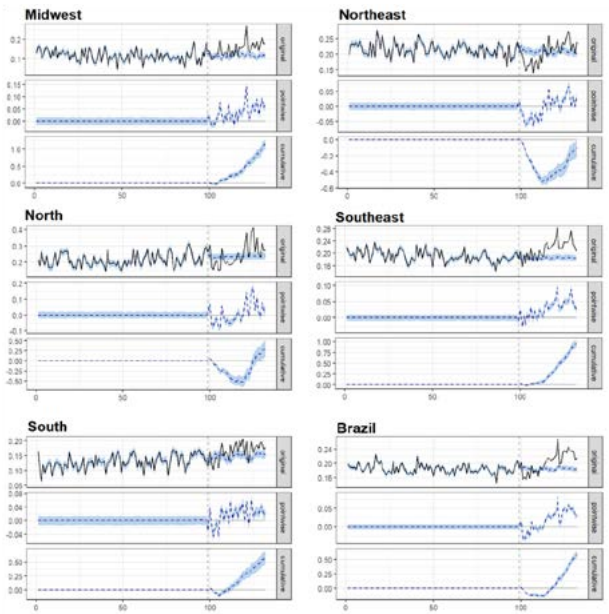


Figure 1. Causal effect analysis on tuberculosis mortality after COVID-19 pandemic period, by regions, Brazil, 2012–2022.

Conclusions: The findings reveal a substantial impact of the COVID-19 pandemic on TB mortality in Brazil, with regional variations highlighting differential vulnerabilities. The excess mortality observed underscores the need for strengthened TB surveillance and recovery strategies, especially in regions disproportionately affected. Bayesian time series models provide a robust framework for evaluating long-term consequences of public health crises on endemic diseases such as TB.

SOA15-673-21 A cross-sectional study to identify comorbidities contributing to deaths among people with TB using verbal autopsy tool in Tamil Nadu, India

A. Frederick,[1] R. Kubendiran,[1] T. Neelakantan,[1] K.K. Shankar,[1]
GOI-WHO NTEP Technical support network Tamil Nadu
[1]Department of Health and Family Welfare, Chennai, India
e-mail: stotn@rntcp.org

Background and challenges to implementation: In the year 2023, 10.8 million people diagnosed with TB and 1.25 million people died. India accounted about 29% of global TB deaths. Death rates increased by 2% following the covid pandemic in Tamil Nadu (TN). In alignment with the End TB objectives pertaining to mortality rates, TN has embarked upon a methodical and organized framework for analysing tuberculosis-related fatalities under the initiative "Tuberculosis Death Surveillance & Response" (TB-DSR).

To understand and plan interventions, Verbal Autopsy (VA) of deaths among registered People with TB (PwTB) were systematically conducted using standardized questionnaire.

Intervention or response: A cross-sectional study was conducted using VA data submitted from April 2023 to March 2024. VA consist of interviews with the close relatives of the deceased PwTB by trained National Tuberculosis Elimination Programme (NTEP) staff within 21 days of occurrence of death and ICD-10 classification assigned by Medical Officer (MO). Responses were analysed using Microsoft Excel by two independent researchers.

Results/Impact: 5,395 deaths were reported, out of which 5078 (94.1%) VA submissions were completed. The mean age of the deceased PwTB were 42±13 years, predominant gender male 2,720 (53.5%) and 3,171 (62.3%) occurrences of death in home. 4,375 (86.0%) PwTB were diagnosed with pulmonary TB. Valid International Classification of Diseases-10 (ICD-10) assigned for 3,458 deaths, wherein TB as underlying cause of death were assigned to 672 (19.4%), 231 (6.7%) were respiratory failure, 80 (2.3%) were cardiac complications, 60 (1.8%) related to kidney diseases, 35 (1.0%) HIV related complications, 31 (0.3%) had co-existing malnourishment and 13 (0.2%) related to diabetes.

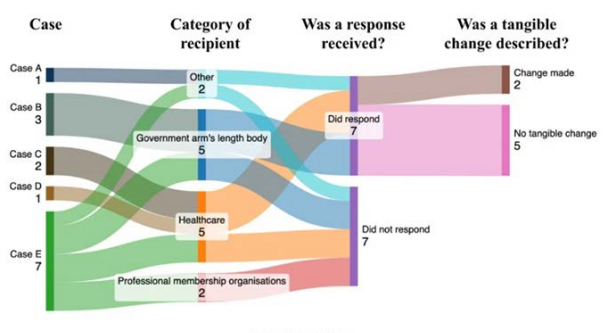
Conclusions: Performing VA by trained health staff and assigning ICD-10 by MO has yielded information on the various comorbidities causing deaths in PwTB. Implementing TB-DSR helps the program managers in addressing comorbidities upfront at the time of initiation of TB treatment which is a key strategy in reducing mortality rates.

SOA15-674-21 Preventable TB deaths reported by coroners in England and Wales: A case series and guideline review

A. Milne,[1] G. Richards,[2] H.-M. van der Westhuizen,[3]
[1]University of Oxford, Medical School, Oxford, United Kingdom of Great Britain and Northern Ireland, [2]Kings College London, Department of Analytical, Environmental & Forensic Science, London, United Kingdom of Great Britain and Northern Ireland, [3]University of Oxford, Centre for Global Health Research in the Nuffield Department of Medicine, Oxford, United Kingdom of Great Britain and Northern Ireland
e-mail: avalmilne@gmail.com

Background: Although the United Kingdom (UK) is a low-incidence tuberculosis country, the incidence is increasing and it has not met global End TB targets to reduce tuberculosis deaths. For preventative deaths, coroners in England and Wales have a duty to write Prevention of Future Deaths reports and send these to recipients who must respond within 56 days with action to prevent similar fatalities.
This study aimed to (1) describe preventable deaths from tuberculosis in England and Wales, (2) analyse recommendations from coroners and subsequent preventative actions, and (3) review how these recommendations align with existing TB guidelines.
Design/Methods: A database of 5036 coroners' reports was searched using the Preventable Deaths Tracker to identify deaths involving tuberculosis in England and Wales between 2013 and 2024. Descriptive statistics were used to synthesise the quantitative data and thematic analysis to identify themes in the concerns reported by coroners and organisational replies to coroners. UK guidelines on tuberculosis related to the coroners' concerns were reviewed.

Figure 6: A Sankey diagram describing the sending of, and responses to, Prevention of Future Death reports (PFDs) describing deaths involving tuberculosis in England and Wales between July 2013 and 19 May 2024.



Results: These were reports on five preventable tuberculosis deaths; median age at death was 28 years. Two of the deceased were nurses, impacted by occupational tuberculosis exposure. Coroners' concerns focussed on the occupational risks of tuberculosis to health workers, lack of awareness of tuberculosis symptoms and risks among health professionals in the UK leading to missed diagnoses, and insufficient guidelines for tuberculosis contact tracing and screening prior to initiative immunosuppressive treatment. Organisational responses to prevention of future death reports were inadequate, only two described tangible changes. (Figure 1) A review of guidelines found that health workers were not consistently identified as an at-risk population.
Conclusions: To achieve the WHO End TB strategy in the UK, greater attention should be given to screening and protection for health workers and raising awareness about the persistent burden of tuberculosis in the UK to avoid missed diagnoses.

SOA15-675-21 How does the family perceive TB deaths? Qualitative analysis of TB deaths in the RATIONS trial

M. Bhargava,[1] A. Meher,[2] A. Bhargava,[3] [1]Yenepoya Medical College, Yenepoya (Deemed to be University), Community Medicine, Mangaluru, India, [2]Swasthya Swaraj Society, Health, Kalahandi, India, [3]Yenepoya Medical College, Yenepoya (Deemed to be University), General Medicine, Mangaluru, India
e-mail: madhavibhargava4@gmail.com

Background and challenges to implementation: With 1.25 million TB deaths in 2023, TB has returned as the world's leading cause of death. We aimed to understand how the family perceives TB death, the context, and family circumstances during TB death in the RATIONS trial.
Intervention or response: Nested within the RATIONS trial in Jharkhand, India, this is a secondary qualitative analysis of field-notes of the trial staff who visited 108 families bereaved due to TB death during the intervention period. The field staff visited the family after a TB death, talked to them, and noted the circumstances, symptoms, and their perceptions to identify strategies to reduce deaths during the trial. The field-notes were manually coded, grouped, and thematically analyzed. Direct quotes were employed to describe the themes.
Results/Impact: The results underscore the vital role of understanding how the family perceives TB death. The most striking symptoms for the family preceding death were severe breathlessness, weakness, hemoptysis, poor appetite, and medication side-effects. Hospitalization and lack of resources like finances, vehicles, and social support systems to accompany a patient to the hospital emerged as important hurdles. COVID-19-related lockdown worsened their ability to navigate.
A reluctance for hospitalization rooted in past unpleasant experiences was evident. Co-morbidities such as severe anemia, diabetes, hypertension, liver problems, jaundice,

and mental health issues were often aggravating factors. Alcohol emerged as an important concern, which the family felt worsened the situation. The belief in evil-eye was common, and a lot of resources were spent dealing with superstitions involving local healers.

Theme	Categories	Representative quote of the family
Disease severity	Hemoptysis, breathlessness, weakness, poor appetite	"had a big bout of blood in cough, huge clots, must have died because of that"
Hospitalization	Scared of the hospital, did not want admission, no one to accompany, no money	"he did not want to go to the hospital because he was scared of the doctor scolding him, hospital people would say swear words so did not want to go there"
Comorbidities	Anemia, diabetes, hypertension, liver failure, kidney disease, depression, alcohol, pregnancy	"there was swelling of abdomen, we took to hospital to remove the fluid, some pipe was also inserted to remove fluid from the lungs and abdomen"
Local beliefs	Evil eye, traditional healer, supernatural phenomenon	"because of evil eye, stopped speaking and one side of body did not move, we offered sacrifice also, but did not work"
Covid-19 pandemic	Scared of Covid-19, lockdown, vaccination	"could not breathe properly, probably had less oxygen, could not go to the hospital due to lockdown, no vehicle also"

Conclusions: Understanding family circumstances and local belief systems is important to improve TB-care. Bolstering an integrated, quality, and easier continuum of care that is respectful and patient-centered and covers prevailing communicable and non-communicable diseases, mental health issues, and injuries is essential. Hospitalization prior to TB death is resource-intensive and is a barrier to mortality reduction efforts.

SOA15-676-21 Navigating the road to recovery: User journeys and barriers among persons with drug-resistant TB in South Africa

P. Mistri,[1] C. Rhea,[2] A. Moolla,[1] N. Ndlovu,[1] Z. Sibeko,[3] N. Ndlovu,[3] V. Chihota,[2,3,4] C. Chetty-Makkan,[1] Y. van der Heijden,[2,3] [1]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Faculty of Health Sciences, Johannesburg, South Africa, [2]Vanderbilt University, School of Medicine, Nashville, United States of America, [3]The Aurum Institute, Research, Johannesburg, South Africa, [4]University of the Witwatersrand, School of Public Health, Johannesburg, South Africa
e-mail: Pmistri@heroza.org

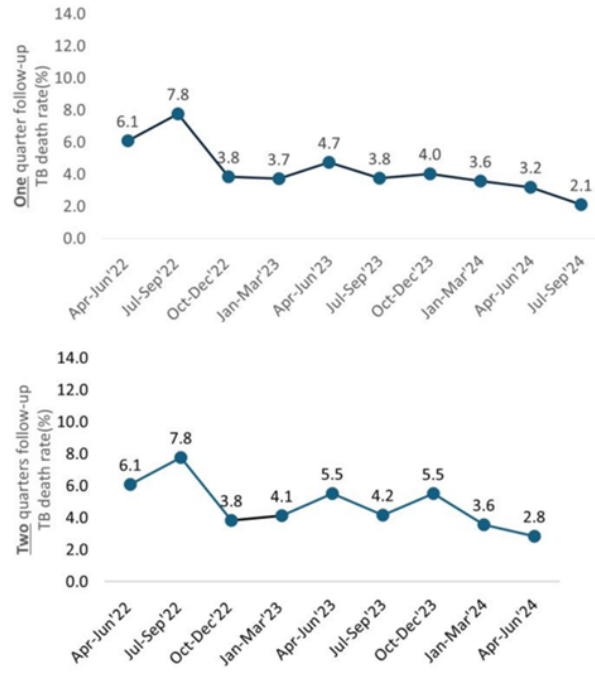
Background: In South Africa, better diagnostics and decentralized treatment have improved care for persons with drug-resistant tuberculosis (PWDR-TB). Despite this, up to 16% of PWDR-TB are lost to follow-up, leading to advanced illness and transmission risks. Understanding the user journey in DR-TB care uncovers behavioural insights to address treatment interruptions.
Design/Methods: We conducted two focus group discussions (FGDs) with adult PWDR-TB; one FGD and two in-depth interviews with healthcare providers (HCP) from August-September 2024 in Gauteng Province. We recruited participants from decentralised DR-TB treatment sites and a DR-TB hospital. We used semi-structured discussion guides informed by human-centred design principles. A behavioural science lens was applied to conduct a thematic analysis of engagement in DR-TB care.
Results: In the PWDR-TB FGDs (n= 15) the majority of participants were males, age range 23-70 years. The HCPs (n=10) were mostly nurses. After actively seeking medical help due to symptoms, PWDR-TB often faced multiple consultations and referrals across health facilities which delayed early treatment initiation. Limited knowledge of DR-TB, disbelief, denial, fear, and stigma impacted information processing and delayed treatment uptake along with cultural beliefs as causes of illness. Fear of disclosure, substance abuse, financial stressors and job loss fears were additional barriers to treatment initiation and adherence. PWDR-TB who reported challenges with treatment adherence, endured severe illness and hospitalization before learning the importance of adherence. Unreliable transport services made clinic attendance challenging necessitating alternate costly travel arrangements. Motivators to remain in TB care included strong relationships with nurses, improved DR-TB knowledge, family support, aspirations to live for children and achieve life goals.
Conclusions: Major challenges in user journeys were lack of knowledge of DR-TB and treatment requirements, adhering to cultural beliefs and stigma. Re-framing DR-TB information using behavioural insights to co-design messaging to be easy, accessible, simple and timely could improve understanding of DR-TB.

SOA15-677-21 Six districts with sustained TB death rate reduction following differentiated TB care in Southern India

R Srinivasan,[1] S Karunakaran,[2] M Balasubramanian,[3] Z. Hassan Mohamed Khan,[4] R Saravanan,[5] S Ganapathy,[6] R Sudhakar,[7] K.V. Suma,[8] K Rambha,[9] M Eraivan,[9] H.D. Shewade,[10] A. Frederick,[9] [1]ICMR National Institute of Epidemiology, Infectious Disease Epidemiology, Chennai, India, [2]NTEP, Tamil Nadu, District TB Office, Cuddalore, India, [3]NTEP, Tamil Nadu, District TB Office, Dharmapuri, India, [4]NTEP, Tamil Nadu, District TB Office, Kanyakumari, India, [5]NTEP, Tamil Nadu, District TB Office, Karur, India, [6]NTEP, Tamil Nadu, District TB Office, Salem, India, [7]NTEP, Tamil Nadu, District TB Office, Villupuram, India, [8]Office of the World Health Organization (WHO) Representative to India, WHO Country Office, New Delhi, Chennai, India, [9]Directorate of Medical and Rural Health Services, State TB Office, Government of Tamil Nadu, Chennai, India, [10]ICMR National Institute of Epidemiology, Division of Health Systems Research, Chennai, India
e-mail: stotn@rntcp.org

Background and challenges to implementation: Starting April 2022 (still ongoing), Tamil Nadu implemented the Tamil Nadu-*Kasanoi Erappila Thittam* (TN-KET), India's first state-wide (n=30 TB districts) differentiated TB care initiative aimed at reducing TB deaths. All adults (≥15 years) with drug-sensitive TB notified from public facilities are triaged at diagnosis. Those with very severe undernutrition or respiratory insufficiency or poor performance status (triage-positive) are prioritized for comprehensive assessment and inpatient care. The focus is on triaging at diagnosis as 70-80% of all TB deaths are early.
Intervention or response: Routine evaluation of the impact on TB death rate following TN-KET is done. For each 'quarterly-diagnosis' cohort, the aggregate number of notified people is the denominator. Among these, the districts track the aggregate number of deaths before the end of next quarter (one quarter follow up TB death rate) and before the end of next-to-next quarter (two quarters follow up TB death rate). Starting July 2022, the TB death rate for each quarterly-diagnosis cohort was compared to April-June 2022. Based on our estimates, 20-30% reduction is of significance to public health. As of July-September 2024 diagnosis cohort (n=9 quarters) for one quarter follow up TB death rate and April-June 2024 diagnosis cohort (n=8 quarters) for two quarters follow up TB death rate, districts with >50% quarters showing reduction were considered as excellent.
Results/Impact: Six districts have shown excellent performance: Cuddalore (9/17 quarters), Dharmapuri (15/17), Kanniyakumari (15/17), Karur (13/17), Salem (9/17) and Villupuram (10/17). In addition to reducing the losses in care cascade, the following are the reasons for excellent performance: quality triaging, quality comprehensive assessment, availability of isolation TB beds with therapeutic nutrition, and leadership by the district TB officers.

Figure. Trend of one quarter and two quarters follow up TB death rate, by quarterly-diagnosis cohorts, Karur district, Tamil Nadu, India (2022-2024)*



*Tamil Nadu *Kasanoi Erappila Thittam* (TN-KET), the differentiated TB care initiative to reduce TB deaths started in April 2022

Conclusions: TN-KET offers a scalable model for sustained TB death rate reduction. This effect needs to be confirmed through confounders adjusted individual level data analysis and is ongoing.

SOA16 Geospatial analytics and mapping for TB prevention, detection and care

SOA16-678-21 Leveraging artificial intelligence to predict potential TB hotspots at the community level in Bangui, Republic of Central Africa

K. Koura,[1,2] S. Hashmi,[3] S. Menon,[4] H. Gando,[5,6] A. Yamodo,[5] A.-L. Budts,[3] V. Meurrens,[3] S.-C. Lapelou,[7] O. Mbitikon,[5] M. Potgieter,[3] C. Cauwelaert,[3] [1]International Union against Tuberculosis and Lung Disease, Tuberculosis, Paris, France, [2]Université Paris Cité, IRD, F-75006, Paris, France, UMR261 MERIT, Paris, France, [3]EPCON, EPCON, Brussels, Belgium, [4]International Union against Tuberculosis and Lung Disease, Tuberculosis, Paris, Myanmar, [5]International Union Against Tuberculosis and Lung Disease, Tuberculosis, Paris, Central African Republic, [6]National Tuberculosis Programme, NA, Bangui, Central African Republic, [7]National Health Information System, NA, Bangui, Central African Republic
e-mail: kgkoura@theunion.org

Background: The Central African Republic (CAR) remains one of the countries with the highest tuberculosis (TB) burdens globally. In the capital city, Bangui, TB risk is fueled by extreme poverty, limited healthcare access, high HIV prevalence, malnutrition, low immunization coverage, and overcrowded living conditions. These challenges contribute to substantial underdiagnosis and under-reporting of TB cases, limiting effective public health responses.

Design/Methods: We developed a digital epidemiological model to estimate undiagnosed TB and predict community-level hotspots across Bangui. Our approach integrated passive TB notification data, population and settlement mapping, clinic catchment areas based on travel time, and socio-environmental covariates. A Bayesian probabilistic model was applied over a 100 × 100 meter grid, enabling fine-resolution predictions of TB positivity. The city was stratified into three risk categories: low (≤5 TB positives/1000 tested), medium (5–10/1000), and high (>10/1000). Neighborhood-level TB diagnosis data were validated against clinic records to support risk classification.

Results: The model produced a detailed prediction map of TB positivity, covering both urban and remote settlements (Figure 1). Of the 12 facilities that provide treatment services, two, seven, and three were classified to be located in high-, medium-, and low-risk regions, respectively (Table 1). Predictive analysis revealed positive correlations between TB positivity and population density, night-time lights, and vaccination coverage. Negative correlations were found with variables such as underweight children and HIV incidence, suggesting disparities in access to care and limitations of passive case detection. (Table 2).

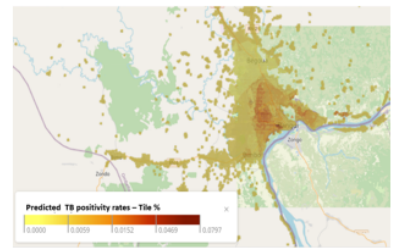


Figure 1. Predicted TB positivity rates in 100 × 100 meter areas in Bangui.

Table 1. Comparison of predicted and notified TB positivity in the vicinity of TB clinics.

TB Clinic	Predicted TB Positivity	Notified TB Positivity
Petevo Centre de Santé	Medium	Low
Lakounanga Urbain Centre de Santé	High	High
Centre de Santé Saint Joseph	Low	No data available
Complexe pédiatrique	Medium	No data available
CNRISTAR CTA	Low	No data available
Castors CSU	High	High
CNHUB HN	Medium	Low
Mamadou Mbaiki Centre de Santé	High	High
Hospital Communautaire	Low	High
Obrou Fidel Camp Centre de Santé	Medium	High
Amis Afrique ONG	Medium	Low
Malimaka	Medium	Medium
Hospital Amitiés	Medium	Medium
Bédé Combattant CSU	Medium	High

Table 2. Pearson correlation coefficients computed for predicted TB.

Variables	Pearson Correlation Coefficient	*p*-Value
Population density	0.67	<0.001
Observed TB positivity rate	0.61	<0.001
Night-time lights	0.47	<0.001
DPT 3 vaccination (%)	0.3	<0.001
DPT 1 vaccination (%)	0.3	<0.001
Children underweight (%)	−0.31	<0.001
HIV Incidence rate	−0.27	<0.001
Distance to built settlements	0.25	<0.001
Children stunted (%)	−0.23	<0.001
Measles vaccination (%)	0.21	<0.001
Access to improved water source (%)	0.205	<0.001
Lacking sanitation services (%)	0.18	<0.001
Distance to major roads	−0.13	<0.001
Elevation	−0.10	<0.001
Literacy among males (%)	0.09	<0.001
Literacy among females (%)	0.05	<0.001
Child mortality rate	0.03	<0.001

Conclusions: This study highlights the value of AI-powered, high-resolution modeling for TB surveillance in resource-limited settings. The approach supports the identification of underserved areas, improved resource targeting, and more strategic public health planning.
Future integration of multidrug-resistant TB and active case-finding data may further enhance its impact and scalability.

SOA16-679-21 Spatial analysis of TB disease and infection: Identifying priority areas for active contact management in Brazil

J.N.d.B. Silva Júnior,[1] D.H.M. Silva,[2] Q.R. Ferreira,[2] G.d.C. Leal,[2] A.B.M. Valença,[2] A.K.A.S. Carvalho,[3] L.H. Arroyo,[1] P.V.d.S. Viana,[4] A.A. Monroe,[2] J.G.d.A. Ballestero,[2] A. Trajman,[5] P.F. Palha,[2] [1]Ministry of Health, Department of HIV/AIDS, Tuberculosis, Viral Hepatitis and Sexually Transmitted Infections, Brasília, Brazil, [2]University of São Paulo, Department of Maternal-Child and Public Health Nursing at the Ribeirão Preto School of Nursing, Ribeirão Preto, Brazil, [3]New Hope Nursing School, FACENE, João Pessoa, Brazil, [4]Oswaldo Cruz Foundation, Sergio Arouca National School of Public Health, Rio de Janeiro, Brazil, [5]Federal University of Rio de Janeiro/ Professor at McGill University, Internal Medicine at the Medical School, Rio de Janeiro, Brazil
e-mail: nildoenfer@hotmail.com

Background: In Brazil, coverage of tuberculosis preventive treatment (TPT) among contacts of people with tuberculosis (TB) is heterogeneous. Identifying areas with high TB incidence and low TPT notification can help guide more effective interventions. This study aimed to identify priority areas with a high TB incidence rate and low programmatic response in contact tracing, measured by TPT notification.
Design/Methods: This was an ecological study using aggregated data at the municipal level from the Notifiable Diseases Information System (Sinan) and the Latent Tuberculosis Infection (IL-TB) database for the year 2023. TB incidence rates were estimated, and spatial scan statistics were applied to identify high-risk clusters. The relative risk (RR) was calculated by comparing the likelihood inside versus outside scanning window. Clusters were then correlated with IL-TB data. All spatial scan and relative risk analyses were performed using SaTScan (version 10.3). Thematic maps were created using QGIS (version 3.40.3).

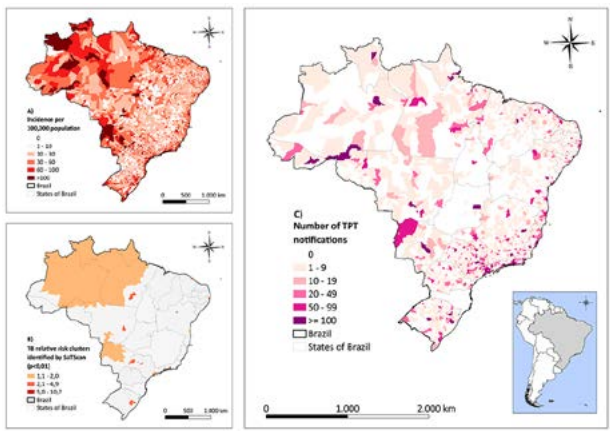

Figure 1. Spatial distribution of tuberculosis incidence, relative risk clusters, and tuberculosis preventive treatment notifications in Brazil, 2023.

Results: A spatial mismatch was observed between the distribution of TB and the programmatic response to TB infection. A significant proportion of municipalities in the North and Central-West regions showed TB incidence rates higher than 100 cases per 100,000 population, while 90% and 96% of these municipalities, respectively, reported fewer than 10 notifications of TPT.
Nationally, 22.3% of municipalities with TB incidence rates above the national average (39.7/100,000) reported fewer than 10 TPT notifications. The highest RR (ranging from 2.0 to 10.7) were found in the metropolitan areas of some state capitals as well as in rural areas.
Conclusions: Our spatial approach sucessfully identified operational gaps in contact management. These gaps concentrate in socially vulnerable territories, and may undermine Brazil's progress toward TB elimination. Prioritizing these areas for active interventions can strengthen equity and impact.

SOA16-680-21 Spatiotemporal dynamics and hotspot identification of TB in Eswatini: A national analysis from 2017 to 2024

S. Ndabezitha,[1] B. Mamba,[2] A. Mandalakas,[1] [1]Baylor College of Medicine, Peadiatrics, Houston, United States of America, [2]Eswatini National TB Control Program, Monitoring and evaluation, Manzini, Eswatini
e-mail: sandile.ndabezitha@bcm.edu

Background: Tuberculosis (TB) remains a significant public health challenge globally. In Eswatini, high TB incidence and prevalence are driven by factors such as TB/HIV co-infection, socioeconomic disparities across geographical areas, and unequal access to healthcare services.
Design/Methods: We analyzed national drug-sensitive TB data from 2017 to 2024, alongside annual population projections. Descriptive statistics, choropleth maps, and joinpoint regression were used to assess temporal trends across Eswatini's four regions and 55 constituencies. Spatial autocorrelation was evaluated using both Global and Local Moran's I statistics. Additionally, bivariate TB risk transitions between 2017 and 2024 were assessed.
Results: The analysis revealed significant spatiotemporal variation in TB prevalence, with distinct clusters (hotspots) observed across the country. Global Moran's I confirmed significant spatial autocorrelation, while Local Moran's I identified persistent hotspots in the lower Hhohho and upper Manzini regions.
Cold spots were found in upper Hhohho and border constituencies near Lubombo, as well as the southern parts of Manzini. Joinpoint regression indicated a significantly increasing TB trend in Manzini (APC = 10.99) and decreasing trends in Lubombo (APC = -4.27) and Shiselweni (APC = -7.94). Hhohho showed an overall downward trend, though not statistically significant. The bivariate

TB risk analysis showed that most constituencies maintained similar risk levels between 2017 and 2024. However, 6 constituencies transitioned from lower to higher risk, while 8 moved from higher to lower risk.
Conclusions: TB patterns in Eswatini are shaped by spatial and temporal dynamics, with neighboring areas often sharing similar risk profiles due to common environmental and social determinants. Identifying high-burden hotspots enables targeted interventions and more efficient allocation of resources.
Spatiotemporal analysis, along with emerging tools such as machine learning and wastewater-based surveillance, presents new opportunities to improve TB detection, forecasting, and response—ultimately supporting more precise and proactive control strategies.

SOA16-681-21 Exploring added value of novel data sources for small area prediction of TB burden in Pakistan: Private sector sales, telecom mobility and satellite imagery data

E. Rood,[1] C. Mergenthaler,[1] P. Stephens,[2] U. Saif,[3] B.Z. Butt,[4] M. Bakker,[1] J. Ifejube,[1] R. Syed,[5] Y.T. Ng,[6] A. Latif,[7] A. Ismail,[8] S. Alba,[1] [1]KIT Institute, Center for Applied Spatial Epidemiology, Amsterdam, Netherlands, [2]IQVIA Ltd, Global Health, London, United Kingdom of Great Britain and Northern Ireland, [3]AI Sight, CEO Office, Lahore, Pakistan, [4]Lahore School of Economics, Operations, Lahore, Pakistan, [5]IQVIA Solutions Pakistan Pvt Ltd, Primary Intelligence, Karachi, Pakistan, [6]IQVIA Solutions Asia Pte Ltd, Global Health APAC, Singapore, Singapore, [7]Mercy Corps Pakistan, TB Program, Islamabad, Pakistan, [8]Common Management Unit for AIDS, TB & Malaria, N/A, Islamabad, Pakistan
e-mail: e.rood@kit.nl

Background: Recently, TB modelers have placed much attention on Pakistan, where burden remains high (5th globally), yet treatment gaps remain (66% treatment coverage). A persisting question is where specifically to focus case-finding efforts to maximize case detection amongst populations who otherwise may not access timely care. As health resources dwindle globally, the importance of efficient geographical targeting increases.
Design/Methods: Our primary research objective was to predict ACF TB positivity rates per 10,000 population in Pakistan using a range of predictors. In addition to TB notification and survey data, we included novel data sources: a health access index derived from telecom mobility data; aggregated rifampicin sales data among private sector vendors collected by IQVIA Pakistan Pharmaceutical Index (2021-2022); and a socioeconomic indicator derived from high-resolution satellite imagery. We fitted a spatially explicit Bayesian zero-inflated Poisson model to model B+ TB positivity rates from ACF events conducted in all Pakistan provinces, and compared performance of models with different sets of indicators.
Results: Fitting a Bayesian approximation of the zero-inflated Poisson model resulted in overall good model fit. Highest predictive power was attained from the full model containing spatial lag, socioeconomic variables, TB notifications and rifampicin utilization (k-fold validation R-sq=84%). Rifampicin utilization and TB notifications share similar predictive accuracy (k-fold validation R-sq=54-55%). A spatially explicit null model had much higher predictive accuracy and was able to explain small scale geographical variation unaccounted for by other models.
Conclusions: In the absence of TB data, socioeconomic predictors are powerful to support initial prioritization of TB case finding and outperform TB notifications and rifampicin utilization. However, highest predictive power is found in spatially explicit models accounting for locally observed TB yield. Geographically targeting higher-risk localities can be based on methodologies of varying levels of complexity, and even simple approaches can contribute to rational and evidence-based decision making for TB control.

SOA16-682-21 Mapping BCG vaccination coverage in Africa, 1990-2022: A novel spatiotemporal modelling study

A. Liyew,[1] B. Gilmour,[1] A.C.A. Clements,[2] P. Gething,[1] S.F. Rumisha,[1] J. Lubinda,[3] K. Alene,[1] [1]Curtin University, School of Population Health, Perth, Australia, [2]Queen's University Belfast, School of Biological Sciences, Belfast, United Kingdom of Great Britain and Northern Ireland, [3]The KIDS Research Institute Australia, Malaria Atlas Project, Perth, Australia
e-mail: alemnehmekuriawliyew@gmail.com

Background: Bacillus Calmette–Guérin (BCG) is the only licensed vaccine for tuberculosis (TB), providing protection against severe forms of the disease in children. Accurate coverage estimates at national and subnational levels are crucial for assessing progress toward TB control and identifying underserved populations across Africa. This study aimed to map BCG vaccination coverage in Africa from 1990 to 2022.
Design/Methods: This analysis included 111 demographic and health surveys, and multiple indicator household surveys conducted from 1990 to 2022, comprising data on 181,765 children from 36 African countries. A Bayesian geostatistical model was used to estimate BCG vaccination coverage and the number of unvaccinated children aged 12-23 months at a 5 × 5 km spatial resolution.
These estimates were aggregated to produce coverage data at the first administrative and national level for the period 1990 to 2022 for 36 countries.
Results: Between 1990 and 2022, BCG vaccination coverage increased in 81.90% (95% uncertainty interval [UI]: 78.41–85.07) of first-level administrative areas across 36 African countries. Despite this progress, significant geo-

graphical disparities persist both within and between countries. In 2022, many first-level administrative units still reported low BCG coverage and high number of unvaccinated children, even in countries with high national coverage rates. Some administrative units had consistently experienced low BCG coverage, remaining below 25% in both 1990 and 2022.
While notable progress was observed in several countries, only Lesotho and Burundi are likely to have met the Global Vaccine Action Plan target of achieving at least 80% coverage in all first-level administrative areas.
Conclusions: Despite significant progress in BCG vaccination coverage across Africa over the past three decades, notable geographic disparities persist, with many subnational areas falling below target coverage levels.
The current findings provide insights for targeted interventions to improve BCG coverage and enhance health outcomes, especially in underserved and unreached areas.

SOA16-683-21 Mapping TB preventive therapy in Ethiopia: Geospatial analysis

A. Liyew,[1] B. Gilmour,[1] A.C.A. Clements,[2] H. Wolde,[1] K. Alene,[1] [1]Curtin University, School of Population Health, Perth, Australia, [2]Queen's University Belfast, School of Biological Sciences, Perth, United Kingdom of Great Britain and Northern Ireland
e-mail: alemnehmekuriawliyew@gmail.com

Background: Although tuberculosis (TB) is a preventable disease, it remains a leading cause of morbidity and mortality worldwide. TB preventive therapy (TPT) is a critical intervention to prevent the progression from infection to disease, particularly in high-risk populations.
However, coverage and completion rates of TPT at subnational and local levels are yet to be investigated in Ethiopia. Therefore, this study aimed to estimate TPT coverage and completion rates at local and district levels across Ethiopia.
Design/Methods: TB notification data reported from July 2022 to June 2023 was utilized for this study. Covariates were accessed from publicly available data warehouses. A total of 1132 and 838 location data points were used for modelling TPT coverage and completion rate, respectively. Bayesian geostatistical model was used to estimate TPT coverage and completion rate across Ethiopia at 5x5 km spatial resolution, and these results were aggregated to produce district-level estimates.
Results: A total of 208,508 individuals were screened for TB during the study period and 169,890 were found to be negative for TB. Of these 53,498 individuals were initiated TPT.
Among a total of 39,760 individuals who started TPT in the previous year, 34,580 completed the treatment. The district-level TPT coverage ranged from 0.01% to 99%, indicating marked variation across districts in Ethiopia. Access to health facilities had negative association with both TPT coverage (β = -0.055; 95% CrI: -0.101-0.008) and TPT completion (β = -0.571; 95% CrI: -0.726-0.416). Population density was negatively associated with TPT completion rate (β = -0.344; 95% CrI: -0.584-0.104). In contrast, HIV/AIDS prevalence showed a positive association with TPT coverage (β = 0.241; 95% CrI: 0.183-0.298).
Conclusions: Our findings revealed marked variation in TPT coverage and completion rate at local and district levels. This suggests that certain areas, particularly those with low coverage and completion rates, require targeted strategies to improve TPT provision.

SOA16-684-21 Geospatial patterns of loss to follow-up from TB treatment: A gender-based analysis in Brazil

B.F. Vigato,[1] R.B.V. Tavares,[1] A.F. Tártaro,[1] W.O.B. Bernardi,[1] M.E.P. Pelodan,[1] J.Q.R.d. Paiva,[1] J.S.T.d. Araújo,[1] M.A.P. Popolin,[2] T.P. Barbosa,[1] T.K.A. Teibo,[1] Y.M. Alves,[1] R.A. Arcêncio,[1] [1]University of São Paulo at Ribeirão Preto College of Nursing, Maternal Infant and Public Health, Ribeirão Preto, Brazil, [2]Federal University of Tocantins, Nursing, Palmas, Brazil
e-mail: ricardo@eerp.usp.br

Background: Brazil has made significant progress in TB detection, with a rate over 70%, but faces challenges in treatment completion. In 2023, 73% completed treatment, increasing the risk of tuberculosis (TB) resistance. Most studies focus on factors related to loss to follow-up (LTFU), neglecting geographic areas and gender disparities.
This study aimed to analyze the spatial distribution and gender differences in LTFU across Brazil.
Design/Methods: This ecological study analyzed TB cases classified as LTFU in Brazil between 2019 and 2022, using data from the Department of Informatics of the Unified Health System (DATASUS). Sociodemographic and clinical characteristics were analyzed with R software (version 3.6.3), and LTFU rates were calculated.
Geospatial analysis identified LTFU clusters, correlating patterns with gender and other factors. Choropleth maps by gender were created using ArcGIS software (10.8).
Results: A total of 91,883 people with TB, or14.7%, were LTFU. Women with HIV had a higher LTFU rate (19.43%) than men (13.21%).
Pulmonary TB accounted for 89% of LTFU cases. High LTFU percentages were seen in the Northeast, North, and Central-West, particularly in Goiás near the Federal District.
Conclusions: The study reveals higher loss to follow-up rates in men, but when considering gender and HIV co-infection, interruptions are more common in women.

Regional variations in LTFU were observed. The findings emphasize gender differences in treatment outcomes and the need for tailored interventions and integrated approaches between TB and HIV.

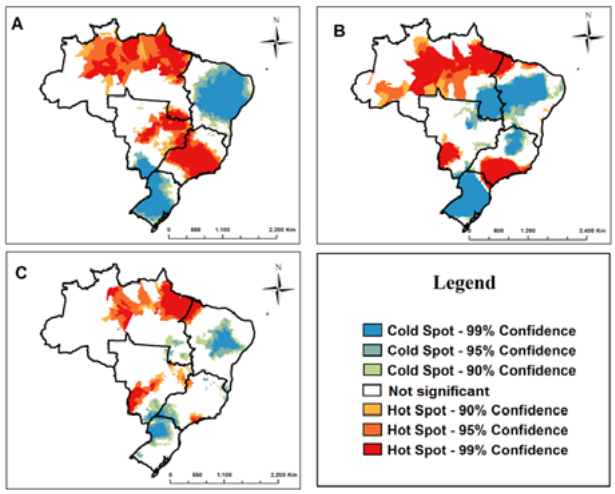

Figure 1 - Clusters of high and low values of tuberculosis lost to follow up rates according to gender and in the general population, Brazil, 2019-2022.
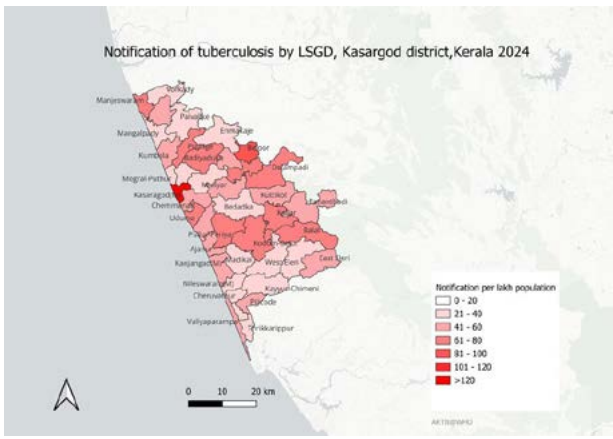
A - Clusters of high and low tuberculosis LTFU rates in the general population; B - Clusters of high and low tuberculosis LTFU rates in males; C - Clusters of high and low tuberculosis LTFU rates in females.

SOA16-685-21 Geospatial intelligence using QGIS tool for localised TB elimination: A multi-sectoral approach in Kasargod district, Kerala, India

R. K. K.,[1] A. T. N.,[2] G. A. V.,[3] A. Mohan,[4] S. Achanta,[5] U. B. S.,[6] R. K. J.,[7] K. Devasu,[1] A. Ranjith,[8] R. A. V.,[9] R. K.,[10] P. K.,[11] [1]State TB Office, Department of Health Services, Thiruvananthapuram, India, [2]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, Kannur, India, [3]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, Kochi, India, [4]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, Thiruvananthapuram, India, [5]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [6]Government of India, Central TB Division, New Delhi, India, [7]Directorate of Health Services, Department of Health Services, Thiruvananthapuram, India, [8]District Tuberculosis Centre, Department of Health Services, Kasargod, India, [9]District Medical Office, Department of Health Services, Kasargod, India, [10]District TB Centre, Department of Health Services, Kasargod, India, [11]District TB Centre, National Health Mission, Kasargod, India
e-mail: avgayathri@rntcp.org

Background: Achieving „TB Mukth Panchayath" (TB-Free Local Self-Government Division - LSGD) status requires a granular understanding of tuberculosis (TB) epidemiology and the implementation of targeted, multi-sectoral interventions aligned with Sustainable Development Goals (SDGs).
This study employed geospatial analysis using QGIS, based on Nikshay surveillance data from 2022–2024 in Kasargod district, Kerala, India, to inform and localize TB elimination strategies.
Design/Methods: Routinely collected programmatic data were analysed at the LSGD level, including TB notification rates, Presumptive TB Examination Rates (PTER), and TB-specific mortality, mapped against population estimates and SDG-aligned thresholds (TB incidence <44/lakh, TB deaths <2/lakh). QGIS was utilized to visualize spatial heterogeneity and stratify Panchayaths by TB burden.
These insights guided the development of a multi-sectoral accountability framework involving representatives from LSGD, tribal welfare, coastal, fisheries, and labour departments.
This structure enabled integrated action planning, monitoring, and periodic district-level task force reviews.
Community engagement was fostered through "Kolayakkoottam" health debates, enhancing participatory governance.
Additionally, targeted media sensitization and capacity-building workshops were conducted to promote responsible TB-related reporting and public awareness.

Results: The application of QGIS enabled effective communication of TB burden and elimination roadmaps to LSGD members and diverse stakeholders. This facilitated collaborative planning and execution of interventions. Consequently, 10 Panchayaths in Kasargod district achieved TB Mukth Panchayath status by the end of 2024, demonstrating the effectiveness of this geospatial intelligence-driven, multi-sectoral approach.



Conclusions: Geospatial mapping of routine surveillance data, coupled with a robust multi-sectoral accountability framework, provides a powerful strategy for localized TB elimination. The experience in Kasargod highlights the potential of utilizing tools like QGIS to empower local administrations to plan and achieve significant progress towards national TB elimination goals.

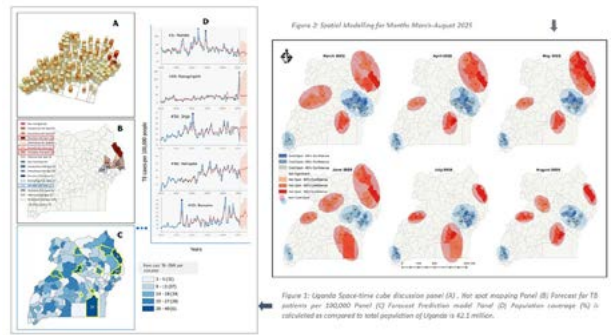
SOA16-686-21 Emerging hotspots of TB in Uganda: Insights from spatiotemporal analysis

G. Amanya,[1] D. Mabirizi,[2] A. Mulindwa,[2] E. Quinto,[2] A. Katamba,[3] M. Nabukenya M,[1] E. Tweyongyere,[2] H. Luzze,[2] M. Nakawooya,[2] S. Zawedde,[1] [1]Makerere University, Infectious Diseases Institute, Kampala, Uganda, [2]National TB and Leprosy Programe, Communicable Disease Prevention and Control, Kampala, Uganda, [3]WALIMU/ Makerere University, School of Medicine, Kampala, Uganda
e-mail: geofreyamanya@gmail.com

Background: Understanding TB incidence's is critical to optimizing control strategies and reducing transmission, we conducted spatial modeling using routine data to assess TB incidence, identified emerging hotspots, and forecasting trends in Uganda for effective disease control.

Design/Methods: We used space-time cube framework to analyze TB notification rates(CNR) surveillance data from the DHIS2. To understand spatial clustering of TB, Getis-Ord Gi* algorithm, was used to ascertain existence of hotspots intensity of clustering in high or low values and using a local z-score and P-values for each bin and space time cube. Mann-Kendall statistic was used to assess time series of z-scores and binning category for each bin, P-values <0.05 indicated statistical significance. Forest based-regression was used to forecast CNR for March-August 2025. Both forecast and validation root mean square errors were computed to evaluate performance of the March 2025 forecast. ARC-Gis was used for analysis, administration boundaries obtained from Uganda Bureau of Statistics.

Results: From 2020 to 2024, 276, 414 TB patients were identified, resulting in an CNR of 71.9 in 2020 to 158 per 100,000, 2024. Space time cube visualized in 3D highlighted colors darker in north east region meaning elevated CNR values (Panel **A**), from this incidence rates revealed statistically significant ($p \leq 0.001$) Hotspots for 5 districts Moroto (Persistent) and Nabilatuk, Amudat, Nakapiripipiti(Sporadic) and Kween (Oscillating)(Panel **B**), same districts have the highest forecasted TB rates as visualized in Panel (**C&D), n**otably only Soroti was replaced by Buvuma district with(53/100,000, 95%CI: 50–57), the model's RMSE for March 2025 was 11.2/100,000 supporting a high predictive accuracy. Forecasts for hotspots were made beyond March as visualized in Figure **2.**



Conclusions: The hotspots have highlighted areas where the results of epidemiological evidence can start to manifest in data, future iterations of this model could be integrated into the national TB surveillance framework for near-real-time hotspot monitoring and resource allocation.

SOA17 Innovations and insights in tobacco control: From community action to policy reform

SOA17-687-21 Who speaks for the margins? Indigenous communities, tobacco, and policy representation in India: A qualitative analysis of parliamentary questions from India (1952-2022)

S.S. Das,[1] U. Bhojani,[2] [1]Institute of Public Health, Bengaluru, CTRITH (Centre for Training, Research, and Innovation in Tribal Health), Bengaluru, India, [2]Institute of Public Health, Bengaluru, CTRITH (Centre for Training, Research, and Innovation in Tribal Health), Cluster on Chronic Health Conditions and Public Health, Bengaluru, India
e-mail: shilpi@iphindia.org

Background and challenges to implementation: Tobacco use is a major public health challenge that is higher among the Indigenous communities in India. In the last few decades there have been a decline in tobacco consumption; however, the social disparities in tobacco use have widen among the indigenous communities. Tobacco policies in India lacks addressing the issues experienced by the Indigenous communities.
This study aims to explore how concerns related to Indigenous communities and tobacco are presented at the national level and explores to draw inferences on the existing disparities in tobacco use among the indigenous communities compared to other communities.
Intervention or response: The study uses digital transcripts of question hours from lower-and-upper houses of the Indian parliament that spans over a period of 70 years (between 1952-2022). The question hours are platform where parliamentarians ask questions and ministers answers them. Different concerns are raised during these sessions; and out of 2556 transcripts on indigenous communities and tobacco, 301 transcripts that were thematically categorized and analyzed for the study.
Results/Impact: While tobacco use among the indigenous communities still remains high, leading to higher disease burden and mortality; it fails to get attention at the national platform. Concerns presenting indigenous communities as workers and contributors in the tobacco industry gets more limelight rather than the impact of the industry on the community. The politics of representation plays a significant role in brining the margins to the core of healthcare policies.
Conclusions: Public health research and advocacy efforts need to acknowledge the complex and multiple intertwining links between tobacco (industry) and indigenous communities. There is a need to sensitize policymakers on the health and environmental impacts of tobacco. It is important to break the chains of selective attention for more inclusive and justice driven policies.

SOA17-688-21 A challenging intervention success: Tobacco use reduction in hard-to-reach communities in Sri Lanka

A.O.B. Tenna,[1] S. De Seram,[1] A. Raheem,[2] N. Selladurai,[2] [1]Alcohol and Drug Information Center (ADIC) Sri Lanka, Policy advocacy and research, Colombo, Sri Lanka, [2]Alcohol and Drug Information Center (ADIC) Sri Lanka, Community Mobilization, Colombo, Sri Lanka
e-mail: tennaamaranath@gmail.com

Background and challenges to implementation: Tobacco use remains a critical public health issue in Sri Lanka, particularly within hard-to-reach communities such as fishers, daily wage earners, and transport workers. Despite a national tobacco use rate of 19.4% (Global Adult Tobacco Survey, 2020), specific subpopulations experience disproportionately high usage due to occupational conditions, limited awareness, social norms, and industry targeting.
Intervention or response: From July to November 2023, the Alcohol and Drug Information Centre (ADIC) implemented a tobacco use reduction project across 10 hard-to-reach communities, directly engaging 270 individuals. Ten Field Level Implementers (FLIs) from within the communities were trained to lead the initiative, ensuring cultural sensitivity and long-term sustainability.
Activities included awareness sessions, informal discussions, and community-led tools such as income-expenditure books and savings tills, designed to visualize the financial burden of tobacco use and encourage behavior change.
Additionally, interactive methods like storytelling, role-plays, and peer sharing were used to foster trust, stimulate dialogue, and enhance personal reflection on tobacco-related harms. This bottom-up approach promoted ownership and deeper community involvement in the intervention process.
Results/Impact: The intervention achieved notable success. A total of 77 individuals (28.5%) reduced their tobacco use, while 33 individuals (12.2%) quit entirely. Additionally, 78 individuals (28.9%) began saving money previously spent on tobacco.
Positive ripple effects included increased time spent with family, better nutrition for children, enhanced economic awareness, and improved well-being. Communities reported strengthened unity, improved knowledge of industry manipulation strategies, and heightened motivation to sustain healthier lifestyles.
Conclusions: Reducing tobacco use in marginalized communities is challenging but possible through tailored, informal, and economically framed interventions. Approaching the issue via financial and social consequences—rather than purely health-based messaging—proved more effective in engaging these groups. Continuous, community-driven follow-up is essential for long-term change and sustainability.

SOA17-689-21 Effects of new pictorial cigarette pack warnings on Vietnamese smokers' perceptions and smoking behaviours: A single-factor, between-subjects experimental study

T.P.T. Tran,[1] S.R. Weaver,[2] L. Popova,[2] [1]Hanoi University of Public Health, Center for Population Health Sciences, Hanoi, Viet Nam, [2]Georgia State University, School of Public Health, Atlanta, United States of America

Background: This study aimed to assess the effects of different cigarette package pictorial health warnings (PHW) configurations that Vietnam might consider in the future.
Design/Methods: A randomized experiment was conducted with 1,010 adult smokers in Vietnam in 2024. Participants were assigned to one of five groups:
1. Branded pack with new PHWs covering 50% (n=200),
2. Branded pack with new PHWs covering 85% (n=202),
3. Branded pack with new PHWs + Quitline, covering 85% (n=204), and (4) plain pack with a new PHWs + Quitline, covering 85% (n=203), and (5) control group with branded packs featuring the current PHWs, covering 50% (n=201).
We measured four sets of outcomes:
1. Emotional and cognitive responses,
2. Attitudes and beliefs about smoking-related harms, and;
3. Behavioral intentions measured immediately after viewing PHWs, and;
4. Recall and behavioral outcomes at two-week follow-up.
Results: Group 2 (new PHWs, covering 85%) had significantly higher negative emotional responses than group 4 (new PHWs+Quitline+Plain packaging, covering 85%).
For smoking causes oral cancer and smoking causes bleeding in the brain and stroke, the mean belief scores of group 2 (new PHWs, covering 85%) were significantly higher than those of the control group.
At two-week follow-up, participants in group 3 (new PHWs+Quitline, covering 85%) and group 4 (new PHWs+Quitline+plain packaging, covering 85%) were more likely to recall the quitline number compared to the control group.
Additionally, participants in group 4 (new PHWs + Quitline + plain packaging, covering 85%) had higher odds of forgoing a cigarette at two-week follow-up compared to the control group.
No significant impact of group on quit intention or cessation behaviors was observed.
Conclusions: Our study supports refreshing PHWs, showing that new PHWs with quitline information enhanced awareness of quitline services. Plain packaging with new PHWs increased the likelihood of forgoing cigarettes, a precursor to cessation attempts.

SOA17-690-21 Leveraging online media for the Tobacco Free Youth Campaign increased the visibility of tobacco control efforts among youth in India

B. Sharma,[1] [1]MP, TC, Indore, India
e-mail: bsharmasilk@gmail.com

Background: Online media is a cost-effective means to promote a social cause, and it can be leveraged to increase the participation of youths. The Indian Health Ministry launched a 60-day Tobacco-Free-Youth-Campaign to empower youth against tobacco use.
The campaign focused on awareness raising, promotion of Tobacco Free Educational Institutions and Tobacco free villages, strengthening the tobacco control acts and enforcement, and social media engagement. Leveraging online media for youth-related campaign promotion significantly increases the outcome.
Design/Methods: The study used a qualitative content analysis approach. Search term "Tobacco Free Youth Campaign 2.0 and #TobaccoFreeYouthCampaign was used in Google search, and the first 50 links were analysed based on utilization of various social media platforms, media coverage, civil society and state government news uploads, and social media influencers' accounts.
Results: The Health Ministry used X, Facebook, Instagram, and YouTube accounts to publicize the event, The Education Ministry has also uploaded details on X. The Campaign was inaugurated (virtually) on YouTube. The Press Information Bureau uploaded the news. Social media influencers shared the campaign on their accounts. Local and major online news portals covered the campaign. Several episodes on youth and tobacco control are made available on YouTube. Campaign visible on the government's MY-Bharat website targeting youth. The online No Tobacco Pledge platform is made available. #TobaccoFreeYouthCampaign #SayNoToTobacco tags used.
Celebrities are involved in the digital awareness campaign. As per the campaign data posted by the Ministry, the influencers' posts regarding the campaign received over 40 million views.
Background and challenges to implementation: Online media is a cost effective means to promote a social cause and it can be leveraged to increase the participation of audience especially youths. Indian Health Ministry launched a 60 Day Tobacco Free Youth Campaign to empower youth against tobacco use. The campaign focused on awareness raising, promotion of tobacco free educational institutions and tobacco free villages, strengthening the tobacco control acts and enforcement and social media engagement. In todays scenario in order to involve youth, visibility on internet medium plays an important as internet is becoming a battle ground for pro tobacco and anti tobacco advocates.
Conclusions: In today's scenario, traditional media are not very effective, and the internet should be leveraged to reach out to youths. There should be more youth-focused

campaigns on social media with the involvement of social media influencers, as youth are spending a lot of time on social media.

SOA17-691-21 Decoding public perception: Knowledge, attitudes, and practices on WHO FCTC Articles 9 and 10 in India

D. Walia,[1] S. Goel,[1] C. Goel,[1] [1]Post Graduate Institute of Medical Education and Research, Chandigarh, Department of Community Medicine and School for Public Health, Chandigarh, India
e-mail: dikshawalia05@gmail.com

Background: Tobacco use kills over 8 million people each year, and India is one of the most affected as a top producer and consumer. Despite robust tobacco control policies, gaps persist, challenging effective implementation. The WHO FCTC Articles 9 and 10 emphasize the regulation of tobacco product contents, emissions, and disclosures to strengthen global tobacco control efforts. Limited research exists on the Indian population's knowledge, attitudes, and practices (KAP) regarding these provisions. This study assesses KAP to provide insights for improving awareness and compliance with these regulations.
Design/Methods: A cross-sectional study was conducted in September 2024 among individuals aged 18 years and above across India. Data were collected using a structured, pre-tested online questionnaire, distributed via Google Forms. The questionnaire assessed participants' demographic characteristics, knowledge, attitudes, and practices related to the regulation of tobacco product contents and disclosures. Descriptive statistics were used to summarize the data, while associations between variables were analyzed using chi-square tests and logistic regression.
Results: The study included 106 participants, mostly aged 21–40 years (68.9%), with an equal gender split (53.8% male, 46.2% female) and 66% holding postgraduate qualifications. Awareness of WHO FCTC Articles 9 and 10 was reported by 54.7% and 56.6%, respectively. Gender showed no significant association with knowledge ($p = 0.808$) or attitudes ($p = 0.148$), though females had slightly more positive attitudes (91.8%). Age significantly influenced knowledge ($p = 0.049$) and attitudes ($p = 0.005$), with younger participants (21–40 years) showing better attitudes (89%) but moderate knowledge (63% poor). Tobacco control experience strongly impacted knowledge ($p = 0.003$), with active professionals demonstrating higher levels.
Conclusions: The findings reveal strong support for tobacco regulation, transparency, and international collaboration, alongside gaps in knowledge, particularly among younger individuals. Targeted education and robust implementation of WHO FCTC Articles 9 and 10 are crucial for addressing these challenges.

SOA17-693-21 Data-driven regulation: Prioritising hazardous constituents in smokeless tobacco in India

C. Goel,[1] D. Walia,[1] S. Goel,[1] [1]Postgraduate Institute of Medical Education and Research, Department of Community Medicine and School of Public Health, Chandigarh, India
e-mail: g.chirag@hotmail.com

Background: Smokeless tobacco (SLT) use is highly prevalent in India, posing a significant public health threat. This study aimed to develop a framework for prioritizing hazardous SLT constituents based on toxicity, attractiveness, and addictiveness to inform regulatory policies
Design/Methods: A comprehensive database of SLT constituents was compiled through a literature review (2005-2024) adhering to PRISMA guidelines, encompassing PubMed, Scopus, and Web of Science databases. The review integrated recommendations from the WHO Study Group on Tobacco Product Regulation, IARC monographs, and the US FDA's list of harmful and potentially harmful constituents.
A multidisciplinary expert panel (n=24) evaluated 120 identified constituents using a structured digital evaluation form and a 10-point Likert scale. Constituent prioritization was conducted using the Analytic Hierarchy Process, equally weighting toxicity, addictiveness, and attractiveness criteria.
Results: The analysis identified over 120 hazardous SLT constituents, including 65 classified as carcinogenic by the IARC (5 Group 1, 10 Group 2A, and 24 Group 2B). Nicotine emerged as the highest priority constituent (priority vector = 0.218), followed by tobacco-specific nitrosamines NNN (0.187) and NNK (0.167), and heavy metals lead (0.165), cadmium (0.162), and arsenic (0.158). Strong inter-rater agreement was observed across all criteria (Kendall's $W = 0.83$, $p < 0.001$), with a particularly high consensus for toxicity assessments ($W = 0.88$).
Background and challenges to implementation: Smokeless tobacco (SLT) use is highly prevalent in India, posing a significant public health threat. This study aimed to develop a framework for prioritizing hazardous SLT constituents based on toxicity, attractiveness, and addictiveness to inform regulatory policies.
Intervention or response: A comprehensive database of SLT constituents was compiled through a literature review (2005-2024) adhering to PRISMA guidelines, encompassing PubMed, Scopus, and Web of Science databases. The review integrated recommendations from the WHO Study Group on Tobacco Product Regulation, IARC monographs, and the US FDA's list of harmful and potentially harmful constituents.
A multidisciplinary expert panel (n=24) evaluated 120 identified constituents using a structured digital evaluation form and a 10-point Likert scale.
Constituent prioritization was conducted using the Analytic Hierarchy Process, equally weighting toxicity, addictiveness, and attractiveness criteria.

Conclusions: This evidence-based prioritization framework provides a crucial tool for advancing SLT regulation in India by identifying key constituents requiring monitoring and control. Policy recommendations include mandatory disclosure of priority chemicals on product packaging, establishing maximum permissible limits for priority toxicants, developing a network of accredited testing laboratories, and implementing standardized testing protocols aligned with WHO FCTC Articles 9 and 10. These measures aim to mitigate SLT-related morbidity and mortality through enhanced tobacco product regulation

SOA17-694-21 Restoring FCTC shadow reporting with the Global Tobacco Control Progress Hub

L. Hagen,[1,2] [1]ASH Canada, HQ, Edmonton, Canada, [2]University of Alberta, School of Public Health, Edmonton, Canada
e-mail: hagen@ash.ca

Background and challenges to implementation: Civil society engagement is a cornerstone of the WHO Framework Convention on Tobacco Control (FCTC), as described in Article 4 of the treaty. Key to this engagement is the preparation and submission of FCTC "shadow reports" by civil society organizations (CSOs). Shadow reports provide an independent analysis of FCTC implementation and adherence to supplement national self-reports from participating countries.
Intervention or response: The Global Tobacco Control Progress Hub (www.globalprogresshub.com) was created in 2023 by ASH Canada and the Institute for Global Tobacco Control at Johns Hopkins Bloomberg School of Public Health. The purpose of this robust open-access data analytics platform is to allow all tobacco control stakeholders to participate in FCTC monitoring, surveillance and reporting. The platform contains five dashboards that portray visualized treaty implementation data representing over 180 countries and over 300 performance indicators spanning 14 years of reporting. One of the core functions of the platform is to support the creation of FCTC shadow reports using the datasets and visuals to report on national treaty implementation. CSOs can prepare national FCTC shadow reports with a user-friendly template developed by ASH Canada.
Results/Impact: Over 35 CSOs from as many countries have produced national FCTC shadow reports using the platform since 2023. Most of these CSOs are from low- and middle-income countries. The total population represented by these reports is 2.7 billion people, or one-third of the global population. ASH Canada recently used the platform to produce a shadow report on SDG Target 3.a (Global FCTC implementation). We will present results and findings from the shadow reporting effort and its potential impact on FCTC implementation.
Conclusions: The Global Tobacco Control Progress Hub has helped restore FCTC shadow reporting by civil society organizations. Independent surveillance and reporting can help improve treaty implementation and government accountability regarding FCTC adherence and execution.

SOA17-695-21 Innovative financing for sustaining tobacco control in low resource settings in the state of Himachal Pradesh, India

G. Chauhan,[1] [1]National Health Mission, Department of Health, Himachal Pradesh (Shimla), India
e-mail: drgopal7475@yahoo.co.in

Background and challenges to implementation: Himachal Pradesh, a north Indian State with a population of about 7 million, has made substantial progress tobacco control in last 15 years. Tobacco use has decreased from 22% to 11.6%, and second hand smoke exposure in homes has dropped from 82.5% to 19.5% between 2010 and 2024 (GATS & State Surveillance System).
Notably, the state has achieved the lowest tobacco use (1.1%) among youth aged 13-15 across all Indian states as per GYTS-4. With the ambitious goal of reducing adult tobacco use to below 10% by 2025 and below 5% by 2030, Himachal Pradesh is working toward achieving Tobacco Endgame.
This study highlights the innovative financing mechanisms to sustain Tobacco Control in Himachal Pradesh since 2010.
Intervention or response: Tobacco control began as a collaborative effort between the Government and NGOs in 2007-08 in the State. The State, District, and Sub-District teams were designated for enforcement and monitoring of tobacco control policies.
The key innovation remained to use the funds collected as fine (for violating tobacco control law) for financing tobacco control initiatives.
Other significant measures include the ban on Electronic Cigarette, adherence to Article 5.3 of FCTC, Tobacco Vendor Licensing Act of 2016, strengthening tobacco cessation centres, Tobacco-free educational institutions and Panchayats (village cluster) scheme.
Results/Impact: The funds collected from tobacco-related violations, approximately 1 Crore INR (115,000 USD) annually are used for awareness, capacity building, and enforcement activities to strengthen tobacco control in the state (*Figure 1*).
Himachal Pradesh achieved "Smoke-free State" status in July 2013 and adult tobacco use has reduced by > 40% in last 15 years.
Conclusions: Innovative financing for tobacco control is essential for sustaining tobacco control particularly in resource-limited settings. This model provides a pos-

sible solution for the ongoing fight against tobacco use. Himachal Pradesh's experience can be replicated in other similar settings.

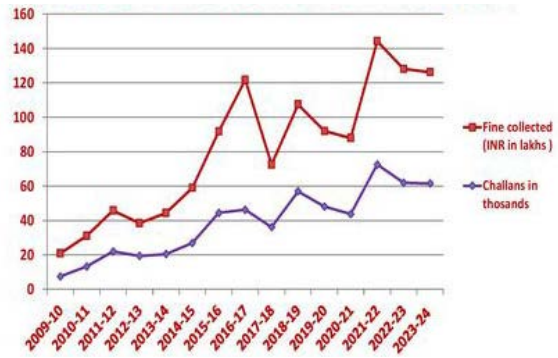


Figure 1. Number of persons fined (challans) for tobacco related volations and funds (INR collected as fine in the State of Himachal Pradesh from 2009 to 2024.

E-POSTER SESSION (EP)

EP46 Asymptomatic TB - reports from the field

EP46-1137-21 Asymptomatic TB: A new challenge

M. Tadolini,[1,2] B. Granozzi,[2] [1]Alma Mater Studiorum University of Bologna, Medical and Surgical Sciences, B ologna, Italy, [2]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Unit of Infectious Diseases, Bologna, Italy
e-mail: mtadolini@hotmail.com

Background: Asymptomatic tuberculosis (aTB) is a recent definition introduced by the World Health Organization, indicating a person with TB disease who did not report symptoms suggestive of TB during screening. One important implication of people with aTB is that they do not seek healthcare as they do not feel sick. Unless active case finding with tools other than symptoms screening is used, diagnosis of such individuals would be missed and this may fuel the TB epidemic as subjects with aTB can contribute substantively to TB transmission, even if they have no cough. We describe the features of bacteriologically confirmed aTB cases diagnosed in a referral centre in Italy.
Design/Methods: Monocentric, retrospective, observational study at Infectious Diseases Unit, IRCCS Azienda Ospedaliero-Universitaria of Bologna, Italy. Inclusion criteria: age ≥15 years old, bacteriologically confirmed TB (positive Xpert MTB/RIF and/or culture), no TB suggestive symptoms reported at the time of screening. Study period: January 2013-December 2024.
Results: We identified 82 individuals with bacteriologically confirmed asymptomatic TB in the study period. Thirty-two (39.1%) individuals were identified during diagnostic workup or follow up due to other reasons (i.e. trauma, cancers) while 50 (60.9%) subjects were detected during screening in high-risk groups (i.e. close contacts, migrants, health workers, candidates to biologics). All subjects underwent chest HRCT, revealing cavities in 30.5.% cases.
All cases were bacteriologically confirmed (61 Rif-S and 2 Rif-R). Out of 63 pulmonary TB cases, 13 (20.6%) had positive smear microscopy, indicating high bacillary load and contagiousness despite lack of symptoms. All individuals started anti-TB treatment, with a treatment success rate of 76.8%.
Conclusions: TB disease can present with advanced radiological findings and high bacillary load also in individuals not reporting symptoms. It is crucial not to rule out TB solely based on the absence of symptoms, especially in high-risk groups.

EP46-1138-21 Effectiveness of hospital-based active case finding using chest X-rays for early detection of asymptomatic TB in Chiangrai, Thailand

W. Imsanguan,[1] I. Simapichet,[1] [1]Chiangrai Prachanukroh hospital, Internal medicine, Chiangrai, Thailand

Background: Chiangrai, one of Thailand's provinces with a high tuberculosis (TB) burden and a significant mortality rate associated with TB treatment outcomes. Notably, many patients present to hospital with advanced disease. Active case finding (ACF) is a crucial strategy for improving outcomes by detecting cases earlier, before they progress to severe disease.
This study aims to evaluate a hospital-based ACF strategy using Chest X-rays (CXR) for TB detection and to classify TB types according to the WHO's new definitions introduced in 2024.
Design/Methods: A retrospective analysis of the TB registry data was conducted, categorizing TB detection using CXR into seven groups based on systematic screening methods:
1. Passive Case Finding (PCF): Walk-in patients with TB symptoms.
2. Active Case Finding (ACF) Methods:
   Outpatient department (OPD) visits for other diseases
   Inpatient admission
   Preoperative evaluation
   Contact investigation
   Mobile CXR screening
   Health checkup

Descriptive analysis was performed to examine these categories.
Results: A total of 320 pulmonary TB cases registered in 2024 were reviewed. Among these, 117 cases (36.6%) presented with TB symptoms (PCF), while 203 cases (63.4%) were detected without reported TB symptoms through systematic ACF methods.
Among all cases, 141 (44%) were asymptomatic TB (aTB), with detection settings including:
   30.5% during OPD visits for other diseases
   24.8% during inpatient admission
   14.2% during preoperative evaluation
   The remaining 30.5% shown in a picture

Of the 141 aTB cases:
   53 (37.6%): Bacteriologically confirmed (aTB-C).
   88 (62.4%): Bacteriologically unconfirmed (aTB-U).

	Bacteriologically confirmed	Bacteriologically unconfirmed
Symptomatic	123	56
Asymptomatic	53	88

320 pulmonary TB cases registered in 2024 at Chiangrai Hospital, Thailand

Conclusions: This study highlights the effectiveness of a hospital-based ACF strategy using CXR for early detection of TB. A significant proportion of TB cases were identified in patients who did not report TB symptoms and more than one-third of aTB cases were bacteriologically confirmed TB (aTB-C), underlining the importance of ACF among asymptomatic patients. These findings reinforce the value of Hospital base systematic ACF strategies in high-burden countries.

EP46-1139-21 Enhancing asymptomatic TB detection through active case finding initiatives using PDX machines and mobile X-ray vans in Lagos, Nigeria

T. Osatuyi,[1] E. Chukwu,[2] M. Sheshi,[2] B. Odume,[2] O. Udunze,[1] O. Sokoya,[3] [1]KNCV Nigeria, Tuberculosis, Lagos, Nigeria, [2]KNCV Nigeria, Tuberculosis, Abuja, Nigeria, [3]Lagos State Ministry of health, Directorate of Disease Control, Lagos, Nigeria
e-mail: otaiwo@kncvnigeria.org

Background and challenges to implementation: Nigeria is first in Africa in Tuberculosis (TB) burden with a 32% gap in TB case notification. Lagos accounts for estimated 10% of Nigeria's TB burden. Lagos TB Programme placed on treatment: 18,546 and 19,052 people affected by TB in 2023 and 2024 respectively.
However, there have been different innovative approaches and strategies deployed to reduce this notification gap from Y2019-Y2024 and to enhance accessibility and coverage of TB services.
Intervention or response: Portable digital X-ray machines and 3 Easy DR mobile trucks are implementing ACF mobile clinics across 20 LGAs in Lagos, where urban poor, migrants, skilled workers, factory workers, artisans and other vulnerable people are concentrated. The mobile teams are equipped with digital chest X-ray augmented with computer-aided detection (CAD) technology. Assigned staff conducted parallel screening in attendees for any TB symptom and CXR and requested sputum samples from those with presumptive TB for diagnostic evaluation.
Results/Impact: Between 2023 and 2024, both innovative AI enabled equipment screened 206,599 attendees using CXR CAD, in which 24,386 cases were flagged as presumptive TB with both CAD and symptom screening. After evaluating CXR findings, clinical presentation, and bacteriological results, 8,282 people were diagnosed with TB among which 3,327(40%) of them were bacteriologically confirmed (BC). Of the 8,282 people with TB, 1,242 (15%) had no TB symptoms. A
mong these diagnosed TB cases with no symptoms, 348(28%) were BC. The findings revealed the high occurrence of subclinical TB and the efficacy of CXR in detecting it.

Conclusions: Asymptomatic TB cases often go undetected due to a lack of symptoms, delaying diagnosis and increasing the risk of transmission. Implementing TB screening using chest X-rays, with or without computer-aided detection, in mobile clinics can enhance early detection, including subclinical cases by reaching communities. This proactive strategy is essential for achieving END TB targets and lowering the national TB burden.

EP46-1140-21 Prevalence and factors associated with asymptomatic pulmonary TB: A secondary data analysis of Uganda TB prevalence survey conducted in 2014-2015

A. Burua,[1,2,3] B. Kirenga,[3] D. Lukoye,[4] F. Cobelens,[5] S. Hermans,[5,6] [1]Ministry of Health, National tuberculosis and leprosy control program, Kampala, Uganda, [2]Amsterdam University Medical Center, Global Health, Kampala, Uganda, [3]Makerere University College of Health Sciences, Makerere University Lung Institute, Kampala, Uganda, [4]United States Centers for Disease Control and Prevention (CDC) Uganda, TB and HIV, Kampala, Uganda, [5]Amsterdam University Medical Centers, location University of Amsterdam, Global Health, Amsterdam, Netherlands, [6]Amsterdam University Medical Centers, location University of Amsterdam, Centre for Tropical Medicine and Travel Medicine, Department of Infectious Diseases, Amsterdam, Netherlands
e-mail: buruaaldo@gmail.com

Background: Nearly half of people with tuberculosis in the population are estimated to have asymptomatic TB but are often missed because most TB screening programs rely on symptoms to initiate diagnostic evaluation. Early detection and treatment of asymptomatic TB can improve patient outcomes and halt transmission of TB.
We assessed the burden and factors associated with asymptomatic TB to inform strategies for early TB case detection, treatment, and control.
Design/Methods: We conducted secondary data analysis of the Uganda TB prevalence survey (2014-2015) and included for analysis bacteriologically confirmed TB cases by culture or Xpert MTB/RIF. We calculated the weighted prevalence of asymptomatic TB for three case definitions, namely, "no persistent cough for $\geq$ 2 weeks," "no cough of any duration," and "no TB symptoms," and performed multivariable logistic regression analysis to identify the associated factors.
Results: Among the 41,003 eligible participants included in the final analysis, 160 had bacteriologically confirmed TB. The overall TB prevalence was 392 cases (95% CI: 336, 458) per 100,000 population, while the prevalence of asymptomatic TB was 195 cases (156, 243), 120 cases (91, 158), and 65 cases (44, 94) per 100,000 population when defined as "no persistent cough for $\geq$2 weeks," "no cough of any duration," and "no TB symptoms," respectively.

Having asymptomatic TB, when defined as "no cough of any duration," compared to symptomatic TB was significantly associated with age ≥55 years, HIV infection, current smoking, and living in an urban setting.

Variable	Participants screened (n)	All TB cases (n)	Prevalence (Number of cases per 100,000 pop. 95% CI)	Asymptomatic TB (defined as "no persistent cough for 2 weeks or more")	Prevalence (Number of cases per 100,000 pop. 95% CI)	Asymptomatic TB (defined as "no cough of any duration")	Prevalence (Number of cases per 100,000 pop. 95% CI)	Asymptomatic TB (defined as "no any TB symptoms")	Prevalence (Number of cases per 100,000 pop, 95% CI)
Total (N)	41,003	160	392 (336, 458)	80 (50%)	195 (156, 243)	50 (31%)	120 (91, 158)	27 (17%)	65 (44, 94)
Male	17,405	119	670 (560, 803)	62	346 (270, 445)	39	214 (156, 293)	22	120 (79, 183)
Female	23,598	41	171 (126, 233)	18	74 (47, 118)	11	45 (25, 81)	5	20 (8, 49)
15-34 years	25,236	73	294 (234, 371)	34	134 (96, 188)	21	81 (53, 124)	12	45 (26, 80)
35-54 years	11,081	60	544 (422, 701)	32	292 (206, 413)	17	155 (96, 249)	10	91 (49, 170)
> 55 years	4,686	27	575 (394, 838)	14	300 (178, 507)	12	254 (144, 447)	5	107 (44, 257)
HIV positive	420	39	9,172 (6761, 12330)	22	5,113 (3384, 7657)	17	3,930 (2451, 6244)	7	1,614 (770, 3351)
HIV negative	3,925	106	2,708 (2241, 3270)	49	1,244 (940, 1645)	28	693 (478, 1003)	16	393 (241, 641)
Unknown	36,658	15	40 (24, 67)	9	24 (13, 47)	5	14 (6, 33)	4	11 (4, 30)

Conclusions: Asymptomatic TB contributed to 17%-50% of the TB burden in the general population depending on the definition used, and was associated with older age ≥ 55 years, HIV infection and living in an urban setting. We recommend scaling up non-symptoms-based strategies such as digital X-ray and rapid molecular tests for TB screening among high risk populations for early TB case detection and treatment initiation.

EP46-1141-21 Breaking the symptom barrier in ACF: Targeting high risk vulnerabilities for efficient asymptomatic TB detection in India

A. Shekhawat,[1] A. Basu,[2] S. Shrivastava,[1] M. Singh,[1]
[1]William J Clinton Foundation (WJCF), TB, Delhi, India, [2]William J Clinton Foundation (WJCF), Communications, Delhi, India
e-mail: ashekhawat@wjcf.in

Background and challenges to implementation: National TB Prevalence Survey in India (2019–21) highlighted that 42.6% of total TB cases that were asymptomatic would have been missed without chest X-rays (CXR). Most screening algorithms begin with symptom screening, thereby inadvertently excluding asymptomatic cases. Furthermore, mobilizing asymptomatic individuals remains challenging due to a lack of tailored outreach strategies.
Intervention or response: William J Clinton Foundation (WJCF), through The Global Fund's C19RM grant and under the aegis of the Central TB Division (Government of India), implemented Integrated ACF camps utilizing Artificial Intelligence (AI) enabled ultraportable X-Ray machines across 11 Indian states. WJCF adopted a parallel screening approach that also offered CXR to Key & vulnerable populations (KVPs), including asymptomatic individuals. These KVPs were identified by leveraging existing public health databases/records, contextual grassroot intelligence, engagement of frontline health cadres, and community influencers. Targeted beneficiaries received customised Information, Education, and Communication (IEC) materials and „Priority camp tickets" that encouraged and incentivized participation.
Results/Impact: The data analysed is for the period April 2023 – February 2025. Among over 600,000 asymptomatic individuals screened from vulnerable cohorts, 1,044 bacteriologically confirmed TB cases were identified. Certain risk factors demonstrated notably higher detection efficiencies: individuals with BMI <18.5 had the lowest Number Needed to Screen (NNS = 200), followed by tobacco users (NNS = 415), and alcohol users (NNS = 452).

Vulnerability / Risk-Factor$	Total Asymptomatic TB confirmations, % of total Confirmation	NNS* (Bacteriologically Confirmed)	NNT# (NAAT)	NNT (Smear Microscopy)
BMI Score <18.5	423, 41%	200	21	41
Tobacco User	378, 36%	415	29	64
Alcohol User	122, 12%	452	31	107
Contact person	103, 10%	507	28	88
Diabetes (Self-Reported)	130, 12%	657	49	224

$ The cohorts only include asymptomatic beneficiaries
*NNS – Total number to be screened for 1 TB confirmation
#NNT – Total number to be tested for 1 TB confirmation

Conclusions: For geographies with high proportions of vulnerable populations and constrained resources, robust mobilisation strategies focusing on high-yield vulnerabilities are critical. WJCF's targeted ACF algorithm effectively identifies and prioritises groups with the highest risk, aligning with WHO's Global TB report 2024 recommendations. This approach significantly enhances detection rates and early diagnosis of asymptomatic TB.

EP46-1142-21 Diagnosis of asymptomatic TB during the nationwide hundred days campaign and the strategies for additional detection: Evidence from West Bengal, India

A. Dey,[1] D. Deka,[1] B. Sengupta,[1] S.K. Roy,[2] T.K. Saha,[2] U.B. Singh,[3] S. Chandra,[1] R. Basu,[1] P.K. Das,[2] R. Biswas,[1] R. Mukherjee,[2] [1]Government of India-WHO Country office for India-Technical Support Network, National TB Elimination Program, New Delhi, India, [2]Government of West Bengal, Department of Health and Family Welfare, Kolkata, India, [3]Government of India, Department of Health and Family Welfare, New Delhi, India
e-mail: drabhijitdey@gmail.com

Background: On December 2024, India launched an innovative nationwide campaign called 100 days intensified TB campaign to find the missing person with TB (PwTB) in the community. This is an effort towards reaching out to those vulnerable individuals (undernourished, close contacts of PwTB, people with diabetes, smokers, alcoholics) who by virtue of having these conditions/situations could be having active TB disease with or without classical symptom of Tuberculosis. All mapped vulnerable population were initially screened using 10 symptoms of TB. In the next step all asymptomatic vulnerable population were screened using Chest X-ray (CXR).
During this campaign India as well as the State of West Bengal could achieve additional TB case detection including asymptomatic TB.
Design/Methods: This is an observational study. A secondary analysis was conducted to calculate the yields & outputs of asymptomatic TB case finding strategies. The study also explores the gaps in the strategies if there was any.

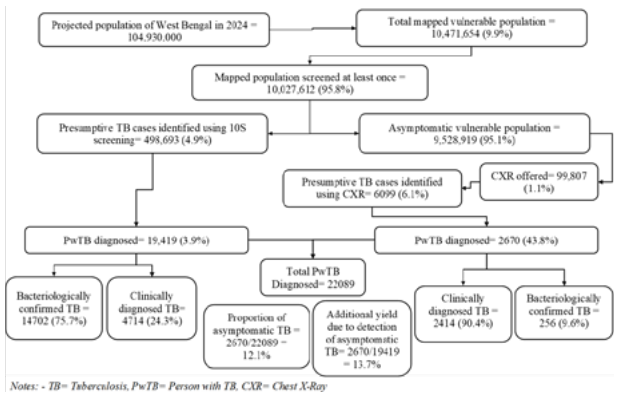

Figure 1. Flowchart depicting the number and percentage of participants at different stages of 100 days intensified TB campaign in West Bengal during Dec '24 - Mar '25

Results: A total of 2670 PwTB detected after evaluation of 6099 asymptomatic person having abnormal CXR. The TB diagnostic yield was 43.8%. On the other hand, 19,419 PwTB diagnosed through symptom screening. Asymptomatic TB detection strategies gave an additional yield of 13.7% (2670/19419). Among the eligible vulnerable population, 1.05% were offered CXR during the campaign period. Mean age of asymptomatic PwTB was 46.5 yrs (SD=18.4). 67.1% were male, 5.8% were 60 yrs or above, 11% were smoker. 60.2% was pulmonary TB & 39.8 % Extrapulmonary TB. Among the Extrapulmonary TB, majorities (82.1%) was pleural TB. 9.6% asymptomatic PwTB was bacteriologically confirmed. *(Fig.1)*
Conclusions: 100 days campaign was fruitful in terms of additional TB case detection including asymptomatic TB cases in West Bengal. With provision of a greater number of X-ray machines, especially portable X-ray suitable for hard-to-reach areas, a greater number of cases could be detected through such campaign.

EP46-1143-21 Tongue swab qPCR for asymptomatic TB screening: A high-accuracy alternative to sputum RMT and AI-based CXR in the general population

F. Sun,[1] J. Chen,[1] J. Li,[2] G. Sui,[3] Y. Li,[1] Y. Miao,[4] S. Ge,[1] W. Zhang,[1] [1]Huashan Hospital, Shanghai Medical College, Fudan University, Infectious Diseases, Shanghai, China, [2]Guizhou Center for Disease Control and prevention, Infectious Diseases, Guiyang, China, [3]National Medical Center for Infectious Diseases, Infectious Diseases, Shanghai, China, [4]National Medical Center for Infectious Diseases, Medical Research, Shanghai, China
e-mail: yang.li@nmcid.org.cn

Background: Tuberculosis (TB) remains a leading global cause of infectious disease-related mortality, despite persistent diagnostic challenges. Tongue swabs quantitative PCR (qPCR) are gaining attention as a potential alternative to sputum-based methods and chest radiograph (CXR), though its diagnostic capability and limitations are still under investigation.
This study aimed to evaluate and compare the diagnostic accuracy of tongue swab and AI-based CXR screening in a general population within a high-TB-burden district in Guizhou, China.
Design/Methods: Two screening modalities of AI-based CXR and tongue swab qPCR were conducted among 1,502 general residents in Guizhou Province. Individuals showing any imaging abnormalities or positive tongue swab qPCR results were considered screening positive and underwent confirmatory testing using standard sputum qPCR.
Results: Among 1,502 participants, 53.2% were female, and median age was 52 years. Prevalent TB was identified in four cases, all of which were asymptomatic. Tongue swab screening demonstrated a high diagnostic accuracy of 99.87% compared to standard sputum qPCR, detecting three TB cases (3/4, sensitivity 75.00%; 1495/1497, specificity 99.93%), with one of four cases being missed by AI-

based CXR. The number needed to test (NNT) one TB case was 1.3 (4/3) for tongue swab screening, compared to 38 (76/2) for AI-based CXR. AI-based CXR supplementation detected one additional TB cases (2/4, sensitivity 50.00%; 1424/1498, specificity 95.06%) that was undiagnosed by tongue swab.
Conclusions: AI-based CXR missed 50% of these asymptomatic cases. Our findings provide critical insights into the potential of tongue swab-based screening, highlighting its diagnostic accuracy and utility, particularly in asymptomatic populations. Further validation in diverse populations is warranted.

EP46-1144-21 Bio-phenotyping undetected TB: Is asymptomatic TB infectious and what is the role of chest radiography?

A.J. Scott,[1,2] T. Perumal,[1,2] S. Oelofse,[1,2] J. Swanepoel,[1,2] S. Jaumdally,[1,2] P. Gina,[1,2] M. Masikati,[1] A. Esmail,[1,2] K. Dheda,[1,2,3] [1]University of Cape Town, Centre for Lung Infection and Immunity, Division of Pulmonology, Department of Medicine, Cape Town, South Africa, [2]University of Cape Town, South African MRC/UCT Centre for the Study of Antimicrobial Resistance, Cape Town, South Africa, [3]London School of Hygiene and Tropical Medicine, Department of Immunology and Infection, Faculty of Infectious and Tropical Diseases, London, United Kingdom of Great Britain and Northern Ireland
e-mail: alex.scott@uct.ac.za

Background: Asymptomatic tuberculosis (TB) represents approximately half of the global TB burden. However, data describing this disease state is limited, including whether these individuals are probably infectious. We aimed to bio-phenotype asymptomatic TB during community-based active case-finding (ACF).
Design/Methods: Individuals with microbiologically confirmed TB (sputum Xpert MTB/RIF Ultra and/or culture positivity), recruited from three large-scale, multicentre, community-based ACF studies, were included. Clinical, microbiological, and radiological data obtained from asymptomatic TB were compared to symptomatic TB. A subset of participants (n=100) underwent fluorodeoxyglucose-positron-emission-tomography-computed-tomography (PET-CT), of which 63/100 (63.0%) were asymptomatic. Chest X-rays (CXRs) were analysed by two expert human readers and computer-aided detection (CAD: CAD4TB v7 and qXR v4.3). Performance of the human reader and CAD to detect TB-related lung abnormalities were evaluated (PET-CT was the radiological reference standard). Probable infectiousness was defined as smear positivity and/or cavitary disease and/or cough aerosol-sampling (CASS) positivity (quantification of culture-positive <5µm cough-aerosol particles).
Results: A total of 17,985 individuals were rapidly questionnaire-screened, of which 7,407 (41.2%) screened positive and were enrolled to undergo diagnostic investigation. 388/7,407 (5.2%) had microbiologically confirmed TB. 153/388 (39.4%) had asymptomatic TB, of whom 35/153 (22.9%) were smear-positive and 42/153 (27.5%) had cavitary disease on CXR. Of the 63 asymptomatic persons who had PET-CT, 36/63 (57.1%) had cavitation of which 17/63 (26.9%) were missed on CXR. CXRs were more frequently reported as 'normal' in asymptomatic TB versus symptomatic TB (21/63 [33.3] vs 3/37 [8.1]; p=0.012). CAD (qXR v4.3) had an area-under-the-curve (AUC) of 0.81 (0.73-0.88) in detecting cavitary disease, but performed sub-optimally in asymptomatic TB (AUC 0.76 [0.66-0.85]). Overall, 61/153 (39.9%) individuals with asymptomatic TB were probably infectious.
Conclusions: More than a third of individuals with asymptomatic TB were probably infectious, with over a quarter of cavitary disease missed on CXR. These data inform disease burden estimation and community-based ACF strategies in endemic settings.

EP46-1145-21 Evaluation of the PATHFAST TB LAM Ag assay in minimally symptomatic and subclinical TB cases and assessing its performance against established laboratory diagnostic tests

A. Kotzé,[1] S. Jaumdally,[1] C. van der Merwe,[1] A. Scott,[1] T. Perumal,[1] A. Esmail,[1] S. Oelofse,[1] M. Tomasicchio,[1] A. Pooran,[1] B. Reyneke,[1] K. Dheda,[1,2] [1]Centre for Lung Infection and Immunity, University of Cape Town Lung Institute, Department of Medicine, Cape Town, South Africa, [2]London School of Hygiene and Tropical Medicine, Department of Infection Biology, London, United Kingdom of Great Britain and Northern Ireland
e-mail: tahlia.perumal@uct.ac.za

Background: The current gold standard for the diagnosis of active TB is MGIT culture. However, this method poses many challenges; its performance is poor in paucibacillary cases, it can take several weeks to yield results, it requires a decent laboratory infrastructure with trained personnel, and contamination can nullify results. The PATHFAST TB LAM Ag assay uses chemiluminescence to measure lipoarabinomannan (LAM) in sputum samples. Compared to MGIT culture, the test requires a smaller sample volume (250µL), provides a quick turnaround time for results (<20 minutes) and a reasonably low limit of detection.
Design/Methods: Frozen sputum samples from 120 actively diagnosed individuals, positive for *M. tuberculosis* (GeneXpert and/or MGIT culture and/or smear microscopy) and 58 TB-negative controls were decontaminated, loaded onto the PATHFAST TB LAM Ag cartridges and run. Samples that were out of range were diluted 10-fold and re-run. The assay performance was evaluated against the other diagnostic outcomes and the impact of biobehavioural characteristics on the assay was assessed.

Results: Using culture as reference standard, the PATHFAST TB LAM Ag at a cut-off of 10 pg/mL displayed a sensitivity of 61.6% and specificity of 86.7%. Sensitivity was higher (77.5%) for sputum MGIT time-to-positivity ≤8 days. Overall, its sensitivity was superior to smear microscopy (61.6% vs 30.1%) while its specificity was better than the GeneXpert (86.7% vs 55.2%). PATHFAST LAM Ag correlated well with time-to-positivity (R=-0.49; p<0.0001), GeneXpert Ct (R=-0.63; p<0.0001) and smear grade (R=0.56; p=0.005). The median LAM Ag level was significantly higher in smokers (2.8 vs 1.2 pg/mL; p=0.01) and symptomatic individuals (9.9 v/s 1.4 pg/mL;p=0.0001) compared to asymptomatic individuals.
Conclusions: The PATHFAST TB LAM Ag assay provides a promising alternative to MGIT culture. The relatively good diagnostic performance in minimally symptomatic and subclinical TB cases highlights its potential as a tool in TB control, treatment evaluation and research in general.

EP46-1146-21 Improving diagnosis of asymptomatic TB among people living with HIV using digital chest X-ray with computer-aided detection in Nigeria

C. Ogbudebe,[1] B. Odume,[1] O. Chukwuogo,[1] E. Chukwu,[1] [1]KNCV Nigeria, Technical, Abuja, Nigeria
e-mail: cogbudebe@kncvnigeria.org

Background: Diagnosis of asymptomatic tuberculosis (TB) in people living with HIV (PLWH) can be challenging using conventional screening methods. It is estimated that approximately two-thirds of global TB transmission may be attributed to asymptomatic TB. The KNCV Nigeria implemented an active TB screening program among PLHIV using portable digital Chest X-ray (CXR) with artificial intelligence (AI) applied to a parallel TB screening algorithm, followed by TB diagnostic testing of presumptive with sequential confirmatory test algorithm. This study assessed the magnitude and characteristics of asymptomatic TB among PLHIV and the relative contributions of clinical diagnosis in its identification in Nigeria.
Design/Methods: This was a retrospective review of medical records of PLHIV screened for TB using a parallel method consisting of any TB symptoms (cough, fever, weight loss, or night sweats) and CXR-AI from October 2023 to September 2024 across 14 health facilities in 3 states. The primary outcome measure is the percentage of asymptomatic TB among PLHIV diagnosed with TB and the prevalence of asymptomatic TB by diagnostic method. Demographic and clinical classifications were compared between asymptomatic and symptomatic TB groups.
Results: Of 7,407 PLHIV screened for TB, 914 presumptive TB clients were identified. Among these, 499 (54.6%) had no TB symptoms (males: 35%, females: 65%). The median age was 34 (interquartile range: 20 – 50) years. The overall prevalence of TB among all presumptive was 39.7% (n = 363), including 206 (56.7%) asymptomatic TB and 157 (43.3%) active TB cases. The proportion of clinical diagnosis using CXR was significantly higher in the asymptomatic TB group than in the active TB group (97.6% vs. 73.2%; P = 0.034, OR = 0.75, 95% CI 0.55–1.02).
Conclusions: Asymptomatic TB contributed 56.7% of the TB burden in this study (40 per 100 presumptive). Diagnosis of such people would have been missed if symptom-only TB screening had been applied.

EP47 Enhancing TB care: Innovations in drug therapy, pharmacokinetics and treatment strategies

EP47-1147-21 Geographical representativeness of participants enrolled in randomised trials for TB treatment: A systematic review

I. Motta,[1,2] D. Wakerley,[1] I. Raza,[3] H. Esmail,[1] [1]University College London, Medical Reasearch Council, Clinical Trial Unit, London, United Kingdom of Great Britain and Northern Ireland, [2]Médecins Sans Frontières, Access Team, Geneva, Switzerland, [3]University College London, Institue of Global Health, London, United Kingdom of Great Britain and Northern Ireland
e-mail: i.motta@ucl.ac.uk

Background: Most people who develop TB disease each year are in 30 high TB burden countries, which accounted for 87% of the global total in 2023. Five countries accounted for 56% of the worldwide total: India (26%), Indonesia (10%), China (6.8%), the Philippines (6.8%) and Pakistan (6.3%).
Geographical representativeness in clinical trials is critical because the efficacy and safety profile of new interventions may vary regionally due to ethnic differences and circulating strains of *Mycobacteria*. Implementation also benefits from studies conducted in the same country or region. This systematic review aimed to evaluate TB treatment trial locations and to identify gaps in trial distributions.
Design/Methods: MEDLINE, Embase and the Cochrane Central Register of Controlled Trials databases were searched from January 1993 to February 2025 for randomised TB treatment trials reporting efficacy endpoints with at least six months of follow-up after the end of treatment.
Studies on TB infection, vaccines, alternative formulations of standard drugs, supplements, or adherence/system-related mechanisms were excluded. Only full-text studies in English were included. The review was registered in PROSPERO (CRD420251002693).
Results: We identified 7273 articles, of which 62 were suitable for analysis (6 had incomplete data). Thirty-one (50%), 26 (41.9%), 24 (38.7%), 13 (21%), 10 (16.1%) and 2 (3.2%) studies recruited participants from WHO South-East Asian, Western Pacific, African, American, European and Eastern Mediterranean Regions, respectively.
Only 6 (9.7%), 2 (3.2%) and 1 (1.6%) studies recruited from the Philippines, Pakistan and Indonesia. A total of 30128 participants were included; 7514 (24.9%), 3678 (12.2%) and 2688 (8.9%) were from India, South Africa and China, respectively.
Conclusions: Geographical distribution of participants in TB trials over the past three decades is only partially representative of people with TB. Countries like Indonesia, Pakistan and the Philippines are underrepresented. Greater efforts are needed to support late-stage clinical trials in these countries.

EP47-1148-21 Population pharmacokinetic modelling of standard- and high-dose rifampicin for TB preventive therapy in the 2R² randomised controlled trial

F. Gafar,[1,2,3] E.M. Svensson,[4,5] V. Yunivita,[3,6] F. Fregonese,[2] D. Fisher,[7] G.J. Fox,[8,9] T.A. Nguyen,[8,10] J. Johnston,[11,12] R. Long,[13] R.E. Aarnoutse,[5] R. Ruslami,[2,3,6] D. Menzies,[1,2,14,15] [1]Research Institute of the McGill University Health Centre, Centre for Outcomes Research and Evaluation, Respiratory Epidemiology and Clinical Research Unit, Montreal, Canada, [2]McGill University, McGill International TB Centre, Montreal, Canada, [3]Universitas Padjadjaran, Faculty of Medicine, Department of Biomedical Sciences, Division of Pharmacology and Therapy, Bandung, Indonesia, [4]Uppsala University, Department of Pharmacy, Uppsala, Sweden, [5]Radboud university medical center, Radboud Institute for Medical Innovation, Department of Pharmacy, Pharmacology and Toxicology, Nijmegen, Netherlands, [6]Universitas Padjadjaran, Research Center for Care and Control of Infectious Diseases, TB Working Group, Bandung, Indonesia, [7]University of Calgary, Cumming School of Medicine, Department of Medicine, Calgary, Canada, [8]The University of Sydney, Faculty of Medicine and Health, Sydney, Australia, [9]The Woolcock Institute of Medical Research, ,, Glebe, Australia, [10]The University of Sydney Vietnam Institute, ,, Ho Chi Minh City, Viet Nam, [11]University of British Columbia, Department of Medicine, Vancouver, Canada, [12]British Columbia Centre for Disease Control, Provincial TB Services, Vancouver, Canada, [13]University of Alberta, Department of Medicine, Faculty of Medicine and Dentistry, Edmonton, Canada, [14]McGill University, Faculty of Medicine and Health Sciences, Department of Epidemiology, Biostatistics and Occupational Health, Montreal, Canada, [15]McGill University Health Centre, Montreal Chest Institute, Montreal, Canada
e-mail: fajri.gafar@mail.mcgill.ca

Background: Recent studies suggest that high-dose rifampicin could improve tuberculosis treatment, raising interest in its potential to shorten tuberculosis preventive therapy (TPT) in individuals with tuberculosis infection. However, rifampicin pharmacokinetics in this population remain poorly characterized. We aimed to characterize rifampicin pharmacokinetics and identify factors contributing to variability in exposure to standard- and high-dose rifampicin for TPT.
Design/Methods: Intensive and sparse pharmacokinetic sub-studies were conducted in Indonesia, Canada, and Vietnam among participants in the 2R² randomized controlled trial (NCT03988933), which compared TPT regimens of two months of high-dose rifampicin (20 or 30 mg/kg/day) with four months of standard-dose rifampicin

(10 mg/kg/day) in adolescents and adults aged ≥10 years. Venous blood samples were collected after 2–8 weeks of treatment. Rifampicin pharmacokinetics were analyzed using nonlinear mixed-effects modeling in NONMEM.

Results: Among 1,368 trial participants, 460 (34%) underwent pharmacokinetic sampling (51 intensive and 409 sparse; median age, 41 years). Of these, 170 (37%), 148 (32%), and 142 (31%) were randomized to the 10, 20, and 30 mg/kg/day dose groups, respectively. A one-compartment model with saturable hepatic extraction and transit-compartment absorption best described rifampicin pharmacokinetics. All disposition parameters were allometrically scaled using fat-free mass. Rifampicin bioavailability was 24% (95%CI: 20-29%) and 15% (95%CI: 9-21%) lower in Canada and Vietnam, respectively, compared to Indonesia. No other significant covariates were identified. Visual predictive checks and nonparametric bootstrap analysis indicated good model performance. Rifampicin total exposure increased more than proportionally with dose (median 24-hour area under the concentration-time curve: 64, 154, and 248 mg*h/L for 10, 20, and 30 mg/kg/day), exceeding levels typically observed in individuals with tuberculosis disease.

Conclusions: High-dose rifampicin for TPT resulted in greater-than-proportional exposure due to non-linear clearance at higher doses, with between-country variability affecting exposure. These findings are important for determining exposure-response relationships and should be considered when designing future trials involving high-dose rifampicin.

EP47-1149-21 Is rifampin as part of fixed-dose combination tablet optimal for people in the with TB? A population pharmacokinetic study

F. Beraldi-Magalhaes,[1,2,3,4] C. Sanches,[5] S. Parker,[6] L. Garcia,[4,3] B. Carvalho,[3] M. Facchi,[7] M. Liz,[8] J. Roberts,[6] M. Cordeiro-Santos,[3,4] [1]Faculdades Pequeno Prínicipe, School of Medicine, Curitiba, Brazil, [2]State of Paraná Health Department, State Tuberculosis Program, Curitiba, Brazil, [3]Dr. Heitor Vieira Dourado Tropical Medicine Foundation, Post-Graduate Program, Manaus, Brazil, [4]University of the State of Amazonas, Post-Graduate Program, Manaus, Brazil, [5]Federal University of São João Del-Rey, Department of Pharmacy, Divinópolis, Brazil, [6]University of Queensland, Center for Clinical Research, Brisbane, Australia, [7]Federal University of Paraná, Department of Pharmacy, Curitiba, Brazil, [8]Federal Technological University of Paraná, Department of Chemistry and Biology, Curitiba, Brazil
e-mail: francisco.beraldi@gmail.com

Background: Tuberculosis (TB) patients admitted to intensive care units (ICU) have high mortality rates. It is uncertain whether the pharmacokinetics of first-line TB drugs in ICU patients are different from outpatients. This study aims to compare the pharmacokinetics of oral rifampin when administered as a fixed-dose combination tablet in TB patients in ICU versus TB outpatients.

Design/Methods: A prospective pharmacokinetic (PK) study was performed in Amazonas State, Brazil. Various socio-demographic, clinical and severity of disease data were collected to explain interpatient pharmacokinetic variability. Probability of target attainment (PTA) was determined using AUC > 34.4 and C_{max} > 8.2 values. Optimized dosing regimens were simulated at steady state.

Results: Five ICU and thirteen outpatients were enrolled. Pharmacokinetic parameter estimates are provided in Table 1. All pharmacokinetic parameters for ICU patients, except volume of distribution (V) and intercompartmental transfer rate constant from the central to the peripheral compartment (KCP), were significantly different to outpatients and were estimated separately in the model using selective execution statements. A two-compartment model with first-order absorption, linear elimination from the central compartment, central and peripheral V and first-order KCP (Δ -2*LL: -555.7; ΔAIC: -576.8) best described the data. The inclusion of total bilirubin and total body weight as a covariate with an allometric scaler on clearance resulted in a significant reduction of the log likelihood ratio (Δ -2*LL: -143.1; ΔAIC: -143.1) and an improvement of the model fit. Thus, the final equation was CLt = CL * (0.75/BILIRR) * (WEIGHT/60)**0.75. On PTA analysis, an AUC > 34.4mg.h/L was achieved by 65.6% of outpatients and 76.9% of ICU patients. None of patients achieved C_{max}>8.2mg/L on this research.

	ICU (n = 5)			Outpatients (n = 13)			P-value
Parameter	Mean (SD)	Median	%CV	Mean (SD)	Median	%CV	
CL/F (L/h)	1.5 (1.5)	0.427	97.8	5.7(4.1)	4.8	71.4	0.0016
V/F (L)	29.2(4.6)	31.3	15.9	32.6(11.7)	28.5	35.8	0.1734
Ka (h^{-1})	0.395(0.12)	0.368	31.8	0.426(0.11)	0.427	27.5	0.0002
KCP	0.655(0.239)	0.750	36.4	0.286(0.12)	0.299	82.4	0.6331
KPC	0.617(0.256)	0.562	41.5	0.063(0.17)	0.010	280.5	0.0004
F 1st dose	0.83(0.08)	0.83	9.7	0.88(0.08)	0.88	9.16	0.0140
F 2nd dose	0.80(0.04)	0.80	5.7	0.54(0.06)	0.52	11.1	0.0002

Table 1: Estimates of Rifampicin pharmacokinetic parameters for the final covariate model (CL, relative clearance; V, relative volume of distribution; Ka, absorption rate constant; F, bioavailability for the 1st and 2nd dose, respectively; KCP, first-order intercompartmental transfer rate constant from the central to the peripheral compartment; KPC, first-order intercompartmental transfer rate constant from the peripheral to the central compartment; SD, standard deviation; CV, coefficient of variation.)

Conclusions: Compared to outpatients, ICU patients displayed significantly different pharmacokinetics for an oral fixed-dose combination administration of rifampin. Total bilirubin and total body weight were important covariates influencing pharmacokinetic parameters.

EP47-1150-21 Could first-line anti-TB drugs in fixed-dose combination tablets be administered through a nasogastric tube? A pharmaceutical technology assay

F. Beraldi-Magalhaes,[1,2,3,4] A.C. Diniz,[5] A. David Meri,[6] A.E. Meri Junior,[5] C. Sanches,[5] A.J. Pereira Santinho Gomes,[5]
[1]Faculdades Pequeno Prínicipe, School of Medicine, Curitiba, Brazil, [2]State of Paraná Health Department, State Tuberculosis Program, Curitiba, Brazil, [3]University of the State of Amazonas, Post-Graduate Program, Manaus, Brazil, [4]Dr. Heitor Vieira Dourado Tropical Medicine Foundation, Post-Graduate Program, Manaus, Brazil, [5]Federal University of São João Del-Rey, Department of Pharmacy, Divinópolis, Brazil, [6]Santa Mônica Divinópolis Hospital Hapvida NotreDame Intermédica, Intensive Care, Divinópolis, Brazil
e-mail: francisco.beraldi@gmail.com

Background: Despite parenteral administration of first-line anti-TB drugs is recommended in ICU, it is unavailable in many high TB burden countries. Therefore, fixed-dose combination (FDC) tablets are crushed and delivered through a nasogastric tube (NGT). Modifying the original pharmaceutical form can alter pharmacokinetic properties, compromising therapeutic efficacy.
Thus, this study aims to evaluate factors influencing the administration of FDC tablets containing RHZE via NGT by a pharmaceutical technology assay.
Design/Methods: Weight and disintegration were tested according to pharmacopeia standards. Tablets were crushed and water dissolved up to suspension, delivered via NGT.
A factorial design Box-Behnken 3^3 (n=15) was used as experimental design to evaluate retention index. Three independent variables: tablet preparation, NGT size and infusion volume were analysed.
Immediate release tablets containing rifampicin (R) 150mg, isoniazid (H) 75mg, pyrazinamide (Z) 400mg, and ethambutol (E) 275mg were used. All elements were weighed at the beginning and at the end of two 20ml flushes. The first flush was used to rinse the accessories (beaker, spatula, syringe, and pestle).
Results: Average pill mass was 1248mg ± 17mg (SD = 1.4%; n=80). Tablets comprise 72% active compounds and 28% excipients, disintegration occurred within 4 minutes, confirming the expected behaviour of immediate-release coated tablets.
Statistical analysis revealed an average residue loss of 20.8% (5.7%-54.7%) and high standard deviation (±18.11%). Gauge and length of NGT were the variables with higher impact retaining tablet particles during the process of suspending and delivering.
Fragmented and pulverized tablets administered in FR 8 (100cm) or FR10 (120cm) presented the lower losses during the process, 5.7% and 10.4% respectively. Infusion volume (20ml, 30ml, 40ml) did not significantly influence the result.
Conclusions: Key factors minimizing losses during FDC tablets containing RHZE include tablet fragmentation and pulverization prior to a 5-minute dilution period; utilization of 8 FR (100cm) and 10 FR (120cm) NGT. Bioavailability was not evaluated.

EP47-1151-21 Cerebrospinal fluid penetration of pyrazinamide, levofloxacin and linezolid in people with pulmonary TB

J.M. Calderin Miranda,[1] C.M. Upton,[2] L. Wiesner,[1] S. Castel,[1] K.E. Dooley,[3] P. Denti,[1] J.A. Tornheim,[4]
[1]University of Cape Town, Department of Medicine, Cape Town, South Africa, [2]TASK, Infectious diseases, Cape Town, South Africa, [3]Vanderbilt University Medical Center, Division of Infectious Diseases, Nashville, United States of America, [4]Johns Hopkins University, Divisions of Infectious Diseases, Baltimore, United States of America
e-mail: cldjos001@myuct.ac.za

Background: Tuberculous meningitis (TBM) is the most severe form of tuberculosis (TB). TBM treatment guidelines are based on pulmonary TB regimens and overlook CNS drug penetration. We characterized CSF penetration of pyrazinamide, levofloxacin, and linezolid in pulmonary TB patients.
Design/Methods: This study included MDR-TB patients receiving WHO-recommended regimens for 24 weeks. Blood samples and a single CSF sample were collected at week 24 (±1 week) and quantified using validated LC-MS/MS assays.
Data were analysed using nonlinear mixed-effects modelling. Previously reported pharmacokinetic models from similar populations were used to fit plasma data. CSF concentrations were characterized by an effect compartment linked to plasma, estimating plasma-to-CSF equilibrium half-life ($T½_{plasma\text{-}CSF}$) and CSF-to-plasma ratio ($Ratio_{CSF\text{-}plasma}$), describing delay and extent of CSF equilibration relative to plasma at steady state.
Results: Data included 51 plasma and 12 CSF observations each for pyrazinamide and levofloxacin from 12 participants (50% with HIV), and 37 plasma and 9 CSF linezolid observations from 9 of them. The cohort had a median (min–max) age 45 (30–55) years, weight 52 (43–65) kg, and fat-free mass 44 (29–52) kg.
Pyrazinamide, levofloxacin, and linezolid CSF concentrations equilibrated with plasma with $T½_{plasma\text{-}CSF}$ of 0.46 h, 2.2 h, and 0.80 h, and $Ratio_{CSF\text{-}plasma}$ of 0.95, 0.55, and 0.38, respectively.
After adjusting for previously reported unbound plasma fractions (*fu*) (pyrazinamide: 0.93; levofloxacin and linezolid: 0.70), $Ratio_{CSF\text{-}plasma}$ increased to 1.02, 0.78, and 0.55, respectively. HIV status, antiretroviral therapy, or other covariates did not affect CSF penetration.

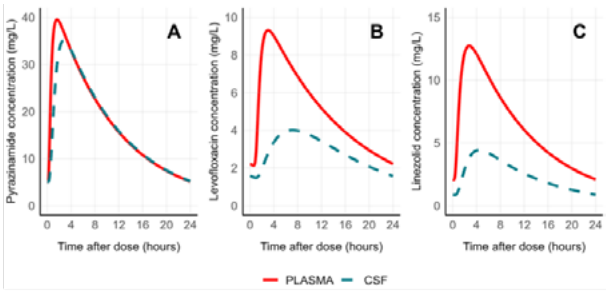

Figure. Simulated steady-state plasma and CSF concentration-time profiles for the typical individual in the cohort with a body weight of 52 kg and a fat-free mass of 44 kg: (A) Pyrazinamide, (B) Levofloxacin, and (C) Linezolid.

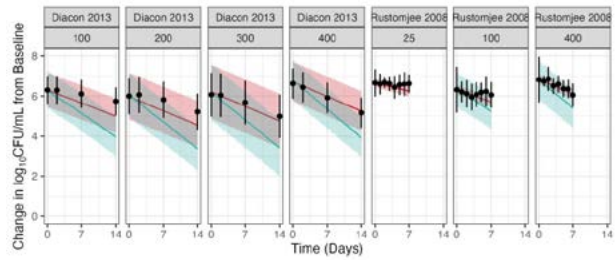
Conclusions: Pyrazinamide, levofloxacin, and linezolid CSF concentrations approached or exceeded their respective plasma *fu*, suggesting good CSF penetration and supporting further clinical evaluation in TBM. The CSF penetration observed in this study aligns with previous reports, including TBM cohorts, demonstrating that applying this methodology in small non-TBM cohorts can provide useful CSF drug penetration assessments for CNS infections.

EP47-1152-21 Improving phase 2a efficacy predictions through parent/metabolite analysis: Insights from bedaquiline

B. P. Solans,[1] E. Yang,[2] R. Savic,[2] [1]University of California San Francisco, Department of Bioengineering and Therapeutic Sciences, San Francisco, Spain, [2]University of California San Francisco, Department of Bioengineering and Therapeutic Sciences, San Francisco, United States of America
e-mail: belen.perezsolans@ucsf.edu

Background: Phase 2a tuberculosis trials typically use early bactericidal activity (EBA), defined as the decline in sputum CFU over 14 days, as the primary endpoint for testing drug efficacy as monotherapy. Better utilization of pre-clinical data to predict and prioritise drugs likely to succed can accelerate development and reduce costs. Many drugs have active metabolites, making it crucial to account for parent/metabolite ratios between species to characterize the true parent efficacy.
We showcase improved predictions using bedaquiline, leveraging pre-clinical in vivo pharmacokinetic (PK)-pharmacodynamic (PD) data and a model-based translational pharmacology approach.
Design/Methods: Mouse PK, PD and clinical PK models were compiled, including bedaquiline and its main metabolite M2. Mouse PK-PD models were built to derive an exposure–response relationship, assuming potency differences between bedaquiline and M2 equal to in vitro MIC values (1:8 bedaquiline:M2).
Translational prediction of clinical EBA studies were performed using refined mouse PK-PD relationships informed by clinical PK models.
Results: A PK model including bedaquiline and its metabolite was built, adequately predicting mouse data. Mouse efficacy was well described by a model including both entities, assuming 1:8 reduction in M2 potency compared to bedaquiline. A reduction in Emax and EC50 compared to the modelling of bedaquiline alone was observed (Emax = 0.254 vs 0.515 and EC50 = 0.12 vs 0.23). Predicted daily CFU decreases in the first 14 days of treatment were consistent with clinical observations, improving previous overoptimistic predictions[1].



Conclusions: Understanding metabolic pathways early in drug development is crucial, especially when metabolite(s) are active compounds. This improved understanding of metabolite activity enhances translation power, improving PKPD translations compared to using the parent drug alone. Assuming in-vivo potency mirrors in vitro MICs aids efficacy predictions.

EP47-1153-21 Pretomanid exposure is not increased by severely impaired renal function

J. Nedelman,[1] D. Hickman,[1] A. Lombardi,[1] M. Beumont,[1] E. Sun,[1] [1]TB Alliance, Research and Development, New York, United States of America
e-mail: maria.beumont@tballiance.org

Background: This Phase 1, open-label, single-dose study, was designed to investigate the safety and pharmacokinetics (PK) of pretomanid in participants with impaired renal function.[1]
Design/Methods: Part A included 6 participants with severe renal impairment (defined by eGFR), including 1 with end-stage renal disease not on dialysis (group 1), and 6 healthy controls matched by race, gender, age, and BMI (group 2);
Part B was planned to enroll participants with moderate and mild renal impairment only if Part A demonstrated at least a 50% increase in the mean pretomanid area under the plasma concentration-time curve (AUC) in group 1 compared to group 2.
The study was conducted at 2 investigational sites. All participants received a single oral dose of pretomanid 200 mg with a high-fat, high-calorie breakfast. Plasma PK was assessed 1 hour pre-dose and at 1, 2, 4, 5, 6, 8, 12, 16, 24, 36, 48, 72, and 96 hours post-dosing.

Results: Mean pretomanid AUC was not increased by >50% in participants with severe renal impairment relative to controls with normal renal function. All but one of the renally impaired participants had reduced pretomanid exposure relative to their matched controls. Mean Cmax was 1470 ng/mL in participants with renal impairment and 2173 ng/mL in healthy controls. Mean $AUC_{0-\infty}$ was 73.8 mg*hr/L in renally impaired participants and 88.7 mg*hr/L in the control group. Treatment was well tolerated, with few adverse events (AEs) and no serious AEs reported.

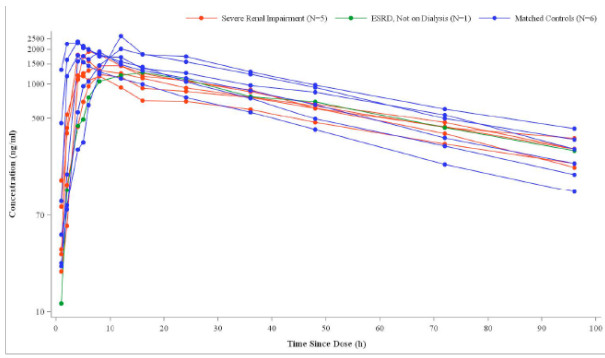


Figure. Pretomanid Plasma Concentrations Individual Time Curves.

Conclusions: Based on the PK results, the study monitoring committee concluded there was no need to proceed to Part B of the study. In conclusion, renal impairment does not increase pretomanid exposure.

EP47-1154-21 Effectiveness and safety of a shortened oral regimen for multi-drug-resistant/rifampicin-resistant in Peru

E. Herrera-Flores,[1,2] D. Vargas-Vásquez,[3,2] J. Cornejo-Garcia,[1,2] Z. Ruiz-Vargas,[4] F. Llanos-Tejada,[5] Z. Puyén-Guerra,[6] C. Figueroa-Benites,[7] D. Vela-Trejo,[2] M. Curisinche-Rojas,[8] M. Franke,[9] L. Lecca-Garcia,[10] V. Alarcon-Guizado,[11]
[1]Hospital Nacional Arzobispo Loayza, Neumología, Lima, Peru, [2]Dirección de Prevención y Control de Tuberculosis - MINSA, Unidad Técnica, Lima, Peru, [3]Hospital Nacional Hipolito Unanue, Neumologia, Lima, Peru, [4]Hospital María Auxiliadora, Neumologia, Lima, Peru, [5]Hospital Nacional Dos de Mayo, Neumologia, Lima, Peru, [6]Instituto Nacional de Salud, Laboratorio de Referencia de Mycobacterias, Lima, Peru, [7]Dirección de Prevención y Control de Tuberculosis - MINSA, Unidad Informática, Lima, Peru, [8]Instituto Nacional de Salud, Oficina General de Investigación y Transferencia Tecnológica, Lima, Peru, [9]Harvard Medical School, Department of Global Health and Social Medicine, Lima, Peru, [10]Socios En Salud sucursal Perú, Tuberculosis, Lima, Peru, [11]Dirección de Prevención y Control de Tuberculosis - MINSA, Direccion Ejecutiva, Lima, Peru
e-mail: edwher00@hotmail.com

Background: Drug-resistant tuberculosis (TB) poses a significant threat to global public health. Emerging bedaquiline-based, all-oral, shortened treatment regimens (6–12 months) offer a promising alternative to the longer regimens used in the past.
Our aim was to evaluate the effectiveness and safety of a nine-month, all-oral regimen implemented under operational research conditions by Peru's National Tuberculosis Program (NTP).
Design/Methods: We conducted a prospective observational study within the NTP. We consecutively enrolled non-pregnant adults (>18 years of age) with confirmed multidrug-resistant or rifampicin-resistant TB (MDR/RR-TB) from four national referral hospitals. The treatment regimen included bedaquiline, linezolid, levofloxacin, clofazimine, and Delamanid. We assessed treatment outcomes, sputum conversion, and reported adverse events.
Results: Fifty participants with confirmed MDR/RR-TB were included. Of these, 48% were women, and the median age was 28.5 years (IQR: 23–59 years). At baseline, 58% had bilateral pulmonary disease, and 76% had cavitary lesions. Three participants (6%) were excluded due to baseline fluoroquinolone resistance. The median time to sputum conversion was 39 days (IQR: 31–61 days). The rate of favorable treatment outcomes was 85.1% (95% CI: 72.3–92.6%). Twenty-two participants experienced at least one adverse event, most of which were mild. Clinically significant adverse events of special interest (AESIs) were infrequent; only one AESI—myelosuppression—led to permanent discontinuation of medication.

Table 1. End-of-treatment Outcomes of Individuals Initiating Shortened Regimens for MDR/RR-TB in Peru (N = 47)

Treatment Outcomes	N, (%) [95%CI]
Favorable	40, (85.1) [72.3 – 92.6]
Cured	39 (83.0)
Completed +	1 (2.1)
Unfavorable	7 (14.9) [7.4 – 27.7]
Died	2 (4.3)
Failed	1 (2.1)
Treatment extended > 12 months++	1 (2.1)
Lost to follow-up	3 (6.4)

+ One individual completed 9 months of treatment and was reported to be clinically asymptomatic upon finishing the drug regimen, but did not present to the clinic for confirmatory assessment at the end of treatment.
++ One individual considered clinically cured after a total of 15 months of treatment, in the setting of recurrent fluoroquinolone discontinuations due to gastrointestinal intolerance

Conclusions: This nine-month, bedaquiline-based, all-oral regimen for MDR-TB was effective and safe when implemented under operational conditions. It represents a valuable alternative for the treatment of drug-resistant TB.

EP47-1155-21 Linezolid pharmacokinetics among people with TB receiving the newly-introduced BPaL/BPaLM regimen in Georgia

N. Shurgaia,[1,2] M. Buziashvili,[1] R. Kempker,[3] [1]National Center for Tuberculosis and Lung Diseases (NCTLD), Research Department, Tbilisi, Georgia, [2]Tbilisi State University (TSU), Exact Sciences, Chemistry, Tbilisi, Georgia, [3]Emory University, School of Medicine, Atlanta, United States of America
e-mail: nikolozshurgaia@gmail.com

Background: Linezolid's (LZD) toxicity, the accumulative nature of Bedaquiline (BDQ) and the limited clinical experience with Pretomanid (PA) underscore the importance of therapeutic drug monitoring (TDM) for the BPaL regimen drugs.
Design/Methods: We developed a *novel* Liquid Chromatography/Mass Spectrometry (LC/MS) method for the *simultaneous analysis* of BDQ, PA, and LZD using deuterated internal standards and used it to assess the pharmacokinetic (PK) profiles of DR-TB patients at 2 distinct time points.

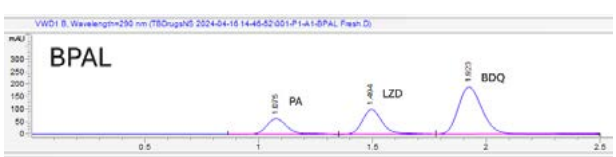

Figure 1. HPLC view of LC/MS simultaneous drug analysis method developed by our team. Peak resolution (Rs) >>1.5 for all peaks, total run time of 2.5min, isocratic elution with less than 1mL eluent waste per run.

In a Prospective Cohort study, we will enroll 30 DR-TB patients receiving BPaL/BPaLM regimens. Utilizing LC/MS simultaneous drug analysis method, BDQ, PA and LZD PK profiles are recorded on 1 and 4 weeks after treatment initiation (PK1 and PK2). PK parameters (C_{min}, C_{max}, AUC, $T_{1/2}$) along with their interpatient and intrapatient variabilities will be assessed.
Results: Out of 16 patients enrolled thus far, data from the first 8 patients (mean age 51 years; 75% male; 13% heavy smokers; 38% MDR/pre-XDR/XDR-TB) and their serum specimens were analyzed. The mean C_{max} values for PK1 and PK2 were 5.4 and 2.5 mg/L for BDQ, 4.5 and 4.9 mg/L for PA, and 14.1 and 13.9 mg/L for LZD. The mean C_{min} values for PK1 and PK2 were 1.8 and 1.3 mg/L for BDQ, 2.7 and 2.82 mg/L for PA, and 0.3 and 0.5 mg/L for LZD. Serum LZD concentrations showed high interpatient variability, σ=6.0 and 4.6 mg/L (PK1 and PK2) for C_{max} and σ=0.4 and 0.9 mg/L for C_{min}.
Conclusions: We developed a fast LC/MS method for simultaneous BDQ, PA, and LZD analysis and utilized it to evaluate the PK parameters of DR-TB patients at two specific time points.

EP47-1156-21 Establishment and application of a method for determination of plasma concentration of sodium aminosalicylate

H. Cui,[1] W. Sha,[1] [1]School of Medicine,Tongji University, TB Department, Shanghai, China

Background: Sodium para-Aminosalicylate (PAS) is worth further study in the treatment of drug-resistant tuberculosis. Plasma drug concentration monitoring is gradually carried out in tuberculosis treatment. This study establishes liquid chromatography-mass spectrometry (LC-MS-MS) to determine the concentration of plasma PAS, provides drug monitoring methods for tuberculosis patients treated with PAS, and provides advice for clinical application.
Design/Methods: Liquid chromatography tandem mass spectrometry (LC-MS-MS) was established to determine the concentration of plasma PAS. After protein was precipitated by acetonitrile solution containing internal standard, the chromatographic column was waters HSS T3 column, methanol water formic acid solution (5 mmol / L ammonium acetate, 0.1% formic acid) was used as mobile phase, the flow rate was 0.3ml/min, the column temperature was 30 ℃, and the injection volume was 5 μ L. An electrospray ionization source (ESI source) was used. The scanning mode was multiple reaction monitoring (MRM) and negative ion mode. The standard curve was prepared by liquid-liquid extraction acetonitrile precipitation protein method; The specificity, accuracy, precision and stability of the method were analyzed. The concentrations of plasma PAS in patients were measured.

Results: LC-MS-MS method was established to determine the concentration of plasma PAS. The peak time of PAS is 2.34 minutes, and the peak shape is satisfactor. The curve showed a good linear relationship in the concentration range from 0.1 to 100 μg/ml, and the lowest quantitative (LLOQ) was 0.1 μg/ml, the intra day and inter day precision (RSD) were less than 11.3%. The LC-MS-MS method established in this study had good specificity, and the rate of recovery was 95.1% - 96.3%. This method offers the advantages of simple operation and high recovery rate.
Conclusions: The determination of plasma PAS by LC-MS-MS is sensitive, accurate, simple and stable. It can be used for the determination of plasma concentration of PAS and clinical pharmacokinetics study.

EP48 Surveillance of drug-resistant TB

EP48-1157-21 Characterisation of *M. tuberculosis* drug resistance using targeted next-generation sequencing: Observations from Indonesia

B.W. Lestari,[1] S.A. Panjaitan,[2] B. Andriyoko,[3] I. Maemunah,[4] I.D. Kulsum,[5] P. Santoso,[5] R.W. Rachman,[6] R.B. Ristandi,[7] J. van Ingen,[8] R. van Crevel,[9] A.Y. Soeroto,[5] [1]Padjadjaran University, Public Health, Bandung, Indonesia, [2]Research Center for Care and Control of Infectious Diseases, Padjadjaran University, Tuberculosis Working Group, Bandung, Indonesia, [3]Hasan Sadikin General Hospital, Department of Clinical Pathology, Bandung, Indonesia, [4]Goenawan Lung Hospital, Department of Microbiology, Bogor, Indonesia, [5]Hasan Sadikin General Hospital, Department of Internal Medicine, Bandung, Indonesia, [6]West Java Provincial Health Laboratory, Department of Biomolecular, Bandung, Indonesia, [7]West Java Provincial Health Laboratory, Department of Clinical Pathology, Bandung, Indonesia, [8]Radboud University Medical Centre, Department of Clinical Microbiology, Nijmegen, Netherlands, [9]Radboud University Medical Centre, Department of Internal Medicine, Nijmegen, Netherlands
e-mail: bony.wiem@unpad.ac.id

Background: Drug-resistant tuberculosis (DR-TB) continues to pose a threat to the effort of TB control, with 175,923 people diagnosed with DR-TB globally in 2023 and only 68% treatment success rate. Accurate and comprehensive drug susceptibility testing is an essential component of DRTB care, and in early 2024, the WHO recommended the use of targeted next-generation sequencing (tNGS) for DRTB detection.
Therefore, we aimed to assess and characterize drug resistance profiles among newly diagnosed DR-TB patients using tNGS in West Java, Indonesia.
Design/Methods: Sputum samples from rifampicin-resistant tuberculosis (RR-TB) patients, from May 2024 to February 2025, were collected for tNGS using the Deeplex Myc-TB™. The diagnostic performance of tNGS was compared to phenotypic DST and Xpert MTB/XDR.
Results: In 43 NGS runs, 404 samples were successfully sequenced, yielding an 82% success rate. Spoligotyping identified the Beijing strain as the most common (55.2%), followed by H (6.4%), T (4.2%), LAM (2.9%), and EAI (1.5%). Rifampicin and isoniazid resistance were detected in 97.3% and 60.4% of samples, respectively, with 49.0% classified as multi-drug resistant (MDR), 9.4% as pre-extensively drug-resistant (pre-XDR), and 0.2% as extensively drug-resistant (XDR) TB.
tNGS demonstrated high concordance (80–99%) and specificity (77.5–100%) with standard tests. Sensitivities against pDST and Xpert MTB/XDR exceeded 87.5% for most drugs, except for isoniazid (79.5%) and bedaquiline/clofazimine (50%) due to limited resistance data. tNGS

specificity for Rifampicin was low (7.1%), increasing only to 16.7% after adjusting for borderline mutations, possibly due to the need to obtain subculture isolates altering sample integrity, leading to false positives and reduced specificity.

	pDST (n=363)			Xpert MTB/XDR (n=241)		
Drug	Concordance, %	Sensitivity, %	Specificity, %	Concordance, %	Sensitivity, %	Specificity, %
Isoniazid	83.2	81.3	88.1	85.5	92.5	76.2
Pyrazinamide	84.3	63.6	93.8	-	-	-
Levofloxacin	95.8	84.2	97.2	97.0	95.2	97.3
Moxifloxacin	95.7	87.5	96.6	97.1	95.2	97.3
Linezolid	99.7	-	100	-	-	-
Bedaquiline	97.7	50.0	98.6	-	-	-
Clofazimine	98.0	50.0	98.6	-	-	-
Ethionamide	-	-	-	96.1	89.5	96.7

Table 1. Performance of tNGS compared to pDST and Xpert MTB/XDR.

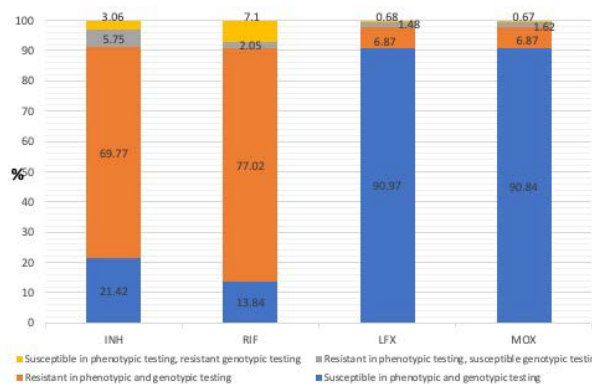
Conclusions: Our study showed that tNGS demonstrates comparable diagnostic accuracy to current standard drug susceptibility tests. However, additional data are needed, particularly for Group A drugs such as linezolid, bedaquiline, and clofazimine.

EP48-1158-21 Phenotypic and genotypic comparison of anti-TB drug-resistant *M. tuberculosis* in Thailand

K. Tohtubtiang,[1] DTB staff team [1]Division of Tuberculosis, Department of Disease Control, Ministry of Public health, Bangkok, Thailand
e-mail: ksornt@gmail.com

Background and challenges to implementation: Drug-resistant tuberculosis is a global public health challenge. The World Health Organization (WHO) recommends the implementation of a universal drug sensitivity testing (DST) policy in endemic areas, encouraging patients to test for tuberculosis drug sensitivity using both genotypic and phenotypic procedures. The patients with DST were identified and used effective medication.
The aim of this study was to evaluate the concordance and efficacy of genotypic and phenotypic DST in *Mycobacterium tuberculosis* for detecting drug resistance.
Intervention or response: Genotypic comparisons were performed among isoniazid, rifampicin, levofloxacin, and moxifloxacin at the National Tuberculosis Reference Laboratory from 2023 to 2024 utilizing multiple methods (LPA, GeneXpert, Real-time PCR), whereas phenotypic DST was performed using the LJ method and MGIT 960. The concordance between genotypic and phenotypic DST was computed utilizing GraphPad software.

Results/Impact: Levofloxacin and moxifloxacin exhibited a concordance 97.84% (kappa coefficient (K) = 0.853, 95% CI 0.782 - 0.924) and 97.71% (K = 0.845, 95% CI 0.772 - 0.917) respectively, signifying almost perfect agreement between phenotypic and genotypic DST. Concordance rate between phenotypic and genotypic DST results was detected for isoniazid 91.19% (K = 0.770, 95% CI 0.720 - 0.820) and rifampicin 90.85% (K = 0.697, 95% CI 0.634 - 0.760) signifying substantial agreement.
In contrast, the discordance between genotypic and phenotypic DST for isoniazid, rifampicin, levofloxacin, and moxifloxacin was 8.81, 9.15, 2.16, and 2.29, respectively. Discordance pattern was commonly resistant in phenotypic testing, susceptible genotypic testing.



Figures Concordance of the phenotypic and genotypic drug susceptibility testing results of the drug-resistant *M. tuberculosis* isolates. Number of tested isolates for each drug is indicated. Abbreviations: INH, isoniazid; RIF, rifampicin; LFX; levofloxacin, MOX; Moxifloxacin

Conclusions: This study serves as a guideline for medical laboratories in selecting the appropriate methodology for DST. Discordance between genotypic and phenotypic drug susceptibility testing may occur due to the limited coverage of genotypic methods, which primarily target hotspot regions and may overlook resistance-conferring mutations outside these areas. Whole genome sequencing (WGS) will be dissolved the limitation in the next stage.

EP48-1159-21 Genomic variants and associated drug resistance profiles revealed by whole genome sequencing in drug-resistant *M. tuberculosis* clinical isolates from Limpopo province

K. Kaapu,[1] I. Rukasha,[2,1] [1]University of Limpopo, Department of Pathology, Unit of Medical Sciences, Polokwane, South Africa, [2]National Health Laboratory Service, Microbiology, Polokwane, South Africa

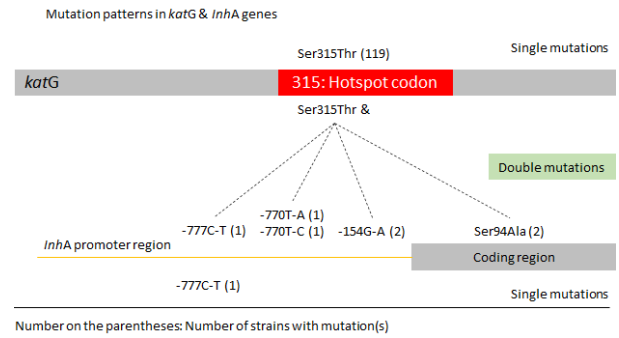
Background: The emergence and spread of drug-resistant tuberculosis (DR-TB) pose a threat to its treatment and management. Thus, the study aimed to investigate the genetic variants and associated drug-resistant mutations in DR-TB isolates from Limpopo province

Design/Methods: This quantitative study employed the use of whole genome sequencing (WGS) to characterise 44 drug resistant MTB clinical isolates selected from the Limpopo tuberculosis repository (2021-2023). Isolates were previously characterised by MTBDR*plus* line probe assay as drug resistant. The isolates were subcultured and further incubated for 2-weeks after initial positivity. Illumina protocol was used for sequencing at 50x depth. Lineages, mutations, drug resistance profiles and potential clusters were identified using relevant bioinformatics tools.
Results: WGS characterised resistance to all currently available antituberculosis drugs. The WGS characterised most of the MTB isolates as extensively drug resistant tuberculosis (XDR-TB) (n= 14/44; 32%), followed by pre-extensively drug resistant tuberculosis (Pre-XDR-TB) (n= 10/44; 23%). The Euro-American lineage 4.1.1 dominated most drug resistance profiles with 70% (7/10) in rifampicin resistant tuberculosis (RR-TB) and 54% (7/13) in XDR-TB. The Beijing lineage 2.2.1 (n = 6/10; 60%) was the dominant lineage in pre-XDR-TB, while other strains belonged to Indo Oceanic lineage 1 and 1 mixed lineage 2 & 4. Cluster analysis showed a 17.5% clustering rate mainly in the Waterberg district and Mopani districts.
Conclusions: This study highlights lineage 4 & 2 as major drivers of infection with drug resistant tuberculosis especially in Pre-XDR-TB and XDR-TB in Limpopo province. Therefore, high-quality data linking quantitative phenotypic drug susceptibility testing (DST) and genomic data is needed in Limpopo.

EP48-1160-21 Prevalence of *katG* and *inhA* mutations in genes associated with isoniazid resistance in *M. tuberculosis* clinical isolates in Kazakhstan

N. Takenov,[1] A. Mukhamadi,[1] A. Kaziyev,[1] L. Chingisova,[1] B. Toxanbayeva,[1] M. Adenov,[1] A. Grinev,[2] A. Gabrielian,[2] A. Rosenthal,[2] [1]National Scientific Center of Phthisiopulmonology, National Reference Laboratory, Almaty, Kazakhstan, [2]National Institutes of Health, National Institute of Allergy & Infectious Diseases, TBportals, Bethesda, United States of America
e-mail: takenovnur@gmail.com

Background: Isoniazid (INH) resistance remains a major challenge in the treatment of tuberculosis (TB), especially in INH-monoresistant and multidrug-resistant TB (MDR-TB) cases. Mutations in the *katG* gene and the *inhA* promoter region are the primary genetic mechanisms underlying INH resistance in *Mycobacterium tuberculosis* (MTB). Understanding the prevalence of these mutations is essential for improving molecular diagnostics and informing TB control strategies in Kazakhstan, where MDR-TB remains a serious public health threat.
Design/Methods: A total of 127 MTB clinical isolates with confirmed INH resistance were analyzed using whole-genome sequencing (WGS). Mutations associated with INH resistance were identified in the *katG* gene, *inhA* promoter, and related regions.
Mutation frequencies were compared to published data from other geographic regions. Clustering and phylogenetic analyses were also performed to explore potential transmission patterns.
Results: Among INH-resistant isolates, the *katG* S315T mutation was detected in 99.21% (126/127) of cases, a significantly higher prevalence than reported in other studies (53–71%). The observed *inhA*-related mutation was -777C>T (1.57%), -154G>A (1.57%), Ser94Ala (1.57%), -770T>A (0.79%), and -770T>C (0.79%). The high frequency of *katG* S315T suggests dominant transmission of resistant strains rather than independent emergence.



Conclusions: The strikingly high prevalence of the *katG* S315T mutation among INH-resistant MTB isolates in Kazakhstan highlights the dominance of a specific resistant clone or lineage. This findings highlight the urgent need to incorporate katG S315T detection into molecular diagnostic tests. The use of the updated Xpert MTB/XDR assay is particularly important, as the older Xpert MTB/RIF test only detects RIF-resistance and may miss INH-monoresistance, which accounts over 10% of cases. Failure to detect INH-resistance can lead to inappropriate treatment and further transmission.

EP48-1161-21 Prevalence and distribution of genomic drug-resistance of anti-TB drugs in West Java, Indonesia

B.W. Lestari,[1,2] I. Maemunah,[3] A. Alifia,[2] S. Alexandra,[2] B. Andriyoko,[4] A. Fibriani,[5] R.W. Rachman,[6] R.B. Ristandi,[7]
[1]Padjadjaran University, Public Health, Bandung, Indonesia, [2]Research Center for Care and Control of Infectious Diseases, Padjadjaran University, Tuberculosis Working Group, Bandung, Indonesia, [3]Goenawan Lung Hospital, Department of Microbiology, Bogor, Indonesia, [4]Hasan Sadikin General Hospital, Department of Clinical Pathology, Bandung, Indonesia, [5]Bandung Institute of Technology, School of Life Sciences and Technology, Bandung, Indonesia, [6]West Java Provincial Health Laboratory, Department of Biomolecular, Bandung, Indonesia, [7]West Java Provincial Health Laboratory, Department of Clinical Pathology, Bandung, Indonesia
e-mail: bony.wiem@unpad.ac.id

Background: Drug-resistant tuberculosis (DR TB) cases has been increasing worldwide, including in Indonesia, where it is already the country with second highest TB burden. However, the profile of emerging resistance is not yet mapped, and this becomes even more important with the rollout of new anti-TB drugs such as bedaquiline and linezolid.
Design/Methods: This is an operational research study that coordinates a provincial level health laboratory and 11 Programmatic Management of Drug-Resistant TB (PMDT) hospitals in West Java, the province with highest TB burden in the country. Clinical samples of individuals with reported rifampicin-resistant (RR) results from the recruitment sites were sent to the laboratory.
If the samples pass the quality checking steps, they will be processed with targeted Next Generation Sequencing (tNGS) using Illumina's iSeq100 instrument and GenoScreen's Deeplex Myc-TB kit. Successful tNGS results are then summarized to get resistance profile among DR TB patients in West Java.

Gene	Drug	Resistant	Uncharacterised	Gene	Drug	Resistant	Resistant
katG	INH	156	13	rpsL	SM	41	2
ahpC	INH	8	27	eis	KAN, AMK, CAP	4	6
inhA	INH, ETH	0	4	rrs	KAN, AMK, CAP, SM	16	10
fabG1	INH, ETH	29	3	tlyA	CAP	3	22
pncA	PZA	53	12	ethA	ETH	0	53
embB	EMB	95	5	rplC	LZD	0	2
gyrA	LFX, MFX	28	1	rrl	LZD	0	7
gyrB	LFX, MFX	3	3	rv0678	CFZ, BDQ	6	3
gidB	SM	28	19				

Results: From August 2024 to early March 2025, 300 samples were successfully characterised using tNGS with a median turnaround time of 10.5 days (IQR 8 – 14), starting from when samples were received until tNGS result came out. The majority of the samples (53%; 160/300) were of BEI (Beijing) spoligotype. The most detected drug resistant-associated gene following RIF's rpoB (100%) was katG mutations (related to INH drug, 52%), embB mutations (related to EMB, 31.7%), and pncA (related to PZA, 17.7%). Shared resistance of CFZ and BDQ through rv0678 gene mutation was found in 2% of the samples, and while there was no resistance detected for LZD yet, there were 3% uncharacterised mutations that could be related to LZD detected among the samples.
Conclusions: Most of the samples confirmed drug resistance to mostly first-line anti-tuberculosis drugs, and a regular surveillance is warranted to monitor second-line drug resistance especially in the era of BPaL/M regimen.

EP48-1162-21 Trends in drug-resistant TB in the Democratic Republic of Congo: A 6-year retrospective analysis (2018-2023)

M. Fina,[1] J.P. Malemba,[2] S. Mbuyi,[3] M. Aloni,[4] E. Yassankia,[5] L. Mbulula,[2] C. Kinkela,[3] N. Anshambi,[6] R. Sentime,[7] D. Muteteke,[1] F. Mukinda,[3] [1]DRC National Tuberculosis control Programme, MDR TB Management unit, Kinshasa, Democratic Republic of the Congo, [2]DRC National Tuberculosis control Programme, NTP Management, Kinshasa, Democratic Republic of the Congo, [3]DRC National Tuberculosis control Programme, Monitoring and Evaluation, Kinshasa, Democratic Republic of the Congo, [4]DRC National Tuberculosis control Programme,, Laboratory, Kinshasa, Democratic Republic of the Congo, [5]DRC National Tuberculosis control Programme, Cliical services, Kinshasa, Democratic Republic of the Congo, [6]WHO, Tuberculosis, Kinshasa, Democratic Republic of the Congo, [7]DRC National Tuberculosis control Programme, Pharmacy, Kinshasa, Democratic Republic of the Congo
e-mail: mawete2014@gmail.com

Background: The detection of drug resistant TB continues to be a challenge for achieving the objectives of the "END TB" strategy in DRC. Only 40% of all expected cases are being diagnosed and put on treatment. Screening for multidrug-resistant TB remains low despite the many efforts implemented by the NTP and partners.
Design/Methods: This retrospective cohort study examined the trends in drug-resistant TB detection, and assessed treatment outcomes. Data were collected from patients followed up between 2018 and 2023 from programmatic management of drug-resistant TB and laboratory registries.
Results: Between 2018 and 2023, 6963 (38%) people were diagnosed with MDR-TB compared to the expected target of 18406. The proportion of children (0-14 years) was 4.3%. About 40% of the expected cases were diagnosed; of these, 90% were initiated to treatment. Overtime, the treatment success rate remained below 90%, and about 12% were lost to follow up in 2023. Mortality rate decreased from 12% in 2018 to 4% in 2023. The gap remains wide for detection and treatment initiation.

Année	Target	Total diagnosed N(%)		Total treated N(%)		Treatment success rate	Death rate	Lost to follow-up
2018	1727	765	44,3	690	90,2	77%	12%	8%
2019	2133	918	43,0	822	89,5	80%	12%	5%
2020	2530	1015	40,1	905	89,2	84%	7%	8%
2021	3532	1236	35,0	1125	91,0	87%	6%	7%
2022	3997	1614	40,4	1403	86,9	87%	5%	8%
2023	4487	1415	31,5	1267	89,5	83%	4%	12%
Total	18 406	6963	37,8	6212	89,2	83%	8%	8%

Table 1 Results.

Conclusions: MDR-TB remains under-detected in DRC. This is challenged by limited access to molecular diagnostic tools (number of GeneXpert, Truenat), sub-optimal sample transportation system, stockout of medicines and reagents, insecurity issues limiting access to TB services especially in mining areas and in the Eastern part of the country.

EP48-1163-21 Shifting narratives of drug-resistant TB enrolment challenges

O. Omofaiye,[1] O. Daniel,[2] T. Adetiba,[3] M. Pedro,[4] O. Olupitan,[5] A. Agbaje,[6] C. Mensah,[6] P. Dakum,[7] S. Dimang,[8] E. Ubochioma,[9] J. Ssekitoleko,[10] J. Kimeu,[11]

e-mail: tadetiba@ihvnigeria.org

Background and challenges to implementation: Nigeria is among 14 high burden DR-TB countries with annual national estimates at 21,000. Sub-optimal notification is a challenge, an abysmal 3,867 cases were notified in 2022. The Institute of Human Virology Nigeria (IHVN) with funding support from Global Fund and USAID TB Local Organization Network (LON) 3 identified and addressed this gap in 4 southwestern states: Lagos, Oyo, Osun and Ogun in Nigeria.
Intervention or response: A retrospective review of program DR-TB data from October 2022-September 2023 was conducted showing an enrollment gap of 46.5% (181/389). A survey amongst healthcare workers in the affected health facilities across the 4 states was conducted to identify reasons for delayed treatment initiation.
This included refusal, denial of diagnosis, inability to reach patients due to incorrect or missing contact information, relocation, and mortality. To address this gap; in December 2023 IHVN implemented patient-centered strategies among individuals diagnosed with DR-TB.
This included specialized patient and family counseling to address fears and misconceptions about DR-TB treatment, systematic tracking of patients through home visits and follow-up phone calls by trained community TB workers and state program teams, inter-state collaboration with DR-TB focal persons to locate and enroll patients who had relocated, improved contact documentation at the point of sputum collection for enhanced patient follow-up. These coordinated efforts aimed to improve patient engagement and ensure timely linkage to care.
Results/Impact: Post-intervention, treatment initiation rate rose from 46.5% to 83.3% (324/389). Leaving 16.7% (65) not enrolled. About 40% (26) had inaccurate contact information, 21.5% (14) died prior to treatment initiation, 32.3% (21) refused treatment and 6.2% (4) had relocated.
Conclusions: Findings from this study highlights the critical need for deploying strategic programmatic interventions and patient centered approaches to address DR-TB enrollment challenges within communities. Implementing and sustaining these strategies is essential in improving treatment uptake and eliminating the vicious cycle of community transmission.

EP48-1164-21 Surveillance of drug-resistant TB, including bedaquiline and delamanid, in Kazakhstan (2020-2024)

N. Takenov,[1] M. Adenov,[1] L. Chingisova,[1] E. Arbusova,[1] V. Bismilda,[1] A. Koptleuova,[2] [1]National Scientific Center of Phthisiopulmonology, National Reference Laboratory, Almaty, Kazakhstan, [2]Global Fund, Administration, Almaty, Kazakhstan
e-mail: takenovnur@gmail.com

Background: Drug-resistant tuberculosis (DR-TB), including resistance to new anti-TB drugs, poses a significant public health challenge in Kazakhstan. Monitoring resistance trends is essential for effective TB control and treatment strategies.
Design/Methods: A retrospective analysis was conducted on 45,040 adult pulmonary TB patients in Kazakhstan from 2020 to 2024. Patients included 32,349 newly diagnosed and 12,691 previously treated cases. Drug resistance patterns, including multidrug-resistant TB (MDR-TB), pre-extensively drug-resistant TB (pre-XDR-TB), and extensively drug-resistant TB (XDR-TB), were assessed annually. Resistance to new drugs, such as bedaquiline and delamanid, was also analyzed.
Results: Among new TB cases, MDR-TB rates ranged from 55.7% to 64.6%, while in previously treated patients, rates ranged from 35.4% to 44.3%. XDR-TB rates were lower in 2022–2024 than in 2020–2021 in both groups.

Pre-XDR-TB rates among new patients decreased after 2021, while rates among previously treated patients stabilized around 50% after 2021.
Bedaquiline resistance first detected in 2021. In 2024, 76.9% of all BDQ-resistant tuberculosis cases were identified among new TB cases. Delamanid resistance emerged in 2022, with rates of 78.9% among new cases and 32.4% among previously treated cases by 2024.
Conclusions: Kazakhstan has seen a relative stabilization in DR-TB rates over the past five years. The emergence of resistance to new drugs is concerning, but improvements in diagnostics and treatment may have contributed to controlling overall resistance levels.

EP48-1165-21 Resistance patterns among treatment-naive drug-resistant people withTB in Nigeria

J. Awotoye,[1] C. Chime,[2] T. Adetiba,[3] M. Bathnna,[4] O. Olupitan,[4] A. Agbaje,[5] C. Mensah,[6] P. Dakum,[5] R. Iniobong,[7] I. Ahmadu,[8] J. Kimeu,[9] M. Zamzu,[9] GF NTHRIP Group [1]Institute of Human Virology Nigeria (IHVN), Laboratory, Abuja, Nigeria, [2]Institute of Human Virology Nigeria (IHVN), Laboratory Services, Abuja, Nigeria, [3]Institute of Human Virology Nigeria (IHVN), International Research Centre for Excellence, Abuja, Nigeria, [4]Institute of Human Virology Nigeria (IHVN), Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria, [5]Institute of Human Virology Nigeria (IHVN), Office of the CEO, Abuja, Nigeria, [6]Institute of Human Virology Nigeria (IHVN), Office of the COO, Abuja, Nigeria, [7]National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Public Health Department,, Abuja, Nigeria, [8]National Tuberculosis and Leprosy Training Centre, Zaria, Laboratory, Kaduna, Nigeria, [9]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Nigerian Country Team, Geneva, Switzerland
e-mail: jawotoye@ihvnigeria.org

Background and challenges to implementation: Nigeria bears a high burden of multidrug- and extensively drug-resistant TB (M/XDRTB). The national guidelines recommend confirmatory Line Probe Assay (LPA) for all GeneXpert-detected Rifampicin-resistant cases. This study characterizes drug resistance patterns among treatment-naive clients retested with LPA over the past three years at National TB Reference Laboratories.
Intervention or response: This is a retrospective secondary analysis of data reported for three-years (1st January 2022-31st December 2024) from nine National TB reference laboratories on Genexpert rifampicin-resistant samples. All sputum samples were subjected to first- and second-line genotypic DST using LPA GenoType® MTBDRplus assay for first line DST and GenoType® MTBDRsl® assay for 2nd-line DST respectively. Only samples with a definite and conclusive result were considered in these analyses. Simple frequencies and percentages were used to analyze the data using Microsoft Excel.
Results/Impact: A total of 3692 Genexpert rifampicin-resistant samples with clear and conclusive LPA results were analysed. Following first-line LPA, 20% (741/ 3692) of samples were susceptible to first-line drugs (i.e., discordant to baseline Xpert) while 45% (1663/ 3692) were rifampicin mono resistant, 4% (150/ 3692) had Isoniazid mono-resistance, and 31% (1138/ 3692) had MDR.
Following 2nd-line LPA, majority of the samples, 93% (3421/ 3692) were susceptible to second-line drugs (fluoroquinolones and aminoglycosides), 3% (94/3692) had fluoroquinolones mono-resistance, and 3% (105/3692) aminoglycosides mono-resistance (injectables) each, while 1% (37/ 3692) were resistant to both 2nd-line anti-TB drugs.
Conclusions: There is significant resistance to first-line and low resistance to second-line TB regimen among treatment-naive patients. Thus, it is critical to ensure 1st line genotypic DST (i.e., LPA) results are available prior to treatment initiation. Consequently, strengthening diagnostic capacities and access to genotypic DST services is still vital for effective TB control in Nigeria.

EP48-1166-21 Baseline and emergent delamanid and pretomanid resistance in people exposed to delamanid in KwaZulu-Natal, South Africa

C. Nimmo,[1] R. Perumal,[2] S. Moodley,[3] M. Zulu,[2] A. Wolf,[4] S. Ngema,[2] S. Rajagopalan,[5] M. Larsen,[5] K. Naidoo,[2] M. O'Donnell,[4] [1]University College London, UCL Respiratory, London, United Kingdom of Great Britain and Northern Ireland, [2]Centre for AIDS Programme of Research in South Africa, Treatment Research, Durban, South Africa, [3]Africa Health Research Institute, Microbiology Core, Durban, South Africa, [4]Columbia University Irving Medical Center, Division of Pulmonary, Allergy, and Critical Care Medicine, New York, United States of America, [5]Albert Einstein College of Medicine, Department of Microbiology & Immunology, New York, United States of America
e-mail: c.nimmo@ucl.ac.uk

Background: Nitroimadazoles (delamanid and pretomanid) are increasingly used in treatment regimens for multidrug-resistant tuberculosis (MDR-TB). Clinical resistance is generally reported to involve mutations in *ddn*, *fgd1*, or *fbiA/B/C/D*.
Design/Methods: Adults at a TB referral hospital and clinics in Durban, South Africa with MDR-TB and HIV, initiating bedaquiline-based treatment, were randomised to an integrated adherence support intervention or enhanced standard care. Sputum microbiological assessments were performed at baseline, month two and month six. Positive sputum cultures from patients exposed to delamanid underwent testing for delamanid and pretomanid resistance. These included MGIT culture, whole

genome sequencing and MGIT minimum inhibitory concentrations. The critical concentrations for delamanid and pretomanid resistance were 0.06 and 0.5 µg/ml (WHO lower threshold) respectively.

Results: From 2018 to 2020, 171 participants were enrolled. 57 patients (33.3%) had a positive baseline sputum culture, of whom 24 (42.1%) were exposed to delamanid for at least two of their initial six months' treatment. Among the patients evaluated, baseline delamanid resistance was present in 6/20 (30.0%), one of whom failed treatment. Pretomanid resistance was present in 2/19 (10.5%). 8/24 (33.3%) remained culture positive at month two, with isolates from six patients undergoing MIC testing and 3/6 (50.0%) demonstrating delamanid resistance. 2/24 (8.3%) patients were culture positive at month six, both of whom had delamanid resistant infection. MIC data and variants in candidate resistance genes are shown in the table.

Patient ID	Baseline			Later timepoint			
	PMD MIC (µg/mL)	DLM MIC (µg/mL)	Mutations	Month	PMD MIC (µg/mL)	DLM MIC (µg/mL)	Mutations
P3051	-	-	fbiC 2565_ indel	6	>4.0	0.25	fbiC 990_indel
P3524	-	0.015	None	6	-	0.5	fbiC 1458_ indel, S534!
P3532	<0.25	0.06	fbiD R57L	2	<0.25	0.25	fbiD R57L
P3535	<0.25	0.03	None	2	<0.25	0.25	None
P3519	<0.25	0.125	None	2	<0.25	0.03	None

P3538	<0.25	0.125	fbiD R57L				
	<0.25	0.25	fbiD R57L				
P3544	<0.25	0.125	fbiC 2565_				
P3551	<0.25	0.25	indel				
P3555	1.0	0.03	fbiC V29G				
P3449*	>4.0	0.25	None				
P3554			fbiC A852V				

*Table: Patients with persistent culture positivity/ nitroimidazole resistance. Excluded fbiD A206G as presumed phylogenetic variant. *lineage 1 isolate.*

Conclusions: In this cohort of culture-positive patients initiating bedaquiline and delamanid treatment, there were high rates of nitroimidazole resistance. Delamanid resistance was more common than pretomanid resistance, but in isolation did not nescessarily to lead to poor outcomes when accompanied by combination therapy. Two cases of persistent culture positivity were associated with acquired delamanid resistance.

EP48-1167-21 The correlation between isoniazid resistance-related gene mutations and resistance levels in M. tuberculosis in Shanghai

W. Xiao,[1] Y. Zhang,[1] Z. Wu,[2] J. Chen,[1] X. Shen,[1]
[1]Shanghai Municipal Center for Disease Control and Prevention (Shanghai Institutes of Preventive Medicine), Division of Tuberculosis and HIV/AIDS Prevention, Shanghai, China, [2]Shanghai Municipal Center for Disease Control and Prevention (Shanghai Institutes of Preventive Medicine), Shanghai Municipal Center for Disease Control and Prevention (Shanghai Institutes of Preventive Medicine), Shanghai, China

Background: This study analyzed INH-resistant *M. tuberculosis* isolates from Shanghai using whole-genome sequencing to characterize mutations (*katG/fabG1/inhA*) and correlate them with resistance levels. By establishing genotype-phenotype relationships, we aim to improve molecular prediction of INH resistance, supporting clinical decision-making for TB control in this low-epidemic urban setting.

Design/Methods: A total of 104 INH-resistant strains collected in Shanghai from January 2018 to December 2022 were retrospectively collected for WGS, and the correlation between phenotypic drug susceptibility testing and drug-related gene mutation was analyzed.

Table 1. Comparison of WGS Results and Phenotypic Drug Susceptibility Testing in 104 HR-MTB Strains

Gene	Nucleotide mutation	Low-level resistance (n=45)	High-level resistance (n=59)	Total isolates (n=104)	χ^2	P
ahpC	C-57T promoter	0 (0.0)	1 (1.7)	1 (1.0)	-	1.000
inhA	G-154A promoter	0 (0.0)	1 (1.7)	2 (1.9)	-	0.500
	Ser94Ala	0 (0.0)	1 (1.7)			
ahpC+inhA	G-48A promoter +G-154A promoter	0 (0.0)	1 (1.7)	1 (1.0)	-	0.452
fabG1	C-15T promoter	15 (33.3)	11 (18.6)	26 (25.0)	2.187	0.139
katG 315	Ser315Thr	15 (33.3)	30 (50.8)	55 (52.9)	4.870	0.027
	Ser315Asn	1 (2.2)	2 (3.4)			
	Ser315Ile	0 (0.0)	1 (1.7)			
	Ser315Gly	1 (2.2)	0 (0.0)			
other katG	Gly299Cys	1 (2.2)	0 (0.0)	5 (4.8)	-	0.173
	Leu387Pro	1 (2.2)	0 (0.0)			
	Asp735Ala	1 (2.2)	0 (0.0)			
	Asp419His	0 (0.0)	1 (1.7)			
	Trp191Arg	1 (2.2)	0 (0.0)			
fabG1+katG	C-15T promoter +Ser315Gly	1 (2.2)	1 (1.7)	3 (2.9)	-	0.588
	C-15T promoter +Ala130Val	1 (2.2)	0 (0.0)

High-level resistance MIC > 1ug/mL; Wild type:No gene mutation site

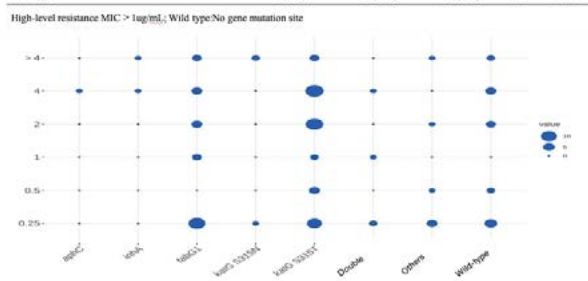

Figure 1. Scatter plot of the distribution of INH-resistance gene mutations and level of MIC

Results: Among the 104 INH-resistant strains, 88 exhibited resistance-related mutations: katG (55.8%,58 strains), fabG1 (27.9%,29 strains), wild-type (15.4%, 16 strains), inhA (2.9%,3 strains), and ahpC (1.9%,2 strain). The concordance rate between phenotypic resistance and

genotypic mutations was 84.6%. There were 16 types of mutations, 95.5% of which were single-site and 4.5% of which were combined mutations. Phenotypic drug susceptibility was low drug resistance in 45 cases and high drug resistance in 59 cases. Among 59 cases with high-level resistance, katG315 mutations were detected in 34 cases, fabG1 mutations in 11 case, and inhA mutations in 3 cases. The mutation rate of katG315 was significantly higher than that of inhA and fabG1(χ^2=4.870, P=0.027). There were 17 mutations in fabG1 among 45 patients with low level resistance. The mutation rate of fabG1 was higher than that of strains with low level resistance, but had no statistical difference.

Conclusions: FabG1 and katG315 mutations were the primary INH-resistance mutation sites in Shanghai, which corresponded to low and high-level resistance, respectively. WGS can effectively distinguish the degree of drug resistance and provide a basis for clinical decision-making. It is recommended to promote molecular diagnosis to improve the prevention and control of drug-resistant TB.

EP49 Journeys through TB: Stories of hope, resilience and recovery

EP49-1168-21 Breaking the silence: Assessing and addressing TB-related stigma in Zimbabwe

K. Mutungamiri,[1] D. Tobaiwa,[2] K. Ndlovu,[3] [1]Kudzaishe Mutungamiri, Strategic Information Knowledge Management, Gweru, Zimbabwe, [2]Jointed Hands Welfare Organisation, Programs, Gweru, Zimbabwe, [3]Ministry of Health and Child Care, National TB and Leprosy Program, Gweru, Zimbabwe
e-mail: kmutungamiri@jointedhands.org

Background: Tuberculosis (TB)-related stigma remains a significant barrier to healthcare access, treatment adherence, and social integration in Zimbabwe. This study assessed the intensity and distribution of TB stigma among people with or who had TB (PWTB), healthcare workers (HCWs), family members, and community members. The objective was to quantify stigma levels and identify key intervention areas.

Design/Methods: We conducted a cross-sectional stigma assessment with 416 PWTB, 30 HCWs, 30 family members/caregivers, and 30 community members. Stigma was measured using adapted Van Rie, Arcencio, and Corrigan scales to assess self-stigma, family secondary stigma, community stigma, and HCW stigma. Data were collected through structured interviews and analyzed using descriptive statistics to determine stigma intensity across different groups.

Results: With an overall TB stigma index of 40.9%, The findings revealed widespread TB stigma, with community stigma being the most severe—93% of respondents endorsed five or more stigma-related items. Self-stigma was also high, with 52% of PWTB reporting strong internalized stigma. Family secondary stigma was moderate, with 43% of family members endorsing at least 1–2 stigma items, and 23% experiencing high-intensity stigma. Among HCWs, 43% exhibited strong stigma, reflecting systemic challenges within healthcare settings. These findings suggest that stigma is deeply rooted in social and healthcare structures, contributing to delayed healthcare-seeking behaviours, treatment non-adherence, and emotional distress among PWTB. The high levels of community and self-stigma indicate a need for targeted psychosocial interventions, while HCW stigma underscores the importance of stigma reduction training in healthcare settings.

Conclusions: TB stigma in Zimbabwe remains a major challenge, affecting treatment outcomes and social reintegration. Addressing stigma requires community education, healthcare worker sensitization, and psychosocial support for PWTB and their families. These efforts are crucial for fostering a stigma-free healthcare environment and improving TB response strategies.

EP49-1169-21 Here is my story! TB Champions on air and unafraid

S. Bollepogu,[1] R. Adepu,[2] A. Singh,[3] J. Sangawar,[2] S. G,[4]
[1]The Union, ACSM NTSU, Hyderabad, India, [2]National TB Elimination Program, Telangana, State TB Cell, Telangana, Hyderabad, India, [3]The Union, ACSM NTSU, New Delhi, India, [4]WHO Country Office, Tuberculosis, Hyderabad, India
e-mail: bollepogu.suresh@theunion.org

Background and challenges to implementation: The deep-rooted stigma around Tuberculosis (TB) in India remains a significant barrier in the fight against the disease. To better understand these stigma-related challenges, The Union conducted focus group discussions (FGDs) across urban and rural Telangana (January–April 2024). The findings revealed that stigma imposes a heavy emotional burden on TB patients and hinders treatment adherence. Participants suggested that sharing real-life recovery stories could help normalize TB conversations.
But as the findings call for openness—do people truly break the silence?
Do they dare to share their stories while still navigating the battles within and around them?
Intervention or response: Building on FGD findings, conversations were initiated with individuals who had recently completed TB treatment. While many TB Champions (those who completed treatment) were open to sharing their stories in private or small groups, most remained hesitant to speak publicly due to persistent fear and stigma. Six courageous TB Champions stepped forward as torchbearers to share their personal journeys on Charminar Community Radio in Hyderabad. These six in-depth, interactive stories aired 12 times between 16th and 22nd November 2024. Each broadcast featured a conversation with the radio jockey, exploring the Champion's experience with TB, their path to recovery, and their present state of health—helping humanize the disease and offer hope to others in silence.

Results/Impact: Post FGD revealed that radio campaign successfully reached a wide audience across Hyderabad, sparking meaningful community-level conversations around TB. Listeners expressed a deeper understanding and empathy toward TB Champions, with many appreciating their courage to speak out. The storytelling format humanized the disease and played a pivotal role in reducing the stigma attached to TB.
Conclusions: These six powerful stories ignited a movement — now, across the state, more TB Champions are stepping forward to share their journeys on various platforms including radio, social media, and community events.

EP49-1170-21 Enhancing TB knowledge and reducing stigma among private healthcare providers through virtual learning platforms in Lagos, Nigeria

N. Umerah-Nwosu,[1] A. Gemmani,[1] A. Agbaje,[2] E. Olashore,[3] C. Nnely-Meri,[4] A. Akande,[5] G. John,[5] O. Odeyale,[4] B. Olaniyi,[6] I. Okekearu,[7] D. Sokoya,[8] [1]Loving Gaze, St Kizito Clinic, Lagos, Nigeria, [2]Institute of Human Virology Nigeria, Projects, Abuja, Nigeria, [3]Palladium Group, DataFI Project, Abuja, Nigeria, [4]Loving Gaze, Projects, Lagos, Nigeria, [5]Loving Gaze, Intermediary Organisation, Lagos, Nigeria, [6]Institute of Human Virology Nigeria, Projects, Lagos, Nigeria, [7]Society for Family Health, Projects, Abuja, Nigeria, [8]Lagos State Ministry of Health, LSTBLCP, Lagos, Nigeria
e-mail: ndnwosu@yahoo.com

Background and challenges to implementation: The link between TB stigma and ignorance is well-established; fueling the TB epidemic in Nigeria, which ranks sixth among high-TB-burden countries globally. Among private healthcare providers (PHPs), outdated knowledge on TB treatment and prevention, misconceptions about patient isolation, and fears of income-loss contribute to stigmatizing practices and limited capacity to deliver TB care. Reinforcing knowledge and addressing stigma are crucial to achieving the End-TB Goal. However, conventional training methods are often expensive, time-consuming, and particularly difficult for PHPs (including Patent Medicine vendors, maternity homes, standalone labs, private clinics) who cannot afford prolonged absences from their practices.
Intervention or response: To bridge this gap, Loving Gaze (LG), as the intermediary organization (IO) for the USAID-funded SHOPS Plus and TB-LON3 projects, strengthened private TB networks using virtual learning platforms from 2020-2024 through 26 geographically and peer-based chatgroup forums, 24 quarterly network meetings, bi-annual webinars, alongside weekly supportive supervision visits to PHP sites. These platforms facilitated continuous learning, identification of challenges, devel-

opment of responsive strategies, and exchange of best practices in systematic TB screening, prompt diagnosis, treatment, prevention, patient counseling and follow-up. The LG Programme Manager coordinated these activities of the virtual platforms providing online supervisory and mentoring support.

Results/Impact: Through these virtual platforms, the capacity of 2681 PHPs was strengthened. TB case notifications increased from 22 cases in July 2018 (with no childhood TB) to a cumulative total of 23,000 cases—including 1,370 childhood TB cases—by January 2025. These outcomes indicate stigma reduction, improved PHP knowledge and performance in TB service delivery in Lagos. PHPs have continued to promote and sustain TB programming despite limited from external donor-funded projects.

Conclusions: Integrating virtual platforms with traditional training approaches effectively bridges knowledge gaps and reduces stigma among PHPs. This holds promise for replication in Nigeria's journey to end TB, in light of donor-fatigue and limited resources.

EP49-1171-21 Assessing TB prevention in university freshmen: An IMB model-based survey on knowledge, motivation, behavioural skills, stigma, and information channels

S. Zhang,[1] Q. Zhang,[1] Q. He,[2] W. Xie,[3] H. Lu,[1] J. Wang,[4]
[1]Nanjing Medical University, Department of Social Medicine and Health Education, Nanjing, China, [2]Nanjing Medical University, Student Affairs Office of the School of Public Health, Nanjing, China, [3]Nanjing Medical University, Outpatient Department, Nanjing, China, [4]Nanjing Medical University, Department of Epidemology, Nanjing, China
e-mail: jmwang@njmu.edu.cn

Background: Tuberculosis (TB) remains a significant public health challenge in China, with medical students representing a critical population for TB control due to their dual roles as future healthcare providers and health communicators. Despite national efforts to integrate TB education into medical curricula, gaps persist in students' knowledge, prevention behaviors, and attitudes toward TB patients. This study applies the Information-Motivation-Behavioral Skills (IMB) model to systematically assess TB prevention determinants among medical freshmen in China, aiming to inform targeted educational strategies aligned with China's TB elimination goals.

Design/Methods: A cross-sectional survey was conducted in a medical university, enrolling 3,479 freshmen. Validated questionnaires measured TB core knowledge (transmission, symptoms), general knowledge, prevention motivation, self-reported behavioral skills, TB-related stigma, and information-seeking preferences. Data were collected via an online platform, with statistical analyses performed using SPSS 26.0.

Results: This study demonstrates that the overall TB core knowledge awareness rate among medical freshmen was 86.3%, surpassing the 85% target set by the National Tuberculosis Control Plan (2019–2022). The lowest awareness (35.9%) pertained to „TB treatment typically requiring six months", highlighting insufficient emphasis on treatment duration and adherence in current health education programs. Although 63.5% reported high prevention motivation, merely 8.9% think it is very likely to be infected with tuberculosis. Stigmatizing attitudes were prevalent (63.5%). 29.3% reported feeling uncomfortable living with classmates who have a history of tuberculosis infection. School curriculum dominated as a preferred information source (87.1%).

Conclusions: This study identifies actionable gaps in TB preparedness among Chinese medical freshmen, advocating for curriculum-integrated education to address knowledge deficiencies and peer-led anti-stigma initiatives. The strong preference for institutionally vetted information underscores universities' pivotal role in health communication. Prioritizing IMB-based interventions could enhance both personal prevention practices and future professional competency, directly supporting China's national TB control agenda.

EP49-1172-21 Documenting rights violations associated with TB in Nigeria: Impact on community rights and gender

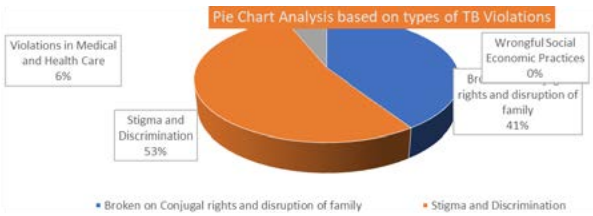
R. Mom,[1] P. Okeshola,[2] N. Bale,[3] [1]Lawyers Alert, Civil Society, Abuja, Nigeria, [2]Lawyers Alert, Legal, Abuja, Nigeria, [3]Lawyers Alert, Programs, Abuja, Nigeria
e-mail: rommym@lawyersalertng.org

Background and challenges to implementation: Tuberculosis (TB) continues to pose a significant public health challenge where the disease is deeply intertwined with rights violations. People affected by TB (PATBs) often faces a barriers, including stigma, discrimination, and restricted access to essential healthcare services. These barriers further impact TB prevention and treatment efforts. Data on TB-related rights violations have been scarce, leaving a critical gap in addressing the systemic inequalities faced by PATBs. Lawyers Alert (LA) began to document and analyze rights violations associated with TB, with the aim of advancing CRG TB interventions.

Intervention or response: This intervention aimed to empower communities to systematically document rights violations experienced by PATBs and use this evidence to advocate for policy and programmatic reforms.LA deployed a community-led monitoring approach that placed PATBs at the forefront of the data collection process. Through strategic partnerships with civil society and Nigeria's National Tuberculosis Program (NTBLCP), rights violations were documented using Lawyers Alert's

online tool, "LadockT," which allows for real-time analysis of qualitative data. The findings aids advocacy actions aimed at promoting a rights-based and equitable TB response.

Results/Impact: The intervention strengthened the capacity of TB-affected communities to document rights violations. Through community-led documentation efforts, a grassroots movement began to emerge, fostering collective action towards advocacy for TB rights. The results of the documentation provides a scientific data for advocacy. The report revealed a landscape of rights violations, were stigma and discrimination were the most prevalent constituting 53% of the documented violations. Breaches of confidentiality and discriminatory practices in healthcare, accounted for 6% underscoring the need for targeted interventions in these areas.



Conclusions: The results of this intervention highlight the urgent need to address human rights violations as an integral part of TB control efforts in Nigeria. The findings call for comprehensive reforms, including the integration of rights based approaches into TB programming.

EP49-1173-21 Leveraging community-led monitoring to identify and address stigma and discrimination through the iMonitor ATM+ system in Kenya

C. Mutai,[1] C. Mwamsidu,[2] D. Kimuyu,[2] B. Ulo,[2] W. Nkirote,[3] P. Nyakwana,[4] T. Kiptai,[2] [1]Amref Health Africa, Global Fund, Eldoret, Kenya, [2]Amref Health Africa, Global Fund, Nairobi, Kenya, [3]National Tuberclosis Program, Public Private Mix, Nairobi, Kenya, [4]Kenya Coordinating Mechanism, Non State, Nairobi, Kenya
e-mail: Caren.Mutai@amref.org

Background and challenges to implementation: Community rights and gender assessment study in Kenya found stigma, experienced by up to 8% of people living with tuberculosis, hinders access to diagnosis and treatment contributing to social isolation, psychological distress and poor health outcomes across various Kenyan counties. Community Led Monitoring (CLM) provides platform for service users to share feedback on their experiences. Supported by Global Fund, Amref, in collaboration with the Kenya Red Cross Society (KRCS) , implemented CLM to identify human rights issues and empower communities with information for action.

Intervention or response: From July 2022 to December 2024, the project implemented CLM across 47 counties, with KRCS leading human rights and gender, and Amref CLM interventions. Communities used iMonitor+ platform to provide real time feedback on their experiences. Duty bearers and paralegals responded to issues raised. This paper focuses on experiences on Discrimination/ Stigmatization among People Living with HIV (PLHIV) and TB service users.

Results/Impact: A total of 4,520 issues on human rights violation were reported across 38 counties, with Discrimination/Stigmatization at 799 issues (18%). Among issues reported, 188 (24%) were by PLHIV and 53 (7%) by TB service users. The issues were verbal abuse, social isolation, forced disclosure of HIV status, denial of services and physical assault. Perpetrators were family members (PLHIV: 43, TB: 17), neighbors (PLHIV: 39, TB: 8), and healthcare providers (PLHIV: 33, TB: 9). In response to reported issues, various actions were taken: 55% received legal advice and counselling, 13% health facility-based resolution, 11% mediation services, and 21% used alternative dispute resolution mechanisms. These findings informed programming, including national surveys and Breaking Down Barriers initiative by Global Fund.

Conclusions: CLM has been critical in bringing key human rights issues to light and ensuring action is taken. Strengthening CLM is essential for providing sustained platform for feedback and advocacy, helping reduce stigma and improve outcomes for service users.

EP49-1174-21 Feasibility and impact of behaviour change solutions for TB response among vulnerable populations: Insights from 'Breaking the Barriers' community engagement project (A NIMHANS-led study)

R. Begum,[1] J. Francis Munjattu,[2] A. Sinha,[2] L Ponnuchamy,[3] S. Majumder,[2] P. Das,[4] R. Dasari,[5] P. Kumar,[2] J. Chakravorty,[6] A. Shah,[7] R. Swamickan,[8] K Karthikeyan,[2] Amar Shah [1]KHPT, TB, Delhi, India, [2]KHPT, TB, Bengaluru, India, [3]National Institute of Mental Health And Neuro Sciences (NIMHANS), Psychiatric Social work, Bengaluru, India, [4]KHPT, TB, Guwahati, India, [5]TB Alert India, TB, Hyderabad, India, [6]KHPT, TB, Patna, India, [7]USAID, TB, Delhi, India, [8]USAID, Health Office, Delhi, India
e-mail: rehana.begum@khpt.org

Background: The Breaking the Barriers (BTB) project developed nine behavior change solutions (BCS) to improve TB case finding and treatment adherence among vulnerable communities in Assam, Bihar, Karnataka, and Telangana. Three case finding solutions—TB Jaanch Coupon, Health Auto, and TB Soochana—and six case holding solutions—TB Starter Kit, TB Buddy, TB Champion Health Workers, Phone a Friend, Sharing Circles, and TB Treatment Completion Certificate—were implemented.

This study aimed to evaluate the impact of these solutions on TB awareness, notification, and treatment adherence, and to assess their feasibility for implementation.
Design/Methods: Implemented across 16 districts from October 2021 to December 2023, one case finding and one case holding solution were piloted per Tuberculosis Unit. Using a phenomenological qualitative approach and in collaboration with National Institute of Mental Health and Neuro Sciences (NIMHANS), data were collected through 195 in-depth interviews and 11 focus group discussions with people with TB, caregivers, National Tuberculosis Elimination Programme staff, and community stakeholders from May–August 2023.
Results: Three case finding solutions—TB Jaanch Coupon, Health Auto, and TB Soochana—effectively addressed delays in diagnosis and improved health-seeking behaviour. Six case holding solutions—TB Starter Kit, TB Buddy, TB Champion Health Workers, Phone a Friend, Sharing Circles, and Treatment Completion Certificate—supported treatment adherence, reduced confusion, and offered emotional support. Health Auto, though useful, was resource-intensive and raised concerns about sustainability. While not all solutions equally addressed stigma, four— TB Champion Health Workers, Jaanch Coupon, Starter Kit, and Treatment Completion Certificate—demonstrated a measurable impact on stigma reduction.
Conclusions: The BCS interventions proved feasible, enhancing diagnosis and adherence through culturally resonant, community-integrated strategies. TB Survivor-driven engagement and stigma reduction emerged as critical, suggesting scalable, multifaceted approaches to optimize TB care in diverse settings.

EP49-1175-21 "You will never be the same": A photovoice study with TB survivors in Uganda

W. Katagira,[1] B. Ringwald,[2,1] R. Hamala,[1] F. Ebil,[1] P. Areco,[3] M. Nattimba,[1,4] J. Nidoi,[1] Z. Namuli,[5] W. Muttamba,[1] B. Kirenga,[1,6] [1]Lung Institute, College of Health Sciences, Makerere University, Research and Innovation, Kampala, Uganda, [2]Liverpool School of Tropical Medicine, Centre for Tuberculosis Research, Liverpool, Uganda, [3]Fellowship of TB survivors, TB survivors, Kampala, Uganda, [4]School of Public Health, Makerere University, Research, Kampala, Uganda, [5]Lung Institute, College of Health Sciences, Makerere University, Publicity and Communication, Kampala, Uganda, [6]Makerere University, College of Health Sciences, Internal Medicine, Kampala, Uganda
e-mail: wincegira@gmail.com

Background: About 80,000 people with Tuberculosis (TB) complete treatment in Uganda annually, adding to the growing population of TB survivors. While the idea of involving 'TB Champions' is popular, current approaches remain largely limited to task-shifting within health facilities. We engaged TB survivors in Central Uganda to express their experiences and views on their meaningful engagement in the TB response using a participatory photography process.
Design/Methods: Fifteen TB survivors (8 men, 7 women), who had completed treatment at Naguru and Kawolo hospitals between February 2022 and August 2024, were trained in ethical photography using digital cameras. They took photos over two weeks and discussed their favourite images and agreed messages in workshops. We analysed photos and audio transcripts from the workshops using thematic analysis.
Results: Many TB survivors were 'unofficial' TB advocates out of compassion and worries about TB exposure due to poverty, poor housing and sanitation, and lack of awareness in their communities. TB survivors changed their lives to protect themselves and prevent re-infection. Women counselled fellow women and persuaded neighbours and friends with cough to test for TB. Men helped with transport to health facilities and encouraged fellow men to reduce alcohol use. Most TB survivors struggled with incomplete physical recovery, experiencing chest pain, breathlessness, and body weakness due to TB-related lung damage; loss or change of work; and social isolation, all of which impacted their mental well-being. TB survivors recommended health education after TB cure as fear, pain, and stress limited learning during treatment to be able to address TB myths and knowledge gaps effectively. They also need public speaking training and empowerment to gain courage to counter TB stigma.

Figure 1 "*Like the parasite that damaged this avocado tree, TB has left scars on us. You will never be the same.*" TB survivor (female), Kawolo, Uganda.

Conclusions: TB policymakers and programmes should listen to and respond to challenges of TB survivors, building their capacity to ensure the TB response is effective and holistic.

EP49-1176-21 Indigenising TB professional development and education through researcher continuity and storytelling: Lessons from Inuit community public health worker training in Nunavik (Quebec, Canada)

A. Dunn-Suen,[1] G. Sandy,[2] B. Geboe (Redlightening),[1] D. Tooktoo,[1] C. Sicilia,[3] N.I. MacDonald,[4] F. Ahmad Khan,[1]
[1]Research Institute of the McGill University Health Centre, Centre for Outcomes Research and Evaluation, Montreal, Canada, [2]Nunavik Regional Board of Health and Social Services, Public Health, Kuujjuaq, Canada, [3]DiscoveryWorks Inc, Education Consulting, Montreal, Canada, [4]Silattusarniq Community Solutions Consulting, Inuit-led Research, Nunavik, Canada
e-mail: anna.dunn-suen@rimuhc.ca

Background and challenges to implementation: Nunavik is home to a thriving Inuit population, Nunavimmiut. Nunavimmiut strongly desire adequate and effective health services yet experience high tuberculosis (TB) incidence and hardships associated with TB care. Hardships are rooted in inadequate medical resourcing, and in cultural and linguistic gaps between services and communities served. A novel community public health worker (Public Health Officer, PHO) program was recently developed to address hardships by strengthening cultural safety, Inuktitut language, and Nunavimmiut-workforce representation within care settings. PHO training poses several challenges including diverse professional and educational backgrounds and a paucity of Nunavik-specific learning resources.
Intervention or response: Indigenous researchers and researchers with lived experience in Nunavik developed a PHO Resource Manual based on Nunavimmiut TB care experiences collected through community-based participatory research. This team of researchers piloted a training curriculum in Nunavik in 2025.
Results/Impact: We developed a versatile training template, emphasizing person-centred support as an integral component of TB treatment and drawing on Indigenous learning methodologies. The training template identified three requisite areas: Knowledge (foundational TB knowledge), Communication Techniques (communicating knowledge to patients), and Resources (accessing available resources, PHO Resource Manual) (Figure 1a). Facilitators honoured Nunavimmiut storytelling tradition as an approach to explore the complexity of TB pathology and Nunavimmiut patient experience (Figure 1b). Storytelling additionally scaffolded learning through scenario-based and observational learning. Participants responded positively on the feedback questionnaire, expressing a desire for future trainings and improved connectedness to their role. Participants supported the development of additional Inuktitut and Inuit-led resources.

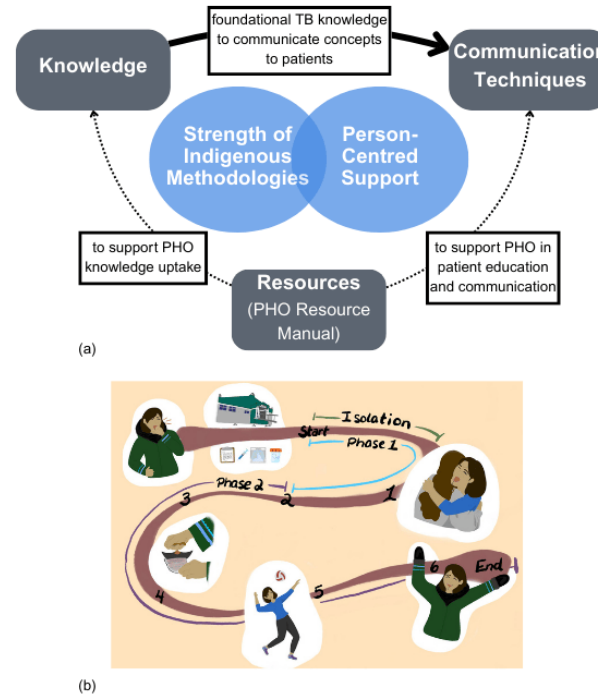


Figure 1. (a) Training template and (b) sample of PHO Resource Manual incorporating storytelling as an Indigenous learning methodology.

Conclusions: Community-based participatory research and researcher continuity throughout the project led to the design of Nunavik-specific resources. The training received positive participant feedback, yet researchers recognize the importance of maintaining ongoing relationships with PHOs to inform future programming. This training template and approach, including researcher, community, and PHO co-creation, inform future trainings in TB, other public health topics, and diverse setting PHO-programs.

EP50 Sick because they are poor: Undernutrition poverty and the TB crisis

EP50-1177-21 Placing a nutritional lens on paediatric TB risk: Variability in definitions and their association with TB

E. Eaton,[1] A. Madan,[1] A. Khan,[2] N. Safdar,[2] L. Locks,[3] H. Hussain,[2] A. Malik,[2] M. Brooks,[1] [1]Boston University School of Public Health, Global Health, Boston, United States of America, [2]Interactive Research & Development-Global, Tuberculosis, Singapore, Singapore, [3]Boston University, Health Sciences, Boston, United States of America
e-mail: mbbrooks@bu.edu

Background: Sub-optimal nutrition in children encompasses a range of biological states including severe acute malnutrition, stunting, micronutrient deficiencies, and overweight and obesity. Pediatric TB research lacks standardized definitions of sub-optimal nutrition, leading to inconsistencies in understanding related associations with TB disease. We assess how various definitions of sub-optimal nutrition impact variability in reported associations with pediatric TB disease.
Design/Methods: Through a literature review, we assessed variability in sub-optimal nutrition definitions across pediatric TB studies. Subsequently, we used data from a large TB screening program in Karachi and Peshawar, Pakistan (2018-2021) for assessment. Of children diagnosed with all forms of TB, child household contacts (HHC) 0-14 years old were enumerated and screened for TB. Among child HHCs we calculated a variety of sub-optimal nutrition measures based on those reported most frequently in existing pediatric TB literature. Accounting for household clustering, we conducted logistic regression analyses assessing the association of the varying sub-optimal nutrition measures with TB disease prevalence.

Term	Definition	Frequency in child HHCs diagnosed with TB (N=499)	Frequency in child HHCs not diagnosed with TB (N=12,506)	p-value comparing the frequency with and without TB	Association with Prevalent TB in child HHCs, OR (95% CI)
Weight-for-Age Z-score (WAZ) ≤-2	Moderate underweight	153 (30.7%)	2813 (22.4%)	<0.001	1.60 (1.31-1.99)
Weight-for-Age Z-score (WAZ) ≤-3	Severe underweight	69 (13.8%)	1096 (8.7%)	<0.001	1.71 (1.29-2.25)
Height-for-Age Z-score (HAZ) ≤-2	Moderate stunting	274 (55.0%)	6295 (50.3%)	0.034	1.20 (0.99-1.46)
Height-for-Age Z-score (HAZ) ≤-3	Severe stunting	191 (38.3%)	4288 (34.2%)	0.057	1.22 (0.99-1.52)
BMI-for-Age Z-score (BAZ) ≤-2	Thinness	81 (16.0%)	1982 (15.8%)	0.818	0.96 (0.74-1.25)
BMI-for-Age Z-score (BAZ) ≤-3	Severe thinness	35 (7.0%)	937 (7.4%)	0.785	0.92 (0.64-1.34)
Weight-for-Height Z-score (WHZ) ≤-3	Severe wasting	7 (4.6%) [out of 153]	183 (4.3%) [out of 4164]	1.00	1.06 (0.48-2.34)
Weight-for-age below 5th percentile	Low weight-for-age	233 (46.7%)	4079 (32.6%)	<0.001	1.80 (1.47-2.21)
Weight-for-age below 3rd percentile	Very low weight-for-age	269 (52.1%)	4965 (39.7%)	<0.001	1.82 (1.48-2.23)

Conclusions: Different sub-optimal nutrition measures in children led to varying associations with prevalent TB in child HHCs, with WAZ having the strongest association, followed by HAZ.
It is essential to understand how different markers of sub-optimal nutrition may impact TB disease in this vulnerable population. New pediatric guidelines should consider addressing this critical area.

EP50-1178-21 High prevalence of TB among Malawian children aged <5 years hospitalised with severe acute malnutrition

B. Vonasek,[1] M. Nyirongo,[2] A. Kondwani,[2] T. Kamwaunamwali,[3] D. Ng'oma,[3] M. Chiunda,[3] K. Chetcuti,[4] M. Kumwenda,[2] A. Garcia-Prats,[5] T. Mvalo,[3] [1]Michigan State University College of Osteopathic Medicine, Osteopathic Medical Specialties, East Lansing, United States of America, [2]Kamuzu Central Hospital, Paediatrics and Child Health, Lilongwe, Malawi, [3]UNC Project Malawi, Paediatrics, Lilongwe, Malawi, [4]Kamuzu University of Health Sciences, Radiology, Blantyre, Malawi, [5]University of Wisconsin School of Medicine and Public Health, Pediatrics, Madison, United States of America
e-mail: vonasekb@msu.edu

Background: Children with severe acute malnutrition (SAM) are at high risk for tuberculosis (TB), but precise estimates of TB prevalence and accurate TB diagnosis in this population remain elusive. The objectives were to define TB prevalence in children hospitalized with SAM and to explore clinical factors associated with TB diagnosis.
Design/Methods: This was a consolidation of two prospective observational studies of children 6 to 59 months admitted to Kamuzu Central Hospital (Lilongwe, Malawi) with SAM. All enrolled children underwent assessment for TB-associated signs and symptoms, chest x-ray (CXR), HIV infection, and Xpert MTB/RIF Ultra on gastric aspirate specimens. Children were followed until hospital discharge. CXRs were independently interpreted by at least two reviewers.
Absolute numbers and proportions of abnormal findings were reported. Children were defined as having 'unlikely,' 'unconfirmed,' and 'confirmed' TB based upon consensus research definitions for TB in children.
Results: From November 2021 to May 2022 and February 2023 to January 2024, 341 children with SAM were enrolled. Their mean age was 20 months (standard deviation: 12 months), 29% had kwashiorkor, 9% were living with HIV, and 4% were HIV exposed. In-hospital mortality was 8%. CXRs were available and of adequate quality for remote review from 261 (77%) children.
Of these, 39% were abnormal and 19% had findings suggestive of TB. TB prevalence in this cohort was estimated at 19% (95% confidence interval: 15- 24%) based upon 59

(17%) having unconfirmed TB and 6 (2%) having confirmed TB. Upcoming analyses will evaluate clinical differences amongst those diagnosed with TB or not.
Conclusions: These results highlight the large burden of TB in children hospitalized with SAM in this setting and the need to prioritize intensive case finding efforts in this high-risk group. Results suggest challenges with microbiologic confirmation in this population, and under-diagnosis of TB in this setting for this population.

EP50-1179-21 Poor nutrition increases the mortality risk in children treated for TB in sub-Saharan Africa

A. Vasiliu,[1,2] A. Seeger,[1] L. Carratala-Castro,[3,4] B. Nkala,[5] L. Komba,[6] S. Acacio,[4] D. Mulengwa,[5] E. Mambuque,[4] B. Mtafya,[7] A. Kay,[1,5] A. Garcia-Basteiro,[3,4] A. Mandalakas,[1] Stool4TB Global Partnership [1]Baylor College of Medicine, Pediatrics, Houston, United States of America, [2]Research Center Borstel, Clinical Infectious Diseases, Borstel, Germany, [3]ISGlobal, Tuberculosis Research Group, Barcelona, Spain, [4]Manhica Health Research Center (CISM), Manhica Tuberculosis Initiative, Manhiça, Mozambique, [5]Baylor College of Medicine Children's Foundation Eswatini, Tuberculosis Research Group, Mbabane, Eswatini, [6]Baylor College of Medicine Children's Foundation Tanzania, Tuberculosis Clinic, Mbeya, United Republic of Tanzania, [7]Mbeya Medical Research Center, Laboratory, Mbeya, United Republic of Tanzania
e-mail: anca.vasiliu@bcm.edu

Background: Poor nutrition weakens the immune system, compromising treatment response and increasing mortality among people with tuberculosis. The impact of nutritional status on tuberculosis outcomes remains insufficiently characterized in many high-burden settings and populations. Hence, we evaluated the relationship between nutritional status and TB treatment outcomes in individuals treated for tuberculosis.
Design/Methods: We conducted a cohort study among individuals receiving tuberculosis treatment in Eswatini, Mozambique, and Tanzania from October 2020 to June 2023. Nutritional status was expressed as body mass index (BMI) for adults and adolescents (age ≥10 years) and weight-for-age Z-score for participants under 10 years. Participants were followed until the end of treatment.
Results: Among 433 participants, 48.3% were female, 40.6% were children <10 years of age, and 43% were living with HIV. Nearly half (49.0%) had normal weight at the start of treatment, while 42.7% were underweight, and 8.3% were overweight or obese. Thirty participants (7.6%) died after TB treatment initiation, with 16 deaths occurring among children (9.1%). In multivariate-adjusted logistic regression, underweight status was associated with a four-fold increased risk of mortality among children (OR 4.35, 95% CI [1.2-21.9]). No significant association was found between being underweight and mortality in adults. Among underweight children, 43.9% (40/91) improved their weight by 5% or more two weeks after starting tuberculosis treatment. Weight change was not associated with TB outcome.
Conclusions: Our findings highlight the considerable impact of poor nutrition on mortality among children. The elevated mortality risk among underweight children argues for detailed nutritional screening and early nutritional support as part of routine tuberculosis care. In addition, children with malnutrition should routinely be screened for tuberculosis. Integrating nutritional interventions into tuberculosis programs could reduce mortality and improve treatment success. Further research is needed to evaluate targeted nutritional interventions for reducing tuberculosis mortality among children.

EP50-1180-21 Rifampin dosing and exposure in undernourished people with TB in India

P. Rao,[1] S. Prakash Babu,[2] S. Jeyakumar,[3] J. Tornheim,[4] M. Paradkar,[5] V. Viswanathan,[6] B. Thangakunam,[7] S. Sarkar,[2] S. Gaikwad,[5] P. Sinha,[8] P. Bhavani,[3] [1]University of Virginia, Department of Infectious Diseases and International Health, Charlottesville, United States of America, [2]Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), Department of Preventive & Social Medicine, Puducherry, India, [3]ICMR-National Institute for Research in Tuberculosis, ICMR, Chennai, India, [4]Johns Hopkins University, Division of Infectious Diseases, Baltimore, United States of America, [5]Byramjee Jeejeebhoy Government Medical College, Sassoon General Hospitals-Johns Hopkins University Clinical Research Site, Pune, India, [6]Prof. M. Viswanathan Diabetes Research Centre, Prof. M. Viswanathan Diabetes Research Centre, Chennai, India, [7]Christian Medical College, Department of Pulmonary Medicine, Vellore, India, [8]Boston University Chobanian and Avedisian School of Medicine, Boston Medical Center, Section of Infectious Diseases, Boston, United States of America
psinha@bu.edu

Background: Undernutrition is associated with more severe tuberculosis and unfavorable treatment outcomes. Undernourished persons with tuberculosis (PWTB) may receive inadequate drug doses due to low body weight. Low doses may impact drug exposure, thereby impeding faster bacteriological clearance. Rifampin plays a crucial role in smear conversion, and we assessed dosing and pharmacokinetic target attainment in undernourished PWTB.
Design/Methods: This study recruited adults with or without undernutrition (body mass index, BMI < 18.5 kg/m^2), diagnosed with drug-sensitive TB. A pharmacokinetic visit was conducted at least two weeks after treatment initiation to quantify anti-TB drug concentrations using validated mass spectrometry methods. Sampling

was conducted at pre-dose and at 2-, 4-, 6-, and 8-hour post-dose. Population modeling and simulations were performed using a nonlinear mixed-effects modeling approach in Phoenix WinNonlin to determine doses for optimal rifampin exposure.
Results: A total of 127 participants completed their pharmacokinetic visit, with 36% having a BMI below 18.5 kg/ m^2. 72% of undernourished PWTB received a dose of 450 mg, and 72% of participants with a BMI greater than 18.5 kg/ m^2 (control group) received a dose of 600 mg or higher. Only 30% of undernourished PWTB attained a target rifampin maximum concentration (C_{max}) of 8 mg/L versus 46% in the control group. Data were fit in a one-compartment model. Simulated doses of 600 mg and 900 mg in undernourished PWTB improved the C_{max} target attainment to 51% and 71%, respectively. A simulated 900 mg dose in all participants improved overall target attainment to 75%.
Conclusions: A lower number of undernourished PWTB reached the rifampin target exposure. A flat 600 mg dose might moderately benefit undernourished PWTB in achieving the C_{max} target. However, all participants, regardless of their nutritional status, may benefit from a higher dose of rifampin.

EP50-1181-21 Improving the diagnosis of TB among children with malnutrition in Niger, Nigeria and South Sudan

H. Huerga,[1] M.B. Abdullahi,[2] A.M. Issa Soumana,[3] L.F. Nyikayo,[4] O.F. Moussa Mamane,[5] J. Armour-Marshall,[6] B. Schramm,[6] E. Briskin,[6] L. Moreto,[7] A. Arias Rodriguez,[6] F. Nackers,[8] C. Hewison,[9] TB ALGO PED Study Group
[1]Epicentre, Field Epidemiology, Brussels, Belgium, [2]Medecins Sans Frontieres, Operational Centre Brussels, Maiduguri, Nigeria, [3]Epicentre, Research Centre, Nyamey, Niger, [4]Medecins Sans Frontieres, Operational Centre Barcelona, Malakal, South Sudan, [5]Medecins Sans Frontieres, Operational Centre West Africa, Nyamey, Niger, [6]Epicentre, Field Epidemiology, Paris, France, [7]Medecins Sans Frontieres, Operational Centre Barcelona, Barcelona, Spain, [8]Epicentre, Research, Brussels, Belgium, [9]Medecins Sans Frontieres, Operational Centre Paris, Paris, France e-mail: helena.huerga@epicentre.msf.org

Background: Tuberculosis (TB) and malnutrition are a deadly combination. We assessed frequency of TB diagnosis and reasons for TB treatment in children with severe acute malnutrition (SAM) in therapeutic feeding centres using new WHO-recommended treatment decision algorithms (TDA).
Design/Methods: Prospective diagnostic study conducted in three therapeutic feeding centres in Niger, Nigeria, and South Sudan. Children with SAM and at least one additional sign or symptom suggestive of TB were included. Xpert MTB/RIF was available at all sites. Chest X-ray was available in Niger and Nigeria. However, not all children with presumptive TB accessed chest X-ray due to logistical constraints. Children with TB were followed for 2 months.
Results: Among 1157 children included, median age was 1.3 years (IQR: 0.8-2.0), 519 (44.9%) were female, and 20 (1.7%) living with HIV (CLWHIV). Most children (1129, 97.6%) were hospitalized. Xpert MTB/RIF was performed in 1137 (98.3%) and was positive in 36 (3.2%). Chest X-ray was performed in 510 (44.4%) children and was suggestive of TB in 33 (6.5%). TB treatment was initiated in 265 (22.9%) children, 140 (52.8%) within three days of first assessment.
The principal reason in the TDA cascade to initiate treatment was clinical features score for 134 (50.6%), clinical-radiological score for 53 (20.0%), contact with person with TB for 31 (11.7%), Xpert MTB/RIF result for 24 (9.1%) and TB-LAM result for 3 (1.1%). Most of the children who started TB treatment (98%) improved clinically at 2-month.
Conclusions: A high proportion of children with SAM were diagnosed with TB in nutritional centers using the new treatment decision algorithms. Xpert MTB/RIF positive rate was low, as expected, however, it remains an important adjunctive diagnostic tool and aids detection of TB resistance. Chest X-ray was a useful tool for diagnosis, where available. TB diagnosis was primarily based on clinical features or history of contact person with TB.

EP50-1183-21 Carbohydrate dominance and gender inequity in diets of TB-affected households in India

C. Cintron,[1,2] P.B. Narasimhan,[3] B. Sack,[4] K. Jain,[5] M. Dauphinais,[2] S. Sarkar,[5] L. Locks,[6] N. Hochberg,[7] P. Sinha,[2,8] S. Lakshminarayanan,[5] [1]Brown University, Epidemiology, Providence, United States of America, [2]Boston Medical Center, Infectious Disease, Boston, United States of America, [3]Jawaharlal Institute Of Postgraduate Medical Education And Research, Clinical Immunology, Pondicherry, India, [4]University of Virginia, School of Medicine, Charlottesville, United States of America, [5]Jawaharlal Institute Of Postgraduate Medical Education And Research, Preventive and Social Medicine, Pondicherry, India, [6]Boston University, Health Sciences, Boston, United States of America, [7]Novartis Institutes for BioMedical Research, Global Health Translational Medicine, Boston, United States of America, [8]Boston University Chobanian & Avedisian School of Medicine,, Infectious Disease, Boston united, United States of America
e-mail: chelsie_cintron@brown.edu

Background: Over half of TB cases in India are attributable to undernutrition, and nutritional support for household contacts (HHCs) of persons with TB can reduce progression to active disease. However, there is no clear

consensus on the ideal composition of food baskets. Understanding what HHCs eat—and don't eat—can guide the design of more effective and equitable interventions.

Design/Methods: We enrolled 285 HHCs of adults with microbiologically confirmed TB in Puducherry and Tamil Nadu, India as part of the TB LION (Learning Impact of Nutrition) study. Baseline dietary intake was assessed via 24-hour recall. Macronutrient composition and dietary diversity were calculated using a modified Women's Dietary Diversity Score (WDDS), with consumption of ≥5 of 10 food groups considered "diverse."

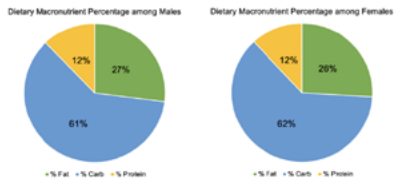
Food security was measured using the Household Food Insecurity Access Scale (HFIAS); participants with a score of 0 were categorized as food secure. Analyses were stratified by sex, BMI, and food security status.

Results: Diets were predominantly carbohydrate-based (62% of energy), with low contributions from fat (26%) and protein (12%) (Fig. 1A). Women (n=180) consumed significantly fewer calories across all macronutrients than men (n=105) but reported higher intake of dark leafy greens and fruits—though these were a small component of their diets (Fig. 1B).

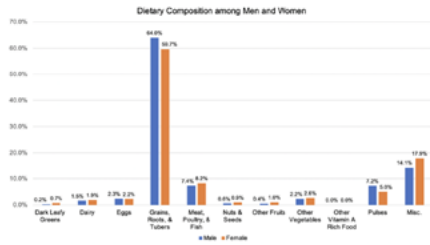
Food insecurity was more prevalent among undernourished (n=86) vs. well-nourished HHCs (n=199) (26% vs. 17%). Among food insecure individuals, 94% had low dietary diversity (<5 food groups), compared to 79% of food secure individuals.

Figure 1. Macronutrient (Panel A) and Dietary Composition (Panel B) among HHC by Sex and BMI status

Panel A.



Panel B.



Conclusions: This cohort's diet reflects a triple concern: gendered nutritional inequity, low diversity, and poor dietary quality despite perceived food security. Interventions must address macronutrient imbalance, incorporate regionally appropriate counseling, and ensure women are not nutritionally disadvantaged. Increased focus on dietary diversity is also critical since micronutrient deficiencies are associated with increased TB progression. These insights can help optimize basket design.

EP50-1184-21 Food with medicines: Impact of nutritional support on nutritional status, body composition, and grip strength in people nested within the RATIONS trial

A. Bhargava,[1] M. Bhargava,[2] A. Meher,[3] [1]Kasturba Medical College Mangalore, Manipal Academy of Higher Education, General Medicine, Mangaluru, India, [2]Yenepoya Medical College, Yenepoya (Deemed to be University), Community Medicine, Mangaluru, India, [3]Swasthya Swaraj Society, Health, Kalahandi, India
e-mail: anuragb17@gmail.com

Background: Information on the effect of nutritional support on body-composition and grip-strength in patients with tuberculosis (PwTB) is sparse. We assessed nutritional status [body mass index (BMI)], body composition (lean body mass, body fat) with bioelectrical impedance analysis (BIA), and handgrip strength in PwTB at enrolment and after 6 months of nutritional support.

Design/Methods: The 2800 PwTB in the RATIONS trial received a monthly food-basket providing 1200 Kcal and 52 gm protein daily during the 6-month treatment period. We enrolled 100 PwTB, of which 97 completed endline measurements. We conducted their weight (SECA 803), height (SECA 213 stadiometer), BIA (Bodystat® Quadscan 4000), and handgrip strength (JAMAR hand dynamometer) at baseline and the end of intervention. We used non-parametric tests with Bonferroni correction for multiple comparisons, with a p-value <0.005 considered statistically significant.

Results: The median (interquartile range) of weights and BMI at baseline in 65 men were 41.6 kg (39.0, 45.4) and 16.0 kg/m² (14.8, 17.7); the same in 32 women were 34.4 kg (31.9, 6.5) and 15.7 kg/m² (14.5,17.7) respectively. Over 80% were underweight (BMI <18.5 kg/m2), and > 50% had BMI <16.0 kg/m² (severely underweight) at baseline. Medians of lean body mass increased from 26.3 kg to 33.3 kg and of grip-strength from 23.7 kg to 28.5 kg. The fat mass reduced from 32.6 kg to 26.3 kg. The correlation coefficient of gain of lean mass with weight was 0.9342. 57% of patients continued to be underweight after 6 months.

Indicator	PwTB (n=97)	PwTB at 6 months (n=97)	Change over the intervention period	P values*
Body mass index, kg/m²	15.9 (14.6, 17.7)	18.1 (16.5, 19.2)	1.5 (0.8, 2.6)	<0.00005
Body weight, kg	39.6 (34.4, 43.6)	44.0 (39.6, 48.6)	4.2 (1.9,6.5)	<0.00005
Fat mass, kg	13.1 (11.1, 15.3)	12.2 (10.0, 14.2)	-0.80 (-2.10,0.4)	<0.00005
Lean body mass, kg	26.3 (21, 32.4)	33.3 (25.9, 37.8)	4.80 (2.4,7.4)	<0.00005
Fat mass (% of body wt.)	32.6 (25.3, 41.7)	26.3 (21.8, 35.0)	-6.4 (-15.6,3.0)	<0.00005
Lean mass (% of body wt.)	67.4 (58.3,74.7)	73.7 (65.0,78.2)	3.7 (1.2,9.40)	<0.00005
Fat-free mass index, kg/m²	11.1 (8.7,12.7)	12.9 (11.1,15.0)	1.8 (0.9,2.9)	<0.00005
Hand-grip strength, kg	23.7 (19.3,30.3)	28.5 (21.85,35.10)	3.9 (0.6,6.9)	<0.00005
Phase angle (degrees)	5.2 (4.3,5.6)	5.4 (4.8,6.0)	0.3 (-0.2,0.9)	<0.00005

**Wilcoxon signed rank test with p values adjusted for multiple comparisons.*

Conclusions: In a setting with high prevalence and severity of undernutrition, nutritional support in PwTB led to clinically significant improvements in nutritional status, body-composition and grip-strength without any increase in fat mass, aiding nutritional and functional recovery. The nutritional support needs to be graded in quantity and duration for optimal effect.

EP50-1185-21 Beyond the diagnosis: Using social determinants to drive targeted TB interventions in South Africa's West Rand District

O. Oladoyinbo,[1] N. Mhlabane,[2] T. Mzobe,[3] S. Modisane,[4]
[1]NIFDAR PBO, Clinical Research Unit, Pretoria, South Africa, [2]NIFDAR PBO, Public Health & Research, Pretoria, South Africa, [3]West Rand District Department of Health Services, Family Medicine, Krugersdoorp, South Africa, [4]West Rand District Department of Health Services, Public Health, Krugersdoorp, South Africa
e-mail: nelisiwe.mhlabane@nifdarconsulting.com

Background: While South Africa has made significant progress in scaling up TB diagnosis and treatment, social and structural determinants continue to undermine health equity and patient outcomes. This study investigates the non-clinical realities shaping TB vulnerability, access, and recovery in the West Rand District, with the goal of guiding programmatic action that addresses root causes.
Design/Methods: A cross-sectional survey was administered to 75 TB patients across three sub-districts . The questionnaire included 43 items covering socio-demographics, housing, food insecurity, healthcare access, digital access, and TB treatment experiences. Descriptive analysis was conducted to map trends in social vulnerability and service engagement.
Results: Most participants were male (68%) and aged 25–54 (66%). Unemployment was high (56%), with 60% earning less than R3,000/month. Nearly half lived in overcrowded or informal dwellings, and 28% reported food insecurity. Despite full reliance on public facilities and strong access to TB diagnosis and treatment (>80%), deeper vulnerabilities persisted 22% were orphans, 100% uninsured, and few had access to digital health support. High adherence (95%) and first-line drug usage (97%) were observed, yet structural inequities—such as low education levels and unstable employment—were prevalent and linked to social exclusion.
Conclusions: Findings from this assessment have directly informed the implementation of a localized **Social Determinants of Health Core Package of Interventions**, currently being rolled out in all facilities in West Rand. This package includes nutrition support, social grant referrals, psychosocial support, and tailored patient education. These actions reflect a shift from biomedical-only models to an integrated, equity-driven TB response. The study underscores the importance of routinely assessing and responding to social vulnerabilities as part of national and sub-national TB programming.

EP50-1186-21 Eureka: Evidence of links between financial help and TB disease and recovery in Victoria, Australia

K. Watts,[1,2] J. Denholm,[1,3] [1]The Peter Doherty Institute for Infection and Immunity, Victorian Tuberculosis Program, Melbourne, Australia, [2]The University of Melbourne, Social Work, Melbourne, Australia, [3]The University of Melbourne, Infectious Diseases, Melbourne, Australia
e-mail: justin.denholm@mh.org.au

Background: Globally it is well recognised that there is an association between TB and financial wellbeing. Australia is generally considered to be a country with "high income, low TB incidence" yet health inequities are observed.
In Victoria, Australia, specific, limited financial assistance for people affected by TB is available on an *ad hoc* basis, with help provided in response to assessed need. However, there has been limited evaluation of this support and clinical or public health outcomes.
Design/Methods: Adopting a data mining approach, routinely collected programmatic data was analysed. Using R, queries were made exploring the possibility of associations between the receipt of TB specific financial assistance across the TB cascade of care. Using data collected from January 2015 to December 2023, inclusive, analysis considered treatment interruption, local transmission, and linkage to care alongside demographic and TB clinical characteristics. A total of 3811 eligible TB notifications were included.
Results: Compared with the broader cohort of people eligible for anti-TB treatment those receiving TB-specific financial assistance were found to have longer treatment periods by 47 days, suggestive of brief treatment interruptions. Further, treatment interruption of two or more months were 6.3 times more likely and incomplete treatment was 2.1 times more likely. Delays in linkage to care and treatment commencement were less likely for those receiving TB-specific financial assistance. There is evidence of a connection between local TB transmission and receipt of TB-specific financial assistance with those receiving financial aid twice as likely to host *M.tb* that clustered at less than 6 SNP on whole genome sequencing.
Conclusions: Provision of directed financial assistance in our context shows evidence of association with important clinical and public health outcomes, potentially remediable with optimal support. These findings highlight the need for improved evaluation of financial burden associated with TB, even in high income settings.

EP51 Finding those missing: Responding to differentiated screening need

EP51-1187-21 Accelerating drug-resistant diagnosis and ending the gap of missing cases in urban India

A. Kalra,[1] M.A. Beig,[1] A.S. ThekkePurakkal,[1] N. Pandey,[1] S.S. Chadha,[1] U.B. Singh,[2] [1]FIND, Programmes, New Delhi, India, [2]National TB Elimination Programme, MoHFW, Central TB Division, New Delhi, India
e-mail: draakshikalra@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a major public health challenge in India, accounting for more than one-fourth of global burden. Drug-resistant TB (DR-TB) amplifies this burden, particularly in urban areas with systemic gaps in universal drug susceptibility testing (U-DST), leading to missed diagnoses and delayed treatment.
Project STRIDE (Strengthen U-DST for Increasing DR-TB Diagnosis and Ending gap of missing DR-TB patients), implemented in collaboration with India's National TB Elimination Programme (NTEP), aimed to strengthen DR-TB care pathways by addressing diagnostic bottlenecks, reducing treatment delays, and building sustainable models for replication in other high-burden settings.
Intervention or response: The project employed NTEP's four-pillar framework—'Detect-Treat-Prevent-Build'—to address gaps in DR-TB care. U-DST coverage was expanded (Detect) from 8 to all 30 Urban Primary Health Centres (UPHCs) in Agra by strengthening on-site sample collection and deploying sample transport coordinators to ensure timely delivery to testing labs. Partnerships with private laboratories addressed diagnostic backlogs and accelerated result turnaround times.
Pre-treatment evaluations (PTEs) were streamlined (Treat) to reduce delays in treatment initiation. This included ensuring comprehensive assessments to rule out underlying conditions at baseline.
Preventive measures (Prevent) included patient counselling on treatment and infection control. Capacity-building efforts (Build) focused on sensitizing UPHC staff and strengthening data reporting to NTEP.
Results/Impact: The project achieved 100% U-DST coverage across 30 UPHCs, collecting 8,224 samples between Jan-Dec-2024 (Figure-1).
Same-day sample transport increased from 73% to 98%. Diagnostic turnaround times were significantly reduced through private lab partnerships.
Approximately 1,000 TB cases were diagnosed, including 100 DR-TB cases (~10% positivity). Nearly 94% were initiated on treatment and PTE delays reduced from seven days to two days.

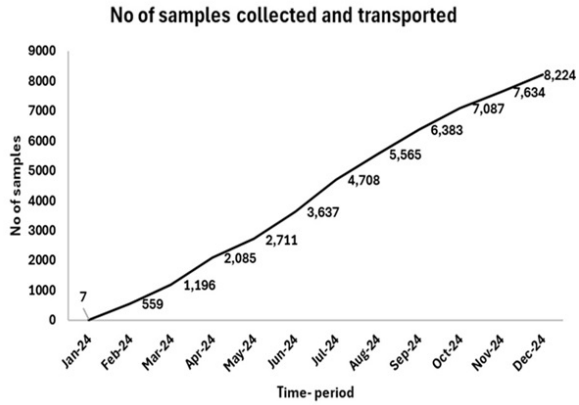


Figure 1. Trends in DR-TB sample collection and transportation (cumulative): Project STRIDE, Agra, India 2024.

Conclusions: Project demonstrates that decentralizing diagnostic services and optimizing sample transport can improve DR-TB detection and treatment linkages in urban settings. Prioritizing resources for transport systems and streamlining PTE are key to achieve India's TB elimination targets.

EP51-1188-21 Active TB detection in nomadic populations: Insights from hard-to-reach communities of Adamawa State, Northeast Nigeria

S. John,[1] S. Abdulkarim,[2] S. John Kwaghe,[1] A. Abdullahi A,[2] T. Garg,[3] J. Creswell,[3] [1]Janna Health Foundation, Programmes, Yola, Nigeria, [2]SUFABEL Community Development Initiative, Programmes, Gombe, Nigeria, [3]Stop TB Partnership, TB REACH, Geneva, Switzerland
e-mail: wizemannstv2@gmail.com

Background and challenges to implementation: Nigeria missed 25% of the estimated people with TB 2024, mostly among key and vulnerable populations, such as nomads. Adamawa State has an estimated 450,000 nomads who are known to have high TB rates due to factors which include poor access to health services, overcrowding, poor ventilation, and low level of awareness on TB. High bovine TB rates, and the prevalent consumption of unpasteurized milk by nomads compounds the problem. Nomadic communities suffer from poor access to health care, and rural areas often lack access to modern tools like AI-enabled CXR (AI-CXR), which can identify people with TB that symptom screening misses. Here, we present findings from active TB screening in Nomadic Communities using AI-CXR in Adamawa State, Nigeria.
Intervention or response: Between August 2024 and January, 2025, screening camps were organized in nomadic communities of Adamawa State; 37 screening sessions were conducted in 31 Nomadic communities using AI-

CXR to screen consenting individuals (≥15). People with AI score of ≥0.3 on qXRv4 were considered to have presumptive TB and had their sputum collected, transported and tested with GeneXpert MTB/RIF Ultra. Results were actively retrieved, people confirmed with TB were promptly linked to treatment while those with negative results were further evaluated by radiologists/medical officers for clinical management.

Results/Impact: A total of 1,348 (including 646 females) adults were screened with CXR-AI. Of these, 219 individuals (16%) had AI scores of ≥0.3 and were tested using GeneXpert MTB/Rif. 75 people were diagnosed with TB including 11 with Bac+ TB; 29 (39%) were females. All people diagnosed with TB were successfully initiated on treatment.

Conclusions: Use of portable AI-CXR for TB screening in Nomadic communities led to increased TB notifications in both Bac+ and all forms. Scaling this approach could improve the treatment coverage gap.

EP51-1189-21 Strengthening cross-border TB prevention and care through a one health approach among nomadic pastoralist communities in Kenya and Uganda

I. Karuga,[1] D. Oira,[1] W. Githieya,[1] J. Okemwa,[2] R. Tarus,[3] W. Tomno,[4] P. Wekesa,[1] N. Mugambi-Nyaboga,[1]
[1]Center for Health Solutions, Health Programs, Nairobi, Kenya, [2]County Government of Turkana, County Department of Health, Turkana, Kenya, [3]County Government of West Pokot, County Department of Health, West Pokot, Kenya, [4]Division of National Tuberculosis, Leprosy and Lung Disease Program, Ministry of Health, Care and Treatment, Nairobi, Kenya
e-mail: jkarugah@gmail.com

Background and challenges to implementation: Cross-border collaboration is essential for TB control, particularly among mobile populations. West Pokot and Turkana counties in northeastern Kenya are high-TB-burden regions bordering Uganda, where nomadic pastoralist communities reside in remote settings with limited healthcare access and inadequate resources.

We share our experiences implementing a collaborative cross-border tuberculosis (TB) project by the Kenyan and Ugandan National TB Programs (NTPs) and two Counties along the Kenya and Ugandan border through a One Health approach.

Intervention or response: The USAID TIFA cross-border project was co-designed with stakeholders to strengthen cross-border TB coordination and capacity. We mapped diagnostic networks, treatment sites, human and veterinary resources, community resource persons (CRPs), and migratory routes. We selected 30 cross-border health facilities and trained healthcare workers (HCWs) and CRPs. Activities included contact tracing and screening, tracking patients lost to follow-up, and integrated community outreaches offering human and animal health services. Implementation was monitored through data review meetings, support supervision, joint review meetings, data quality assessments, and cross-border technical assistance from Uganda and Kenya NTP teams.

Results/Impact: Between May and December 2024, we trained 43 HCWs and 946 CRPs. TB was diagnosed in 477 patients, 286 (60%) with bacteriologic confirmation. Among 832 listed contacts; 571 (68.6%) were traced and 407 (48.9%) screened; 62 (15.2%) were presumptive and 21 were diagnosed with TB. Of 51 patients lost to follow up, 32 (62.7%) resumed treatment.

Further, 27 patients were referred across borders for continued treatment. A cross-border TB service directory and social media platforms were established to enhance coordination. A sustainability plan and documentation of lessons learned were developed.

Conclusions: Multisectoral cross-border TB control using the One-Health approach can enhance TB detection, treatment adherence, and continuity of care by improving coordination, data sharing, and access to services for mobile populations in remote, high-TB-burden pastoralist communities.

EP51-1191-21 Leaving no one behind: Targeted TB case finding in correctional facilities in Niger State, Nigeria

I. Ibrahim,[1] D. Philip,[1] L. Shehu,[2] A. Agbaje,[3] E. Ubochioma,[2] O. Chijioke-Akaniro,[2] O.A. Fadare,[4] D.S. Hananiya,[5] [1]Ministry of Secondary and Tertiary Health, Niger State, Department of Public Health, Minna, Nigeria, [2]Federal Ministry Of Health, Department of Public Health, Abuja, Nigeria, [3]Institute of Human Virology of Nigeria (IHVN), Department of Public Health, Abuja, Nigeria, [4]WHO Nigeria, UCN Cluster, Abuja, Nigeria, [5]WHO Nigeria, UCN/Field Presence Cluster, Minna, Nigeria
e-mail: isahibrahim73@gmail.com

Background and challenges to implementation: Congregate settings like correctional (prison) and detention facilities are high-risk environments for TB transmission, particularly in Nigeria where overcrowding is common. Undiagnosed TB cases in such settings can fuel rapid transmission.

This intervention aimed to identify and treat TB among incarcerated populations in Niger State, a key population often missed in routine surveillance.

Intervention or response: The approach involved mapping all prisons and detention facilities in Niger State, engaging correctional authorities, and retraining healthcare workers (HCWs) in facilities with clinics. For those without clinics, specimen referral systems were strengthened. NTBLCP R&R tools were introduced to improve data documentation. TB screening was institutionalized at clinic entry points and upon inmate admission.

Results/Impact: A total of 875 inmates were screened from the five (5) correctional facilities mapped in the state, with 520 presumptive TB cases identified and tested. Of these, 164 were diagnosed with TB, with no TB/HIV co-infections detected. The majority of cases (87%) were in the 15–54 age group, with those aged 45–54 years contributing the highest burden. Only 2% (3 cases) were female. However, only ten contacts were screened, and 4 eligible contacts were initiated on TPT, constrained by limited availability of shorter TPT regimens.

Screening Cascade									
	Total number of Person Screened for TB	Total number of presumptives	Presumptive DS-TB	Presumptive DR-TB	Examined for diagnosis	Total Examined with Xpert	Total Diagnosed	Total TB cases notified	HIV positive
Q3, 2024	428	332	330	2	332	332	115	115	0
Q4, 2024	447	188	183	5	188	188	49	49	0
Total 2024	875	520	513	7	520	520	164	164	0
Sex Disagregation of Notified persons with TB									
Q3, 2024	0-4	5-14	15-24	25-34	35-44	45-54	55-64	>65	Total
Male	0	0	21	23	23	40	5	0	112
Female	0	0	0	0	0	0	3	0	3
Total	0	0	21	23	23	40	8	0	115
Q4, 2024	0-4	5-14	15-24	25-34	35-44	45-54	55-64	>65	Total
Male	0	0	11	9	7	9	9	4	49
Female	0	0	0	0	0	0	0	0	0
Total	0	0	11	9	7	9	9	4	49

Conclusions: This targeted intervention demonstrated the effectiveness of active TB case finding in congregate settings. Strengthened collaboration with correctional services, consistent screening at entry points, and improved diagnostics were key to success. Introducing the use of portable digital X-rays (PDX) procured by the NTBLCP with Global Fund support for screening will improve the yield. Expanding this model nationally could close TB detection gaps in high-risk, underserved populations.

EP51-1192-21 Transforming TB preventing and care in prisons through policy and person-centered active case finding: A case from Padang City, Indonesia

R. Machmud,[1] F.F. Yani,[2] A.N. Sary,[3] [1]Universitas Andalas, Public Health, Padang, Indonesia, [2]Universitas Andalas, Department of Child Health, Padang, Indonesia, [3]Universitas Andalas, Public Health Post Graduate Study Program, Padang, Indonesia
e-mail: rizandamachmud@med.unand.ac.id

Background and challenges to implementation: Indonesia remains a high-TB-burden country, and correctional facilities are high-risk environments due to overcrowding, poor ventilation, and limited access to care. In Padang City, West Sumatra, three prisons housing 2,097 inmates reported only one TB case in 2021 and two in 2022. Low detection was linked to the absence of systematic screening, stigma, inadequate diagnostic capacity, and poor coordination between prison and public health services.

Intervention or response: In 2023, a joint TB control program between the Ministry of Health and the Ministry of Law and Human Rights was implemented, following Presidential Regulation No. 67/2021. The intervention included mass TB screening for all 2,097 inmates using mobile digital chest X-rays and symptom assessment.
A total of 451 individuals underwent GeneXpert (TCM) testing. Diagnosed cases were recorded in the national Si-TB registry, which enabled treatment initiation, monitoring, and continuity of care. Peer educators supported treatment adherence and TB awareness inside the prisons.
Results/Impact: The intervention identified 81 new TB cases in 2023, a significant increase from previous years. All cases received treatment and were monitored through Si-TB. This result demonstrated that active case finding, supported by national policy and cross-sector collaboration, dramatically improves detection in prisons. The integration of peer support also helped reduce stigma and improved engagement with TB services.
Conclusions: Person-centered, policy-supported TB services in prisons can significantly strengthen detection and treatment outcomes. The Padang experience highlights the importance of inter-agency collaboration, digital integration, and peer-led support in high-risk settings. This model offers a scalable and effective approach for TB control in correctional facilities across Indonesia and other high-burden countries.

EP51-1194-21 Impact of alcohol use on treatment outcomes amongst drug-resistant people with TB in Kenya

M. Odhiambo,[1] I. Ronoh,[2] L. Odeny,[1] B. Ulo,[1]
[1]Amref Health Africa, GF-TB Project, Nairobi, Kenya, [2]National TB Program, Monitoring and Evaluation, Nairobi, Kenya
e-mail: Michael.Odhiambo@amref.org

Background and challenges to implementation: Drug-resistant tuberculosis (DR-TB) is a major health challenge in Kenya, exacerbated by alcohol use, which is linked to poor treatment outcomes such as delayed care, poor adherence, and treatment failure. Local data on the impact of alcohol on DR-TB outcomes is limited. This study aims to assess this relationship and inform integrated interventions.
Intervention or response: This retrospective cohort study analyzed data from 1,613 MDR-TB and XDR-TB patients diagnosed between 2023 and 2025 across 47 counties in Kenya. Demographics, alcohol use, treatment adherence, and outcomes (treatment success, failure, loss to follow-up) were extracted from the NTLD-P TIBU system.
Multivariate logistic regression was used to evaluate the relationship between alcohol use and treatment outcomes, adjusting for confounders.

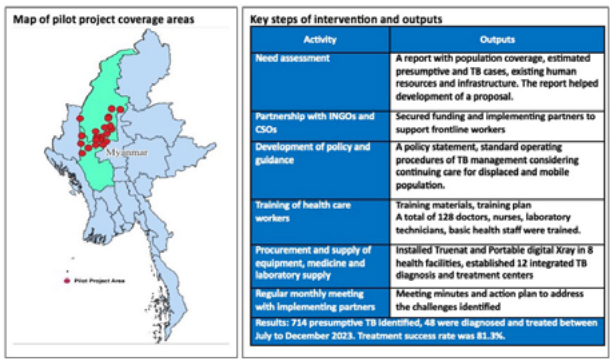
Results/Impact: Among 1,521 patients, 27% reported alcohol use. Factors independently associated with alcohol consumption included male sex (aOR: 3.14), age (aOR per year: 1.02), severe malnutrition (aOR: 1.39), and community-based care (aOR: 0.53). Regional differences also affected alcohol use. Alcohol use was not independently linked to treatment outcomes after adjustment, though it was inversely associated with treatment success in univariate analysis (OR: 0.78). Favorable outcomes were associated with private/public sector care, longer treatment duration, and mono-resistant TB.
Conclusions: . Alcohol consumption negatively impacts DR-TB treatment, emphasizing the need for integrated care approaches that include alcohol reduction strategies to enhance TB treatment outcomes.
While alcohol use was associated with certain demographic and clinical factors, it did not directly influence treatment outcomes after multivariable adjustment. Its impact on adherence and immune function may indirectly affect treatment success. These findings highlight the need for integrated care, including alcohol management, to improve DR-TB outcomes, especially in high-risk areas.

EP51-1195-21 Leaving no one behind: Experience of piloting TB diagnosis and treatment service delivery to the conflict affected population in Myanmar

H. Myay Latt,[1] S. Serena,[2] F. May,[3] S. Tharaphi,[4] B. Shwe,[2] A. Simon,[5] A. K,[6] W. Timothy,[2] NTCP Study Group [1]Ministry of Health - National Unity Government, National Tuberculosis Control Program, Maesot, Thailand, [2]Ministry of Health - National Unity Government, National Tuberculosis Control Program, Yangon, Myanmar, [3]Ministry of Health - National Unity Myanmar, National Tuberculosis Control Program, Chaing Mai, Thailand, [4]National Unity Government, Ministry of Health, Chiang Mai, Thailand, [5]NTCP Study Group, Health, Yangon, Myanmar, [6]NTCP Study Group, Health, Bangkok, Thailand
e-mail: aaron@hlu-mm.org

Background and challenges to implementation: The 2021 Myanmar coup and ongoing conflict severely disrupted healthcare access, including TB diagnosis and treatment in the conflict affected areas, exacerbated by medical supply restrictions, power outages, and communication disruptions.
To address this, volunteer health professionals formed the TB Technical Support Team (TB-TST) in mid-2022 and piloted a project in 21 townships of 2 administrative regions in 2023.
Intervention or response: The team conducted needs assessments, secured funding, and partnered with INGOs and CSOs, developed TB diagnosis and management policies and guidance and provided virtual training for healthcare workers, including medical technicians. Eight high-attendance health facilities were installed with Truenat and portable digital X-ray machines. The TB-TST also provides ongoing support and holds monthly partner meetings to address challenges.

Figure: Map of pilot project coverage areas and key steps of interventions



Results/Impact: In 2023, the integrated fixed/mobile primary health care clinics provided TB diagnosis and treatment services through ambulatory care with community health volunteer support. Between July to December 2023, 714 people with presumptive TB were identified and 48 were diagnosed and treated for TB.
Among those treated, medium age was 48 years (8-88 years in range), 75% were male, 25% were female, 90% were pulmonary TB and 10% were extra-pulmonary TB. Treatment success rate was 81.3% with 8.4% died, 6.3% loss to follow-up and 4.2% not evaluated.
The pilot's success enabled expanding TB service provision in 88 townships of 9 administrative regions in 2024. Monthly meeting minutes recorded that availability of essential medical and laboratory supply was the most profound challenge among others.
Conclusions: The use of advance technology such as Truenat and portable digital Xray, virtual training coupled with integrated ambulatory service delivery make possible providing essential TB services to the conflict affected population. Neglecting such underserved population would cost their lives and continuing transmission in the population.

EP51-1196-21 Bridging the rural TB care gap: Impact of Ayushman Arogya Mandir (AAM) integration into National Tuberculosis Elimination Programme in Uttar Pradesh, India

H. Himanshu,[1] S. Bhatnagar,[2] B.K. Shetty,[1] R. Washington,[3]
[1]India Health Action Trust, Tuberculosis, Lucknow, India, [2]State Medical & Health Department, State TB Cell, Lucknow, India, [3]India Health Action Trust, Tuberculosis, Banglore, India
e-mail: shettybharat074@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a significant public health challenge in India, with rural populations disproportionately affected compared to urban. Despite existing services, nearly 64% of individuals with TB symptoms do not seek care from qualified providers, leading to delayed diagnosis and sustained transmission. Addressing this gap requires community-driven approaches to improve early detection and early treatment care access. The integration of Ayushman Arogya Mandirs (AAMs)—government-designated health and wellness centres—into the TB care pathway offers a strategic solution.

Armed with community-based health workers coordinated by Community Health Officer, AAMs are well-positioned to improve TB systematic screening, referral, and treatment outcomes in rural areas.

This study examines the impact of rural AAM engagement on presumptive TB enrolment, diagnosis, and treatment initiation within the public health system in Uttar Pradesh, India.

Intervention or response: Programmatic data (2023–2024) from Ni-kshay portal, India's web-based TB surveillance system in Uttar Pradesh was analysed. A structured AAM integration process, including facility registration, capacity building, monitoring and reviews for constructive actions, was implemented. Key TB indicators were compared across two years to assess improvements in service delivery.

Indicator	2023	2024
Total Enrolment in Public sector	18,23,390	33,83,380
Total AAMs engaged	12,166	14,744
Enrolment from AAM	4,14,265	12,21,546
% Enrolment from AAM to Total PHI	23%	36%
Total Positive from AAM (% positive of tested)	22,087 (5%)	29,235 (2.4%)
Microbiological confirmed cases from AAM	10,733	12,694
% Microbiological confirmed	49%	43%
Treatment initiation from AAM cases	10,254	28,217
% Treatment initiation	95%	97%

Results/Impact: The presumptive TB enrolment through AAMs increased three-fold from 0.41M (23%) to 1.22 M(36%) of the total public sector enrolment of 1.82M(2023) to 3.38 M(2024). The numbers of TB diagnosed increased from 22,087 to 29,235 and microbiological confirmation among diagnosed TB rose in number from 10,733 to 12,694. Although the proportion declined from 49% to 43%, indicate expanded reach but potentially broader screening of lower-risk individuals. Treatment initiation among AAM-diagnosed cases improved from 95% to 97%.

Conclusions: Integrating AAMs into the National Tuberculosis Elimination Programme significantly enhanced early TB case identification and early treatment initiation in rural communities. Scaling and sustaining this community-based model can play a pivotal role in achieving TB elimination goals, especially in high-burden, rural and hard-to-reach settings.

EP52 Preventing and finding TB in children and household contacts

EP52-1197-21 Reaching children where they are: The role of community and school-based TB screening during World Tuberculosis Day 2025 activities in Rivers State, Nigeria

N. Kadiri-Eneh,[1] O. Ezeanyim,[2] O. Maduka,[3] O. Chukwuogo,[4] B. Odume,[4] V. Oris-Onyiri,[5] [1]KNCV Nigeria, Rivers State, Port Harcourt, Nigeria, [2]KNCV Nigeria, Rivers, Port Harcourt, Nigeria, [3]University of Port Harcourt, Community Medicine/Public Health, Port Harcourt, Nigeria, [4]KNCV Nigeria, Abuja, FCT, Nigeria, [5]Rivers State Ministry of Health, Rivers State Tuberculosis, Leprosy and Buruli Ulcer Control Program, Port Harcourt, Nigeria
e-mail: neneh@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains underdiagnosed in children due to non-specific symptoms, limited access to diagnostic tools, and poor health-seeking behavior. During the 2025 World TB Day activities in Rivers State, Nigeria, a strategic focus was placed on identifying TB in children by integrating community and school-based screening initiatives.
This study evaluates the effectiveness and TB yield from community and school-based TB screening activities among children during the World TB Day 2025 campaign in Rivers State.
Intervention or response: A one-week intensified TB case-finding campaign was conducted across selected communities, schools, and hospital outpatient departments (OPD) in Rivers State. Health education and TB awareness sessions were also conducted; children aged 0–14 years were screened using symptom checklists and portable digital X-rays (PDX). Sputum and stool samples from presumptive cases were tested with GeneXpert.
Children with symptoms or abnormal chest X-rays with negative bacteriological results were further evaluated clinically for TB diagnosis and treatment initiation. Data was analyzed using SPSS.
Results/Impact: A total of 5,746 children were screened: 44.4% in schools, 31.1% in OPD, and 24.6% in community settings. Overall, 1,029 children were identified as presumptive TB cases, resulting in a presumptive yield of 18%. Among these, schools accounted for 51.1% of presumptive cases, communities for 31.6%, and OPD for 17.3% ($X^2 = 96.4$, $p < 0.001$). TB was confirmed in 50 children (TB yield: 5.1%). Of the confirmed cases, 24 (46.2%) were detected in schools, 21 (40.4%) in communities, and 7 (13.4%) in OPD ($X^2 = 10.6$, $p = 0.005$); treatment initiation rate was 100%.
Conclusions: The 2025 World TB Day campaign strategy demonstrated that school- and community-based screening significantly enhances pediatric TB case detection.
These findings support the integration of TB services into child-centered environments and suggest that school health programs offer a viable strategy to improve pediatric TB control in Nigeria.

EP52-1198-21 Finding TB in children living with HIV: Results using the WHO-recommended algorithms in Conakry, Guinea

E. Briskin,[1] I. Barry,[2] M. Kéita,[2] A. Dore,[2] F.B. Sako,[3] A. Shyaka,[2] F. Guilavogui,[4] S. Camara,[5] E. Casas,[6] A. Arias-Rodrigues,[1] F. Nackers,[7] H. Huerga,[1] [1]Epicentre, Field Epidemiology, Paris, France, [2]Médecins Sans Frontières, Operational Centre Brussels, Conakry, Guinea, [3]Direction Nationale de l'Epidémiologie et de la Lutte contre la Maladie (DNELM), Director, Conakry, Guinea, [4]Programme National de Lutte contre le VIH/SIDA et les Hépatites (PNLSH), HIV Unit, Conakry, Guinea, [5]Programme National de Lutte contre la tuberculose (PNLT), HIV/TB Unit, Conakry, Guinea, [6]Médecins Sans Frontières, Southern Africa Medical Unit, Johannesburg, South Africa, [7]Epicentre, Research, Brussels, Belgium

Background: The diagnosis of pediatric tuberculosis (TB) remains a challenge, particularly in children living with HIV (CLWHIV). To guide clinicians' treatment decisions in children under 10 years of age, the WHO recommends two treatment decision algorithms (TDAs) that include scores to assess clinical and radiographic signs. We assessed the diagnostic cascade for pulmonary TB (PTB) in CLWHIV using these TDAs under programmatic conditions.
Design/Methods: From November 2023-December 2024, ambulatory CLWHIV under 10 years of age, followed on a bimonthly basis, and presenting with signs or symptoms suggestive of PTB were recruited from four health facilities in Conakry, Guinea, in a prospective observational study.
Results: Among 321 CLWHIV assessed for signs or symptoms suggestive of PTB, 159 presented with symptoms of PTB and were enrolled in the study and evaluated using the TDAs. Of the 321 children, 227 were assessed multiple times (median 3 times in the 14-month period). Among the 159 children with PTB symptoms, 106 (73%) underwent a TB-LAM test, 24 (15%) a GeneXpert stool test, and 93 (58%) a chest X-ray, due to intermittent availability issues. Only 3/59 (5%) children for whom the TDAs recommended a follow-up visit 7-14 days after consultation returned. In total, 105 children (66%) were initiated on anti-tuberculosis treatment.
Main reasons for starting treatment were a clinical or radiological TDA score above 10 points for 48 (46%) children, contact with a TB patient for 27 (26%), a positive TB-LAM for 26 (25%) and positive GeneXpert for 1 (1%) child.

Conclusions: The systematic use of TDAs led to a high proportion of CLWHIV receiving TB treatment, despite challenges with test availability and low follow-up return at 7-14 days in this ambulatory cohort. The clinical and radiological scores, history of TB contact and TB-LAM were the main algorithm elements leading to initiation of anti-tuberculosis treatment.

EP52-1199-21 Improving childhood TB diagnosis and notification through advanced sample collection technologies intervention: An insight from Malawi

K. Banda,[1] H. Kkanyerere,[2] K. Mbendera,[2] T. Mwenyemkulu,[2] B. Shigutti,[2] H. Chafulumira,[2] M. Mmanga,[2] M. Jeke,[3] [1]Quality Management Department, Zonal Health Office-South West, Blantyre, Malawi, [2]Ministry of Health, National Tuberculosis and Leprosy Elimination Programme, Lilongwe, Malawi, [3]Ministry of Health, Quality Management Office-Zomba, Zomba, Malawi
e-mail: knoxbanda1965@gmail.com

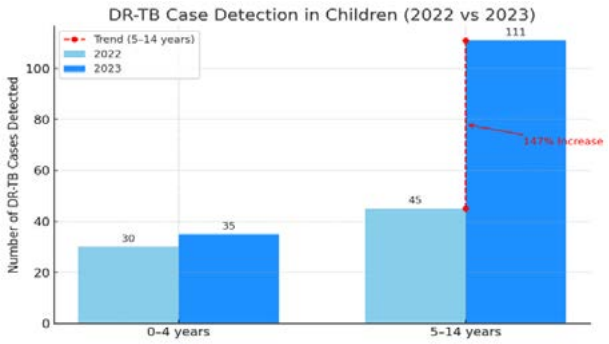
Background and challenges to implementation: World Health Organisation (WHO) estimates that 1.25 million children aged 0-14 years developed TB in 2022 worldwide, but over half remained undiagnosed or unreported. In 2023, Malawi reported 19,029 TB patients. Of these, 1,333(7%) were children aged 0-14 years against a national target of 2,295 childhood TB patients. This gap may be due to factors relating to childhood TB diagnosis.
Intervention or response: In 2023, Malawi National TB and Leprosy Elimination Program (NTLEP) trained healthcare workers from 15 selected health facilities in advanced sample collection technologies (ASCT) such as gastric lavage (GL), nasopharyngeal aspirate (NPA), induced sputum (IS); and other non-respiratory specimen collection techniques.
The intervention aimed at improving childhood TB diagnosis and case notification through advanced sample collection technologies (ASCT).
During implementation (January-December,2024), facilities conducted systematic TB screening to identify children with presumed TB and referred them for sample collection. Children who were unable to expectorate sputum were referred for GL; and if unsuccessful, samples were obtained through NPA or IS or stool. Non-respiratory samples were collected through other techniques.
All samples were tested through GeneXpert/MTB Rif Ultra. Children who either tested negative or failed to submit samples were clinically evaluated to determine if they had active TB and managed accordingly.
Results/Impact: The number of samples obtained through ASCT increased by 107% from 396 (January-December, 2023) pre-intervention period to 822 during intervention period (January-December, 2024). Concurrently, the number of children diagnosed with bacteriology-confirmed TB increased by 82%, from 11 to 20 patients. The proportion of childhood TB among total notified TB patients also improved from 7.7% to 8.6%.
Conclusions: Implementation of ASCT TB intervention by health facilities under routine health services delivery conditions can greatly improve childhood TB diagnosis and case-notification. NTLEP in collaboration with its stakeholders needs to put in place measures on how to sustain and scale up ASCT strategy in Malawi.

EP52-1200-21 The socio-cultural challenges affecting diagnosis of drug-resistant TB in children aged 0-4 years: Insights from KNCV Nigeria's experience

C. Igwetu,[1] H. Ma'ab Baffa,[1] M. Tukur,[1] S. Useni,[1] B. Odume,[2] C. Anyaike,[3] [1]KNCV Nigeria, Technical and Program Department, Federal Capital Territory, Nigeria, [2]KNCV Nigeria, Technical and Program Department, FCT Abuja, Nigeria, [3]Federal Ministry of Health, Public Health, FCT Abuja, Nigeria
e-mail: cigwetu@kncvnigeria.org

Background and challenges to implementation: Children under five are a vulnerable, often underdiagnosed group in the fight against drug-resistant tuberculosis (DR-TB). Unlike older children who can expectorate sputum, younger children require alternative samples like stool, which pose technical and socio-cultural challenges. Parental misconceptions, discomfort, and low awareness further hinder the uptake of stool sample collection.
This study explores how socio-cultural factors influence diagnostic barriers in pediatric DR-TB detection based on KNCV Nigeria's experience.
Intervention or response: In 2022 and 2023, KNCV Nigeria, through the USAID-funded TB LON 1 & 2 project, conducted active case finding in 14 supported states, screening children aged 0–4 years using stool samples and children aged 5–14 with sputum. Healthcare and laboratory staff were trained on pediatric DR-TB clinical features, GeneXpert diagnosis, and sample handling.
A qualitative survey involving key informant interviews and focus group discussions with mothers of children aged 0–4 identified barriers to stool sample collection. Low awareness and cultural discomfort were significant obstacles.
However, following targeted community sensitization and caregiver education, perceptions improved, leading to increased willingness to provide stool samples
Results/Impact: The data in the chart below shows that there is still a wide margin in DR-TB case detection among children aged 0-4 and 5-14. Case notification among children under five remained low despite screening efforts, underscoring the continued impact of both technical difficulties and caregiver-related barriers in stool sample uptake. The post-sensitization phase, however, showed im-

proved sample submission, suggesting that socio-cultural resistance is modifiable through engagement and education.



Conclusions: Low DR-TB detection in children under five is driven by technical and socio-cultural barriers. Improved caregiver's willingness for post-sensitization highlights the value of community engagement. Scaling caregiver education, culturally tailored awareness, and health worker training—while leveraging influences and support groups—can boost stool sample uptake and early diagnosis in this group.

EP52-1201-21 Prevalence of TB infection in school-going children in India: A scoping review

R. Calderara,[1] M. Sharma,[2] A.H. Moe,[3] S. Cox,[4] [1]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States of America, [2]Johns Hopkins India, Gupta Klinsky India Institute, New Delhi, India, [3]Johns Hopkins University, Department of Medicine Division of Infectious Diseases, Baltimore, United States of America, [4]Johns Hopkins University, Bloomberg School of Public Health; Department of International Health, Baltimore, United States of America
e-mail: rcalde14@jh.edu

Background: Over one-third of India's adult population is estimated to be infected with tuberculosis (TB). However, TB infection (TBI) prevalence among children in India is poorly characterized. School-aged children are at elevated risk of TB disease due in part to recency of infection and the unique immunological changes that occur during adolescence. As part of the TB Free Schools Initiative, we conducted a scoping review to estimate TBI prevalence among India's school-going children.
Design/Methods: We searched PubMed for papers published up to 2025 in English using a combination of MeSH terms and relevant keywords. Studies containing primary data on TBI positivity among school-going children in India were included. We abstracted data on school type, ages, and criteria for positivity. We pooled prevalence, calculated number needed to screen (NNS) to identify one child with TBI, and analyzed results by BCG vaccination status.
Results: A total of 84 relevant studies were identified, and 7 met inclusion criteria. All used purified protein derivative (PPD)-based tuberculin skin testing (TST) to identify TBI, each with a sample size >100 children (ages 5-19). The prevalence of TBI ranged from 5.0 -18.6%, and pooled prevalence was 13.4%. The NNS ranged from 5 to 10.
One study included children in a boarding school setting; otherwise, estimates were from day schools. Among 7 studies with estimates by BCG status, 5 reported higher TST positivity among vaccinated children.

Author	Year	Location	Age range	Type of TST	TU	Definition	Prevalence estimate	Number needed to screen
Dorjee et al.	2019	Himachal Pradesh[a]	5-19 years	PPD RT23 (Span Diagnostics)	5	Algorithm included: ruling out disease + ≥10 mm, measured after 24-72 hours	17.8% (930/5234)	6
Uppada et al.	2014	Andhra Pradesh	11-18 years	PPD RT23 with Tween 80 (Span Diagnostics)	2	≥10mm, measured after 48-96 hours	12.0% (794/6608)	8
Serane et al.	2014	South India[b]	10-14 years	PPD RT23 with Tween 80 (BCG lab, Guindy, Chennai)	1	≥10 mm measured after 24-72 hours	18.6% (112/601)	5
Kumar et al.	2009	Kerala	5-9 years	PPD RT23 with Tween 80	1	>10 mm measured after 72 hours	5.0% (241/4821)	10
Chadha et al.	2008	Banglore	5-8 years	PPD RT23 with Tween 80 (BCG lab, Guindy, Chennai)	1	>10 mm, measured after 72 hours	13.5% (452/3354)	7
Pulickalet al.	2007	Kerala	5-9 years	PPD RT23 (BCG lab, Guindy, Chennai)	1	≥10 mm in unvaccinated, ≥15mm in vaccinated, measured after 72 hours	15.6% (65/418)	6
Serene et al.	2001	Pondicherry	5-9 years	PPD RT23 (BCG laboratory, Guindy, India)	1	≥10 mm measured after 72 hours	18.6% (93/500)	5

Footnotes: State is not specified in the Serane et al. paper.[b] Abbreviations: PPD RT 23=Purified Protein Derivative RT 23; TST=Tuberculin Skin Test; TU=Tuberculin Units; BCG=Bacillus Calmette-Guérin; mm=millimeter.

Table. TB infection prevalence estimates among school-going children in India.

Conclusions: TST positivity among school-going children in India was high and suggests that up to half of all TBI in India occurs before adulthood. Active case finding for TB among school-children in India may be a high-yield strategy and targeting prevention efforts in this population may have population-level impact. Further research is needed to update TBI prevalence estimates among school-children in India and determine the yield of active case finding in this high-risk group.

EP52-1202-21 Integrated approach on case detection in children with unknown TB history in Nigeria: RAISING study

P. Ilueme,[1] A. Okoh,[2] M. Sheshi,[3] B. Odume,[3] U. Chukwulobelu,[4] [1]KNCV NIGERIA, Technical, Awka, Nigeria, [2]KNCV Nigeria, Technical, Abuja, Nigeria, [3]KNCV Nigeria, Management, Abuja, Nigeria, [4]Anambra State Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Public Health, Awka, Nigeria
e-mail: ugoo.chukwulobelu@gmail.com

Background: Tuberculosis detection and notification in children is quite poor, not up to national benchmark of 15%, and in 2023 Nigeria childhood TB notification was 10% amidst the high notification the country is reporting. The aims of this research are to determine the baseline of childhood tuberculosis detection among children (0-14

years), explore factors affecting poor childhood detection and integrate childhood tuberculosis screening as form of basic health screening using relevant stakeholders.
Design/Methods: This study approach was a mixed-method research that involved cross-sectional survey, qualitative research as well as workshop for relevant stakeholders.
Cross-sectional study survey was carried out and communities were randomly selected in Anambra state for the first phase of the research, stratified random sampling was also used to select the study sites. A serialized list of all DOTS clinic in Anambra state were included. Thereafter, DOTS sites were stratified based on their level of care as well as by ownership.
In all 20 facilities was selected, in 20 communities with 20 primary schools, 20 parents, 20 community leaders were all invited to this survey, with a simple random sampling applied. Sample size of 390 (3) was determined using the formula shown {n = [DEFF*Np(1-p)]/ [(d2/Z21-α/2*(N-1)+p*(1-p)]}.
Results: The baseline of the study showed that tuberculosis diagnosis in children were basically by clinical screening by Physician and the use of Chest X-ray accounting for 92% of childhood TB notified with stool accounting for barely 8%. Childhood TB case finding algorithm is not really in place in health facilities, making it difficult for health workers to detect tuberculosis in children. Integrating TB screening for immunization can help improve TB case detection.
Conclusions: Finding the missing tuberculosis cases in children require integration of programmes, improving simple point of care testing for children and building capacity of health care workers in identifying tuberculosis in children.

EP52-1203-21 Isoniazid preventive therapy (IPT) and TB infection in intrahousehold contacts: Results from a cohort in Peru

O. Zazueta,[1] M. Becerra,[2] R. Calderon,[3] C. Contreras,[4] C.-C. Huang,[5,2] J. Jimenez,[4] L. Lecca,[4,5] R. Yataco,[4] Z. Zhang,[5] M. Murray,[5,2,1] [1]Harvard T.H. Chan School of Public Health, Epidemiology, Boston, United States of America, [2]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States of America, [3]Advanced Research and Health, Advanced Research and Health, Lima, Peru, [4]Socios En Salud, Socios En Salud, Lima, Peru, [5]Brigham and Women's Hospital, Division of Global Health Equity, Boston, United States of America
e-mail: megan_murray@hms.harvard.edu

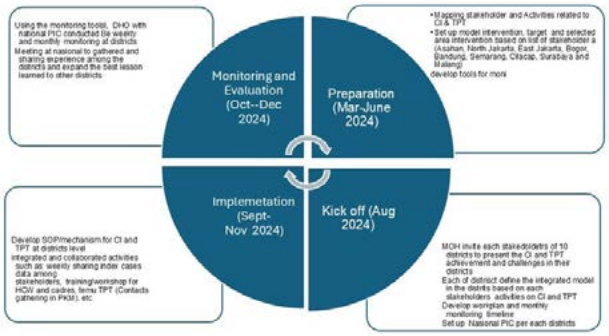
Background: Isoniazid Preventive Therapy (IPT) prevents TB progression among individuals with a positive tuberculin skin test (TST). However, its role in preventing TB infection remains uncertain. In Peru, IPT is recommended for all under five-year-old who are household contacts (HHCs) of TB patients, regardless of their TST status. We assessed the effectiveness of IPT in preventing TB infection—as measured by TST conversion at six months among initially TST-negative child HHCs.
Design/Methods: We conducted a longitudinal cohort study in Lima, Peru, in which we enrolled and followed HHCs of index TB patients. Here, we assessed the risk of TST conversion at 6 months among under-5s who tested TST-negative at enrollment, comparing those who received IPT to those who did not.
Although all under-5s were offered IPT, uptake was limited due to parental or physician preference. We used univariate and multivariate models to control for possible confounders.
Results: Among 1,004 under-5s who were TST negative at baseline, 562 (56%) received IPT. IPT did not protect against TST conversion but instead was associated with a modest increase in TST conversion at six months (Crude OR 1.49, 95% CI: 1.00–2.26, Adjusted OR 1.49, 95% CI: 0.98–2.30). Each additional week of IPT was associated with higher odds of TST conversion (adjusted OR 1.02, 95% CI: 1.00–1.04).
Conclusions: Although IPT is known to protect TST positive children from TB disease progression, here we find that IPT is associated with a modestly higher rate of TST conversion. This finding raises the possibility that IPT enhances the immune response to TB infection, paradoxically leading to increased TST induration size at the same time that it protects against TB disease progression.

EP52-1204-21 Cracking the code: How local leadership and smart collaboration boosted contact investigation and TB prevention in Indonesia

E. Varella,[1] B. Nababan,[2] S. Nadhilah Rahmah,[3] K. Karima,[4] Y. Anandita,[5] F. Asnely Putri,[6] R. Hidayat,[1] H. Pramaiswari,[2] [1]PR Consortium Penabulu-STPI, Program, Jakarta, Indonesia, [2]PR Consortium Penabulu-STPI, Executive, Jakarta, Indonesia, [3]Ministry of Health Indonesia, ACSM, Jakarta, Indonesia, [4]Country Coordination Mechanism Global Fund Indonesia, Technical, Jakarta, Indonesia, [5]WHO, Technical, Jakarta, Indonesia, [6]FHI360, Technical, Jakarta, Indonesia

Background and challenges to implementation: To support TB elimination by 2030, Indonesia introduced contact investigation (CI) and tuberculosis preventive treatment (TPT) for household contacts in 2018. Despite multi-stakeholder support, by 2023 CI coverage reached only 32% and TPT coverage just 3.2%, both far below national targets. These gaps led to the development of an integrated and scalable CI-TPT model to accelerate progress.
Intervention or response: From September to November 2024, a pilot was conducted in 10 districts with support from the National TB Program, community organiza-

tions, and development partners. The intervention included coordinated planning, local data validation, and stakeholder alignment to boost performance.



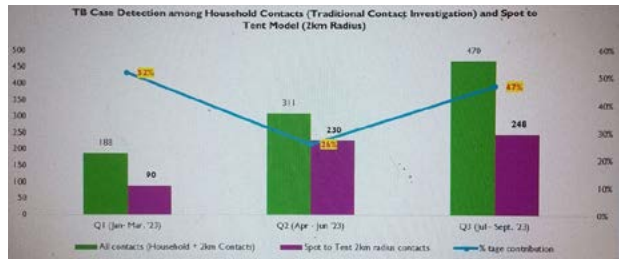
Results/Impact: Three months post-intervention, CI coverage among household contacts increased to 79 % (21453/27096). TPT coverage rise to 14.8% (59,180 contacts who have been screened and eligible for TPT), marking significant progress from the 3.2% baseline.
Conclusions: Strong local leadership, regular data validation, and stakeholder coordination were key to improving CI and TPT performance. Tailoring interventions to district contexts and ensuring alignment among multiple partners enhanced efficiency. This collaborative model is being scaled up to 229 districts in 2025 to support Indonesia's TB elimination goals.

EP52-1205-21 Enhancing TB prevention and care through innovative contact tracing: Evaluating the effectiveness of the 2 km radius Spot-to-Tent Onion Model in Akwa Ibom State, Nigeria

B. Noah,[1] A. Josiah,[1] O. Nissi,[2] C. Ogbudebe,[3] I. Gordon,[4] O. Chukwuogo,[4] B. Odume,[4] B. Akpan,[5]
[1]KNCV- Nigeria, Strategic Information, Uyo, Nigeria, [2]KNCV- Nigeria, Programs, Uyo, Nigeria, [3]KNCV- Nigeria, Strategic Information, Abuja, Nigeria, [4]KNCV- Nigeria, Programs, Abuja, Nigeria, [5]Akwa Ibom State Tuberculosis, Leprosy and Buruli Ulcer Control Program, Programs, Uyo, Nigeria
e-mail: bnoah@kncvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains a significant public health concern, particularly in low- and middle-income countries like Nigeria. Contact tracing of contacts of index people diagnosed with TB is crucial for early detection and prevention of TB transmission. However, traditional contact tracing methods often have limitations, particularly in resource-constrained settings like Akwa Ibom State, Nigeria leading to low TB case detection among contacts – 6,023 Index Patients' contacts screened for TB, 1975 presumptive for TB evaluated, 272 contacts diagnosed with TB and 265 enrolled on TB treatment between January – September 2022.

Intervention or response: Implemented by KNCV Nigeria, the intervention involved TB Symptomatic screening around the residence of Index persons diagnosed with TB, within a 2 km radius "spot" using a "tent onion" approach, which prioritized high-risk contacts. Trained community health workers carried out TB symptom screening, sputum/stool collection, referral for diagnosis including Chest X-rays and linkage for TB treatment for persons diagnosed with TB across the 31 Local Government Areas of Akwa Ibom State.
Results/Impact: Within 9 months (January to September 2023) of implementation, **180,483** contacts were screened using the 2 km Radius Spot to Tent Onion Model, yielding **12,541** presumptive for TB. Of these, **12326** presumptive were evaluated for TB and results retrieved, **568** TB cases were diagnosed of which **4** were diagnosed with Drug Resistant TB and **546** enrolled on TB treatment, representing a **15%** increase in TB case detection for the state and an overall **41**% contribution to TB case finding among contacts during the period.



Conclusions: The 2 km Radius Spot-to-Tent Onion Model is a highly effective and sustainable intervention for increased TB detection among contacts of persons diagnosed with TB, particularly in resource-limited areas, by expanding contact tracing beyond households. This adaptable community-based screening strategy can be applied in various settings to enhance TB control and break the cycle of transmission.

EP53 Mobilising communities: The heartbeat of TB response

EP53-1206-21 Community-led monitoring for TB services in Geita, Tanzania: Lessons from the OneImpact TB Kiganjani approach

R.A. Khaji,[1] V.M. Kabwebwe,[2] T.A. Nyaracha,[1]
[1]SHDEPHA+, Health and Program Management, Kahama Municipal Council, United Republic of Tanzania, [2]SHDEPHA+, Administration and Governance, Kahama Municipal Council, United Republic of Tanzania
e-mail: rabiabeid@gmail.com

Background and challenges to implementation: Geita, Tanzania faces significant TB service gaps, with 3,939 people engaged but persistent challenges in access to social support (77% of reported issues), nutritional support (15%), and financial support (3%). Stigma (12%) and human rights violations (3%) further complicate care, particularly for women (78% of reporters) and Key and vulnerable populations (KVP) including miners, fisherfolks, people living with HIV (PLHIV).
Intervention or response: With funding from the Stop TB Partnership through UNOPS, SHDEPHA+ implemented the Challenge Facility for Civil Society Round 12 from November 2023 to March 2025. The intervention utilized the **OneImpact TB Kiganjani** Community-Led Monitoring (CLM) approach to enhance health system accountability and foster meaningful community engagement.
Ten community health workers (CHWs) with Smartphones were trained in digital, app-based reporting tools, enabling the registration of 3,939 TB patients and facilitating active reporting from 5,354 individuals on TB-related service delivery issues.
To translate data into action, SHDEPHA+ convened five multi-stakeholder accountability meetings, during which 4,622 community-reported challenges were reviewed and discussed directly with health facility representatives.
Results/Impact: This community-driven CLM model reached 3,939 TB patients and generated 5,354 reports highlighting service gaps. Top issues included lack of social support (34%), nutrition (27%), and financial assistance (17%). Gender disparities were evident, with women accounting for 78% of reports. District-level variations showed reporting rates from 92% (Nyang'hwale) to 60% (Bukombe).
Overall, 61% of challenges were resolved through joint efforts between communities and facilities. These results underscore the power of digital tools and grassroots advocacy to promote equitable and accountable TB services.
Conclusions: The OneImpact TB Kiganjani model strengthened community-led accountability in TB services. By combining digital reporting with local engagement including women and KVPs it enabled timely identification and resolution of service gaps. District and gender differences signal the need for tailored interventions. This approach offers a replicable model for responsive, community-driven TB care.

EP53-1207-21 A systematic TB screening to improve notification rates in vulnerable and high-risk populations in Kathmandu Urban, Nepal

R.S. Gopali,[1,2] A. Shimouchi,[1] K. Okada,[3] I. Onozaki,[3] B. Maharjan,[2] P. Bhattarai,[2] D.N. Sharma,[2] Y. Shrestha,[2] S.R. Tiwari,[4] N. Bajracharya,[5] [1]Japan Anti-Tuberculosis Association, Public Health, Kathmandu, Nepal, [2]Japan-Nepal Health and Tuberculosis Research Association (JANTRA), Public Health, Kathmandu, Nepal, [3]Japan Anti-Tuberculosis Association, International Cooperation, Tokyo, Japan, [4]National Tuberculosis Centre, National TB Centre, Kathmandu, Nepal, [5]Kathmandu Metropolitan City, Public Health Division, Kathmandu, Nepal
e-mail: gwala73@hotmail.com

Background and challenges to implementation: The National Tuberculosis (TB) Prevalence Survey, 2018-2019 showed TB prevalence in the Kathmandu Valley was 276/100,000. It also revealed that 72% of confirmed TB patients with abnormal chest X-rays (CXR) had no symptoms. Therefore, active TB case finding using CXR should increase TB case detection.
Intervention or response: Systematic TB screening using ultraportable digital chest x-ray (d-CXR) powered by artificial intelligence (AI) by a mobile team was conducted targeting vulnerable and high risk communities. Every participant above 15 years of age participated in the screening camp was eligible for CXR taking. The medical doctor read the CXR images with the necessary reference to the AI.
When the CXR images indicated presumptive TB, the field team advised sputum examination by WHO recommended mWRD. When d-CXR suggested TB disease such as cavitary and infiltrate, clinical diagnosis was made by the doctors even with a bacteriologically negative result. TB patients were linked to the nearest DOTS centre for treatment after the confirmation.
Results/Impact: From July 2022 to January 2025, out of 37020 participants screened with d-CXR, 2259 (6%) participants were eligible for sputum examination. As a result, a total of 323 (14%) TB patients were diagnosed, of which 56% were asymptomatic.Among them, 103 (32%) were bacteriologically positive and 220 (68%) diagnosed as bacteriologically negative.
The yield rate from this intervention is 0.87%, which is two times higher than the national average and treatment success rate was more than 90%.

Conclusions: Systematic TB screening with d-CXR in community and congregate settings is effective especially for asymptomatic TB patients, both bacteriologically (+) and bacteriologically (-) TB. In systematic TB screening, targeting the right population with the support of community volunteers is key to maintain high yield rates, however strengthening counseling sessions is equally important to improve treatment adherence among TB diagnosed cases in early stage.

EP53-1208-21 Designing effective TB programmes through community engagement: Lessons from TB REACH projects in South Asia

A. Njarattil Parameswaran,[1] M. Bakker,[2] Y. El Addouli,[3] C. Mergenthaler,[4] T. Garg,[5] [1]KIT Royal Tropical Institute, Education, Amsterdam, Netherlands, [2]KIT Royal Tropical Institute, Global Health, Amsterdam, Netherlands, [3]KIT, Royal Tropical Institute, Education, Amsterdam, Netherlands, [4]KIT Royal Tropcial Institute, Epidemiology, Amsterdam, Netherlands, [5]Stop TB Partnership, Innovations and Grants, Geneva, Switzerland, Switzerland
e-mail: archivesofabhijith@gmail.com

Background: Tuberculosis (TB) remains a major public health challenge in South Asia. Alongside other health system barriers, stigma, limited awareness, and low levels of community involvement hinder timely diagnosis and treatment. Community engagement to adapt the design and implementation of TB programs is increasingly recognized as a crucial strategy to address these challenges and enhance access to care.
Design/Methods: We examined the role of community engagement in TB REACH projects across South Asia (2017–2021) through a mixed-methods approach. Quantitative analysis covered data from 59 interventions across 36 projects to assess the effectiveness of various community-based approaches in reducing pre-diagnostic and pre-treatment lost to follow-up. We conducted semi-structured interviews with programme implementers to understand best practices and challenges in incorporating community engagement for active case-finding projects for TB elimination.
Results: Key engagement strategies implemented were sputum transport (implemented by 64% of projects), incentives (49%), and awareness campaigns (86%). Overall, 70% of 533,573 people with presumptive TB were tested, ranging from 15%-96% across interventions and 82% of 38,968 confirmed patients started treatment (27%-100%). Testing rates were higher among interventions with awareness campaigns (table 1), which was supported by qualitative findings. Local stakeholders, including community health workers, played a pivotal role in bridging gaps between patients and services. Implementers stressed the importance of integrating community engagement for scalability and long-term impact. They also noted the difficulty of achieving project targets within a short timeframe without strong community support. Sustaining the long-term involvement of informal providers, CHWs, and volunteers remained a challenge.

Testing rate for strategy	Yes	No
Incentive Strategy	66% (13%–107%, n=16)	81% (15%–104%, n=20)
Awareness Activity Strategy	77% (13%–107%, n=31)	32% (15%–90%, n=5)
Sputum Transportation Strategy	63% (13%–107%, n=22)	86% (15%–104%, n=14)

Conclusions: Considering community engagement strategies are crucial in enhancing the delivery of TB care. Future TB initiatives should prioritize long-term community involvement, expand funding for grassroots interventions, and strengthen CHW training to support TB elimination goals.

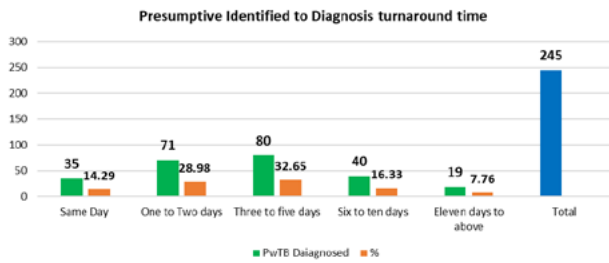
EP53-1209-21 Addressing TB diagnostic delays in urban marginalised and unhoused populations of Delhi, India in project LEAD (Leveraging, Engaging, and Advocating to Disrupt TB Transmission)

J. Alam,[1] M.K. Sharma,[2] M. Singh,[2] S. Mukhopadhyay,[3] N. Singh,[2] R. Singh,[2] [1]Humana People to People India, Partnership, Delhi, India, [2]Humana People to People India, Project Management, Delhi, India, [3]Humana People to People India, Partnership and TB Projects, Delhi, India
e-mail: jahangeer.alam@humana-india.org

Background and challenges to implementation: Several scientific studies in India have revealed that delays in TB diagnosis contribute to increased TB transmission, increased morbidity, and higher mortality rates, especially among marginalised people like the urban unhoused, migratory and slum population. Furthermore, the frequent intra-city and inter-state mobility of these populations traditionally has been a challenge for the health system to locate and track, thereby lengthening the diagnostic pathway.
Humana People to People India (HPPI), a national-level NGO in India, demonstrated feasible ways to address the challenges of diagnostic delays through the LEAD project, implemented among urban unhoused, migratory, and slum-dweller populations in Delhi from October 15, 2024, to January 31, 2025.
Intervention or response: HPPI gave high priority to early tuberculosis diagnosis in project LEAD. Key implementation strategies included:
1. Community-convenient outreach activities.
2. High-quality screening with various tools (symptomatic, Chest X-ray and Cough-AI) to identify presumptive cases and facilitation of TB testing by NAAT at the local chest-clinics by SCT.

3. Tracking the missing presumptive cases by engaging local community members, and shelter caretakers.
4. Reduction of patient out-of-pocket expenses.
5. Partnerships and engagement with private laboratories for time flexible X-ray access.
6. Mobilise and accompanied for TB presumptive people to doctor consultation for clinical assessment.
7. Strengthening collaboration with National TB Elimination Program (NTEP).

Results/Impact: The detection of presumptive TB cases, and subsequently the diagnosis of PwTB was accelerated in project LEAD. PwTB were subsequently linked to local public health facilities for treatment, public health actions, and nutritional support, improving treatment adherence and contributing to TB prevention. (Detailed information in the attached table).



Conclusions: The targeted approaches of LEAD showcased, close support to TB presumptive cases, multi-partner collaboration, and community stakeholder engagement significantly improved prompt TB diagnosis and reduced diagnostic delays in the targeted populations in Delhi. This approach was appreciated by the state and central level NTEP and encouraged replication in other states.

EP53-1210-21 Accelerating cures: The race to fast-track BPaL access in Indonesia

Y. Runtu,[1] J. Sugiharto,[1] M.I.H. Soemarno,[2] J.J. Sabono,[2] A.N.Y. Yudha,[2] M. Ripai,[2] J. Nabila,[2] T.T. Pakasi,[3] A. Patil,[4] L. Caraulan,[5] J. Malar,[5] [1]Yayasan KNCV Indonesia, Management Team, Jakarta, Indonesia, [2]Yayasan KNCV Indonesia, Yayasan KNCV Indonesia, Jakarta, Indonesia, [3]Kementerian Kesehatan Republik Indonesia, Indonesia National TB Program, Jakarta, Indonesia, [4]TB Alliance, Market Access, New Delhi, India, [5]Stop TB Partnership, Country and Community Support for Impact, Geneva, Switzerland
e-mail: yeremia.runtu@yki4tbc.org

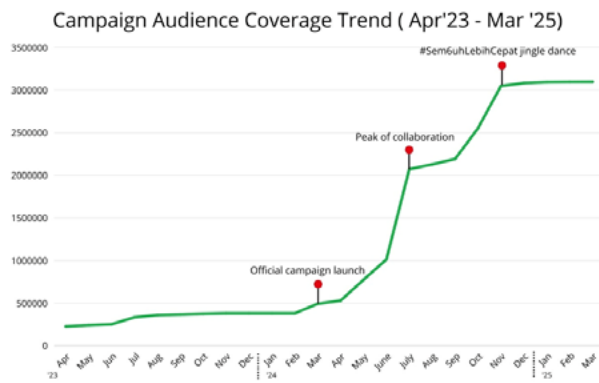
Background and challenges to implementation: In April 2023, Yayasan KNCV Indonesia (YKI), supported by the Stop TB Partnership and TB Alliance, joined the global Fast Track The Cure (FTTC) initiative to drive awareness, policy implementation, and healthcare worker capacity for the BPaL/M regimen. Prior to the campaign, only 87 patients had been enrolled, reflecting the limited reach of the regimen. Through targeted campaigns, the initiative strengthened community demand generation, engagement, and policy support. By November 2024, the regimen had benefited 4,309 patients across 38 provinces in Indonesia, highlighting the impact of sustained advocacy and stakeholder collaboration.

Intervention or response: 2023: Limited programmatic implementation of the bedaquiline-pretomanid-linezolid/moxifloxacin (BPaL/M) regimen, followed by campaign planning through focus group discussions, interviews, and surveys with TB stakeholders, including the Ministry of Health (MoH), healthcare workers (HCWs), DR TB survivors and TB civil society organizations (CSOs).

January 2024: Nationwide BPaL/M rollout and campaign development.

March 2024: Launch of the national campaign #Sem6uhLebihCepat to promote awareness and support for the new regimen, through 90 digital poster, 10 DR-TB survivor story, a short comic, a jingle dance competition, and 3 email newsletters.

Results/Impact: The campaign made a powerful impact, reaching 3.1 million people across social media as part of broader demand generation. This was fueled by widespread engagement, connecting with 2.07 million individuals, alongside collaborations with influencers that drew in 503,000 more. Campaign partner insights contributed an additional 273,000 individuals, while the lively, resonant Jingle Dance initiative engaged 252,000 participants. These efforts created a ripple effect, enhancing awareness. However, challenges such as stigma, limited access to digital materials, and insufficient stakeholder involvement must be addressed to sustain impact.



Conclusions: By engaging and empowering communities, the campaign helped accelerate BPaLM adoption in Indonesia, and amplified support for demand generation. Campaign underscores the transformative role of community engagement in expanding access to new TB treatments.

EP53-1211-21 Faith, culture and artificial intelligence in action: A people-centered community-led approach to TB elimination in hard-to-reach tribal communities of Mizoram, India

A. Das,[1] L. Chawhte,[2] Z. Awmi,[2] [1]National Health Mission, Mizoram, State TB Cell, Aizawl, India, [2]State TB Cell, Mizoram, State TB Cell, Aizawl, India
e-mail: dasagniswar@gmail.com

Background and challenges to implementation: Mizoram, a 100% tribal state in Northeast India, presents unique challenges to TB elimination — ranging from difficult terrain and scattered populations to high HIV prevalence, tobacco use, and social stigma. Despite high literacy rates, health-seeking behavior remains low, especially among marginalized tribal groups such as the Mizo, Bru, and Chakma communities. Limited diagnostic infrastructure and health access further exacerbate underreporting and delayed care, leaving a significant proportion of TB cases undetected and untreated.
Intervention or response: To address these challenges, the State TB Cell of Mizoram, with support from freelance consultants and development partners under the Stop TB Partnership, launched the TB Elimination Accelerator Initiative in two key districts: Aizawl and Lunglei. The intervention was deeply rooted in cultural relevance and community ownership.
Faith-based platforms—particularly church congregations—were engaged to promote awareness and trust. Community leaders played a central role in mobilizing participation. Health camps were organized at preferred timings (evenings, early mornings, post-worship), and integrated screening for TB, diabetes, and hypertension was offered. AI-enabled tools such as handheld digital chest X-ray and cough analysis enhanced early detection. Trained community volunteers facilitated door-to-door outreach, identification of symptomatic individuals, and linkage to confirmatory testing and care services.
Results/Impact: (Within 7 months)
- Total individuals screened: 161,684
- Presumptive TB cases identified: 18,290
- TB cases diagnosed: 2,284

The initiative significantly improved case detection, reduced stigma, and increased uptake of TB Preventive Therapy (TPT), demonstrating success in high-burden, underserved areas.
Conclusions: The Mizoram model showcases an effective fusion of community trust, cultural insight, and technological innovation. It offers a scalable and adaptable framework for TB elimination in tribal and hard-to-reach populations, contributing meaningfully to India's and the global End TB strategy.

EP53-1212-21 Empowering youth in TB detection and linkage to care: Lessons from community-driven interventions in Turkana County, Kenya

V. Faith,[1] [1]Network of TB Champions - Kenya, TB- Adolescents and Young People, Nairobi, Kenya
e-mail: vivianfaithatieno@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a leading cause of death from infectious diseases globally. A significant gap in TB control is the limited engagement of young people, particularly in high-burden, resource-constrained areas like Turkana County, Kenya, where the TB case notification rate is 345/100,000 far above the national average of 135/100,000. Stigma, low awareness, and barriers to healthcare access contribute to delayed diagnosis and treatment among youth.
This study examined the impact of participatory, youth-centered interventions on enhancing TB knowledge, reducing stigma, and improving healthcare linkages.
Intervention or response: The intervention used a multi-component, community-driven approach targeting youth aged 15–35 years. School-based outreach programs incorporated TB education into student health clubs. Social media campaigns via WhatsApp and Facebook disseminated tailored messages. Community theatre groups performed interactive dramas to tackle myths and stigma around TB with support from Amref and NTLD. Trained youth volunteers conducted door-to-door visits, offering TB screening and referrals. Community health promoters and local leaders supported these efforts to ensure cultural relevance and sustainability.
Results/Impact: The interventions led to significant improvements. Pre- and post-campaign surveys showed a 40% increase in TB knowledge among youth, who demonstrated improved understanding of transmission and prevention. Stigma reduction was observed as more youth openly discussed TB and sought testing. Over six months, the intervention reached 12,500 youths, a 60% increase over prior outreach efforts. Active case-finding identified 85 new TB cases among youth, all linked to treatment. Health facilities reported a 35% rise in youth-initiated TB screenings.
Conclusions: Community-driven strategies that prioritize youth participation, through school programs, social media, edutainment, and peer-led mobilization, effectively improve TB awareness, early detection and treatment in Turkana County. This approach holds promise for replication in other nomadic and underserved setting that help to bridge youth engagement gaps.

EP53-1213-21 Stakeholders' absolute engagement: A proven approach towards increasing community TB notification in rural Nigeria

U. Ebenezer,[1] A. Ikpeamarom,[2] C. Uzor,[2] S. Nwite,[3] A. Uduma,[4] K. Ukwaja,[5,1] [1]Annabelles Bogi Development Initiative, Program Management, Abakaliki, Ebonyi State, Nigeria, [2]Annabelles Bogi Development Initiative, M & E, Abakaliki, Ebonyi State, Nigeria, [3]State Ministry of Health, Program Management, Abakaliki, Ebonyi State, Nigeria, [4]State Ministry of Health, M & E, Abakaliki, Ebonyi State, Nigeria, [5]Ebonyi State University, Internal Medicine, Abakaliki, Ebonyi State, Nigeria
e-mail: uuebenezer@gmail.com

Background and challenges to implementation: Community TB case finding has been challenging in rural settings due to poor community buy-in. The GF Grant Cycle 7 (GC7) provided funding to support CBOs to engage community stakeholders and contribute to TB case finding. We report our experience of CBO-led stakeholder engagement and TB case finding in Nigeria.
Intervention or response: The study was a retrospective trend analysis of CBO-led stakeholder engagement and TB case finding from May 2024-February 2025 across 13 districts. The lead CBO deployed systematic community entry via advocacy to community leaders/gate keepers, this was followed by training of community volunteers (CVs) recruited within the districts. Then, active engagement of community stakeholders was carried out. Community outreaches and house-to-house active case search was performed. Also, sputum collection from presumptive TB cases, sample transportation by motorcycle riders and linkage-to-care of diagnosed TB cases was conducted by the CVs. Electronic data collection was performed using the CommTB App.
Results/Impact: During the period, over 150 engagement meetings among 857 stakeholders of underserved communities was performed. A total of 33,413 community members were screened for TB, 4372 persons had presumptive TB, and 433 community TB cases were notified consisting of 239 (55.2%) males and 194 (44.8%) females. Overall, monthly notification of community TB cases increased from 6 patients in May 2024 to 84 patients in February 2025. Community-based TB cases notified accounted 21% of total TB cases notified during the study period.
Conclusions: A CBO-lead stakeholder engagement and community-led TB case finding resulted in improvement in TB notification. This demonstrates the effectiveness of engaging stakeholders in ending TB.

EP53-1214-21 Leveraging health and wellness centres to strengthen decentralised TB services: A successful model in Himachal Pradesh, India

G. Beri,[1] K. Venkatesan,[2] A.G. Nair,[2] N. Soni,[2] Y.P. Sharma,[3] R. Kumar,[4] S. Rajan,[2] N. Satapara,[2] S. Chandra,[2] U. Singh,[5] [1]Ministry of Health and Family Welfare, National Health Mission, Himachal Pradesh, Shimla, India, [2]Government of India- WHO country office for india - TB Technical Support Network, National Tuberculosis Elimination Program, New Delhi, India, [3]Department of Health and Family Welfare, National Health Mission, Himachal Pradesh, Shimla, India, [4]Department of Health and Family Welfare, National Health Mission, Shimla, India, [5]Ministry of Health and Family Welfare, Central TB Division, New Delhi, India
e-mail: venkateshank@rntcp.org

Background and challenges to implementation: Himachal Pradesh, a high TB burden state of India with a prevalence rate of 208 per 100,000, faces challenges in TB care due to its mountainous terrain. The Ayushman Bharat initiative has strengthened primary healthcare through Health and Wellness Centres (HWCs), improving access to TB services at the community level.
This study evaluates HWC performance on key TB indicators and examines the accessibility of TB care, identifying strengths and areas for improvement.
Intervention or response: Since June 2022, Himachal Pradesh has implemented targeted interventions through its HWCs, focusing on trained human resources, community outreach, and case detection. A structured framework was aligned with the NTEP strategic plan.
Parameters assessed included i) referrals for presumed TB, ii) TB case holding capacity, iii) diagnostic yield, iv) Active case finding outcomes, v) post-TB follow-up results, and vi) access measured by median distance.
These parameters were compared for the year 2024 vs year 2022. Data was sourced from Ni-kshay (India's TB digital surveillance system) and state-specific mobile app, analyzed using SPSS v22.
Results/Impact: As of 2024, 2,483 Health and Wellness Centre (HWCs) are delivering TB services. From 2022 to 2024, number of presumed TB referrals increased from 10% to 27% [$z=128.67$, $p<0.05$], and diagnostic yield improved by 3.2%. Case holding rose from 18.6% to 37% [$z=36.50$, $p<0.05$]. Active case finding screened 1.7 million people (25% of the state population), identifying 4% as presumed TB. Post-TB follow-up reached 85% of 32,004 cases, with 2.4% as recurrent TB. Median distance for diagnostic access improved from 16 km (IQR: 20.5) to 4 km (IQR: 3) [$p<0.05$], reflecting better accessibility.
Conclusions: Himachal Pradesh has demonstrated that its successful implementation framework for decentralized TB services through HWCs effectively addresses service delivery gaps. This approach enhances TB care and presents a replicable model for achieving end-TB goals in similar remote and hard-to-reach areas.

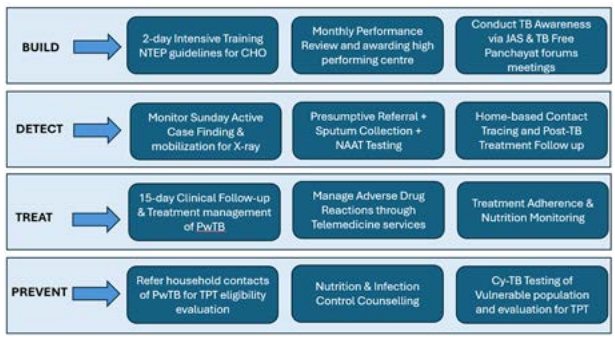


Figure. Implementation framework for decentralized TB services at the HWC.

EP54 Understanding tobacco use in a changing world: Insight on policy, risk and communication

EP54-1215-21 Communicating tangible research findings to non-statisticians: A case study of Tanzania GATS-2018

E. Milonga,[1] [1]FikraHub Co. Ltd, Social Science, Shinyanga MC, United Republic of Tanzania

Background and challenges to implementation: Tobacco use is one of the most common risk factors for non-communicable diseases (NCDs). 27% of all deaths in Tanzania are due to NCDs,

Tanzania conducted the Global Adult Tobacco Survey (GATS) in 2018, this was the first and nationally representative survey on tobacco use in Tanzania that aimed at informing stakeholders and guiding evidence-based decision-making in tobacco control.

Intervention or response: 4,976 households and 4,797 individuals 15 years of age and older were interviewed. households were sampled, and one adult (defined as 15 years of age or older) was randomly selected from each participating household to complete the GATS individual questionnaire. The overall response rate was 91.7%, with a household response rate of 95.1% and an individual response rate of 96.4%.

Results/Impact: 8.7% of adults currently use tobacco (smoking or smokeless), with a higher prevalence among men (14.6%) compared to women (3.2%). Rural populations exhibit a higher tobacco use rate than urban areas, indicating regional disparities in consumption patterns. Additionally,13.8 % of adults are exposed to secondhand smoke at home, while 32.9% face exposure in workplaces, highlighting the widespread health risks of involuntary smoke exposure.

Despite these challenges, the survey indicates that 76.8% of smokers are interested in quitting, yet access to cessation programs remains limited.

Conclusions: The findings call for strengthened tobacco control policies, enhanced public education, and improved cessation support to reduce tobacco use and its associated respiratory disease burden eg. Tuberculosis in Tanzania however the findings have not been effectively disseminated locally and internationally.

This abstract aims to communicate Findings and suggest innovative counseling and quitline to a wide community through this conference to inform policymakers, public health practitioners, and activists with actionable insights to help invest and advance tobacco control initiatives in the developing world especially in Tanzania.

EP54-1216-21 The effectiveness of quitline intervention on knowledge of harmful effects of smokeless tobacco use among residents of Ebonyi State, Nigeria

U. Ofonakara,[1] N. Ngozi,[2] F. Onwe,[3] [1]National Primary Health Care Development Agency, Primary Health Care System Development, Asaba, Nigeria, [2]Nigerian National Primary Health Care Development Agency, Primary Health Care System Development, Abuja, Nigeria, [3]David Umahi Federal University of Health Sciences, Community Medicine, Uburu, Nigeria
e-mail: druzochukwu01@gmail.com

Background: Smokeless tobacco is any product containing tobacco placed in the mouth or nose and not burned. Besides smoking, it is chewed, "dipped" or sniffed into the nose as finely powdered snuff. The use of Smokeless tobacco in Ebonyi state is of concern because while the use is widespread, knowledge of the harmful effects is poor.
The aim of this study was therefore to determine the effectiveness of quitline intervention on knowledge of the detrimental effects of smokeless tobacco use *among residents of Ebonyi state.*
Design/Methods: A quasi-experimental study to evaluate the effectiveness *of telephone quitlines on knowledge of the harmful effects of smokeless tobacco use.* Data were collected using anonymous pre-tested interviewer-administered questionnaires adapted from the Global Adult Tobacco Survey(GATS).
*K*nowledge was computed and the mean scores were ascertained. Poor knowledge was a knowledge score below 50 % while good knowledge was a knowledge score of 50% and above.
The mean scores were compared between groups using the independent samples t-test. P values of < 0.05 were considered statistically significant.
Results: There was a statistically significant difference in the proportion of participants who knew that using smokeless tobacco was dangerous to health 19(31.7%) pre-intervention and 52(86.7%) post-intervention $p<0.001$. In the intervention group, there was a statistically significant increase in participants with good knowledge of the harmful effects of smokeless tobacco use 0(0.0%) pre-intervention and 36(60.0%) post-intervention.
In the control group, there was a statistically significant increase in the proportion of participants with good knowledge of the harmful effects of smokeless tobacco use 0(0.0%) at the beginning of the study and 7(11.7%) at the end of the study.
Conclusions: There was a significant increase in the proportion of participants with good knowledge of the harmful effects of smokeless tobacco use post-intervention. Therefore, community members should be educated on the dangers of smokeless tobacco use.

EP54-1218-21 Dissecting Article 5.3: Understanding stakeholders' perspectives on tobacco industry interference and gaps in governance

J. Vij,[1] S. Goel,[1] R. Yadav,[1] R. Kumar,[1]
[1]PGIMER, DCM & SPH, Chandigarh, India
e-mail: jatinavij6@gmail.com

Background: Article 5.3 of the WHO Framework Convention on Tobacco Control (FCTC) mandates governments to protect public health policies from tobacco industry interference. Yet, its enforcement remains uneven across Indian states and Union Territories (UTs). The current study estimated the strengths, weaknesses, opportunities, and threats (SWOT) associated with Article 5.3 implementation through multi-sectoral stakeholder consultation.
Design/Methods: A structured SWOT framework was used in a cross-sectional qualitative study across India. Purposive sampling was used to identify key informants such as government officials, NGO leaders, legal experts, public health professionals, and researchers. Data were gathered through over three months (Jan- Mar) using a questionnaire with six themes: respondent background, strengths, challenges, opportunities, threats, and recommendations. Qualitative data were analyzed thematically using framework analysis; quantitative Likert-scale responses were summarized descriptively.
Results: Stakeholders provided a mixed perspective of Article 5.3 implementation, with an average effectiveness score of 2.8/5. Weaknesses included enabling legal frameworks (72%), inter-sectoral collaboration (65%), and best practices in certain states. However, 87% indicated policy gaps in conflict-of-interest, and 80% mentioned that policymakers and health staff had insufficient awareness or training. Weak monitoring (68%) and funding issues (74%) were also identified.
In spite of adversity, opportunities for enhancing implementation were graded 4.2/5, with most opportunities lying in civil society activism, online media, youth mobilization, and foreign technical assistance. Threats graded 4.1/5, with more than 60% citing frequent industry interference via lobbying, CSR initiatives, and policymaker contacts, in addition to economic interdependencies.
Background and challenges to implementation: Article 5.3 of the WHO Framework Convention on Tobacco Control (FCTC) mandates governments to protect public health policies from tobacco industry interference. Yet, its enforcement remains uneven across Indian states and Union Territories (UTs). The current study estimated the strengths, weaknesses, opportunities, and threats (SWOT) associated with Article 5.3 implementation through multi-sectoral stakeholder consultation.
Intervention or response: A structured SWOT framework was used in a cross-sectional qualitative study across India. Purposive sampling was used to identify key

informants such as government officials, NGO leaders, legal experts, public health professionals, and researchers. Data were gathered through over three months (Jan-Mar) using a questionnaire with six themes: respondent background, strengths, challenges, opportunities, threats, and recommendations. Qualitative data were analyzed thematically using framework analysis; quantitative Likert-scale responses were summarized descriptively.

Results/Impact: Stakeholders provided a mixed perspective of Article 5.3 implementation, with an average effectiveness score of 2.8/5. Weaknesses included enabling legal frameworks (72%), inter-sectoral collaboration (65%), and best practices in certain states.

However, 87% indicated policy gaps in conflict-of-interest, and 80% mentioned that policymakers and health staff had insufficient awareness or training. Weak monitoring (68%) and funding issues (74%) were also identified.

In spite of adversity, opportunities for enhancing implementation were graded 4.2/5, with most opportunities lying in civil society activism, online media, youth mobilization, and foreign technical assistance. Threats graded 4.1/5, with more than 60% citing frequent industry interference via lobbying, CSR initiatives, and policymaker contacts, in addition to economic interdependencies.

Conclusions: Strengthening Article 5.3 enforcement in India calls for firm legal protection, capacity development, and relentless multisector efforts. These conclusions provide strategic guidance to policymakers, advocates, and international partners seeking to counteract tobacco industry meddling.

EP54-1219-21 Oral nicotine pouches: A summary of potentially applicable laws and regulatory challenges in India

R. Gupta,[1] T. Jangwal,[1] [1]Strategic Institute for Public Health Education and Research (SIPHER), Department of Public Health, Chandigarh, India
e-mail: rakesh60.mahajan@gmail.com

Background and challenges to implementation: ONPs are small rectangular pouches made of organic cellulose compounds, of the size of Chicklet gums. Nicotine in ONPs can be derived from tobacco plants or is synthetic. In traditional smokeless tobacco products such as chewing tobacco or snus, there is tobacco leaf. are used for Nicotine intake with hundreds of youth-attracting flavours and varied content of 1-43 mg/pouch. Nicotine Replacement Therapy (NRT) products help people quit smoking safely and are approved by the FDA or similar national agencies.

While ONPs are available worldwide, there is little information on how to regulate them. This study summarises ONP regulatory policies in India.

Intervention or response: This review summarises findings obtained from various Indian websites dealing with policies and legislation. We also requested information on the applicable policies and analyzed responses from subject experts from various states in India.

Results/Impact: The study found that India regulates both synthetic and tobacco-derived nicotine products and generally relies on existing policies for Tobacco/Nicotine products. ONPs can be acted upon in India under multiple laws such as the Drugs and Cosmetics Act of 1940, the Food Safety and Standards Act, of 2006, the Poisons Act of 1919, the Insecticides Act of 1968, the Juvenile Justice Act of 2015 which prohibits sale to minors, Environmental Act 1986, Legal Metrology Act 2009 and Directorate of Revenue Intelligence can act under the Customs Act of 1962. The online sale of illegal Nicotine can be curbed by the State Cyber Crime Wings. There are challenges in the enforcement of various applicable laws in the country.

Conclusions: Our work offers novel insight into ONP national regulatory approaches in India. These are regulated under the existing laws. It offers a roadmap for how India and other countries can add effective measures to the use of these and other non-medicinal nicotine.

EP54-1220-21 TAPS exposures, smoke-free area policies, and individual factors influence the intention and smoking behaviour among adolescents in Central Java, Indonesia

N. Nurjanah,[1,2] A. Sugihantono,[3,2] B. Widjanarko,[4,2] N. Handayani,[5,2] S. Budi Musthofa,[4,2] S. Indah Puspitaningtyas,[2] A. Wulandari,[2] N. Fadhilah,[2] [1]Universitas Dian Nuswantoro, Faculty of Health Science, Public Health Department, Semarang, Indonesia, [2]Indonesian Society for Health Promotor and Educator of Central Java Province, -, Semarang, Indonesia, [3]Politeknik Kesehatan Kementerian Kesehatan Semarang, Medical Laboratory Technology Department, Semarang, Indonesia, [4]Universitas Diponegoro, Health Promotion Department, Faculty of Public Health, Semarang, Indonesia, [5]Universitas Diponegoro, Public Health Department, Faculty of Public Health, Semarang, Indonesia
e-mail: sugihantonoa@yahoo.com

Background: The Indonesia Health Survey 2023 reveals that about 70 million people smoke, with 7.2% including teenagers aged 10 to 18. Central Java province shows one of the highest child prevalence rates in Indonesia, reported at 9.6%. This study aims to evaluate the impact of environmental factors (tobacco advertising, promotion, and sponsorship exposure), policy, and personal factors on smoking intentions and behavior in adolescents.

Design/Methods: This is a cross-sectional study involving a sample of 882 students from ten junior high schools, eleven high schools, and five universities from the three

main municipalities in Central Java Province: Semarang City, Pekalongan District, and Banjarnegara District. The stratified sampling was employed to select respondents and self-administered questionnaires were utilized to gather data. Consent from parents is required for respondents under 18 years of age before participation. The prevalence odds ratios (POR), were calculated to evaluate the impact of tobacco marketing and other factors on smoking.
Results: The percentage of smoking among students is 26.3% (47.4% in males, 12.4% in females). Most of them smoke cigarettes (44.9%), 23.3% use e-cigarettes, and 31.7% are dual users. The individual and environmental factors significantly influence smoking intention. The male, with lower attitudes and knowledge, is more likely to intend to smoke, with POR of 4.4, 2.0, and 1.6, respectively. The high exposure to TAPS (POR 1.4) and inadequate enforcement
of smoke-free regulations (POR I.4) convey a higher opportunity for the intention to smoke. Moreover, adolescents with the intention to smoke are 11.4 times more likely to become smokers. Additional risk factors for smoking behavior include male gender (POR 6.0), low knowledge (POR 2.0), low attitude (POR 1.8), and high TAPS exposure (POR 1.4).
Conclusions: Enacting total TAPS ban regulation is essential for reducing smoking prevalence. Educational and empowering initiatives for youth must be implemented to avert tobacco marketing influences.

EP54-1221-21 Vaping and pregnancy in the last decade: Mapping scientific progress, research gaps, and evolving themes (2014–2025)

N. Bhatnagar,[1] K. Upadhyay,[1] A. Sharma,[1] C. Goel,[1] S. Goel,[1] [1]Postgraduate Institute of Medical Education and Research, Department of Community Medicine and School of Public Health, Chandigarh, India
e-mail: nanditabhatnagar21@gmail.com

Background: The use of electronic cigarettes (e-cigarettes) has increased alongside declining traditional smoking rates. Marketed as a safer alternative to tobacco, e-cigarettes contain fewer toxicants, leading to widespread perceptions that they pose minimal health risks, even during pregnancy. However, research on vaping's impact on maternal and fetal health remains limited. This bibliometric analysis examines publication patterns, identifies research gaps, and highlights emerging themes related to vaping in pregnancy.
Design/Methods: This study quantitatively assessed scientific publications indexed in Scopus between 2014-2025, using specific keyword combinations related to pregnancy and electronic cigarette exposure. The final sample included 3529 articles. Analysis focused on three key bibliometric domains: publication trends, geographic contributions, and thematic areas. VOSviewer and PyBibX facilitated visualization through co-authorship and keyword co-occurrence analysis.
Results: Analysis revealed significant growth in publications, particularly accelerating from 2019 onward. The International Journal of Environmental Research and Public Health, Nicotine & Tobacco Research, and Tobacco Control were most productive, accounting for 18.3% of publications. Research was geographically concentrated in the United States (41.2%), United Kingdom (17.6%), and Australia (11.8%), with developing nations contributing only 7.4%. Publications averaged 14.2 citations, with 2018-2020 articles showing highest impact. Keyword co-occurrence analysis identified four distinct clusters: nicotine neurodevelopmental pathways (32.7%), comparative risk assessment (28.4%), adverse birth outcomes (24.3%), and cessation interventions (14.6%). Co-citation networks revealed limited integration between toxicological and clinical research.

Conclusions: This analysis emphasizes escalating scholarly concern regarding impact of vaping during pregnancy. The predominance of research originating from high-income countries highlights a lack of representation from developing countries, limiting generalizability of findings. Thematic analysis indicates a shift from broad safety concerns to pregnancy-specific investigations; however, disciplinary silos, especially between toxicological and clinical research, hinders understanding of vaping's effects on pregnancy. Addressing these limitations through interdisciplinary collaboration, geographically diverse research is essential to inform evidence-based public health policies.

EP54-1222-21 Digital epidemiology of tobacco consumption: A Google Trends analysis of lung cancer and e-cigarette interest in India

J. Vij,[1] S. Goel,[1] R. Kumar,[1] R. Yadav,[1]
[1]PGIMER, DCM & SPH, Chandigarh, India
e-mail: jatinavij6@gmail.com

Background: Lung cancer is rapidly emerging as one of India's most concerning health concerns, and its increasing popularity is proving difficult to overlook. The primary risk factor is smoking, and India is the second-

largest consumer globally, after China. Despite the ban on e-cigarettes in 2019, public debate regarding their health implications continues, influencing public attitude and information seeking. This research uses Google Trends to examine e-cigarette and lung cancer web search volume in India and delineates regional trends for effective tobacco control intervention**.**

Design/Methods: Google Trends data (Jan 2020–Mar 2025) were also contrasted for the search terms of „lung cancer" and „e-cigarettes" in 28 states and 8 union territories. Search Volume Index (SVI) values were also adjusted for population variation.

Geographic intensity of search was GIS-mapped, and Pearson's and Spearman's association tests were used to determine correlations between searches. K-means cluster separated the states according to interest levels in searches, while Moran's I test tested spatial autocorrelation to identify geographic clustering.

Results: Interest by region differed; Delhi (SVI: 87), Maharashtra (SVI: 82), and Karnataka (SVI: 78) reported the highest combined interest. E-cigarette and lung cancer search had a strong positive correlation ($r = 0.48$, $p < 0.01$). E-cigarette searches corresponded to a 10 unit increase in search units being associated with a 3.1 unit increase in interest units in lung cancer ($\beta = 0.31$, $p = 0.007$) per the regression analysis. Spatial clustering analysis (Moran's $I = 0.25$, $p < 0.01$) indicated extensive geographic patterns.

Conclusions: Local differences in search patterns indicate differences in public perception and possible misinformation. The resilience of e-cigarette popularity after the ban underscores the necessity for highly focused digital health campaigns. Google Trends is a good way to track public opinions and guide tobacco control interventions among high-burden nations.

EP54-1223-21 Smoke and strain: A global bibliometric exploration of smoking's impact on TB treatment outcomes

D. Walia,[1] C. Goel,[1] S. Goel,[1] [1]Post Graduate Institute of Medical Education and Research, Chandigarh, Department of Community Medicine and School for Public Health, Chandigarh, India
e-mail: dikshawalia05@gmail.com

Background: Smoking is a significant risk factor for poor tuberculosis (TB) treatment outcomes. Evidence suggests that smokers are more likely to experience treatment failure, delayed sputum conversion, relapse, and mortality. Despite the increasing volume of research, a comprehensive bibliometric synthesis of global evidence on this association is lacking. This study aims to map and evaluate global scientific output on the association between smoking and TB treatment outcomes.

Design/Methods: A bibliometric analysis was conducted using the Scopus database, yielding 2,471 documents related to smoking and TB treatment outcomes. A comprehensive search strategy was developed using Boolean operators (AND, OR) to combine terms such as "tuberculosis," "TB treatment," "smoking, "tobacco use," "treatment failure," "mortality," and "sputum conversion." The search included title, abstract, and keyword fields.

Data were analyzed using Biblioshiny (R software), to assess publication output, citation trends, author and institutional productivity (Lotka's Law), core journals (Bradford's Law), co-authorship patterns, keyword co-occurrence, and thematic evolution.

Results: Analysis showed that 5% of journals accounted for nearly 33% of publications, and the top 10 authors contributed about 6% of the total output. High-frequency keywords such as "treatment failure," "mortality," "sputum conversion," and "smoking cessation" highlighted the global research focus on the association between smoking and TB outcomes. Thematic mapping showed a shift toward integrated tobacco cessation within TB programs. The United States, India, China, and the United Kingdom together contributed over 35% of publications. International collaborations were seen in over 40% of the documents. Research gaps persist, particularly in standardizing outcome measures and covering low-resource high-burden countries.

Conclusions: This study confirms the global scientific commitment to exploring the smoking–TB outcome link and underlines the need for integrated cessation interventions in TB care. Findings will inform policy and guide future research priorities.

EP55 Novel diagnostics and treatment monitoring methods

EP55-1224-21 Rapid detection of drug-resistant *M.tuberculosis* using a multiplexed CRISPR droplet platform

B. Ning,[1] H. Gou,[1] L. Chen,[1] T. Hu,[1] [1]Tulane University, Biochemistry and Molecular Biology, New Orleans, United States of America
e-mail: bning1@tulane.edu

Background: Drug-resistant tuberculosis (TB) poses a critical threat to global health, with multidrug-resistant (MDR) and extensively drug-resistant (XDR) strains undermining treatment success. Conventional drug susceptibility testing (DST) is time-consuming and inaccessible in many low-resource settings. Rapid, multiplexed genetic testing methods are urgently needed to improve patient care and inform public health interventions.
Design/Methods: We developed a CRISPR-Cas12a-based diagnostic platform for rapid detection of key drug resistance mutations in *Mycobacterium tuberculosis*. The system uses multiplex PCR with primers targeting conserved regions adjacent to drug resistance-associated mutations (e.g., *rpoB*, *katG*, *inhA*, *gyrA*, *rrs*). Each amplicon contains mutation hotspots specific to resistance phenotypes. Guide RNAs (gRNAs) were engineered to recognize these mutations, enabling Cas12a activation and fluorescent signal release. A color-coded droplet system was used to isolate individual CRISPR reactions, each tagged with a unique color for simultaneous analysis.
Results: The assay successfully distinguished wild-type from drug-resistant alleles in clinical isolates within 90 minutes. The color-encoded droplet format allowed unambiguous multiplexing of up to six drug resistance markers in a single reaction. Sensitivity and specificity exceeded 95% when benchmarked against sequencing-confirmed clinical samples. The platform was robust, portable, and required minimal instrumentation.
Conclusions: Our multiplexed CRISPR droplet platform enables rapid, precise identification of drug-resistant *Mtb*, offering a scalable tool for clinical diagnostics and surveillance. This approach holds promise for decentralized TB testing and accelerated treatment decisions, particularly in high-burden, resource-limited settings.

EP55-1225-21 A CRISPR-Cas13a-based molecular assay for rapid and accurate detection of *M. tuberculosis*

U.D. Ranganathan,[1] V. Padmanaban,[1] [1]ICMR_National Institute for Research in Tuberculosis, Immunology, Chennai, India
e-mail: krumadevi@gmail.com

Background: The growing global burden of tuberculosis (TB) underscores the urgent need for rapid, cost-effective, and accurate diagnostic tools to enhance disease detection and management. Current diagnostic methods often face limitations in sensitivity, turnaround time, and accessibility—particularly in resource-constrained settings. To address these gaps, we aimed to develop a sensitive and specific molecular assay for detecting *Mycobacterium tuberculosis* (M.tb) using a CRISPR-based platform.
Design/Methods: We developed a new molecular assay integrating a preamplification step with CRISPR-Cas13a-based detection. The assay was designed using CRISPR-derived RNAs (crRNAs) targeting the conserved *rpoB* gene of M.tb. Its performance was evaluated using DNA from 200 clinical M.tb isolates, non-tuberculous mycobacteria (NTM), and other bacterial species.
Further validation was carried out using clinical pulmonary sputum samples (n=60) and urine samples (n=60), with culture as the reference standard. Based on the initial results, we incorporated additional targets—*IS6110* and *IS1081*—to develop a multiplex version of the assay to enhance sensitivity.
Results: The CRISPR-Cas13a assay targeting *rpoB* achieved a limit of detection (LOD) of 20 copies/µL of M.tb DNA and showed no cross-reactivity with NTM or other bacteria. It demonstrated 100% sensitivity (200/200) for detecting DNA from clinical M.tb isolates. In sputum samples, the assay showed a sensitivity of 95.5% and specificity of 93.3%. In non-invasive pediatric urine samples, it achieved a sensitivity of 68% and specificity of 100%. The multiplex assay, targeting *rpoB*, *IS6110*, and *IS1081*, further improved sensitivity, reaching an LOD of just 1 copy/µL, while maintaining high specificity.
Conclusions: CRISPR-Cas13a assay demonstrates excellent sensitivity without compromising specificity for detecting *M.tb* in sputum and urine samples. The inclusion of multiplex targets significantly improved assay performance and warrants further validation in clinical settings. These findings highlight the potential of this platform as a promising, alternative diagnostic approach for TB, especially in low-resource environments.
High sensitivity without compromising the specificity.

EP55-1226-21 One-pot CRISPR gel assay for urine-based diagnosis of TB

M. Hikone,[1] Y. Kondo,[2] I. Uehara,[2] N. Uno,[3] N. Saito,[1]
[1]Nagasaki University, Institute of Tropical Medicine, Kenya Research Station, Nairobi, Kenya, [2]Nagasaki Univeristy, School of Medicine, Nagasaki, Japan, [3]Nagasaki University, Graduate School of Biomedical Sciences, Department of Medical Virology, Nagasaki, Japan
e-mail: mayu.hikone@nagasaki-u.ac.jp

Background: Urine-based molecular diagnostics for tuberculosis (TB) offer non-invasive testing but face several limitations, including low sensitivity and less optimized in resource-limited settings. A novel diagnostic platform, the CRISPR gel assay, combines the traditional CRISPR-Cas12a reaction with recombinase polymerase amplification (RPA) in a one-pot isothermal gel-based format. This approach enables target nucleic acid detection with minimal equipment and manual handlings. It has shown promise for rapid and sensitive nucleic acid detection but not yet been applied to *Mycobacterium tuberculosis* (MTB).
Our objective was to evaluate its analytical performance in detecting MTB and compare it with the Xpert MTB/RIF Ultra.
Design/Methods: DNA was extracted from the H37Rv strain of MTB cultured in Löwenstein–Jensen medium using DNeasy Blood & Tissue Kit (QIAGEN) and spiked into urine samples from healthy individuals. CRISPR gel was prepared by combining an agarose gel with the CRISPR-Cas12a reaction mix. RPA reagents (TwistAmp Basic kit, TwistDx) were added to the gel, and the reaction was incubated at 40˚C for 90 minutes.
We experimentally selected the best primer set targeting MTB and compared the CRISPR gel assay with the Xpert MTB/RIF Ultra.
Results: The CRISPR gel assay successfully detected MTB DNA in urine without background noise. When using the most sensitive primer set among those tested, the assay achieved a limit of detection of 0.001 ng/μL, comparable to that of the Xpert MTB/RIF Ultra (0.001 ng/μL).

	Neg cont	Pos cont	1x (0.1ng/μL)	10^{-1} x	10^{-2} x	10^{-3} x	10^{-4} x	10^{-5} x
CRISPR gel	–	+	+	+	+	–	–	–
XpertMTB/RIF Ultra		+ Mid Ct:16.5	+ Low Ct:17.5	+ Low Ct:19.9	+ Trace Ct:27.2	– Neg	– Neg	

Conclusions: Under optimal conditions, the CRISPR gel assay demonstrated detection sensitivity comparable to the Xpert MTB/RIF Ultra, highlighting its potential as a sensitive diagnostic tool for TB in resource-limited settings. To advance the diagnostic applicability of the CRISPR gel assay, further optimization of transrenal DNA detection and clinical validation in TB-endemic settings is needed.

EP55-1227-21 Utility of Nanopore sequencing for the detection of drug-resistant TB in Kyrgyzstan

A. Kulzhabaeva,[1] A. Iskakova,[2] B. Myrzaliev,[3,4] A. Soorombaeva,[1] A. Kadyrov,[5] G. Kalmambetova,[5] A. Toktogonova,[5] A. Slyzkyi,[3] M. Ahmatov,[6,4] E. Tiemersma,[3] K. Kremer,[3] [1]KNCV Kyrgyzstan, Monitoring, Evaluation and Research, Bishkek, Kyrgyzstan, [2]National Center for Phthisiology, National Reference Laboratory, Bishkek, Kyrgyzstan, [3]KNCV TB Plus, Technical division, The Hague, Netherlands, [4]Kyrgyz State Medical Academy, Department of Phthisiology, Bishkek, Kyrgyzstan, [5]National Center for Phthisiology, Management, Bishkek, Kyrgyzstan, [6]KNCV Kyrgyzstan, Management, Bishkek, Kyrgyzstan
e-mail: akulzhabaeva11@gmail.com

Background and challenges to implementation: Rapid and accurate detection of drug-resistant tuberculosis is critical for timely and appropriate treatment initiation. Targeted next generation sequencing (tNGS) represents a promising alternative to conventional drug susceptibility testing (DST).
This study evaluated the utility of nanopore sequencing for TB drug resistance detection in Kyrgyzstan.
Intervention or response: From January 2024 to February 2025, adults with Xpert MTB/RIF-positive sputum were enrolled from four regions in Kyrgyzstan. Sputum samples were subjected to standard of care (SOC) DST, including line probe assay (LPA) and phenotypic DST (pDST). Nanopore sequencing was performed using the early access tNGS TB assay targeting 24 resistance-associated genes covering 16 anti-TB drugs, including all BPaL drugs (OND-CUST-KIT on MinION MK1B, Oxford Nanopore Technologies (ONT).
Results/Impact: Of 997 enrolled participants, 597 (60%) had complete tNGS and SOC results. Among these, 267 (45%) had TB resistant to ≥1 drug by SOC: 115 (19%) to isoniazid but not rifampcin and 117 (20%) to both rifampicin and isoniazid. Median turnaround times for LPA, pDST and tNGS were 4 (IQR:3–6), 26 (IQR:20–34) and 28 (IQR:15–50) days, respectively. The long turnaround time for tNGS was due to frequent delays in shipment of reagents and lack of trained staff in the first months of the study. In times when reagents and staff were available, the turnaround time of tNGS was 6 days (IQR: 5–8).
Six patients showed bedaquiline resistance, detected by either tNGS only (n=2), pDST only (n=1), or by both (n=3). tNGS predicted pretomanid resistance in six cases, while pDST for pretomanid was not performed.

Conclusions: tNGS has the potential to significantly enhance the speed of TB drug resistance detection. The ONT tNGS TB assay showed added value for detecting resistance to newer drugs like bedaquiline and pretomanid. These findings support the integration of tNGS into national diagnostic algorithms.

EP55-1228-21 Nanopore targeted next-generation sequencing for the timely prediction of drug resistance in *M. tuberculosis* complex clinical specimens in Tanzania

N. Mnyambwa,[1,2] A. Slyzkyi,[3] A. Samson,[1] C. Lubinza,[1] M. Mafie,[4] D. Mtunga,[5] S. Mfaume,[1] T. Maya,[5] A. Wilfred,[1] S. Mfinanga,[1] E. Tiemersma,[3] K. Kremer,[3]
[1]National Institute for Medical Research, Muhimbili Research Center, Dar es Salaam, United Republic of Tanzania, [2]Kampala International University, Microbiology, Dar es Salaamta, United Republic of Tanzania, [3]KNCV Tuberculosis Foundation, TB Elimination and Health System Innovations, The Hague, Netherlands, [4]Central Tuberculosis Reference Laboratory, Molecular section, Dar es Salaam, United Republic of Tanzania, [5]Central Tuberculosis Reference Laboratory, Microbiology, Dar es Salaam, United Republic of Tanzania
e-mail: tmaya.tz@gmail.com

Background: Targeted next-generation sequencing (tNGS) presents a unique opportunity for early detection of drug-resistance-conferring mutations in *Mycobacterium tuberculosis* complex to the most important anti-tuberculosis drugs in a single test, which can be conducted within one day.
This study aims to determine patient-important outcomes of using tNGS compared to standard of care (SOC) drug susceptibility testing (DST) using line probe assays (LPAs) and phenotypic DST for the detection of tuberculosis (TB) drug resistance in Tanzania.
Design/Methods: Since the end of January 2025, we have been enrolling adults (≥18 years) with TB confirmed on Xpert MTB/Rif Ultra (Xpert) in a multicenter prospective study including 24 health facilities in Tanzania. Patients are followed up for TB treatment outcomes.
Nanopore sequencing is done using the early access TB assay on MinION devices, targeting 24 genes related to 16 anti-TB drugs, including all BPaL drugs, followed by data analysis using the wf-tb-amr (v2.0.0-alpha.3) EPI2ME analysis workflow (Oxford Nanopore Technologies (ONT)).
Results: Thus far, till April 2025, 163 patients have been enrolled, and for 92, sputum samples were sequenced. All 92 samples were rifampicin susceptible on Xpert; the ONT TB assay showed consistent results for all but one sample, for which rifampicin resistance, as well as resistance to isoniazid, ethambutol, pyrazinamide, and ethionamide, was predicted. The ONT tNGS TB assay predicted isoniazid resistance for three additional samples, with one confirmed by LPA. One sample showed resistance to delamanid and pretomanid only. Phenotypic DST results are pending.
Conclusions: The preliminary results indicate that the ONT tNGS TB assay provides a comprehensive evaluation of drug resistance compared to the currently approved SOC methods, for which phenotypic DST results are pending.
Our study highlights the potential of tNGS to support accurate and timely clinical decision-making, which will ultimately improve treatment outcomes among TB patients.

EP55-1230-21 Evaluation of urine lipoarabinomannan and host transcriptional molecular biomarkers for diagnosing TB in symptomatic individuals with negative culture results

R. Reiss,[1] K. Lopez Tamara,[1] W. Honnen,[1] N. Modi,[1] P. Salgame,[1] A. Pinter,[1] Y. Xie,[1] [1]Rutgers New Jersey Medical School, Department of Medicine and Public Health Research Institute, Newark, United States of America
e-mail: rnr28@njms.rutgers.edu

Background: Urine and blood-based molecular tests for tuberculosis (TB) are promising additions to the rapidly developing TB diagnostic pipeline that can aid in diagnosing sputum culture-negative TB. We evaluated the performance of two novel assays in detecting TB in symptomatic culture-negative individuals.
Design/Methods: TB culture-negative and culture-positive sputum, blood, and urine were collected from a study of symptomatic adults undergoing clinical evaluation for TB in Uganda, Kenya, and South Africa.
Participants were followed over 12 months, and culture-negative individuals were classified as TB positive or negative using a microbial criterion (MC) based on Mtb mRNA and longitudinal Ultra and culture (standard and augmented) results and a clinical criterion (CC) based on clinical diagnosis.
Urine was analyzed directly via a novel urine lipoarabinomannan enzyme immunoassay (uLAM) that uses an S4-20 IgG capture antibody and an A194 IgM detection antibody. Total RNA was extracted from blood and analyzed using an 81-gene Nanostring panel for PREDICT29 and ACS-COR TB-associated host response signatures (HRS). Cutoffs were derived from the Youden index for ROC curves separating TB-negative controls from clinically confirmed positives.
Results: From 184 followed participants, 112 were TB culture-negative but microbiologically or clinically classified as positive. 4 subjects (3.6%) were uLAM positive only, 47 (42.0%) were HRS positive only, 3 (2.7%) were positive for both and 58 (51.8%) were negative for both. Sensitivity, specificity and AUCs for each assay were estimated (Table 1).

A significant association was observed between TB status and uLAM positivity for the MC (OR=4.48,p=0.005). Positive trends were observed between TB status and uLAM positivity (OR=2.68,p=0.07) and HRS positivity (OR=1.71,p=0.09) for the CC.

	Microbial criteria			Clinical criteria			Controls	
	Sensitivity (95% CI)	Specificity (95% CI)	AUC (95% CI[1])	Sensitivity (95% CI)	Specificity (95% CI)	AUC (95% CI[1])	Sensitivity[2] (95% CI)	Specificity[3] (95% CI)
uLAM	0.13 (0.05–0.28)	0.96 (0.90–0.99)	0.66 (0.54–0.77)	0.08 (0.03–0.18)	0.95 (0.87–0.98)	0.54 (0.43–0.65)	0.45 (0.26–0.66)	1.00 (0.78–1.00)
HRS	0.47 (0.31–0.64)	0.56 (0.45–0.67)	-	0.49 (0.36–0.62)	0.59 (0.46–0.70)	-	0.90 (0.70–0.97)	0.95 (0.76–0.99)
PREDICT29	-	-	0.53 (0.43–0.64)	-	-	0.57 (0.46–0.67)	-	-
ACS-COR	-	-	0.53 (0.41–0.64)	-	-	0.51 (0.40–0.62)	-	-

[1]From 2000 stratified bootstrap replicates.
[2]Based on 20 culture positive, smear positive samples.
[3]Based on 14 healthy volunteers for uLAM and 20 healthy volunteers for HRS.

Table 1. Sensitivity and specificity of the uLAM and HRS assays to detect culture-negative TB based on microbial and clinical criteria (n = 112), and to detect TB based on results from culture-positive, smear positive subjects and healthy volunteers.

Conclusions: uLAM and HRS assay performances were limited against exploratory microbiologic and clinical criteria based on longitudinal data. However, logistic regression results suggest the biomarkers are associated with TB status and imply that test performance could improve with additional optimization.

EP55-1231-21 Microfluidic-based molecular rapid diagnosis for tongue swab and sputum samples: A multicentre study

Y. Chen,[1] Pengfei Ren, Yingxia You, Zhongfeng Cui, Ling Gao, Rui Li, Xin Li, Ruixia Chang.
[1]Henan Provincial Infectious Diseases Hospital, Department of Tuberculosis and Critical Care Medicine, Zhengzhou, China
e-mail: chenyuhnzz@163.com

Background: Tongue swabs, as a non-invasive sampling modality, have been investigated for tuberculosis diagnosis in multiple countries. However, China has not yet conducted research on tongue swab-based tuberculosis (TB) detection using molecular rapid diagnostics, particularly low-complexity automated nucleic acid amplification tests (LC-aNAATs).
This study evaluated the diagnostic accuracy of a novel molecular rapid diagnostic system Genewise-MTBC for pulmonary tuberculosis using tongue swab and sputum samples.

Design/Methods: This study was conducted across 4 designated TB hospitals in China, enrolling 547 participants with suspected pulmonary TB. The LC-aNAAT used was Genewise-MTBC from Genewise Bio, a microfluidic technology-based system integrating magnetic bead-based nucleic acid extraction and qPCR, capable of detecting TB within 45 minutes.
Tongue swabs and sputum samples were obtained from all participants. Sputum samples underwent smear, MGIT culture, and Xpert MTB/RIF (Xpert), while both tongue swabs and sputum samples were tested using Genewise-MTBC.
Results from all methods were compared and analyzed using the microbiological reference standard (MRS) of sputum as the reference.
Results: Among the 547 enrolled patients, a total of 448 (81.90%) cases were clinically diagnosed with pulmonary tuberculosis, including 283 (63.17%) MRS-positive patients; 99 (18.10%) cases were diagnosed with other pulmonary infections. Based on sputum MRS, the sensitivities of sputum smear, sputum MGIT culture, and sputum Xpert were 42.05%, 57.24%, and 88.69% respectively. Sputum Genewise-MTBC achieved superior performance with 94.35% sensitivity, 100% specificity, and 97.07% concordance. Using sputum MRS as the reference, tongue swabs tested with Genewise-MTBC showed 80.85% sensitivity, 100% specificity, and 90.13%.
Conclusions: Our findings establish that LC-aNAATs exhibit superior sensitivity compared to sputum smear and culture. Genewise-MTBC demonstrated higher sensitivity than Xpert.
Additionally, tongue swab testing with Genewise-MTBC shows promising sensitivity, suggesting that tongue swabs could be considered as a complementary or alternative sample type for TB diagnosis and even screening.

EP55-1232-21 Machine learning combined with plasma multi-omics analysis helps diagnose TB progression in high-risk populations

M. Qian,[1] X. Lin,[1] J. Zhou,[1] Q. Yang,[1] Q. Ruan,[1]
[1]Huashan Hospital, Fudan University, Department of Infectious Diseases, National Medical Center for Infectious Diseases, Shanghai, China
e-mail: 23211220010@m.fudan.edu.cn

Background: Non-sputum blood tests have the potential for rapid diagnosis of active tuberculosis (ATB) in high-risk populations. Our goal is to develop new biomarker combinations using multi-omics approaches to assist in the diagnosis of TB progression.
Design/Methods: This is a sub-study of an open-label, randomized clinical trial of preventing TB in the silicosis patients (ClinicalTrials.gov number: NCT02430259). 26

ATB participants (TB progressor group) were matched in a 1:1 ratio with 26 individuals (non-TB progressor group).

Metabolomic and proteomic analyses of plasma were performed using ultrahigh-performance liquid chromatography-tandem mass spectrometry. Potential markers were selected based on differential analysis, univariate and Receiver Operating Characteristic Analysis. The joint diagnosis model was constructed using Support Vector Machine (SVM) and internal cross-validation was performed

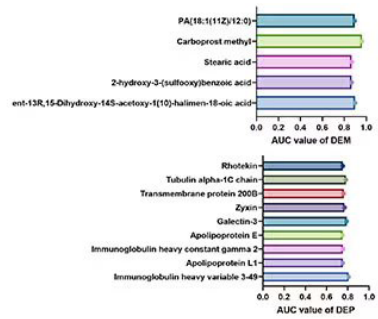

Figure1.AUC value of seleced DEP and DEM
*DEP:differentially expressed proteins
*DEM:differentially expressed metabolites

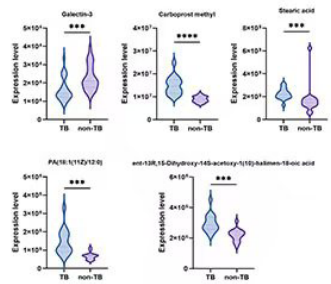

Figure2.Expression level of comprehensive biomarkers

Table1 . Relevant parameters of SVM machine learning method.

Diagnostic Biomarker Panel	AUC	Sensitivity	Specificity	95% CI	Accuracy
Proteome Biomarkers Panel	0.9375	1.0000	0.8750	0.6977-0.9984	0.9250
Metabolome Biomarkers Panel	0.8000	1.0000	0.6000	0.4439-0.9748	0.8667
Comprehensive Biomarker panel	1.0000	1.0000	1.0000	0.6915-1.0000	1.0000

*Proteome Biomarkers Panel: Immunoglobulin heavy variable 3-49; Apolipoprotein L1; Immunoglobulin heavy constant gamma 2; Apolipoprotein E; Galectin-3; Zyxin; Transmembrane protein 200B; Tubulin alpha-1C chain; Rhotekin.
*Metabolites Biomarkers Panel: Stearic acid;PA(18:1(11Z)/12:0); Carboprost methyl; ent-13R,15-Dihydroxy-14S-acetoxy-1(10)-halimen-18-oic acid;11-Dehydro-2,3-dinor-txb2;2-hydroxy-3-(sulfooxy)benzoic acid
*Comprehensive biomarker panel: Galectin-3; Stearic acid; Carboprost methyl; PA (18:1(11Z)/12:0); ent-13R,15-Dihydroxy-14S-acetoxy-1(10)-halimen-18-oic acid.

Results: 75 differentially expressed proteins were identified between progressors and non-progressors. Nine proteins with the area under the curve (AUC)>0.75 were selected to form the proteome biomarkers panel (Galectin-3; Immunoglobulin heavy variable 3-49; Apolipoprotein L1; Immunoglobulin heavy constant gamma 2; Apolipoprotein E; Zyxin; Transmembrane protein 200B; Tubulin alpha-1C chain; Rhotekin). The AUC of the panel was 0.9375 (95% confidence interval (95%CI): 0.6977-0.9984; specificity: 87.50%; sensitivity: 100%).

Among the 144 differentially expressed metabolites in the two ionization modes, 5 metabolites with variable importance in projection >2 and AUC >0.85 (PA(18:1(11Z)/12:0); Stearic acid; Carboprost methyl; ent-13R,15-Dihydroxy-14S-acetoxy-1(10)-halimen-18-oic acid;2-hydroxy-3-(sulfooxy)benzoic acid) were selected as metabolites biomarkers panel. The AUC was 0.8 (95%CI:0.4439-0.9748; specificity: 60%; sensitivity: 100%).

Based on the variable importance order obtained by SVM analysis, a comprehensive biomarker panel including 1 protein and 4 metabolites (Galectin-3; Stearic acid; Carboprost methyl; PA (18:1(11Z)/12:0); ent-13R,15-Dihydroxy-14S-acetoxy-1(10)-halimen-18-oic acid) was developed. This combination can characteristically and correctly allocate the progression and non-progression groups with an AUC of 1 (95%CI: 0.6915-1) and a specificity and sensitivity of 100%.

Conclusions: We proposed a comprehensive biomarker panel for predicting tuberculosis progression to enhance early diagnosis and treatment in high-risk populations.

EP55-1233-21 Development and clinical validation of a novel method for simultaneous rapid molecular drug susceptibility testing of rifampicin, isoniazid and fluoroquinolones

J. Cui,[1] C. Guo,[1] Y. Gao,[1] Z. Li,[1] [1]The First Affiliated Hospital of Xinxiang Medical University, Department of Tuberculosis, Xinxiang, China
e-mail: 49993803@qq.com

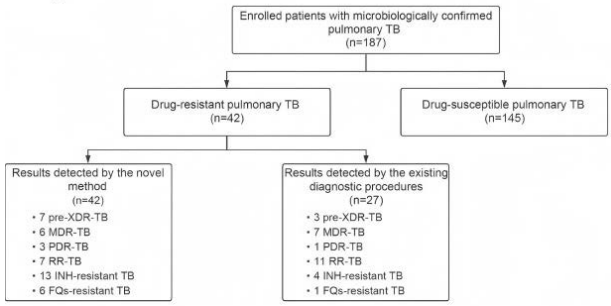
Background: Laboratory-based drug resistance diagnosis plays a central role in therapeutic decision-making for drug-resistant tuberculosis (DR-TB). Molecular drug susceptibility testing (DST), characterized by its rapidity and accuracy, holds significant clinical value for the early diagnosis of DR-TB. The WHO recommends fluoroquinolone resistance testing for multidrug-resistant TB (MDR-TB) and rifampicin-resistant TB (RR-TB) patients. Although genetic mutations associated with resistance to rifampicin (RIF), isoniazid (INH), and fluoroquinolones (FQs) demonstrate strong predictive efficacy, there is currently no molecular DST kit in China capable of rapidly and simultaneously diagnosing resistance to these three drug classes.

Design/Methods: Using the low complexity automated nucleic acid amplification test (LC-aNAAT) system from Genewise Bio, we developed a detection kit capable of identifying resistance-associated mutations for RIF, INH, and FQs within approximately 60 minutes as a novel rapid molecular DST method. We consecutively enrolled 187 microbiologically confirmed pulmonary TB patients from our hospital. MGIT-cultured strains or sputum samples were tested using the new kit, with results compared against GeneXpert MTB/RIF outcomes and conventional DST results. Resistance findings from the new kit were validated by Sanger sequencing.

Results: Among the 187 cases, the novel method detected 42 DR-TB cases (Fig.A), including RR-TB, mono-resistant TB (MR-TB), poly-drug-resistant TB (PDR-TB), MDR-

TB, and pre-extensively drug-resistant TB (pre-XDR-TB). Except for one failed sequencing case, all resistance results were confirmed by Sanger sequencing. Of the 42 DR-TB cases, 27 were previously identified through existing diagnostic procedures, while 15 were newly detected by the novel method (including 9 INH-resistant, 5 FQs-resistant and 1 MDR-TB cases). Notably, INH/FQs-resistance was detected in 8 known cases (Fig.B).

A. Study profile



B. Record table of drug resistance results

No.	Resistance diagnosis results				No.	Resistance diagnosis results			
	RIF	INH	FQs	Classify		RIF	INH	FQs	Classify
1	●	●	○	pre-XDR-TB	22		○		MR-TB（INH）
2	●	●	○	pre-XDR-TB	23		○		MR-TB（INH）
3	●	●	○	pre-XDR-TB	24		○		MR-TB（INH）
4	●	●	○	pre-XDR-TB	25		○		MR-TB（INH）
5	●	●	●	pre-XDR-TB	26			○	MR-TB（FQs）
6	●	●	●	pre-XDR-TB	27			○	MR-TB（FQs）
7	●	●	●	pre-XDR-TB	28			○	MR-TB（FQs）
8	○	○		MDR-TB	29			○	MR-TB（FQs）
9	●	○		MDR-TB	30			○	MR-TB（FQs）
10	●	○		MDR-TB	31	●			RR-TB
11	●	●		MDR-TB	32	●			RR-TB
12	●	●		MDR-TB	33	●			RR-TB
13	●	●		MDR-TB	34	●			RR-TB
14	●		○	PDR-TB	35	●			RR-TB
15	●		○	PDR-TB	36	●			RR-TB
16	●		●	PDR-TB	37	●			RR-TB
17		○		MR-TB（INH）	38		●		MR-TB（INH）
18		○		MR-TB（INH）	39		●		MR-TB（INH）
19		○		MR-TB（INH）	40		●		MR-TB（INH）
20		○		MR-TB（INH）	41		●		MR-TB（INH）
21		○		MR-TB（INH）	42			●	MR-TB（FQs）

● The drug resistance results of the novel method are consistent with those of existing diagnostic procedures
○ The drug resistance results additionally detected by the novel method
○ The drug resistance results missed by the novel method

Conclusions: Reliance solely on RIF-resistance testing may overlook INH or FQs resistance, introducing uncertainty in treatment. Our novel method enables rapid combined resistance detection with excellent sensitivity and specificity, providing robust support for the early diagnosis of DR-TB patients.

EP55-1234-21 TB-MBLA: Design and development of TB molecular bacterial load assay, a monitoring tool for treatment response

R. Gray,[1] A. Bell,[1] H. Buchanan,[1] P. Emanuel,[1] S. Williams-MacDonald,[1] P. Dand,[1] P. Smith,[1] W. Sabiiti,[2] S. Gillespie,[2] [1]LifeArc, Integrated Diagnostics, Edinburgh, United Kingdom of Great Britain and Northern Ireland, [2]University of St Andrews, School of Medicine, St Andrews, United Kingdom of Great Britain and Northern Ireland
e-mail: rowan.gray@lifearc.org

Background: There are several Standard of Care (SoC) tests to diagnose Mycobacterium tuberculosis (MTB), but they are not suited to monitor disease progress in real time. Molecular tests targeting DNA and smear microscopy do not differentiate between viable and dead bacteria. Culture methods detect viable bacteria but can take up to six weeks and are prone to contamination. The Tuberculosis Molecular Bacterial Load Assay (TB-MBLA), developed by Professor Stephen Gillespie's group at the University of St Andrews (UStAn), uses 16S rRNA as a marker of TB viability in sputum. This Reverse Transcriptase (RT)- qPCR is molecular, quantitative, culture-free and allows for treatment monitoring in real time.
Design/Methods: A collaboration between UStAn and LifeArc took the TB-MBLA through Feasibility and Analytical Verification to ISO 13485 Design and Development (D&D) standards, and included real-time stability testing. Performance of TB-MBLA was assessed using Smear-positive sputum samples (FIND Biobank).
Results: During Feasibility the cycling conditions and primer/probe concentrations were optimised by carrying out a thorough assessment of the assay design to check for cross homology.
During Analytical Verification several performance parameters were tested using three independently manufactured kit batches. This included Limit of Detection (LoD), which was established at 128 copies-per-reaction (c/rxn), and Limit of Quantification (LoQ) at 256 c/rxn. All performance parameters met Design Input requirements.
Real-time stability testing was run over a period of 24 months to assess the TB-MBLA assay mix and controls at several time points. No significant change in performance was observed during this testing period, showing the components to be highly stable.
Testing of Biobank sputa demonstrated a strong concordance of TB-MBLA and Smear grading, with 100% sensitivity and 97% specificity.
Conclusions: Overall, testing showed the TB-MBLA to be very robust and was ready for clinical evaluation in the LifeArc sponsored TIME Study.

EP56 From policy to practice: Strategic alignment to fight TB

EP56-1235-21 Collaboration practices in TB research in Peru: Perspectives from TB researchers and clinicians

L. Villa-Castillo,[1,2] N. Young,[3] C. Rojas Vargas-Corbacho,[1] N. Hilario Huapaya,[1] C. Ugarte-Gil,[1,4] [1]Instituto de Medicina Tropical Alexander von Humboldt at Universidad Peruana Cayetano Heredia, TB Research Unit, Lima, Peru, [2]McGill University, Department of Epidemiology, Biostatistics and Occupational Health, Montréal, Canada, [3]Duke University, Duke University School of Medicine, North Carolina, United States of America, [4]University of Texas Medical Branch, School of Public and Population Health, Galveston, United States of America
e-mail: luz.villa.castillo@hotmail.com

Background: Peru has the highest incidence of tuberculosis (TB) in the Americas. The World Health Organization has identified collaborative research practices as key actions needed to achieve the End TB Strategy. Peru's National TB Program (NTP) has implemented the National Tuberculosis Research Network (RENAI-TB) to achieve this goal. This study identifies the main facilitators and barriers experienced by TB researchers and NTP provincial directors (NTPPDs) regarding the collaboration practices.
Design/Methods: We conducted a two-part explanatory sequential study comprising a mixed-methods analysis of survey and interview data. The first part comprises a survey targeting researchers who have published at least one scientific article about TB between 2017-2019, and TB clinicians working as NTPPDs. The second part includes semi-structured interviews. Both components focus on their experience doing TB research and RENAI-TB. Responses were analyzed following the grounded theory framework, using Atlas.ti.
Results: Of the 65 participants invited, 36 completed the survey, and 9 TB researchers and 7 NTPPDs participated in follow-up interviews. Researchers identified conferences and pre-existing relationships with peers as facilitators of collaboration practices, and government bureaucracy, researchers' territorial attitudes around research sites, competitive funding opportunities, and lack of protected time for research as major obstacles. NTPPDs reported no participation in research activities due to their heavy workloads, lack of dedicated research time, and limited institutional prioritization. Respondents proposed the creation of financial incentives to support research engagement, professional recognition, and state-funded research training. RENAI-TB was recognized as a potential vehicle that might be leveraged to support this effort.
Conclusions: Collaborative practices in TB research occur among researchers through natural interactions with peers. It is necessary to address systemic health barriers and create policies that support new models of collaboration and research training initiatives for NTP TB clinicians and researchers to advance the country's efforts toward TB elimination.

EP56-1236-21 A global survey of TB management policies in prisons

L. Faust,[1] A. Zheng,[2] A.D. Harries,[3,4] L. Martinez,[2] [1]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, Department of Clinical Research, London, United Kingdom of Great Britain and Northern Ireland, [2]Boston University, Department of Epidemiology, Boston, United States of America, [3]International Union Against Tuberculosis and Lung Disease, -, Paris, France, [4]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom of Great Britain and Northern Ireland
e-mail: amyzheng@bu.edu

Background: Due to overcrowding and poor ventilation, prisons are high-risk environments for transmission of tuberculosis. However, little is known about how tuberculosis control programs approach management of the disease in these settings.
Design/Methods: We conducted a global survey among national tuberculosis program representatives in all World Health Organisation (WHO) regions to better understand policies regarding tuberculosis management in prisons at the country-, regional-, and global-level.
We included questions regarding tuberculosis screening, diagnosis, preventive treatment, and continuity of care after prison release, amongst other aspects of tuberculosis control. Responses were analysed by country and WHO region.
Results: We received 125 responses from 89 countries spanning all six WHO regions. Most responses (n=41, 33%) were from the European region. Almost half (N = 54 / 114; 47%) of respondents reported that their national tuberculosis guidelines included policies specific to prisons. 49 of 92 (53%) officials reported that all detainees are screened for tuberculosis at prison entry. Most respondents (94%) reported using some form of directly observed therapy for tuberculosis treatment in prisons. The most-reported challenge regarding implementation of guidelines for tuberculosis management in prisons was overcrowding (52% of respondents) (*Table 1*).
The use of GeneXpert for TB diagnosis was highly heterogeneous by region; almost all respondents from Southeast Asia (100%) and Africa (95%), responded positively while only half (50%) responded positively in the Eastern Mediterranean region.
Challenges to policy implementation also varied by region; prison overcrowding was cited by most respondents in Southeast Asia and Africa, but by only 32% in the Western Pacific.

Table 1. Policies for TB management in prisons and barriers to their implementation, by WHO region (percent of respondents indicating each policy/barrier)

WHO Region, N responses	Prison-specific policies included in national TB guidelines	Challenges to implementation of TB management guidelines in prisons (a)			All detainees screened for TB at entry into prison (b)	Screening tools used at entry: chest X-ray or molecular test in addition to clinical evaluation	GeneXpert used for initial TB diagnosis	Directly observed therapy (DOT) implemented (c)	Post-release follow-up of those on treatment: policy in place for referral to local health centre
		Prison overcrowding	Lack of healthcare staff	Lack of healthcare infrastructure					
AFRO, N = 25	66.7	83.3	45.8	58.3	57.9	57.9	94.7	100.0	100.0
AMRO, N = 17	50.0	37.5	56.2	37.5	53.8	83.3	69.2	86.7	73.3
EMRO, N = 2	50.0	50.0	50.0	50.0	0.0	100.0	50.0	100.0	100.0
EURO, N = 41	50.0	45.7	40.0	40.0	56.7	63.0	75.9	100.0	100.0
SEARO, N = 10	66.7	75.0	62.5	50.0	60.0	60.0	100.0	66.7	60.0
WPRO, N = 30	18.5	32.1	32.1	32.1	47.8	80.0	73.3	90.9	78.3

Percent of respondents indicating each policy/barrier
0.0 20.0 40.0 60.0 80.0 100.0

TB=tuberculosis. WHO=World Health Organisation. WHO Regions: AFRO=Africa, AMRO=Americas, EMRO=Eastern Mediterranean, EURO=Europe, SEARO=Southeast Asia, WPRO=Western Pacific.
(a) Only the top 3 reported challenges are included in this table.
(b) Only those reporting that all detainees are screened (in all prisons) are included in this category –those reporting that detainees are screened in some but not all prisons are not counted here.
(c) Includes detainees receiving DOT either directly in prison cells or by reporting to DOT centres. Only those reporting DOT use in all prisons are counted here.

Conclusions: This is the first global survey of current policies regarding tuberculosis screening, diagnosis, and treatment in prisons. Results suggest that, while many countries have prison-specific tuberculosis management guidelines, challenges in this setting hinder implementation. Furthermore, heterogeneity in responses across and within countries suggests variation in policy implementation.

EP56-1237-21 Improving grants management through business central systems to fight TB, leprosy and lung diseases in Kenya

O.M. Koyieke,[1] J. Mungai,[2] B. Ulo,[3] L. Odeny,[4] D. Omondi,[5] The Division of National Tuberculosis, Leprosy and Lung Disease Program (DNTLD-Program)
[1]Amref Health Africa, Grants, Nairobi, Kenya, [2]Amref Health Africa, Program, Nairabi, Kenya, [3]Amref Health Africa, Programming, Nairobi, Kenya, [4]Amref Health Africa, M&E, Nairobi, Kenya, [5]Amref Helath Africa, Grants, Nairobi, Kenya
e-mail: moses.onyango@amref.org

Background and challenges to implementation: Kenya has long faced persistent challenges in community-based TB case finding. Donor-funded programs have played a key role in implementing various interventions, however, smooth implementation is hindered by weak grants management systems. Inefficient fund disbursement slows down implementation and affects the supply of essential commodities, tools, and implementation of various interventions.
Intervention or response: To enhance grants accountability and TB outcomes, Amref Health Africa, the Global Fund's non-state Principal Recipient deployed Microsoft Dynamics 365 Business Central ERP across 38 subrecipients in all 47 Kenyan counties. The system replaced manual sub-granting processes that caused disbursement delays, financial discrepancies, and limited oversight. It enabled real-time financial tracking, automated reporting, and performance monitoring. A phased rollout (2021–2023) included training, data migration, and testing. Monitoring was conducted via built-in dashboards and quarterly reports. Data on reporting accuracy, turnaround time, and absorption rates assessed system impact, supported by regular feedback sessions.
Results/Impact: All 38 subrecipients transitioned to digital grants management. Through the implementation of this system, financial cost eligibility rose from 50% (2021) to 76% (2023), Financial submission errors were reduced by 24%, quarterly cash disbursement delays dropped by 50% and fund absorption rose from 63% to 98% by year two. Improved grant performance led to timely procurement and enhanced TB implementation of TB interventions. Kenya saw a 25% rise in TB notifications (2021–2023) and national declines in TB mortality (37 to 27), TB/HIV mortality (24 to 14), and incidence (267 to 223 per 100,000, 2019–2023).
Conclusions: Digital solutions like Business Central can significantly enhance grants management, enabling timely disbursements, better reporting, and resource tracking which is critical for timely TB interventions. Sustained capacity building and scaling to other programs can accelerate progress toward ending TB and achieving universal health coverage.

EP56-1238-21 Inequities in the production of TB-related social protection policies across municipalities in Rio de Janeiro, Brazil (2014–2024)

Y.M. Alves,[1,2] R.B.V. Tavares,[1,2] V.M.S. Araújo,[2] D.S. Duarte,[2] V.C. Lima,[2] M. Guazzi,[3] M. Martins,[4] C.M. Morgado,[5] R.A. Arcêncio,[1,2] E.L.N. Maciel,[6,2] [1]University of São Paulo at Ribeirão Preto College of Nursing, Maternal-Infant and Public Health, Ribeirão Preto, Brazil, [2]Brazilian Tuberculosis Research Network (REDE-TB), Projects, Rio de Janeiro, Brazil, [3]Rio de Janeiro State Health Department, Social Assistance, Rio de Janeiro, Brazil, [4]Rio de Janeiro State Health Department, Tuberculosis, Rio de Janeiro, Brazil, [5]Pan American Health Organization, Tuberculosis, Rio de Janeiro, Brazil, [6]Federal University of Espírito Santo, Nursing, Vitória, Brazil
e-mail: reginaldobazon@usp.br

Background: Normative regulation is a critical step for implementing social protection measures. In high TB burden settings, the absence of formal policies may hinder access to comprehensive care.
This study assessed the municipal-level distribution of normative documents related to TB and social protection in the state of Rio de Janeiro from 2014 to 2024.
Design/Methods: We analyzed 79 records corresponding to 75 normative documents collected from official municipal sources. Documents were grouped by municipality and year of publication. Descriptive analysis was performed, supported by a grouped bar chart to visualize the frequency and distribution of documents over time.

Results: The analysis revealed marked disparities in normative activity across municipalities. Cities such as Magé and Belford Roxo showed relatively high production of social protection regulations. Conversely, other municipalities with high TB burden—such as São João de Meriti and Duque de Caxias—did not publish any related normative acts during the study period.
These findings point to significant inequities in institutional engagement and capacity for policy development in critical areas (Figure 1).

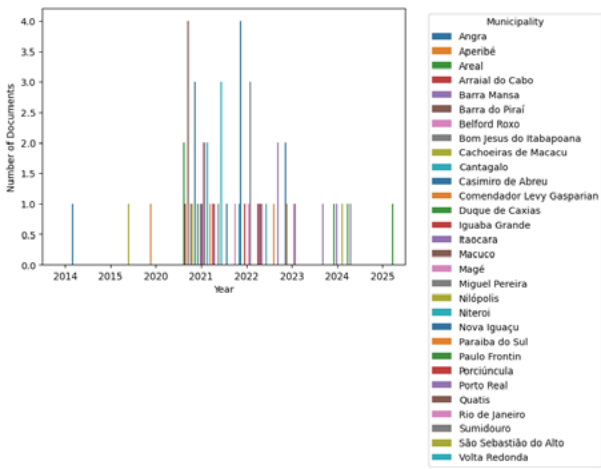


Figure 1 - Distribution of Social Policy Documents by Municipality and Year.

Conclusions: The unequal distribution of social protection policy production reveals structural differences in institutional capacity and political will across municipalities. These disparities may undermine TB care continuity, especially in vulnerable regions. To address this, regionalized technical support and federative coordination strategies should be prioritized to reduce normative gaps and promote equitable policy action. Strengthening local governance capacity is essential to ensure all high-burden municipalities are equipped to implement and sustain TB-related social protection measures.

EP56-1239-21 Institutionalising nutritional support for people with TB into the local self-governance annual plans in Kerala, India: A policy reform initiative

E. Joy,[1] R. Kizhakkekkandiyil,[2] K. Devadhas Sulochana,[2] A. Mohan,[3] R. Babu,[4] D.D. Rao,[5] R. Begum,[5] K Karthikeyan,[6] B.S. Kushwaha,[7] S.K. Mattoo,[7] U. B Singh,[7] M. HL,[8]
[1]KHPT, Programme-Tuberculosis, Thiruvananthapuram, India, [2]State TB Cell, Directorate of Health Services, Thiruvananthapuram, India, [3]World Health Organisation, Programme-Tuberculosis, Thiruvananthapuram, India, [4]KHPT, Programme-Tuberculosis, Jammu, India, [5]KHPT, Programme-Tuberculosis, Delhi, India, [6]KHPT, Programme-Tuberculosis, Bengaluru, India, [7]Central TB Devision, Ministry of Health and Family Welfare, Delhi, India, [8]KHPT, Programmes, Bengaluru, India
e-mail: mohana@rntcp.org

Background and challenges to implementation: In 2023, Kerala, India, reported 21,309 tuberculosis (TB) cases. The state has a strong local governance structure comprising 941 Grama Panchayats (GPs) and 93 Urban Local Bodies (ULBs) which has supported TB elimination efforts since 2012, including nutritional support for Persons with TB (PwTB). However, audit concerns and the lack of clear policy guidelines led many local bodies to withdraw their support. Further challenges arose from the inconsistent participation of *Nikshay Mitras (*voluntary donors encouraged to provide nutritional support to PwTB) affecting the goals of the Pradhan Mantri TB Mukt Bharat Abhiyaan.
In response, the State TB Cell engaged policymakers for sustainable, policy-backed nutritional support mechanism.
Intervention or response: To address this policy gaps related to TB nutrition support in GPs and ULBs, the State TB Cell under the Directorate of Health Services conducted a series of policy deliberations, stakeholder dialogues, analytical reviews, and expert consultations. This has explored various mechanisms, and policy instruments for integrating TB nutrition support into Local Self Governance.
Results/Impact: These discussions generated strong momentum and brought attention to challenges in financial audits and compliance. On March 6, 2025, the Local Self Government Department issued an official directive (G.O. (Rt) No. 623/2025/LSGD) with new policy guidelines to all GPs and ULBs to include nutritional support for TB patients in their annual plans. The directive provides permissive sanction for GPs and ULBs to supply monthly nutritional food kits worth INR ₹1,500 to consented TB patients for up to 21 months. The policy enables implementation through multiple funding sources, including Development Grants, Own Funds, Fifteenth Finance Commission Grants while emphasizing monitoring, awareness, systematic evaluation and sustainability.

Conclusions: This policy advocacy successfully integrates the TB nutritional support within Kerala's decentralized governance, creating a scalable and accountable model. This initiative is expected to strengthen local ownership, ensure sustainable funding, and enhance TB treatment outcomes.

EP56-1240-21 Strategies for managing global shortages of first-line anti-TB medicines: A case study of the National TB Programme in Nigeria

R. Mobolaji,[1] B. Rosiji,[1] I. Momoh,[1] C. Mgbemena,[2] A. Aderounmo,[2] R. Gurumnaan,[2] A. Agbaje,[2] C. Mensah,[3] P. Dakum,[4] C. Adesigbin,[1] J. Kimeu,[5] M. Zamzu,[5] [1]National TB and Leprosy Control Programme, Public health, Abuja, Nigeria, [2]Institute of Human Virology Nigeria, Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria,, Abuja, Nigeria, [3]Institute of Human Virology Nigeria, Office of the COO, Abuja, Nigeria, [4]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [5]The Global Fund to Fight AIDS, Tuberculosis and Malaria ,, Global Health Campus, Geneva, Nigerian Country Team, Geneva, Switzerland
e-mail: rajimobolaji@yahoo.com

Background and challenges to implementation: Nigeria is classified as a high-tuberculosis(TB)-burden country, with an estimated 361,000 new cases reported in 2023. The country has a TB prevalence of 219 per 100,000 population. The global supply chain shortage of Rifampicin, a key component of drug-sensitive treatment regimens emerged, driven by scarcity of the active ingredient and supply chain interruptions emerged in early 2024, threatened TB control efforts in Nigeria.
Intervention or response: At the onset of the TB medicine shortages, the National Tuberculosis and Leprosy Control Programme (NTBLCP) swiftly engaged key stakeholders including implementing-partners, donor agencies, and patient advocacy groups to communicate the impending crisis. This early engagement helped prepare healthcare-providers and inform patients about potential treatment disruptions. In response, an emergency Standard Operating Procedure (SOP) for TB case management was developed and rolled out.
A series of coordinated strategies were implemented, including a comprehensive analysis of Logistics Management Information System (LMIS) to guide the redistribution of anti-TB medicines from overstocked, low-burden sites to high-burden facilities. To manage less frequent medicine shipments, the distribution cycle was shortened from quarterly to monthly.
Emergency logistics capacity was increased with the Global Fund's procurement of 37 Toyota-Hilux vehicles and over 1,500 motorbikes, enabling swift medicine delivery and interfacility transfers. Simultaneously, the clinical team ensured treatment continuity by identifying and line-listing eligible new clients, initiating them on therapy as soon as medicines became available.
Results/Impact: These emergency supply chain management strategies ensured that patient enrollment increased from over 361,000 in 2023 to 405,324 in 2024; this represents a 10.8% increase in patient enrollment despite acute medicine shortages.
Conclusions: Through these strategic interventions, NTBLCP successfully navigated the global shortage of first-line anti-TB medicines, minimizing disruptions in treatment services and maintaining continuous care for TB patients. This highlights the importance of early communication, adaptive logistics, data-driven decision-making, and international collaboration in maintaining essential medicine supply chains.

EP56-1241-21 Translating evidence into policy: A mixed-methods approach to guideline development for differentiated TB care in India

S. Mattoo,[1] S. Chauhan,[2] H. G,[2] L. Mehandru,[2] A. Chauhan,[3] S. Chandra,[2] U. Singh,[1] [1]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [3]South Asian Institute of Health Promotion, -, New Delhi, India
e-mail: mattoos@rntcp.org

Background and challenges to implementation: India accounts for 27% of the global tuberculosis (TB) burden—the highest worldwide. Despite progress under the National Tuberculosis Elimination Programme(NTEP), TB-related mortality remains high. To accelerate progress toward the End TB targets, a differentiated care model responsive to both clinical and social vulnerabilities was urgently needed.
Intervention or response: A sequential exploratory mixed-methods approach guided the development of the 2025 Differentiated TB Care guidelines. The process included desk review to identify models of differentiated care, analysis of programmatic data on TB Deaths, followed by qualitative interviews with stakeholders to capture priorities for patient-centered care. These insights shaped a quantitative analysis to identify high-risk groups. Triangulated findings informed the design of a tiered care framework, outlining level-specific roles for triaging, referral, and follow-up.
Results/Impact: This first-of-its-kind global guidance institutionalizes a patient-centered, risk-stratified model to reduce TB mortality. Drawing insights from various differentiated TB care projects in the country including Tamil Nadu KET (TN-KET), it introduces early triaging

by frontline workers, decentralizing critical care to the community level. Evidence from national data shows that nearly 50% of adults with TB are undernourished, and 25% face severe undernutrition (BMI <14 kg/m²)—a key predictor of early mortality. To address this, the model incorporates AI-based risk prediction(PATO), structured clinical assessments, and risk-informed referral pathways. The inclusion of TB Social Autopsy (TBSA) further supports systemic learning by identifying barriers contributing to TB-related deaths. With 70% of TB deaths occurring early—half within the first two weeks of treatment—this framework enables timely identification and care for vulnerable patients, aiming to reduce preventable mortality and improve outcomes.

Conclusions: The Differentiated TB Care guidelines mark a strategic, evidence-informed shift in TB management in India. By integrating clinical, social, and system-level interventions into NTEP, this scalable, equity-driven model enhances responsiveness, reduces mortality, and offers a replicable blueprint for other high-burden settings worldwide.

EP56-1242-21 What happens when people with drug-resistant TB are not supported by the community? A survival analysis in Indonesia

Q.N. Salamah,[1] R. Afni,[1] I. Suryana,[1] H. Paramaiswari,[1] B. Nababan,[1] F.M. Aulia,[1] R.W. Khumaeroh,[1] I. Nurul'Aini,[1] M.S. Susilastuti,[1] S. Mulyana,[1] B. Aditya,[1] [1]Consortium Penabulu-STPI, Principal Recipient of the Global Fund TB Community, Jakarta, Indonesia
e-mail: qonita.salamah@penabulu-stpi.id

Background and challenges to implementation: iLTFU/LTFU is one of the challenges to the successful treatment of DRTB patients. Community assistance interventions can decrease the ILTFU/LRTFU during the treatment period. Consortium Penabulu-STPI of Global Fund funding determined the probability of iLTFU/LTFU survival of DRTB patients during the treatment period in community-assisted and unassisted settings.

Intervention or response: DRTB patients are assistance by patient supporter during the treatment period until completion/cured. Revisit is conducted 2-3 times a month and provided enabler funds. This study was retrospective cohort through secondary data analysis of interoperability data from the National TB Information System (SITB) to the Community Information System (SITK-RO) who were diagnosed and started treatment between January and December 2023 from 190 districts/cities in 30 provinces. The Kaplan-Meier survival analysis method was conducted with a log-rank test and a Cox regression proportional hazard. Data were analyzed using SPSS IBM statistic 20 software and STATA version 16.

Results/Impact: There were 2,249 DRTB patients met the inclusion criteria with 238 (12%) patients iLTFU/LTFU of 1,974 community-assisted patients and 78 (28%) patients iLTFU/LTFU of 275 unassisted patients. The cumulative survival probability of community-assisted patients was 77%, while the probability in unassisted patients was only 32%. More than 50% of community-assisted DRTB patients survived iLTFU/LTFU even up to year 3, while unassisted patients only survived in the first year.

There was a statistically significant difference between the cumulative survival probability of community-assisted and unassisted DRTB patients (p=<0.001). Unassisted patients are more likely to iLTFU/LTFU compared to community-assisted patients (HR 3.5; 95% CI 2.731-4.567).

Conclusions: Community assistance significantly increases the survival probability of DRTB patients to complete treatment and reduces the risk for iLTFU/LTFU during the treatment period compared to patients who are not assisted by the community. Strengthening community support is essential for improving adherence and ensuring treatment success among DRTB patients.

EP56-1243-21 Accelerated BPaLM scale-up in high burden multi-drug-resistant/rifampicin-resistant TB setting: A mixed methods study on health-system strengthening through capacity building in India

S. Mattoo,[1] H. G,[2] S. Chauhan,[2] L. Mehandru,[2] S. Suryawanshi,[2] A. Chauhan,[3] S. Chandra,[2] U. Singh,[1] [1]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [3]South Asian Institute of Health Promotion, New Delhi, India
e-mail: mattoos@rntcp.org

Background: India has 26% of the global Multi-Drug/Rifampicin Resistant Tuberculosis (MDR/RR-TB), posing significant challenges in favourable treatment outcomes. India declared policy to roll out countrywide implementation of BPaLM regimen for management of DRTB cases.

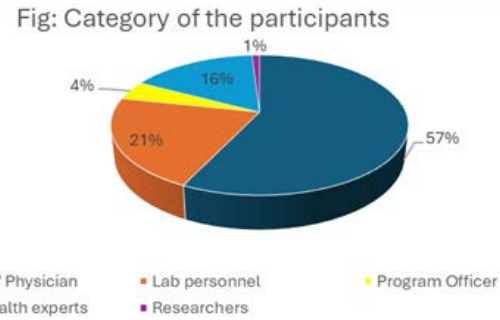
This study evaluates the impact of a nationwide, rapid capacity-building initiative designed to accelerate the state wise scale-up of the BPaLM regimen, as a game-changer - across India's complex health system.

Design/Methods: A national and series of regional workshops were conducted over 1.5-month, targeting a multidisciplinary audience including clinicians, laboratory personnel, supply chain managers, public health technocrats, and administrators. The workshops had well-planned agenda focusing global and country evidence, focusing on guideline dissemination, complex diagnostic challenges,

integrated algorithm, implementation strategies, interactive case-scenario-based discussions. A mixed methods design was used to assess the impact. Quantitative data were collected through pre- and post-training assessments, while qualitative data from semi-structured interviews (conducted three months post-training) explored implementation enablers and barriers. Descriptive statistics and thematic analysis were applied.
Results: A total of 525 master trainer were trained with post-training knowledge increasing by 65%.

These trainers along with program officers enabled cascade trainings in 20 out of 26 states/UTs, leading to BPaLM initiation. Qualitative findings highlighted improved interdisciplinary coordination, enhanced clinical confidence, and effective translation of guidance into practice.
Direct engagement with experts and case-based discussions were cited as key enablers. Identified challenges included variable readiness across states, logistic challenges and the need for ongoing mentoring.
Background and challenges to implementation: India has 26% of the global Multi-Drug/ Rifampicin Resistant Tuberculosis (MDR/RR-TB), posing significant challenges in favourable treatment outcomes. India declared policy to roll out countrywide implementation of BPaLM regimen for management of DRTB cases. This study evaluates the impact of a nationwide, rapid capacity-building initiative designed to accelerate the state wise scale-up of the BPaLM regimen, as a game-changer - across India's complex health system.

The workshops had well-planned agenda focusing global and country evidence, focusing on guideline dissemination, complex diagnostic challenges, integrated algorithm, implementation strategies, interactive case-scenario-based discussions. A mixed methods design was used to assess the impact. Quantitative data were collected through pre- and post-training assessments, while qualitative data from semi-structured interviews (conducted three months post-training) explored implementation enablers and barriers. Descriptive statistics and thematic analysis were applied.
Results/Impact: A total of 525 master trainer were trained with post-training knowledge increasing by 65%.



These trainers along with program officers enabled cascade trainings in 20 out of 26 states/UTs, leading to BPaLM initiation. Qualitative findings highlighted improved interdisciplinary coordination, enhanced clinical confidence, and effective translation of guidance into practice. Direct engagement with experts and case-based discussions were cited as key enablers. Identified challenges included variable readiness across states, logistic challenges and the need for ongoing mentoring.
Conclusions: This nationwide initiative, featuring direct interaction with guideline developers and fostering multidisciplinary collaboration across laboratory, supply chain, and public-private sectors, effectively drove BPaLM implementation in India, highlighting the critical role of targeted training and expert engagement in rapid DR-TB scale-up.

EP56-1244-21 Social protection and TB: Policy production before, during, and after the COVID-19 pandemic in Rio de Janeiro, Brazil

Y.M. Alves,[1,2] R.B.V. Tavares,[1,2] V.M.S. Araújo,[2] D.S. Duarte,[2] V.C. Lima,[2] M. Guazzi,[3] M. Martins,[4] C.M. Morgado,[5] R.A. Arcêncio,[1,2] E.L.N. Maciel,[6,2] [1]University of São Paulo at Ribeirão Preto College of Nursing, Maternal-Infant and Public Health, Ribeirão Preto, Brazil, [2]Brazilian Tuberculosis Research Network (REDE-TB), Projects, Rio de Janeiro, Brazil, [3]Rio de Janeiro State Health Department, Social Assistance, Rio de Janeiro, Brazil, [4]Rio de Janeiro State Health Department, Tuberculosis, Rio de Janeiro, Brazil, [5]Pan American Health Organization, Tuberculosis, Rio de Janeiro, Brazil, [6]Federal University of Espírito Santo, Nursing, Vitória, Brazil
e-mail: reginaldobazon@usp.br

Background: The COVID-19 pandemic disrupted health and social systems globally, prompting emergency responses and policy adaptations. However, its specific impact on the formulation of TB-related social protection policies remains under-investigated. This study examines the annual trend in municipal normative document production concerning social protection and tuberculosis in the state of Rio de Janeiro, Brazil, from 2014 to 2024.

Design/Methods: A documentary analysis was conducted using 75 normative documents with valid publication dates, identified from municipal databases. Documents were classified by year and organized into a time series to visualize trends across three periods: pre-pandemic (2014–2019), pandemic (2020–2022), and post-pandemic (2023–2024). The analysis focused on changes in volume and timing of social protection policies referencing TB or related vulnerabilities.
Results: There was a significant increase in normative document production during the pandemic period, with a peak in 2021. This suggests that emergency contexts can catalyze intersectoral policy action. The years 2014 to 2018 showed consistently low levels of normative activity, indicating limited policy engagement in TB-related social protection during stable periods. In contrast, a notable decline in new policies occurred in 2023 and 2024, signaling a potential risk of discontinuity in social support actions related to TB.

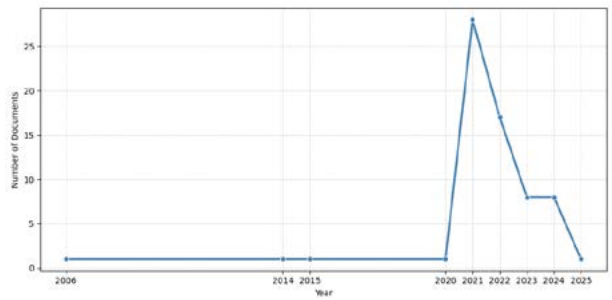


Figure 1 - Total Number of TB-Related Social Policy Documents Published per Year (2014–2024).

Conclusions: The COVID-19 pandemic functioned as a policy accelerator, driving the rapid creation of social protection norms. However, the post-pandemic decline underscores the fragility of emergency-driven initiatives and the lack of institutionalization of long-term policies. Strengthening the integration of social protection into TB control strategies requires the transition from reactive to permanent, structured policy responses. Ensuring continuity beyond crises is critical to address social determinants and reduce TB vulnerability sustainably.

EP57 Rapid diagnostic and resistance testing

EP57-1245-21 Validating proficiency testing panels for Xpert® MTB/XDR assay using CDC's DTS technology for EQA PT program

S. Bhargava,[1] S.K. Shanmugam,[2] S. Suzanna,[1] S.K. Mohanvel,[2] S. Jacob,[2] M.P. Kumar,[2] V. Gumma,[1] T. Shah,[1] S.S. Chadha,[1] [1]FIND, India, New Delhi, India, [2]ICMR-National Institute for Research in Tuberculosis, Bacteriology, Chennai, India
e-mail: drshiprabhargava@gmail.com

Background: Following WHO's 2021 endorsement, the Xpert® MTB/XDR assay has been widely adopted for detecting drug-resistant tuberculosis (DR-TB). The assay is a reflex test to detect resistance to fluoroquinolones (FLQ), isoniazid (INH), ethionamide (ETH) and second-line injectables (SLI).
However, unlike other molecular tests, currently no External Quality Assurance (EQA) Proficiency Testing (PT) program exists for this assay.
Indian Council of Medical Research-National Institute for Research in Tuberculosis (ICMR-NIRT), Chennai, India with support from FIND, validated PT panels using CDC's Dried Tube Specimen (DTS) technology to address this gap.
Design/Methods: Seven well characterized *M.tb* isolates were selected, sub-cultured and chemically inactivated in July' 24. For selection, before inactivation, *M.tb* quantification was done by checking Growth Units (GU) in liquid culture (LC) and by testing on Xpert® MTB/Rif.
Non-viability was confirmed by sub-culturing isolates in LC for 84 days in Oct'2024. Inactivated stocks were stored at 4^0C.
Validation criteria for *M.tb* detection includes:
a. Quantification within medium to low range,
b. Standard deviation within 3 and;
c. Coefficient of variation within 10 for Probe A Ct values on Xpert® MTB/Rif assay as quantification results are not available on MTB/XDR assay.
For drug resistance, detection of resistance to FQs, IHN, SLID and ETO, on Xpert® MTB/XDR assay against known results, was considered as validation criteria.
Since, diluted stock gave "very low" results on MTB/Rif assay, validation of panels was done using direct stock for five aliquots of each strain on both assays in Oct'24.
Results: Test results on five aliquots of seven strains confirmed that the isolates met the validation criteria for detection of *M.tb* and drug resistance profiles (Figure 1).
Conclusions: PT panels for Xpert® MTB/XDR assay can be successfully prepared using CDC's DTS technology, enabling the introduction of EQA programs to ensure testing quality.

Figure 1: Validation of EQA PT panel using Xpert® MTB/Rif and Xpert® MTB/XDR Assay

#	Expected results of the strain	GeneXpert MTB/Rif assay (Quantitative results)				Xpert MTB/XDR assay (Qualitative results)	Validation
		Result	MTB Probe A Ct value				
			Mean	SD	CV		
Isolate 1	MTB Detected Resistance Detected (RIF, INH, AMK, KAN, CAP) Resistance not detected (FLQ, ETH)	MTB Detected (Low) Resistance Detected (RIF)	27.10	0.96	4%	MTB Detected Resistance Detected (INH, AMK, KAN, CAP) Resistance not detected (FLQ, ETH)	Successful
Isolate 2	MTB Detected Resistance Detected (RIF, FLQ) Resistance not detected (INH, AMK, KAN, CAP, ETH)	MTB Detected (Low) Resistance Detected (RIF)	24.27	0.42	2%	MTB Detected Resistance Detected (FLQ) Resistance not detected (INH, AMK, KAN, CAP, ETH)	Successful
Isolate 3	MTB Detected (Medium) Resistance Detected (RIF, INH, FLQ, AMK, KAN, CAP, ETH)	MTB Detected (Low) Resistance Detected (RIF)	25.87	0.30	2%	MTB Detected (Medium) Resistance Detected (INH, FLQ, AMK, KAN, CAP, ETH)	Successful
Isolate 4	MTB Detected (Medium) Resistance Detected (RIF, INH, FLQ) Resistance not detected (AMK, KAN, CAP, ETH)	MTB Detected (Low) Resistance Detected (RIF)	25.30	1.30	5%	Mtb detected Resistance Detected (INH, FLQ) Resistance not detected (AMK, KAN, CAP, ETH)	Successful
Isolate 5	MTB Detected (Medium) Resistance Detected (RIF, INH) Resistance not detected (FLQ, AMK, KAN, CAP, ETH)	MTB Detected (Low) Resistance Detected (RIF)	25.67	0.80	3%	Mtb detected Resistance Detected (INH) Resistance not detected (FLQ, AMK, KAN, CAP, ETH)	Successful
Isolate 6	MTB Detected (High) Resistance not detected (RIF, INH, FLQ, AMK, KAN, CAP, ETH)	MTB Detected (Medium) Resistance not Detected (RIF)	19.63	1.10	6%	Mtb detected Resistance not detected (INH, FLQ, AMK, KAN, CAP, ETH)	Successful
Isolate 7	MTB Detected (Medium) Resistance not detected (RIF, INH, FLQ, AMK, KAN, CAP, ETH)	MTB Detected (Low) Resistance not Detected (RIF)	25.07	0.60	2%	Mtb detected Resistance not detected (INH, FLQ, AMK, KAN, CAP, ETH)	Successful

Results: A total of 3,639 specimens were included in the sample for testing, of which 1,809 used SoC and 1830 SSC. Among SoC rejections, 84% (215) were due to insufficient volume, 1.6% (four) due to defective closure, and 13% (33) were salivary. In contrast, SSC rejections were primarily due to insufficient volume (71%; 65), with minimal issues from leakage (1.1%; one) and salivary content (27.5%; 25). The difference in rejection rates between SoC and SSC was statistically significant ($p < 0.001$) with 14% vs 5%.

Conclusions: The SSC significantly reduced specimen rejection rates, particularly those due to insufficient volume and leakage. Continued training is vital to sustain improved clinical practices in TB specimen collection.

EP57-1246-21 Sinapi Specimen Cups to reduce Xpert MTB/RIF testing rejection rate in Mali

H.B. Drame,[1] B. Degoga,[1] B. Diarra,[1] A.C.G. Togo,[1] I. Sanogo,[1] M. Botha,[2] F. Lynn,[3] C. Achenbach,[3] A. Maiga,[4] Y.d.S. Sarro,[1] M. Konate,[5] S. Doumbia,[1] [1]University of Sciences, Techniques and Technologies of Bamako, University Clinical Research Center (UCRC), Bamako, Mali, [2]SINAPI Biomedical, Sales department, Stellenbosch, South Africa, [3]Northwestern University, The Center for Innovation in Point-of-Care Technologies for HIV/AIDS and Emerging Infectious Diseases, Chicago, United States of America, [4]University Teaching Hospital of Point-G, Medical Laboratory, Bamako, Mali, [5]Ministry of Health and Social Development, Mali TB, HIV/AIDS, and Hepatitis control program, Bamako, Mali
e-mail: bdiarra@icermali.org

Background: In 2011, the World Health Organization (WHO) endorsed the use of GeneXpert (Xpert® MTB/RIF) for tuberculosis (TB) diagnosis and, in 2014, introduced the End Tuberculosis Strategy aiming for a 95% reduction in TB-related deaths by 2035. Mali adopted Xpert MTB/RIF in 2014 and, as of 2022, recommends it as the primary diagnostic tool for TB. However, sample rejections due to issues such as insufficient volume and container leakage have hindered effective testing. The Sinapi Specimen Cup (SSC) was developed to address these challenges by ensuring secure containment and appropriate sputum volume collection, thus improving diagnostic outcomes.

The aim of this study was to compare the current standard of care (SoC) with the SSC for TB diagnosis using Xpert MTB/RIF testing

Design/Methods: This was a cross-sectional study enrolling in 2024 suspected TB patients aged 13 and older at TB diagnosis and treatment centers in Bamako in an IRB approved protocol. Consented participants used either current SoC, or the SSC for TB diagnosis using Xpert MTB/RIF.

EP57-1247-21 Implementing Bangladesh's first EQA program for GeneXpert MTB/XDR: Ensuring quality diagnosis of drug-resistant TB

I.A. Ifa,[1] M.Z. Kabir,[2] T.H. Rusel,[1] S. Tarin,[3] A. Mourin,[4] [1]National Tuberculosis Control Program, National Tuberculosis Reference Laboratory, Dhaka, Bangladesh, [2]National Tuberculosis Control Program, DGHS, Dhaka, Bangladesh, [3]National Tuberculosis Control Program, HQ, Dhaka, Bangladesh, [4]USAID LEAP Project, NTP, Dhaka, Bangladesh
e-mail: iffataraifa@gmail.com

Background: External Quality Assessment (EQA) is a key component of a robust quality assurance system designed to ensure the quality of diagnosis of drug resistance TB. National Tuberculosis Control Program (NTP) of Bangladesh has introduced the Xpert MTB/XDR assay in its Tuberculosis laboratory network in 2023. Bangladesh is the first country in the Asian region to implement EQA for the MTB/XDR Assay.

Design/Methods: In 2024, the NTP of Bangladesh launched an Xpert MTB/XDR External Quality Assessment (EQA) program in collaboration with the National Institute for Research in Tuberculosis (NIRT) in Chennai, India, and the Foundation for Innovative New Diagnostics (FIND). A total of 81 laboratories were enrolled in the program. Each EQA proficiency testing (PT) panel consisted of five labeled dried tube specimens, prepared from well-characterized Mycobacterium tuberculosis (MTB) strains, which were sent to participating laboratories.

The panel was tested according to specific instructions, and results were submitted within the designated timeframe via the EQA portal. Testing accuracy was evaluated by comparing reported results with expected outcomes, and percentage scores were assigned.

Feedback reports were provided to the laboratories, and on-site evaluations (OSE) were conducted for those laboratories that demonstrated underperformance.

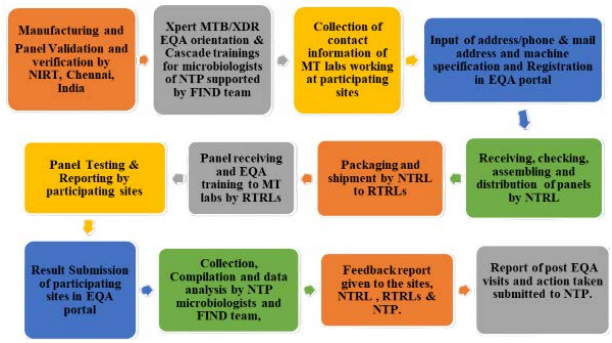

Fig: EQA implementation cascade.

Results: Among the 81 participating sites, 98.2% (80/81) achieved satisfactory results in the proficiency testing, with scores exceeding 80%. However, 1.2% (1/81) of the sites demonstrated performance below 80% in the 2024 round. Overall, the results were highly satisfactory. To enhance the quality of testing, participants with discordant results were advised to review their current procedures, identify the root causes of discrepancies, and implement corrective actions promptly to prevent unreliable test outcomes.
Conclusions: The EQA program for Xpert MTB/XDR has significantly improved the quality of drug-resistant TB diagnosis. To ensure sustained high performance across TB laboratories, it is recommended to scale up this program to all DR-TB testing sites.

EP57-1248-21 Innovo GenMax MTB-RIF/INH: A moderate-complexity automated NAAT for rapid simultaneous detection of *M. tuberculosis* complex and rifampin/isoniazid resistance

H. Zheng,[1] [1]Beijing Children's Hospital, Laboratory of Respiratory Diseases, Beijing, China
e-mail: hanhui820@126.com

Background: To evaluate the performance of the Innovo GenMax MTB-RIF/INH (GenMax), a moderate-complexity automated nucleic acid amplification test (NAAT), for detecting *Mycobacterium tuberculosis* complex (MTBC) and resistance to rifampin (RIF) and isoniazid (INH).
Design/Methods: Analytical sensitivity (limit of detection, LOD) was determined using serial dilutions of MTB strains. Diagnostic accuracy was assessed in clinical sputum specimens against microbiological reference standards (MRS: smear, culture, or Xpert MTB/RIF) and phenotypic drug susceptibility testing (DST). Discordant results were resolved by sequencing (IS6110, rpoB, katG, inhA, ahpC) and follow-up diagnosis results.
Results: GenMax demonstrated a calculated LOD of 8.8 CFU/mL (95% CI: 7.4-11.4) for MTBC, 674.1 CFU/mL (95% CI: 578.8-923.5) for RIF resistance, and 747.3 CFU/mL (95% CI: 613.7-1081.3) for INH resistance. In clinical evaluation, the sensitivity and specificity for MTBC detection were 97.52% (95% CI: 92.38–99.36) and 93.65% (95% CI: 88.91–96.53), respectively. For RIF and INH resistance, sensitivities were 88.46% (95% CI: 68.72–96.97) and 85.19% (95% CI: 65.39–95.14), with specificity of 92.42% (95% CI: 82.50-97.18) and 94.12% (95% CI: 84.86-98.10).
Conclusions: Innovo GenMax MTB-RIF/INH is a rapid and automated assay with high sensitivity for MTBC detection, suitable for decentralized settings. While its performance for RIF/INH resistance detection is competitive with existing assays, sensitivity gaps relative to WHO targets necessitate optimization.

EP57-1249-21 Evaluation of the STANDARD M10 MTB-RIF/INH assay: A rapid solution for drug-resistant TB detection

A. David,[1] V. Molepo,[1] T. Mhaso,[1] L. Singh,[1] R. Jeche,[1] Z. Nsingwane,[1] P. Da Silva,[2] W. Stevens,[1,2] L. Scott,[1]
[1]University of the Witwatersrand, Wits Diagnostic Innovation Hub, Johannesburg, South Africa, [2]National Health Laboratory Services, National Priority Programmes, Johannesburg, South Africa
e-mail: anura.david@witsdih.ac.za

Background: Accurate and rapid diagnosis of tuberculosis (TB) and drug-resistant TB (DR-TB) is essential for effective disease control. The STANDARD M10 MTB-RIF/INH assay (MTB-RIF/INH) (SD Biosensor, Inc, Republic of Korea) is a molecular test designed for the simultaneous detection of *Mycobacterium tuberculosis* complex (MTBC) and resistance to rifampicin (RIF) and isoniazid (INH).
In this study, we aimed to investigate the diagnostic performance of the MTB-RIF/INH assay on sputum in a clinical setting.
Design/Methods: We consented and enrolled 86 eligible participants at the Hillbrow Community Health Centre and Yeoville Clinic in Johannesburg, South Africa. Each participant provided three sputum specimens across two visits. Specimens were transported to the laboratory at 2–8°C. Two sputum underwent routine testing using Xpert MTB/RIF Ultra (Ultra) (Cepheid, Sunnyvale, CA, USA) and Mycobacterial Growth Indicator Tube (MGIT) (Becton, Dickinson and Company, Sparks, MD, USA) culture. The third specimen was tested using the MTB-RIF/INH assay, with results compared to MGIT and phenotypic drug susceptibility testing (pDST) as the gold standard, and to Xpert MTB/XDR (Cepheid) as a comparator for INH resistance.
Results: Valid results from 73 participants were included in the statistical analysis, with assay performance detailed in Table 1. The median age was 40 years (54% male), 48% were HIV-positive and 13% bacteriologically confirmed

using MGIT. RIF and INH resistance profiles were available for six specimens. Although no resistant cases were detected, the MTB-RIF/INH assay demonstrated 100% agreement with Ultra for RIF, Xpert MTB/XDR for INH, and pDST for both RIF and INH.

Assay	Sensitivity (95% CI)	n/N	Specificity (95% CI)	n/N	Unsuccessful test rate
Xpert Ultra	100% (71.5%-100%)	11/11	95.2% (86.5%-99.0%)	59/62	1/86 (1%)
STANDARD M10 MTB-RIH/INH	90.9% (58.7%-99.7%)	10/11	98.4% (91.7%-99.9%)	61/62	0/86 (0%)

Table 1: Assay performance compared with liquid culture.

Conclusions: Preliminary results on the STANDARD M10 MTB-RIF/INH assay demonstrated high diagnostic accuracy. With its ability to detect resistance RIF and INH in a single test, the assay has the potential to enhance treatment decision-making, reduce diagnostic delays, and support global efforts in TB control and resistance surveillance.

EP57-1250-21 Real-time monitoring of performance of GeneXpert machines through a locally developed web-based application

A. Shrestha,[1] S.R. Tiwari,[2] P. Ghimire,[3] L.R. Joshi,[1] M. Hada,[3]
[1]Save the Children, Nepal, Global Fund Programs, Kathmandu, Nepal, [2]National Tuberculosis Control Center, Program Management, Bhaktapur, Nepal, [3]National Tuberculosis Control Center, Clinical section, Bhaktapur, Nepal
e-mail: drshrestha.ashish@gmail.com

Background and challenges to implementation: National TB Program in Nepal has considered GeneXpert MTB/RIF testing as primary tool for diagnosis of Tuberculosis among presumptive TB cases since 2019. The program has installed 133 GeneXpert machines across 117 sites. There were challenges in monitoring functionality of these machines on real-time basis leading to delay in maintenance/calibration and low utilization.
Intervention or response: GXMIS, web-based connectivity application, was developed by national IT experts following Health Level Seven (HL7) protocol: international standards for transfer of clinical and administrative data between software applications used by various healthcare providers. GeneXpert machines were configured through onsite/remote desktop support and networked to the GXMIS system.
Through this application, functionality of each module of a machine is monitored. This feature monitored and analyzed errors, positivity rate, Rifampicin Resistance rate and utilization at the central and provincial level. The GeneXpert sites were able to report any issues related to functionality of the machines and modules by raising tickets in the system. GeneXpert service engineers responded to the issues visiting to the sites or through remote assistance at the earliest possible. A total of USD 8000 was spent to develop the system.
Results/Impact: Out of 117 GeneXpert sites under the NTP, 112 are enrolled in the GXMIS system. In 2024, 125,796 tests, 5833 errors, 683 invalid tests, MTB positivity rate of 13%, RR rate of 3% and the utilization rate 28.4% were reported in the system nationally. 88 issues were reported by arising tickets and service engineers responded to 88 of them by physical and virtual means. The functionality of the GeneXpert machine was higher in 2024 (avg. 95%) compared to that in 2021 (avg 85%).
Conclusions: GXMIS is low-cost web-based application for real-time monitoring of the performance of the GeneXpert machines, to improve utilization of the machines through real-time reporting of functionality issues and immediate response from service engineers.

EP57-1251-21 Operational feasibility of 'TB Concentration & Transport' and 'TB DNA Extraction' kits for bio-safe dry sputum transport for drug resistance detection using Line Probe Assay

K. Chauhan,[1] R.K. Gupta,[1] D. Anthwal,[1] N. Panwalkar,[2] P. Desikan,[2] M. Bhalla,[3] S.K. Shanmugam,[4] S. Giri,[5] N. Kant Gupta,[6] J. Sivaswami Tyagi,[7] S. Haldar,[1] [1]PGIMER, Department of Experimental Medicine and Biotechnology, Chandigarh, India, [2]Bhopal Memorial Hospital and Research Centre, Department of Microbiology, Bhopal, India, [3]NITRD Hospital, Microbiology, New Delhi, India, [4]Indian Council of Medical Research (ICMR)-National Institute for Research in Tuberculosis (NIRT), Department of Bacteriology, Chennai, India, [5]ICMR-Regional Medical Research Centre (RMRC), Department of Microbiology, Bhubaneshwar, India, [6]mdi, mdi, Ambala, India, [7]AIIMS, Department of Biotechnology, New Delhi, India
e-mail: sagarika.haldar@gmail.com

Background: We recently described the utility of 'TB Concentration & Transport' kit for bio-safe, ambient-temperature transport of dried-sputum on *Trans*-Filter, and 'TB DNA Extraction' kit for DNA extraction from *Trans*-Filter for the early diagnosis of drug-resistant Tuberculosis (TB). This study aimed to assess the feasibility and compatibility of these kits with Line Probe Assay (LPA) under National Tuberculosis Elimination Programme (NTEP) settings.
Design/Methods: Presumptive pulmonary TB/MDR-TB/XDR-TB patients (n=8491) who attended Designated Microscopy Centres (DMCs, n=13) under National Reference Laboratories (NRLs) at Bhopal, New Delhi, Chennai and Bhubaneswar were screened by smear microscopy. The performance of *Trans*-Filter-extracted-DNA-based-LPA (Kit-LPA) was assessed against Direct-LPA on smear-positive sputum (n=681) and feedback was obtained from Scientists (n=10) and Laboratory techni-

cians (n=42) regarding logistics, kit-usage, training, and troubleshooting. A scoring questionnaire was used to assess (i) 'Transport kit' *vs*. conventional sputum transport and (ii) 'TB DNA Extraction' kit *vs*. Hain's GenoLyse kit (statistical significance of the scores was calculated using paired t-test).
Results: Kit-LPA showed a sensitivity and specificity in the range of 89-96% and 99-100%, respectively, for RIF and INH resistance detection and was comparable to Direct-LPA [concordance=99-100% (κ value=0.94-0.97)]. Overall scores indicated that (i) sputum transport on *Trans*-Filters was more convenient as compared to conventional sputum transport (p<0.0001) and (ii) *Trans*-Filter extracted DNA was easily amalgamated with LPA testing for MDR-TB detection.
Conclusions: These findings provide evidence for incorporation of these kits into the NTEP. Their use can facilitate sputum-transport from DMCs to NRLs and provide "Universal-DST" to TB subjects residing in remote areas.

EP57-1252-21 Drug-resistance characterisation of *M. tuberculosis* using ONT in Mongolia

O. Tumenbayar,[1,2] B. Erkhembayar,[2] T. Borolzoi,[1,2] A. Takaki,[3] T. Boldoo,[4] M. Yoshiro,[3] B. Tsolmon,[5] N. Dambaa,[2] B. Burneebaatar,[2] S. Jav,[1] S. Mitarai,[3]
[1]Mongolian National University of Medical Sciences, School of Pharmacy and Biomedicine, Ulaanbaatar, Mongolia, [2]National Center for Communicable Diseases, TB Research and Surveillance Department, Ulaanbaatar, Mongolia, [3]Research Institute of Tuberculosis, Japan Anti-Tuberculosis Association, Department of Mycobacterium Reference and Research, Tokyo, Japan, [4]World Health Organization, Communicable diseases, Ulaanbaatar, Mongolia, [5]Mongolian National University of Medical Sciences, Research and International Affairs, Ulaanbaatar, Mongolia
e-mail: baasansuren0624@gmail.com

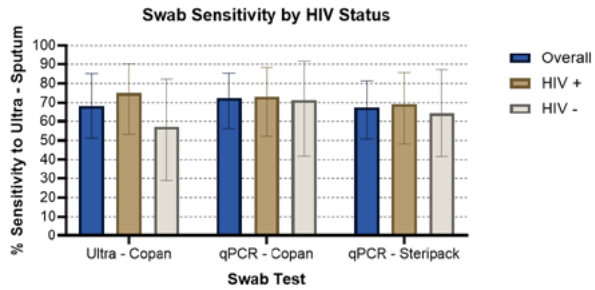
Background and challenges to implementation: Mongolia is among the 30 countries with a high TB burden and is also categorized as one of the countries with the highest MDR-TB burden. RR and MDR-TB rates were 7.2% in new cases and 8.2% in previously treated cases. To address the growing threat of drug-resistant TB, there is a critical need for advanced diagnostic tools. Oxford Nanopore Technologies (ONT) offers significant potential for early detection, comprehensive drug resistance profiling, and optimized treatment strategies.
This study implemented ONT sequencing at the National TB Reference Laboratory in Mongolia to evaluate its accuracy and feasibility by comparing genomic drug susceptibility testing (gDST) with phenotypic DST (pDST).
Intervention or response: We selected *M. tuberculosis* isolates from our culture bank and performed subcultures for next-generation sequencing (NGS) using the GridION platform. As of 2024, 553 isolates were sequenced, with 115 compared to drug susceptibility testing (pDST). Sequencing data were processed and quality-checked using the EPI2ME platform.
Results/Impact: Comparison of pDST and gDST showed high concordance rates for first-line drugs: 99% for isoniazid and rifampicin, and 95% and 96% for ethambutol and streptomycin, respectively. Among the 21 samples analyzed for second-line drugs, a comparison between pDST and NGS revealed 100% concordance for kanamycin (KM), amikacin (AM), and ofloxacin (OFX) and 95% for capreomycin (CPM). A comparison of new TB drugs in 27 samples showed high concordance rates: 100% for linezolid (LZD), delamanid (DLM), and clofazimine (CFZ), with bedaquiline (BDQ) slightly lower at 96%. These results demonstrate strong agreement between pDST and NGS-based gDST.
Conclusions: ONT-based sequencing proved highly reliable and accurate for detecting *M. tuberculosis* drug resistance. This approach offers a promising alternative to traditional methods, enabling faster, comprehensive DST results to guide effective treatment decisions. The next step will be to evaluate targeted NGS and maintain a stable and affordable supply of reagents and licenses.

EP57-1253-21 Equivalency for HIV: Tongue swabs offer robust alternative to sputum testing for PLHIV

C. Connors,[1] R. Dalmat,[2] E. Budiawan,[2] M. Ngwane,[3] K. Heard,[1] Z. Magcaba,[3] N. Ngcobo,[3] E. Rechkina,[2] S. Bosman,[4] D. Wilson,[3] P. Drain,[2] L. Turnbull,[1] [1]Quantigen, Global Public Health Research, Fishers, United States of America, [2]University of Washington, Department of Global Health, Seattle, United States of America, [3]Umkhuseli Innovation and Research Managment, Edendale Hospital, Pietermaritzburg, South Africa, [4]Human Sciences Research Council, HSRC, Pietermaritzburg, South Africa
e-mail: kelsey.heard@quantigen.com

Background: *Mycobacterium tuberculosis* (MTB) diagnosis requires adequate sputum production which can be difficult, especially for people living with HIV (PLHIV). To diagnose MTB in PLHIV, an easy-to-collect sample type like tongue swabs is an appealing alternative. Historically, tongue swab tests have shown lower sensitivity among PLHIV because of a lower bacillary load; however, these populations still need sensitive, accessible diagnostics. MTB tongue swab tests with equivalent sensitivity to sputum among PLHIV would expand diagnostic options for PLHIV.
Design/Methods: Tongue swabs were collected using a 30-second dry collection protocol on two Copan FLOQSwabs and one Steripack XpressCollect from 288 people living in South Africa with presumed TB. Then, sputum samples were collected from the same individuals and

tested by Xpert Ultra (Ultra) to use as a reference (HIV-: 40% high, 7% medium, 27% low, 20% very low, 7% trace; HIV+: 23% high, 31% medium, 31% low, 4% very low, 12% trace). Copan swabs were tested on both Ultra and qPCR, and Steripack swabs were tested only on qPCR.
Results: Using sputum tested on Ultra as the reference, sensitivity of Copan swabs tested on Ultra was 75.0% (18/24) in PLHIV and 57.1% (8/14) in those without HIV. Sensitivity of Copan swabs tested on qPCR was 73.1% (19/26) in PLHIV and 71.4% (10/14) in those without HIV, respectively. Sensitivity of Steripack swabs tested on qPCR was 69.2% (18/26) in PLHIV and 64.3% (9/14) in those without HIV, respectively.



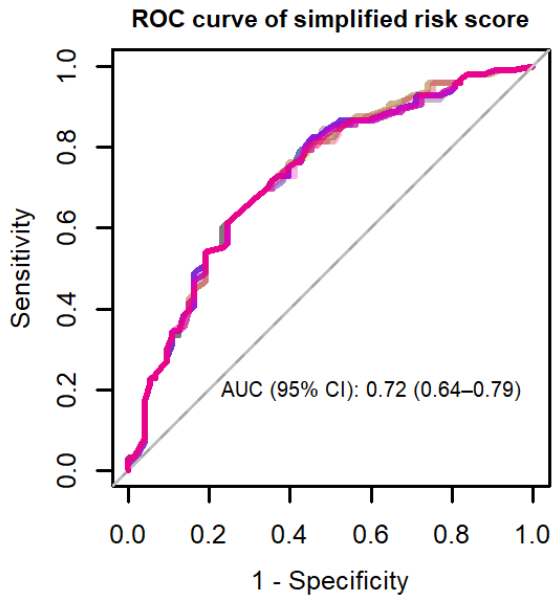
Conclusions: Copan swabs tested on qPCR had similar detection regardless of HIV status, with comparable sensitivity to sputum on Ultra in PLHIV across all swab tests. Tongue swab collection and qPCR protocols with equivalent sensitivity regardless of HIV status present a new diagnostic opportunity for PLHIV and may continue to improve with further optimization.

EP58 Outcomes of drug-resistant TB

EP58-1255-21 Predicting delayed culture conversion in people receiving treatment for rifampicin-resistant TB

T.C.T. Ha,[1] E. Costa Conceicao,[2] E. Ayodeji Ogunbayo,[3] F. Wells,[2] E. Getie Mekonnen,[1,4] F. Ndebele,[5] L. Setlhare,[6] B. Fanampe,[6] S. Charalambous,[5] G. Churchyard,[5] R. Warren,[2] A. Van Rie,[1] [1]Global Health Institute, University of Antwerp, Family Medicine and Population Health, Antwerp, Belgium, [2]SAMRC Centre for Tuberculosis Research; Division of Molecular Biology and Human Genetics, Faculty of Medicine and Health Sciences, Stellenbosch University, Biomedical Sciences, Cape Town, South Africa, [3]University of the Free State, Faculty of Health Sciences, Bloemfontein, South Africa, [4]University of Adelaide, Medical and health science, Adelaide, Australia, [5]Aurum Institute, Clinical Research, Johannesburg, South Africa, [6]Free State Department of Health, Free State Department of Health, Bloemfontein, South Africa
e-mail: annelies.vanrie@uantwerpen.be

Background: Rifampicin-resistant tuberculosis (RR-TB) remains a global burden, with only 65% of treated patients achieving successful treatment outcomes. Delayed culture conversion is a strong predictor of poor treatment response. We aimed to develop a simplified risk score to predict delayed culture conversion based on baseline patient characteristics.
Design/Methods: The source cohort was the SMARTT trial, which enrolled adults with uncomplicated RR-TB in South Africa. Delayed culture conversion was defined as failure to achieve at least two consecutive negative cultures within one month of treatment initiation. Candidate predictors were selected based on clinical relevance, ease of interpretation, and routine availability. Missing data were handled using multiple imputation. Logistic regression analyses were performed to build the prediction model. A simplified risk score was constructed based on the model's β coefficients. The performance of the prediction model and simplified risk score was assessed via discrimination (area under the receiver operating characteristic curve, AUC-ROC) and calibration (calibration plots and Hosmer-Lemeshow test). The model was internally validated using bootstrapping, and the optimal cut-off point was determined using the Youden Index.
Results: A total of 56.8% (96 out of 169) of patients experienced delayed culture conversion. The final prediction model included mycobacterial load, malnutrition, anemia, impact on usual activity, prior TB treatment, and age. The model's AUC was 0.732 (95% CI: 0.648–0.802), with the optimism-corrected AUC of 0.693 (95% CI: 0.666–0.815). The simplified risk score, ranging from 0 to 7, had an AUC of 0.718 (95% CI: 0.637–0.788). Risk probability of 0.554 was the optimal cut-off point. Calibration assessments indicated no significant deviation between predicted and observed probabilities.



Conclusions: The simplified risk score, with satisfactory predictive performance, can serve as a tool for clinicians to estimate the risk of delayed culture conversion in RR-TB patients, facilitating early risk stratification and individualized management.

EP58-1256-21 Treatment outcomes of rifampicin-resistant TB under programmatic conditions in Vietnam in 2021 - 2022

T.M.P. Nguyen,[1,2,3] T. Decroo,[2] B.H. Nguyen,[4] T.T.T. Hoang,[1] V.L. Dinh,[1] [1]National Lung Hospital, Network Steering Department, Hanoi, Viet Nam, [2]Institute of Tropical Medicine, Department of Clinical Sciences - Unit of HIV and Tuberculosis, Antwerp, Belgium, [3]Ghent University, Faculty of Medicine and Health Sciences, Ghent, Belgium, [4]National Lung Hospital, Research Center, Hanoi, Viet Nam
e-mail: phuongnguyen1186@gmail.com

Background: Vietnam is a high tuberculosis (TB) and rifampicin-resistant TB (RR-TB) burden country. New RR-TB regimens keep being recommended in recent years and more evidence about nationwide implementation of different RR-TB regimens is essential to inform treatment guidelines in Vietnam.
Design/Methods: A retrospective cohort study of all RR-TB patients treated nationwide in Vietnam from 2021 to 2022. Short treatment regimens (STR) were 9-11-month standardized 7-drug regimens with either bedaquiline (BDQ/STR) or an injectable drug (inj/STR), and a modified 9-11-month 5-drug regimen (mod/STR). Long regimens were 18-20-month individualized regimens for fluoroquinolone-susceptible RR-TB (RR-TB/long) or fluoroquinolone-resistant RR-TB (pre-XDR-TB/long). With logistic regression we estimated predictors of unfavorable outcome.
Results: Of 4814 RR-TB patients, 71.2% had treatment success. Treatment failure, death, lost-to-follow-up (LTFU) and not evaluated accounted for 3.6%, 7.8%, 13.3% and 4.2%, respectively. Long regimens had higher mortality (>10%) and LTFU (>15%). Among STR, inj/STR had the lowest success rate (73.3%) in comparison to BDQ/STR (76.7%) and mod/STR (78.9%), the difference was significant after adjusting for confounding factors. LTFU rate is still high (>11%) in both BDQ/STR and inj/STR. Treatment with injectable based short regimen, long regimens, re-treatment after LTFU and being male are predictors of unfavorable RR-TB treatment outcomes.

	Total N	Treatment outcome		Odds ratio (OR)	[95%CI]	adusted OR	[95%CI]
		Favorable# N (%)	Unfavorable$ N (%)				
Regimen							
BDQ/STR	1603	1221 (76.2)	382 (23.8)	1.00		1.00	
inj/STR	1441	1035 (71.8)	406 (28.2)	1.60***	[1.37,1.86]	1.58***	[1.35,1.84]
mod/STR	144	114 (79.2)	30 (20.8)	0.84	[0.56,1.27]	0.78	[0.51,1.18]
RR-TB/long	1370	882 (64.4)	488 (35.6)	2.08***	[1.78,2.42]	1.86***	[1.59,2.18]
pre-XDR-TB/long	256	174 (68.0)	82 (32.0)	1.66***	[1.26,2.18]	1.49**	[1.13,1.98]
Total	4814	3426 (71.2)	1388 (28.8)				

*Legend: * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$*
 # Favorable: cured, completed
$ Unfavorable: failure, death, lost-to-follow-up, not evaluated

Conclusions: During the transition from long to short regimens, nationwide data showed 71.2% RR-TB treatment success in Vietnam. The wider use of short regimens and addressing LTFU can improve outcomes. More robust and better managed long regimens are needed for those not eligible for any STR.

EP58-1257-21 Comparative analysis of bedaquiline-based treatment outcomes in peope who are HIV-positive and HIV-negative with rifampicin-resistant TB in Gauteng Province, South Africa

N. Ndlovu,[1] C. Rhea,[2] Z. Sibeko,[1] N. Nkosi,[1] Z. Mabuse,[1] N. von Knorring,[3,4] P. Xavier,[5] V. Chihota,[1,6,7] Y. van der Heijden,[1,2,7] [1]The Aurum Institute, Implementation Research, Johannesburg, South Africa, [2]Vanderbilt University School of Medicine, Vanderbilt Tuberculosis Center, Nashville, United States of America, [3]National Health Laboratory Service, Mycobacteriology Referral, Johannesburg, South Africa, [4]University of the Witwatersrand, School of Pathology, Clinical Microbiology and Infectious Diseases, Johannesburg, South Africa, [5]Sizwe Tropical Diseases Hospital, Department of Health, Johannesburg, South Africa, [6]University of Witwatersrand, School of Public Health, Johannesburg, South Africa, [7]Vanderbilt University School of Medicine, Division of Infectious Diseases, Department of Medicine, Nashville, United States of America
e-mail: charles.h.rhea@vanderbilt.edu

Background: The co-epidemic of Human Immunodeficiency Virus (HIV) and tuberculosis (TB) remains a critical public health challenge with a 58% co-infection rate in South Africa, further exacerbated by drug-resistant TB (DR-TB), which has a global treatment success rate of 60%. Bedaquiline has shown promise in improving DR-TB outcomes, however its efficacy in persons living with HIV (PLWH) remains understudied.
This study aims to compare bedaquiline-based treatment outcomes by HIV status.
Design/Methods: We conducted a retrospective cohort analysis of rifampicin-resistant TB patients initiating bedaquiline-based regimens at 4 districts in Gauteng province, South Africa between February 2023- March 2025. Data were extracted from clinical records and laboratory reports. Analyses included descriptive statistics, logistic regression, and Kaplan-Meier curves.
Results: Preliminary analysis included 433 participants (333 HIV+, 100 HIV−), with 97% of HIV+ patients on antiretroviral therapy (ART). PLWH were older than those who were HIV- (median age 38 vs. 35; p=0.01). Persons living with and without HIV did not differ in gender (male: 62.2% HIV+ vs. 68.0% HIV−; p=0.29), underweight body mass index (BMI) (39.6% HIV+ vs. 37.0% HIV−; p=0.89) or treatment regimen (BPaL: 79% HIV+ vs. 82% HIV−; p=0.72).
The median time to culture conversion did not differ, (57 days HIV+ vs. 58 days HIV−; p=0.72) and culture conversion rates at 2 months (51.9% vs. 52.7%; p=0.90), and 6-months (93.4% vs. 96.0%; p=0.42) were similar. PLWH had higher unfavourable outcomes (death, loss to follow-up, treatment failure), (37.2% vs. 26.0%; p=0.04), with 1.65-fold increased odds of unfavourable outcomes after adjusting for age and gender (95% Confidence Interval:1.01–2.72; p=0.046).
Conclusions: Despite comparable TB treatment efficacy (culture conversion rates), and high ART coverage, systemic factors disproportionately affect PLWH, resulting in higher unfavourable DR-TB outcomes. This underscores the urgent need for integrated care models and tailored bedaquiline-based strategies to address inequities in this population.

EP58-1258-21 Outcomes of short-course regimens in the treatment of drug-resistant TB in people with TB & HIV, TB & hepatitis, TB & HIV & hepatitis, and TB in Kazakhstan

M. Rashitov,[1] Y. Algozhin,[2] A. Ciobanu,[3] [1]NGO, Partners In Health Kazakhstan, Almaty, Kazakhstan, [2]NGO Partners In Health, Partners In Health Kazakhstan, Almaty, Kazakhstan, [3]European Region WHO, Tuberculosis, HIV and Viral Hepatitis, Kishinev, Republic of Moldova

Background: The implementation of short-course regimens (mSTR) for drug-resistant tuberculosis (DR-TB) in patients with coexisting conditions such as HIV and viral hepatitis B, C presents unique challenges.
This study evaluates treatment outcomes and adverse events among different patient cohorts receiving mSTR in Kazakhstan.
Design/Methods: A total of 1945 patients (1320 males, 67.9%;) underwent treatment with one of the following regimens:
- Bdq Lzd Cfz Lfx Cs – 1873 patients (96.3%)
- Bdq Lzd Cfz Lfx Dlm – 72 patients (3.7%)

All patients with HIV received antiretroviral therapy (ART), whereas patients with viral hepatitis B, C did not receive antiviral therapy, potentially impacting observed outcomes.
Results:
- **TB+HIV (n=49, 2.5% of total cohort):**
  Treatment success: 82.6%
  Death: 2.2%
  Failure: 15.2%
  Adverse events: 63.3%
- **TB+Hepatitis (n=88, 4.5% of total cohort):**
  Treatment success: 81.2%
  Death: 3.5%
  Failure: 9.4%
  Adverse events: 47.7%
- **TB+HIV+Hepatitis (n=44, 2.3% of total cohort):**
  Treatment success: 64.1%
  Death: 7.7%
  Failure: 12.8%
  Adverse events: 88.6%
- **TB without coinfections (n=1,764, 90.7% of total cohort):**
  Treatment success: 85.5%
  Death: 3.3%
  Failure: 9.4%
  Adverse events: 34.8%

Conclusions:
- TB-only patients had the highest success rate (85.5%), followed by TB+HIV (82.6%), TB+Hepatitis (81.2%), and TB+HIV+Hepatitis (64.1%).
- The highest mortality was in TB+HIV+Hepatitis (7.7%).
- Adverse events were most frequent in TB+HIV+Hepatitis (88.6%).

Short-course regimens are effective for RR/MDR-TB, especially in patients without co-infections. Co-infected patients had lower success rates and higher adverse events, highlighting the need for tailored approaches and antiviral therapy in TB+Hepatitis cases.

EP58-1259-21 PZA resistance and treatment outcome among people with drug-resistant TB at Respiratory Referral Hospital in Indonesia in 2020-2024

S. Hulwani,[1] A.F. Rhamadianti,[1] M.P. Wardoyo,[1] F. Azzumar,[2] E. Burhan,[2,3,4] [1]Respiratory Programmatic Implementation and Research Institute, Medical and Scientific Writing Department, Jakarta, Indonesia, [2]Respiratory Programmatic Implementation and Research Institute, Research, Jakarta, Indonesia, [3]Faculty of Medicine Universitas Indonesia, Department of Pulmonology and Respiratory Medicine, Jakarta, Indonesia, [4]Persahabatan Central General Hospital, Pulmonology and Respiratory Medicine, Jakarta, Indonesia
e-mail: salsabila.hulwani@yayasanrpri.org

Background: Indonesia is in the third rank of DR-TB (Drug-resistant Tuberculosis) burden globally in 2023, accounting for 7,4% of DR-TB worldwide. Recommended treatment for both DR-TB and DS-TB (Drug-sensitive Tuberculosis) includes PZA (pyrazinamide) in the treatment regimen, but treatment for DR-TB patients was longer compared to DS-TB. This leads to a lower success rate of DR-TB treatment in Indonesia. This study aims to determine the prevalence of PZA resistance and assess the factors associated with treatment outcomes among DR-TB patients at Persahabatan National Respiratory Referral Hospital Jakarta in 2020-2024.
Design/Methods: This is a single-center cross-sectional study utilizing data from the TB Information System (Sistem Informasi Tuberkulosis, SITB). The proportion of PZA resistance among DR-TB cases was calculated, and factors associated with treatment outcomes were analyzed for each eligible individual. Bivariate analysis was conducted using the chi-square test, with variables showing $P \leq 0.25$ included in the multivariate analysis. Cox regression was performed to identify factors associated with treatment outcomes, with loss to follow-up (LtFU) as the event of interest.
Results: PZA resistance status was determined in 25.19% of patients. The prevalence of PZA resistance among TB patients was highest in 2024, reaching 40.00%. Overall, 28.82% of DR-TB patients were found to be resistant to PZA. After adjusting with confounding variables, sex (aHR 3.56, 95% CI 1.62-7.79) was independently associated with an increased risk of LtFU, whereas MDR-TB diagnosis (aHR 0.36, 95% CI 0.15-0.85) was associated with a lower risk of LtFU.
Conclusions: The high prevalence of PZA resistance underscores the need for strengthened treatment strategies to ensure treatment adherence among DR-TB patients, particularly those with PZA resistance. The association between sex and MDR-TB suggests that gender plays a role in treatment adherence.
Enhanced patient support systems and stricter follow-up protocols for MDR-TB patients may contribute to higher treatment completion rates compared to other TB diagnoses.

EP58-1260-21 Treatment success rate of people with drug-resistant TB on BPaL regimen in the Democratic Republic of Congo

M. Fina,[1] L. Lukaso,[2] S. Mbuyi,[2] J.P. Malemba,[3] M. Aloni,[4] L. Mbulula,[3] I. Kashongwe,[5] R. Sentime,[6] F. Mukinda,[2] D. Muteteke,[3] [1]DRC National Tuberculosis Control Programme, MDR TB Management Unit, Kinshasa, Democratic Republic of the Congo, [2]DRC National Tuberculosis Control Programme, Monitoring and Evaluation, Kinshasa, Democratic Republic of the Congo, [3]DRC National Tuberculosis Control Programme, NTP Management, Kinshasa, Democratic Republic of the Congo, [4]DRC National Tuberculosis Control Programme, Laboratory, Kinshasa, Democratic Republic of the Congo, [5]University Clinics / University of Kinshasa, Internal Medecine, Kinshasa, Democratic Republic of the Congo, [6]DRC National Tuberculosis Control Programme, Pharmacy, Kinshasa, Costa Rica

Background: In May 2022, The World Health Organization (WHO) has recommended a combination of Bedaquillin, Pretomanid and Linezolid (BPaL) regimen for the treatment of patients with multidrug-resistant tuberculosis (MDR-TB). The Democratic Republic of Congo (DRC), one of the 3 countries in the WHO African Region with the highest burden of MDR-TB, has implemented the BPaL regimen for the treatment of rifampicin-resistant (RR) tuberculosis patients.
Design/Methods: We conducted a document review and dissemination of the treatment guidelines, followed by a training of health professionals involved with MDR-TB and implementation of the BPaL regimen in one site Centre of Excellence Action Damien for the management of MDR-TB patients in Kinshasa province. Were included, all rifampicin resistant TB patients with documented resistant to fluoroquinolone enrolled in the BPaL regimen from May 2022 to December 2024.

Results: A total of 47 patients were enrolled and started the BPaL regimen. At the end of 6-month treatment follow-up, 23 (49%) completed the treatment; 21 (45%) were confirmed cured making a treatment success rate of 94%; 2 (4%) patients were lost-to-follow-up, and 1 (2%) death was reported.
Observed side effects included peripheral neuropathy [8(18%)], skin rash [8(18%)], severe anaemia [3(6%)] and hyper-creatininemia [1(2%)].
Background and challenges to implementation: In May 2022, The World Health Organization (WHO) has recommended a combination of Bedaquillin, Pretomanid and Linezolid (BPaL) regimen for the treatment of patients with multidrug-resistant tuberculosis (MDR-TB).
The Democratic Republic of Congo (DRC), one of the 3 countries in the WHO African Region with the highest burden of MDR-TB, has implemented the BPaL regimen for the treatment of rifampicin-resistant (RR) tuberculosis patients.
Conclusions: The BPaL regimen offers many advantages in terms of treatment duration and compliance. It was well tolerated by patients in the study setting. To be scaled up, considerations should be the training of health professionals in identifying and managing side effects, on early management of patients presenting side effects and availability of drugs for the treatment of side effects.

EP58-1261-21 Treatment outcomes of bedaquiline-resistant TB: A retrospective and matched cohort study

L. Mdlenyani,[1] Z. Mohamed,[2,3] J.A. Stadler,[2,3] N. Mtwa,[1] G. Meintjes,[2,3,4] R. Warren,[5] M.J. Saunders,[6] J. Kuhlin,[2,7,8] S. Wasserman,[2,6] [1]Eastern Cape Province, Department of Health, Mdantsane, South Africa, [2]University of Cape Town, Wellcome Discovery Research Platforms in Infectious Diseases, Centre for Infectious Diseases Research in Africa, Institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa, [3]University of Cape Town, Department of Medicine, Cape Town, South Africa, [4]Queen Mary University of London, Blizard Institute, London, United Kingdom of Great Britain and Northern Ireland, [5]Stellenbosch University, Division of Molecular Biology and Human Genetics, SAMRC Centre for Tuberculosis Research, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [6]City St George's, University of London, Institute for Infection and Immunity, London, United Kingdom of Great Britain and Northern Ireland, [7]Karolinska Institutet, Department of Medicin, Solna, Stockholm, Sweden, [8]Karolinska University Hospital, Department of Infectious Diseases, Stockholm, Sweden
e-mail: johanna.kuhlin@ki.se

Background: Rising prevalence of bedaquiline resistance undermines benefits from this life-saving drug for rifampicin-resistant tuberculosis (RR-TB). Despite increasing awareness, patient-level outcomes for bedaquiline-resistant TB have not been well-characterised and case management poorly defined.
Design/Methods: We conducted a retrospective cohort study of bedaquiline-resistant TB with matched RR-TB controls at a TB referral hospital in South Africa. Cases included patients ≥13 years with a phenotypic bedaquiline-resistant *Mycobacterium tuberculosis* isolate identified between January 2018 and June 2023. Controls with confirmed bedaquiline-susceptible TB, matched 1:1 by culture, age and HIV status, were selected from a prospective observational study conducted during an overlapping period at the same facility. Primary outcomes included time to sputum culture conversion (SCC), a modified WHO-defined unfavourable outcome, and TB-free survival (alive, with SCC, and in care or treatment completed) through 18 months. Adjusted analyses used Cox proportional hazards models.
Results: Eighty-two patients with bedaquiline-resistant TB were included, 57/82 (70%) of whom were HIV-positive. Bedaquiline was prescribed for 72/82 (88%) and meropenem for 32/82 (39%), Figure 1. Together with bedaquiline, the most frequently prescribed drugs included clofazimine, linezolid and terizidone. Median time to SCC was 175 (IQR 100–254) days in the bedaquiline resistant cohort and 32 (IQR 30–42) days in matched controls. In analysis of the combined cohorts, bedaquiline resistance (aHR 0.03, 95% CI 0.01–0.29, p=0.003) was associated with reduced SCC when adjusted for baseline microscopy grade and baseline fluoroquinolone resistance. WHO treatment outcomes in those with bedaquiline-resistant TB were unfavourable in 54/81 (67%) patients, driven by treatment failure in 35/81 (43%). At 18 months, 43/82 (52%) cases had achieved TB-free survival; 19/82 (23%) had died, and 50/63 (80%) survivors were still on treatment.

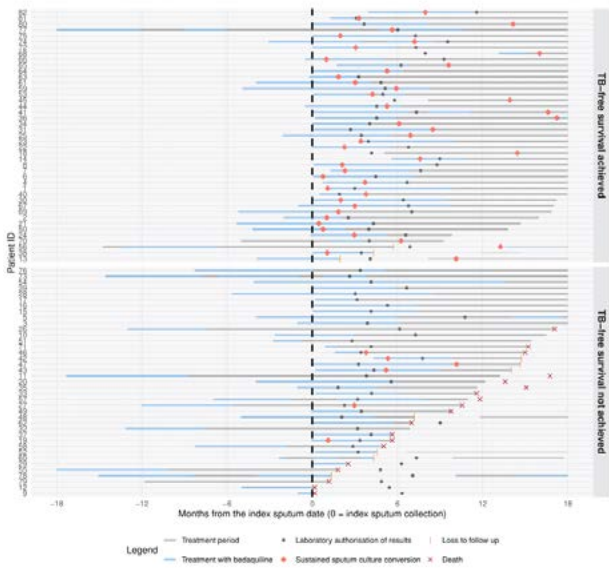


Figure 1: Treatment timeline for patients with bedaquiline-resistant tuberculosis.

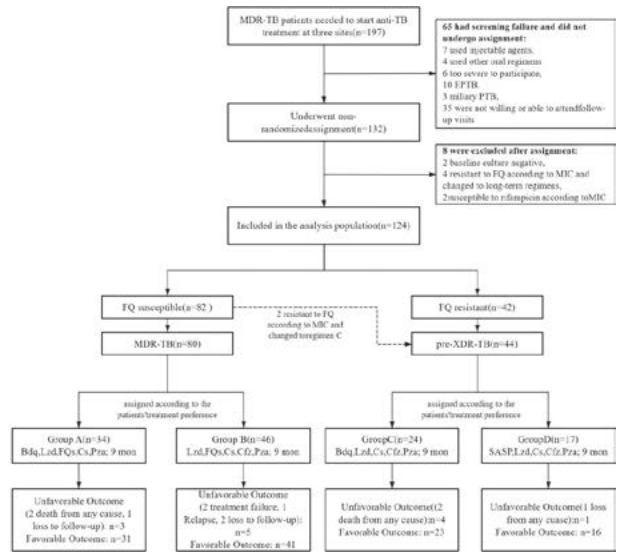
Conclusions: Current treatment options for bedaquiline-resistant TB result in prolonged therapy, delayed microbiological responses, and poor clinical outcomes.

EP58-1262-21 Long-term efficacy and safety of 9-month all-oral regimens for multi-drug-resistant and pre-extensively drug-resistant TB: A multicentre, prospective cohort study in China

S. Zhan,[1,2] H. Shi,[3] L. Fu,[1] P. Zhang,[4] G. Deng,[4] J. Zhang,[2]
[1]Southern University of Science and Technology/Shenzhen Third People's Hospital, Pulmonary Disease Department, Shenzhen, China, [2]Tianjin Medical University General Hospital, Department of Respiratory and Critical Care Medicine, Tianjin, China, [3]Shenzhen University/Shenzhen University Medical School, School of Public Health, Shenzhen, China, [4]Southern University of Science and Technology/Shenzhen Third People's Hospital, Pulmonary Diseases Department, Shenzhen, China
e-mail: 470783463@qq.com

Background: Our previous study demonstrated favorable outcomes with tailored 9-month all-oral five-drug regimens for multidrug-resistant tuberculosis (MDR-TB) and pre-extensively drug-resistant tuberculosis (pre-XDR-TB) at 12 months post-treatment.
We aimed to evaluate long-term efficacy and safety through a 36-month follow-up period after treatment completion.
Design/Methods: This prospective multicenter cohort study involved MDR-TB patients receiving regimen A (bedaquiline, linezolid, moxifloxacin, cycloserine, pyrazinamide) or B (linezolid, moxifloxacin, cycloserine, clofazimine, pyrazinamide), and pre-XDR-TB patients receiving regimen C (bedaquiline, linezolid, cycloserine, clofazimine, pyrazinamide) or D (sulfasalazine, linezolid, cycloserine, clofazimine, pyrazinamide), based on drug susceptibility and affordability. The primary endpoint was unfavorable outcomes (treatment failure, relapse, death, or loss to follow-up) within 36 months post-treatment. Secondary endpoints included adverse events and overall survival.
Results: Between April 2019 and December 2024, 124 patients (median age 39.7 years [IQR 27.1–42.3]) were enrolled and analyzed. The overall favorable outcome rate was 89.5% (111/124). Favorable outcomes did not significantly differ between regimen groups for MDR-TB (A: 91.1%, 41/45 vs. B: 89.1%, 41/46; p=0.76) or pre-XDR-TB (C: 85.1%, 23/27 vs. D: 94.1%, 16/17; p=0.37). Thirteen (10.5%) patients experienced unfavorable outcomes, primarily due to death (n=6) and loss to follow-up (n=4).
Persistent peripheral neuropathy occurred in 19.4% (24/124) of participants. No significant difference in survival was observed between MDR-TB groups (A vs. B; p=0.69) or pre-XDR-TB groups (C vs. D; p=0.41).



Conclusions: Tailored 9-month all-oral five-drug regimens demonstrated sustained long-term efficacy and acceptable safety profiles for MDR-TB and pre-XDR-TB patients during 36 months of follow-up, supporting their broader implementation in clinical practice.

EP58-1263-21 The hidden challenge: Impact of *M. tuberculosis* strains With *rpoB* I491F mutation on outcomes of the BPaLM regimen

D. Vambe,[1,2] M. Ziyane,[1] B. Mamba,[3] M. Thunzini,[4] T. Nkomo,[5] S. Masina,[6] L. de Araujo,[7,8] N. Ruswa,[9] G. Maphalala,[10] A. Kay,[1,2] A. Mandalakas,[2] S. Niemann,[11]
[1]Baylor College of Medicine Children's Foundation, Global TB Program, Mbabane, Eswatini, [2]Baylor College of Medicine, Pediatrics, Global Immigrant Health, Houston, United States of America, [3]National TB Control Program, Monitoring and Evaluation, Manzini, Eswatini, [4]Eswatini Health Laboratory Services, Tuberculosis and Research, Mbabane, Eswatini, [5]National TB Control Program, Tuberculosis and Research, Manzini, Eswatini, [6]National TB Control Program, PMDT, Manzini, Eswatini, [7]University of Lübeck, Respiratory Medicine & International Health, Lubeck, Germany, [8]Research Center Borstel, Leibniz Lung Center, Clinical Infectious Diseases, Borstelgger, Germany, [9]National TB and Leprosy Program, Management, Windhoek, Namibia, [10]Eswatini Health Laboratory Services, National Public Health Laboratory, Mbabane, Eswatini, [11]Leibniz Lung Center, Research Center Borstel, Borstel, Germany
e-mail: dvambe@gmail.com

Background and challenges to implementation: Eswatini adopted BPaLM (bedaquiline, pretomanid, linezolid and moxifloxacin) and BPaL as primary regimens for patients with rifampicin resistant tuberculosis (RR-TB) and implemented targeted next generation sequencing for rapid drug resistance diagnosis and detection of multi-

drug resistant (MDR) *Mycobacterium tuberculosis* strains with *rpoB* I491F mutation which are not detected by Xpert® MTB/RIF, line probe assays(LPA) or conventional diagnostics. Locally, the Rv0678 M146T mutation that correlates with resistance to bedaquiline and clofazimine is associated with the presence of *rpoB* I491F strains. The clinical significance of these mutations in patients initiated on BPaLM regimen remains unclear.

This study aimed to assess whether infection with I491F strains affected the treatment outcomes of patients enrolled on the BPaL/M regimen.

Intervention or response: Patients diagnosed with isoniazid monoresistance, polydrug resistance, or rifampicin-resistant TB (RR-TB) via Xpert MTB/RIF, LPA, or MGIT culture underwent tNGS using Genoscreen Deeplex® Myc-TB kits on the Illumina iSeq 100 platform to detect additional resistance-conferring mutations. Those with confirmed or presumed RR-TB were considered for BPaL or BPaLM based on fluoroquinolone resistance status. Routine monitoring and evaluation systems were used to assess BPaLM uptake, treatment outcomes, and the prevalence of rpoB I491F mutation among enrolled patients. Associations between this mutation, bedaquiline resistance, and treatment success were analyzed.

Results/Impact: Of 252 patients enrolled in DR-TB treatment between January 2023 and December 2024, 177 were eligible for BPaLM, and 147 were initiated on the regimen.

HIV positive	151(59.9%)	N=252
On ART	141(93.4%)	N=151
Elligible BPaLM/BPaL	177(70.2%)	N=252
Initiated BPaLM/BPaL(Uptake)	147(83.1%)	N=177
Sequencing done	91(51.4%)	N=177
I491F Mutation	53(58.2%)	N=91
Rvo678 mutation(BDQ/CFZ resistance)	39(42.9%)	N=91
BPaLM Treatment success without I491F mutation	17(94.4%)	N=18
BPaLM Treatment success with I491F mutation	19(90.5%)	N=21
BPaLM Treatment success without tNGS results	42(84.0%)	N=50

Conclusions: The high prevalence of rpoB I491F mutation in this cohort highlights the need for expanded molecular diagnostics to guide DR-TB treatment. Moreover, its strong association with bedaquiline and clofazimine resistance raises concerns about potential treatment challenges.

Although this study did not find a statistically significant impact of rpoB I491F-associated resistance on BPaLM treatment outcomes, further research is warranted to assess its long-term effects, particularly on treatment efficacy and the selection of additional resistance.

EP59 Digital and AI-driven approaches to integrated TB and respiratory health management

EP59-1264-21 Integrated, community-centered screening for chronic respiratory diseases in high-risk Nairobi hotspots using digital chest X-rays with artificial intelligence (AI)

E. Mueni,[1] C. Ngunu,[1] S. Olwande,[2] P. Kimani,[2] D. Karambi,[2] B. Mwangi,[2] V. Wanjohi,[2] I. Kathure,[3] I. Umuro,[3]
[1]County Government of Nairobi, Health, Nairobi, Kenya,
[2]Clinton Health Access Initiative, Health, Nairobi, Kenya,
[3]National Tuberculosis Program, Health, Nairobi, Kenya
e-mail: mlitswa03@gmail.com

Background and challenges to implementation: Chronic respiratory diseases such as chronic obstructive pulmonary disease (COPD), tuberculosis, asthma, and lung cancer represent a major global health challenge. In 2024, Nairobi reported 55,052 lower respiratory tract diseases, 94,890 pneumonia, and 13,916 cases of tuberculosis(TB).

Although these statistics are concerning, significant gaps remain in the early detection and efficient management of these diseases. To address this gap, the County together with implementing partners piloted an integrated lung health outreach in high-risk areas of Nairobi, using digital chest X-rays with artificial intelligence (AI) for early diagnosis.

Intervention or response: From February to March 2025, the County organized 10 targeted community screenings on chronic respiratory diseases. The efforts were focused on tuberculosis hotspot areas, deliberately chosen to act as strategic entry points for targeted screening initiatives. Community health promoters sensitized population living within the sites on lung health and mobilized them to visit designated screening centers.

Counseling was provided, and those who consented underwent an initial digital chest X-ray with AI. Individuals with abnormal X-ray results were subsequently evaluated by clinicians and referred for Gene Xpert testing and other diagnostic investigations.

Results/Impact: A total of 2,863 individuals received messages about chronic respiratory disease. 77% (2,191) underwent screening using digital chest X-rays. Among those screened, 15% (336/2191) exhibited abnormal X-ray results indicative of tuberculosis and were referred for GeneXpert testing.

Ultimately, 130 (39%) TB cases were identified, with 86 bacteriologically and 44 clinically confirmed.

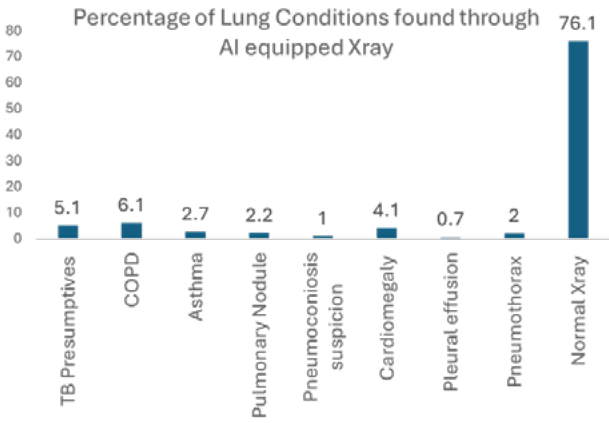
Additionally, 3% (67/ 2191) had other abnormal chest findings. Among these cases, 34 (51%) were indicative of asthma, 11(16%) of COPD, 16 (24%) of post-TB lung disease, 4 (6%) lung cancer, and 2 (3%) pneumothorax.

Conclusions: Digital chest X-rays with AI have proven to be highly effective tool for screening chronic respiratory diseases. It facilitates the early identification of abnormalities, including tuberculosis, COPD, asthma, and lung cancer, enabling timely intervention and treatment.

EP59-1265-21 Reimagining integrated screening: Preliminary findings from an AI-driven TB and lung health initiative in Pakistan

K.U. Eman,[1] B. Kirubi,[2] U.R. Lodhi,[1] T. Asif,[1] M. Ali,[1] G.N. Kazi,[1] J. Creswell,[2] S. Tahseen,[1] [1]Dopasi Foundation, Programs, Islamabad, Pakistan, [2]Stop TB Partnership, TB Reach, Geneva, Switzerland
e-mail: u.lodhi@dopasi.org

Background and challenges to implementation: Occupationally exposed and socially marginalized populations in Pakistan—including coal-miners, brick-kiln workers, cotton-ginners, transgenders etc.—carry a high burden of TB and other respiratory-diseases. These groups often live and work in areas with limited access to diagnostic services. Seeking care frequently means wage loss, discouraging early detection. Traditional TB screening often overlooks individuals with respiratory symptoms who test negative.
This initiative introduces an integrated service delivery model combining AI-enabled TB screening, lung function testing, and community outreach to deliver equitable, multi-disease diagnosis at the community and workplace level.
Intervention or response: Mobile teams conducted ACF in four provinces using AI-enabled ultraportable digital X-rays, outreach workers, and real-time digital tools. Individuals with TB symptoms were tested via GeneXpert. For non-TB lung conditions, a tiered strategy was applied: peak flow testing for symptomatic individuals, followed by digital spirometry only if abnormal, improving efficiency and reducing burden.
Portable digital spirometers were used in the field. Data were integrated into electronic systems. Upcoming phases will pilot TB tongue swabs, cough AI, and multipathogen diagnostics.
Results/Impact: Preliminary findings show:
• CXR coverage: 99.8%, with 5.1% AI-flagged presumptive TB.
• TB Detection: 1.5% positivity
• Pulmonary findings included:
o COPD (6.1%)
o Asthma (2.7%)
o Cardiomegaly (4.1%)
o Pulmonary nodules (2.2%)
o Pneumothorax (2.0%)
o Pleural effusion (0.7%)
o Pneumoconiosis suspicion (1%)
Field-based peak flow testing and spirometry were successfully implemented with high acceptance and clinical utility for triage



Conclusions: This model demonstrates the feasibility and operational innovation of integrating TB and lung health services in high-risk populations. By leveraging AI for triage, using symptom-guided peak flow testing, and selectively applying digital spirometry, ReachTB+ ensures high-yield diagnosis with efficient resource use.
As the project scales, integration with national strategies and newer Next-Gen Tools, can support broader implementation of ISD models and position Pakistan as a leader in digitally enabled, community-centric TB and NCD prevention.

EP59-1266-21 Artificial intelligence-driven increase in TB preventive treatment in prison settings in Mozambique

A. Olotu,[1] I. Calder,[2] M. Vincente,[3] E. Prophete,[4] C. Anli,[3] R. Boehm,[1] V. Brown,[1] A. Spaulding,[1] [1]Emory University, Center for the Health of Incarcerated Persons, Atlanta, United States of America, [2]Health through Walls, Executive Office, North Miami, United States of America, [3]National Penitentiary Service of Mozambique, Health Department, Maputo, Mozambique, [4]Health through Walls, HIV/TB, North Miami, United States of America
e-mail: amadin.olotu@emory.edu

Background: Mozambique has a high burden of incident tuberculosis (TB): 361 per 100,000 population. Incarcerated persons have a higher risk for TB disease than the general population. WHO recommends tuberculosis preventive treatment (TPT) for TB infection and active case finding for TB disease in high-risk populations. The National Penitentiary Service of Mozambique, in a Health through Walls-led project, expanded TPT delivery in prisons while deploying artificial intelligence (AI) interpreted chest x-rays to systematically screen for TB disease, facilitating diagnosis and treatment.

Design/Methods: A longitudinal, integrated health TB screening (Q3 July 2023 to Q2 June 2024) was implemented at three intervention prisons, using symptoms and digital chest x-rays, interpreted by AI-enabled software (qXR v3.2, Qure.ai). Data was obtained from two control prisons, which continued symptom screening without the AI-interpreted-chest-x-ray intervention. Residents were offered tuberculin skin tests (TST); TPT was delivered to those at highest risk for developing TB disease (including HIV infection and TB contacts) following exclusion of TB disease with AI-read chest x-rays. The Mozambican National Bioethics Committee and Emory University IRB approved the project.

Results: Of 7912 individuals screened at the intervention prisons, 264 residents with TB disease were notified and 2819 considered for TPT initiation based on risk assessments. TST acceptance was spotty, reportedly due to misconceptions regarding what was injected. Nevertheless, 1346 initiated TPT. Comparing against a historical baseline (Q3 July 2022 to Q2 June 2023), TPT initiations in intervention prisons increased in number and proportion: from 156 to 1346 and 1.78% to 17.01% of total screened residents. While TPT initiations increased by only 52% in the control prisons, the increase was 763% in the intervention prisons.

TPT initiation before and during the intervention period

Parameters	Year & Quarter	Number of persons initiated on TPT		Total screened over 4 quarters	TPT initiation/ Total screened (intervention prisons only)
		Intervention Prisons (Total ADP* = 4292)	Control Prisons (Total ADP* = 2672)		
Historical Baseline (Pre -AI Implementation Period)	Q3 2022	64	33	8759	156/8759 (**1.78%**)
	Q4 2022	64	64		
	Q1 2023	17	22		
	Q2 2023	11	21		
	Total	**156**	**170**		
AI Implementation Period	Q3 2023	278	41	7912	1346/7912 (**17.01%**)
	Q4 2023	516	127		
	Q1 2024	303	66		
	Q2 2024	249	25		
	Total	**1346**	**259**		
% change in TPT initiations from historical baseline		763%	52%		

*ADP: Average daily population

Conclusions: AI interpretation of chest X-rays appeared to have facilitated an increase in TPT delivery, in addition to higher notification of newly diagnosed TB cases, in this prison system.

EP59-1267-21 Perceptions of smartphone-based cough-audio TB triage among health facility clients: Findings from qualitative implementation research in CAGE-TB

H. Myburgh,[1] C. Pell,[2] L. Mabe,[1] A. Nangonzi,[3] J. Nsubuga Kikoyo,[3] W. Ssengooba,[3] K. Zajac,[4] D. Naidoo,[5] F. Cobelens,[2] G. Theron,[5] [1]Stellenbosch University, Desmond Tutu TB Centre, Cape Town, South Africa, [2]Amsterdam Institute for Global Health and Development, Global Health, Amsterdam, Netherlands, [3]Makerere University, School of Biomedical Sciences, Kampala, Uganda, [4]University of Göttingen, Digital Health Research Group, Göttingen, Germany, [5]Stellenbosch University, Division of Molecular Biology and Human Genetics, Cape Town, South Africa
e-mail: hmyburgh@sun.ac.za

Background: In sub-Saharan Africa, undiagnosed tuberculosis (TB) and delayed care-seeking contribute to ongoing disease transmission. Supported by EDCTP2, Cough Audio triaGE for TB (CAGE-TB) aims to develop a smartphone-integrated cough-audio classifier for TB triage in high-burden settings. We prospectively explored the perspectives of smartphone-based cough-audio TB triage among health facility clients.

Design/Methods: We conducted semi-structured interviews with clients (≥18 years) at four health facilities in Cape Town, South Africa and six in Kampala, Uganda in 2023 and 2024. Participants were purposively sampled for diversity from clients seeking care for TB suggestive symptoms or enrolled in TB/HIV care.

Interviews addressed experiences of TB and health services, technology use, and the CAGE-TB prototype. Interviews were audio recorded, transcribed, and translated to English if necessary. Transcripts were thematically analysed using MAXQDA 24.

Results: We interviewed 55 participants (31 in South Africa; 24 in Uganda), 58% women, aged 18-84 (avg. 35 years). Participants' knowledge about TB symptoms, prevention, and treatment varied, with some misconceptions. There were reports of delayed care-seeking and long pathways to diagnosis in a context of widespread TB-associated HIV and TB-related stigma. Participants described their communities and living conditions as overcrowded/unhygienic, with increased risk for disease.

Participants viewed the concept of smartphone-based cough-audio TB triage in health facilities as innovative, identifying the potential for earlier TB detection and increased TB awareness. Many expressed a desire for using it at home/community.

There were however concerns/distrust from older, less tech-savvy participants, with a preference for familiar/routine TB care. Other concerns related to privacy/TB stigma as well as infection control.

Conclusions: Clients in South Africa and Uganda are open to a smartphone-based cough-audio TB triage test. The design must however align with existing TB services,

include infection control, and TB-related advocacy to facilitate trust and use. Continued end-user engagement is essential to minimise potential for TB stigma.

EP59-1268-21 Active case finding and detection of TB infection among incarcerated populations using an artificial intelligence-aided portable handheld X-ray machine in Himachal Pradesh, India

G. Beri,[1] S. Rajan,[2] Y.P. Sharma,[3] N. Soni,[2] A.G. Nair,[2] R. Kumar,[3] A. Bharadwaj,[4] N. Satapara,[2] L.R. Sharma,[3] S. Chandra,[2] U. Singh,[5] [1]Ministry of Health and Family Welfare, Himachal Pradesh, Directorate Health Services, Shimla, India, [2]Government of India-WHO Country Office for India - TB Technical Support Network, National Tuberculosis Elimination Program, New Delhi, India, [3]Department of Health and Family Welfare, National Health Mission, Shimla, India, [4]National Task force (Medical College), National Tuberculosis Elimination Program, New Delhi, India, [5]Ministry of Health and Family Welfare, Central TB Division, New Delhi, India
e-mail: rajans@rntcp.org

Background and challenges to implementation: Tuberculosis (TB) remains a significant health challenge in congregate settings. The National Tuberculosis Elimination Program's (NTEP) 100-Day intensified case-finding TB campaign targets vulnerable groups, including the incarcerated population. In Mandi District Prison, Himachal Pradesh, the health administration, coordinating with the prison department and community stakeholders, conducted AI-enabled handheld X-ray screenings to detect active TB and identify infections, demonstrating effective multi-sectoral collaboration.
Intervention or response: In December 2024, a targeted TB screening initiative was implemented in Mandi jail, screening 206 incarcerated individuals with an AI-equipped handheld X-ray and 10 TB symptoms. Those with symptoms or abnormal X-rays were classified as presumed TB cases, and samples were sent for NAAT. Confirmed cases entered the TB care cascade, while asymptomatic individuals with normal X-rays underwent Cy-TB skin testing. Positive cases started a shorter TB Preventive Treatment (3HP), and others were scheduled for follow-up in three months. Data was analyzed on Nikshay using SPSS ver22.
Results/Impact: Of the 206 incarcerated people screened, 15 asymptomatic individuals had abnormal chest X-rays. NAAT testing confirmed TB in 3 persons (20% diagnostic yield), all of whom began treatment (*Figure1*).
Among 203 people deprived of their liberty who underwent Cy-TB testing, 72 (35%) were positive for latent TB infection and were started on preventive therapy. Rest were followed up after three months, with no progression to active TB.

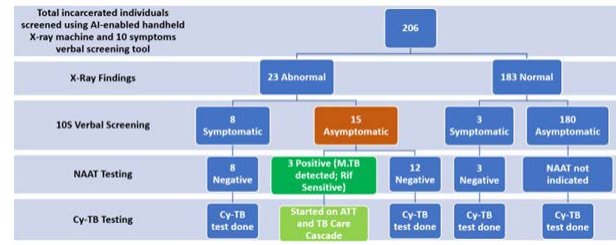


Figure 1. TB diagnostic cascade in Mandi Prison, Himachal Pradesh (2024).

Conclusions: AI-assisted handheld X-ray screening was effective in detecting asymptomatic TB in a prison setting. This initiative underscores the importance of technology and coordinated efforts in enhancing TB detection and prevention in high-risk environments.

EP59-1269-21 A quarter of a century of TB-CAD research: A bibliometric overview of themes, tools, and global partnerships

I. Aulianisa,[1] D.K. Ryuk,[1] M. Yang,[1] J. Son,[1] W. Shreeya,[1] D.-E. Kim,[1] Y. Park,[1] M. Kohli,[2,1] H. Sohn,[1]
[1]Seoul National University College of Medicine, Department of Preventive Medicine, Seoul, Republic of Korea, [2]FIND, Evidence and Policy, Geneva, Switzerland
e-mail: irinaaulia@snu.ac.kr

Background: In 2020, the World Health Organization recommended the use of computer-aided detection (CAD) for chest X-ray assessment in adults for screening and triage. Since then, uptake has increased at the country level, with many new CAD products now available. Using bibliometric analysis, we map the evolution of tuberculosis-CAD (TB-CAD) research from 2000 to 2024, identifying core publication sources, thematic shifts, and assessing geographic distribution, collaboration patterns, and tool adoption.
Design/Methods: We conducted a comprehensive literature search across PubMed, Scopus, Embase, Cochrane and Web of Science to identify original research articles meeting our inclusion criteria. We used Microsoft Excel, Bibliometrix (R), and Python to synthesize data, and perform bibliometric analyses. Our analysis covered nine indicators: publication trends, journal dispersion using Bradford's Law, study type evolution, funding sources, geographic and research collaboration trends, study population distribution, keyword trends, CAD software usage, and deep learning architectures.
Results: A total of 9,190 articles were identified; 349 met inclusion. Publications increased markedly after 2018, with Scientific Reports as the leading journal. India led first-author publications (20%), while the USA was the top funder (6%). CAD4TB was the most used tool, with Qure.ai and Lunit gaining traction post-2019. ResNet and

EfficientNet were the most applied deep learning models. China and the USA contributed the largest study populations, mostly via public datasets for algorithm development. Strong collaborations were seen between high-income and TB-endemic countries. Thematic analysis showed a shift from earlier CAD to deep learning, with publications rising from under 5 before 2019 to over 20 annually by 2020–2022.

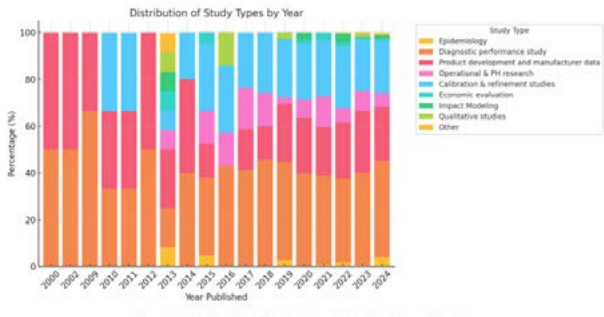

Figure 4b. Distribution of Study Types in TB-CAD Research by Year

Each stacked bar shows the percentage distribution of study types by publication year. Early research focused on product development, while later years show diversification into operational, economic, and implementation-oriented studies.

Conclusions: TB-CAD research has grown rapidly and shifted toward implementation-oriented, artificial intelligence-based diagnostics. Our study highlights research and development trends and identifies research gaps in the expanding field of artificial intelligence and digital tools for TB and global health, supporting TB screening through strategic investment and cross-sector collaboration.

EP59-1270-21 Evaluating CAD software performance in handling erroneous chest radiograph images

Z.Z. Qin,[1] S. Gelaw,[2] A. Klosovsky,[1] T.S. Egzertegegne,[3] N.L. Leyso,[2] [1]International Organization for Migration, Migration Health Division, Geneva, Switzerland, [2]International Organization for Migration, Migration Health Division, Manila, Philippines, [3]International Organization for Migration, IOM Africa Regional Teleradiology Centre, Nairobi, Kenya
e-mail: zzq.gis.intl@gmail.com

Background: The reliability of computer-aided detection (CAD) systems depends on their ability to handle erroneous or poor-quality images effectively in real-world clinical settings. Many CAD software are designed to read exclusively frontal chest X-ray images (CXRs) and claim to reject CXRs with quality issues affecting interpretation, but this has not yet been tested.
Design/Methods: We created a specialized dataset (n=2,912), mixing 2,812 frontal CXRs of radiologist-verified quality with 100 CXRs with radiologist-verified errors. Errors were evenly distributed between CXRs with image quality challenges, CXRs taken from additional angles, non-CXR images, and pediatric CXRs below the designated manufacturer age limit. 3 CAD software read the mixed dataset. Rejected images and reasons for rejection were recorded for calculation of metrics including Rejection Rate (RR), Error Detection Rate (EDR), and False Alarm Rate (FAR) when processing both error datasets alongside standard datasets.
Results: CAD1 had the highest overall RR, rejecting 63% of erroneous images but correctly identifying the error in only 25% of these. CAD1 also had the highest FAR (6.44%), rejecting the most images without errors, as verified by radiologists. CAD2 and CAD3 demonstrated substantially lower error-detection capability, rejecting 10% and 2% of the error dataset respectively. CAD2 correctly identified the error in 6% of cases, while CAD3 failed to correctly identify the error in both of the erroneous images it correctly rejected. CAD2 and CAD3 also had the lowest false alarm rates. CAD3 did not reject any of the verified CXRs (FAR=0%), while CAD2 had FAR of 1.14%.

	CAD1	CAD2	CAD3
Number of correctly detected errors (of 100)	25	6	0
Number of detected errors, incorrect error message (of 100)	38	4	2
Number of errors not detected (of 100)	37	90	98
Number of false errors (of 2,812)	181	32	0
Rejection rate (%)	63.0	10.0	2.0
Error detection rate (%)	25.0	6.0	0
False alarm rate (%)	6.44	1.14	0

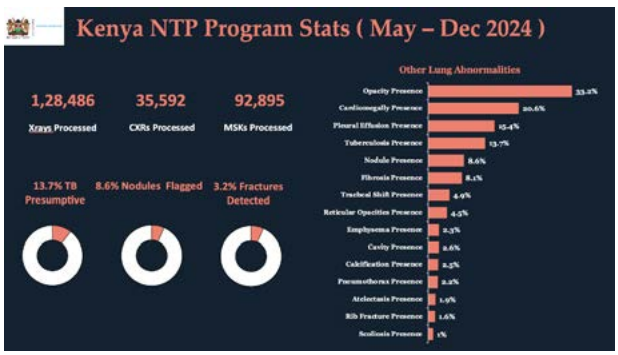
Table 1. Errors correctly detected, mistakenly detected, and missed by CAD.

Conclusions: All three CAD technologies showed limitations in handling erroneous images, with different strengths and weaknesses. CAD1 was most effective at detecting errors but generated more false alarms with standard images. CAD3 processed almost all images regardless of quality, largely failing to flag technical errors.

EP59-1271-21 Use of multimodal computer aided detection software for optimisation of lung health services in Kenya

I. Kathure,[1] M. Githiomi,[1] B. Nzano,[2] R. Choto,[3] B. Mwangi,[4] D. Karambi,[5] J. Okari,[1] I. Umuro,[1] G. Brigden,[6] J. Harwell,[7]
[1]Ministry of Health, National TB Program, Nairobi, Kenya, [2]Clinton Health Access Initiative, Clinical Sciences, Nairobi, Uganda, [3]The Global Fund, High Impact Africa 2 Department, Grant Management Division, Geneva, Switzerland, [4]Clinton Health Access Initiative, Clinical Services, Nairobi, Kenya, [5]Clinton Health Access Initiative, Infectious Diseases, Nairobi, Kenya, [6]The Global Fund to fight AIDS, TB and Malaria, Technical Advice and Partnerships, Geneva, France, [7]Clinton Health Access Initiative, Clinical Sciences, Nairobi, Australia

Background and challenges to implementation: Kenya had an estimated 124,000 TB cases in 2024, with 96,865 cases notified, leaving a 20% diagnostic gap and emphasizing the need for better TB detection methods. TB and chronic lung diseases share patient care pathways, increasing patient vulnerability, healthcare costs, and straining resource-limited programs. A lack of lung health data hinders decision-making. Referrals due to shortage of radiologists increase patient costs and delay diagnosis. Recent changes in funding underscore the need for cost-effective interventions that optimise the impact of lung health programs.
Intervention or response: In May 2024, the Kenya TB program through Global Fund support deployed multimodal Computer-Aided Detection software (CAD) in 69 healthcare facilities. We revised the diagnostic algorithm to incorporate the use of CAD and trained healthcare workers on its use. The CAD was used to analyze all scans, regardless of clinical indications, broadening TB screening and enabling timely detection of other thoracic abnormalities.
Results/Impact: CAD data for 128,000 digital chest x-rays from 69 health facilities between May and December 2024 detected 13.7% (4,725) scans as potential TB cases who were referred for TB testing and treatment.



Other thoracic abnormalities, including Pulmonary nodules (8.6%, 916 cases), Rib/thoracic fractures (3.2%, 414 cases), Cardiomegaly (20.6%, 6,171 cases), Pleural effusion (15.4%, 2,866 cases), Emphysema (2.3%, 493 cases), Pneumothorax (2.2%, 437 cases) and Pulmonary fibrosis (8.1%, 1,312 cases) were identified and patients referred for further evaluation and management.
Conclusions: Use of multimodal CAD software enables simultaneous screening for TB, post-TB sequelae, and other lung conditions allowing timely diagnosis and management. This reduces radiology referrals and streamlines patient care pathways for TB and chronic lung diseases. It maximizes the impact of lung health programs, reducing the strain on resource-limited settings.
Scale-up will focus on strengthening monitoring and referral systems, validation of CAD for other lung conditions and Quality Assurance programs for CAD.

EP59-1272-21 Accuracy of computer-aided detection systems for identifying specific non-TB pulmonary findings

A. Klosovsky,[1] S. Gelaw,[2] Z.Z. Qin,[1] T.S. Egzertegegne,[3] N.L. Leyso,[2] [1]International Organization for Migration, Migration Health Division, Geneva, Switzerland, [2]International Organization for Migration, Migration Health Division, Manila, Philippines, [3]International Organization for Migration, IOM Africa Regional Teleradiology Centre, Nairobi, Kenya
e-mail: zzq.gis.intl@gmail.com

Background: Beyond tuberculosis (TB) detection, computer-aided detection (CAD) systems have the potential to identify various pulmonary abnormalities, enhancing their utility in comprehensive chest radiograph (CXR) interpretation. This study evaluated the accuracy of two CAD technologies in detecting specific non-TB pulmonary findings.
Design/Methods: We analyzed CXRs from both adult (n=2,812) and pediatric (n=1,476) datasets. Performance was evaluated against a radiological reference standard (RRS) established through consensus readings by expert radiologists.
We focused on three findings with sufficient sample sizes for statistical power: consolidation, fibrosis, and atelectasis. For each finding, we calculated the area under the receiver operating characteristic curve (AUC-ROC). CAD systems were only evaluated for age groups recommended by manufacturers.
Results: In the adult dataset, the AUC-ROCs of CAD1 were 0.82 (95% CI: 0.79-0.85) for atelectasis, 0.73 (0.71-0.75) for consolidation, and 0.66 (0.64-0.66) for fibrosis. CAD2 significantly outperformed CAD1 when identifying consolidation (AUC-ROC: 0.86 [0.84-0.87]), achieved similar performance for fibrosis (0.66 [0.64-0.68]) and was less accurate at detecting atelectasis, although this was not significant (0.79 [0.77-0.81]). In children 3 years and older (n=1,216), CAD1 achieved perfect accuracy in detecting pleural effusion (AUC-ROC: 1), followed by fibrosis, atelectasis, and consolidation, which all achieved AUC-ROC > 0.75.

Similarly, in children aged 14 years and older (n=142), CAD2 achieved perfect accuracy for pleural effusion (AUC-ROC: 1), followed by atelectasis, consolidation, and fibrosis, all with AUC-ROC > 0.85.

	CAD1 AUC (95% CI)	CAD2 AUC (95% CI)
Adults (15 years and older)	n= 2,812	
Fibrosis	0.66 (0.64-0.69)	0.66 (0.64-0.68)
Consolidation	0.73 (0.71-0.75)	0.86 (0.84-0.87)
Atelectasis	0.82 (0.79-0.85)	0.79 (0.77-0.81)
Children (< 15 years)	n= 1,216	n= 142
Consolidation	0.76 (0.73-0.80)	0.89 (0.80-0.97)
Fibrosis	0.85 (0.78-0.93)	0.86 (0.73-0.99)
Atelectasis	0.84 (0.72-0.96)	0.97 (0.93-1.0)
Pleural effusion	1	1

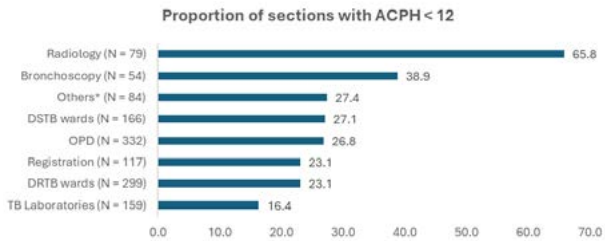
Table 1. CAD AUC for selected individual findings in adults and children.

Conclusions: CAD1 and CAD2 demonstrated good accuracy in detecting specific non-TB pulmonary findings in adults and children. These results highlight the potential of CAD technologies to support comprehensive CXR interpretation beyond TB screening, particularly for identifying non-TB abnormalities.

EP59-1273-21 Radiology a high-risk section for airborne infections including TB: Array of possible interventions in India

D. Khismatrao,[1] A. Shrivastava,[1] T. Shah,[2] S.K. Mattoo,[3] S. Chauhan,[4] H. Gangaiah,[4] R. Taralekar,[4] S.S. Chadha,[2] U.B. Singh,[3] [1]FIND, Airborne Infection Control, Delhi, India, [2]FIND, Senior Management team, Delhi, India, [3]Ministry of Health and Family Welfare, Dte. GHS, Government of India, Central TB Division, Delhi, India, [4]Government of India, WHO Country office for India, National TB Elimination Program, Delhi, India
e-mail: dkhismatrao@gmail.com

Background and challenges to implementation: Health care facilities (HCF) have risk of airborne infections including TB, but focus is more on Infection prevention and control. For airborne infection control (AIC), ventilation with air changes per hour (ACPH) is critical parameter which is not routinely monitored. CDC and ASHRAE guidelines recommend ACPH > 12 in high-risk sections of HCF. Identifying sections within HCF for risk of airborne infection is imperative for designing, implementation and monitoring of AIC measures.
Intervention or response: National TB Elimination program (NTEP) of India with FIND and WHO conducted risk assessment in 185 Drug resistant TB (DR-TB) centres in two phases (100 sites from Sep'22 – Jun'23) and (85 sites from Apr – Dec'24). Phase-1 six sites are not included in analysis due to shifting or demolition. Special emphasis on assessment of radiology section as TB and respiratory symptoms patients visit this section. Air changes per hour (ACPH) calculated using ASHRAE standards.
Results/Impact: ACPH was measured in total 1290 of 1641 sections assessed across 179 DR-TB centres since others were closed rooms. In radiology ACPH measured in 79 of 200 sections assessed. Fig 1 shows proportion of different sections assessed with ACPH < 12.



Radiology has maximum (65.8%) proportion of sections with ACPH < 12 making it most vulnerable section within HCF for airborne infections. Shifting of radiology section not possible since equipments are fixed.
Conclusions: Improving ventilation (ACPH) in radiology section is challenging. Array of alternative solutions are creation of well-ventilated waiting areas; triage, segregation and fast tracking of TB and respiratory symptoms patients; provision of mask to these patients by HCF; identified dedicated machines (digital x-ray, USG) for these patients; token systems for crowd management; segregated radiology facilities for vulnerable patients like pregnant mothers, and children; separate x-ray facility in TB OPD. New radiology facilities should have well-ventilated waiting areas and implement above-mentioned interventions.

EP60 Innovations in TB Modelling for vaccination, diagnosis and treatment

EP60-1274-21 Modelling the Covid-19 pandemic impact on the diagnosis of child and adolescent TB in South Africa

L. Brown,[1] K. Du Preez,[2] M. Smith,[3,4] E. Mohr-Holland,[5] H.S. Schaaf,[2] J.A. Seddon,[2,6] M. Davies,[3,4] A. Boulle,[3,4] A.C. Hesseling,[2] C. Van Schalkwyk,[1] [1]Stellenbosch University, South African Centre for Epidemiological Modelling and Analysis, Cape Town, South Africa, [2]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Cape Town, South Africa, [3]Western Cape Department of Health, Provincial Health Data Centre, Cape Town, South Africa, [4]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa, [5]City of Cape Town Health Department, Specialised Health, Epidemiology Unit, Cape Town, South Africa, [6]Imperial College London, Department of Infectious Disease, London, United Kingdom of Great Britain and Northern Ireland
e-mail: karendp@sun.ac.za

Background: A global modelling study estimated that observed versus predicted tuberculosis notifications in children aged <5 years had declined by 35.4% in 2020 due to COVID-19 pandemic-related effects, approximately double the estimated decline in people ≥15 years (-18.8%). We used enhanced surveillance data from the Western Cape (WC) to investigate the impact of COVID-19 on tuberculosis diagnoses in children and adolescents versus adults.

Design/Methods: We analysed de-identified aggregate data on tuberculosis episodes for 2017-2022, by HIV status, setting and age (0-1, 2-4, 5-9, 10-14, 15-19, ≥20 years). Tuberculosis diagnosis incidence was calculated using mid-year population estimates from the provincial Thembisa model.

Autoregressive integrated moving average (ARIMA) time-series modelling was used to forecast expected tuberculosis episodes and incidence from March 2020 onward, based on pre-pandemic trends (Jan 2017-Feb 2020).

Results: From 2017 through 2022, there were 286,194 tuberculosis episodes diagnosed, with 48,126 (16.8%) in 0-19-years-olds. ARIMA models estimated the largest percentage difference in observed versus forecasted tuberculosis diagnoses in the 0–1-year age group at -39.9% (95% prediction interval [PI]: -28.2 to -48.4), almost double the estimated difference in adults (-22.1; 95%PI: -15.9 to -27.5).

Decline in tuberculosis diagnosis incidence varied by HIV status in children, with those with unknown HIV status having the largest estimated percentage difference (-31%; 95%PI: -27.1 to -34.5), followed by children living with HIV (CLHIV) (-22%; 95%PI: -20.2 to -23.7). Similar percentage differences (~19%), were estimated for children in urban versus. rural areas. By 2022, the observed values had realigned with forecasted diagnoses for each age group, with adults realigning the fastest (Figure).

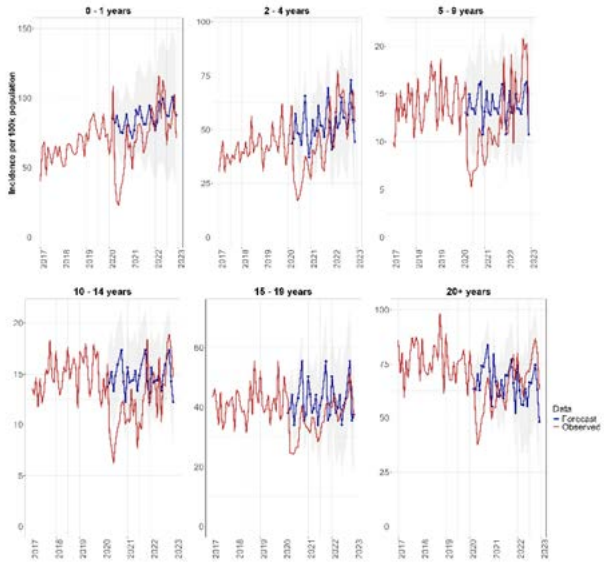


Figure. Monthly time-series of tuberculosis incidence of diagnosis by age group in the Western Cape.
Dark blue lines represent forecasted data, red lines observed data, and grey shading 95% prediction intervals.

Conclusions: We found noticeable differences between observed and forecasted numbers of tuberculosis diagnosis across all age groups. Children and adolescents experienced the most severe and longest duration of impact, particularly infants (<1 year of age), highlighting their increased vulnerability during pandemic response periods.

EP60-1275-21 Targeted TB vaccination strategies in India: Impact of risk-based vs. geographic approaches using mathematical modelling

R. Jalal,[1] S. Pandey,[2] A. Bhaskar,[3] J. Joseph,[1] M. Muniyandi,[4] S. Chatterjee,[5] R. Goyal,[6] N. Arinaminpathy,[7] V. Dhawan,[8] R. Rao,[8] U. B Singh,[8] S. Swaminathan,[9]
[1]IAVI, Global Access Research, Gurugram, India, [2]BL Pandey Foundation for Social Initiatives, NA, Gurugram, India, [3]ICMR-National Institute for Research in Tuberculosis, Department of Statistics, Chennai, India, [4]ICMR-National Institute for Research in Tuberculosis, Department of Health Economics, Chennai, India, [5]Translational Health Science and Technology Institute (THSTI), Computational and Mathematical Biology Centre, Faridabad, India, [6]IAVI, Country Director, Gurugram, India, [7]World Health Organization, TB Monitoring, Evaluation & Strategic Information, Geneva, Switzerland, [8]Ministry of Health and Family Welfare, Government of India, Central TB Division, New Delhi, India, [9]M S Swaminathan Research Foundation, Chairperson, Chennai, India
e-mail: RJalal@iavi.org

Background: Tuberculosis (TB) vaccination will be critical for achieving the End TB goals. India, with world's highest TB burden, faces key policy questions on what targeting strategies – e.g. high-risk groups or specific geographies – would be most effective.
Mathematical modeling of TB transmission dynamics offers a valuable tool to assess the potential impact of these strategies.
Design/Methods: We developed a mathematical model of TB transmission in India, incorporating key factors such as age, nutritional status (Body mass index (BMI) below and above 18.5 kg/m^2), diabetes mellitus (DM), urban and rural settings, and public and private healthcare sectors.
Assuming a prevention-of-disease (PoD) vaccine with 50% efficacy, we evaluated three targeting strategies:
i. Vaccinating individuals with low BMI,
ii. Vaccinating those in urban areas, and
iii. Vaccinating individuals with DM.
The vaccine was modelled to become available in 2027, scaling up linearly by 2030, assuming a coverage of 80% in all scenarios, with a single lifetime dose providing immunity for an average of ten years.
Results: Targeting individuals with low BMI led to the most substantial reductions in both TB incidence and mortality rates by 2040, decreasing cumulative incidence by 6.8% (95% CI 5.1–9.0) and cumulative mortality by 5.5% (95% CI 4.1–7.5). The DM focused strategy reduced cumulative incidence by 3.7% (95% CI 2.4–6.2), and cumulative mortality by 3.0% (95% CI 1.9–4.9).
The urban-targeted strategy had a comparable impact in morality cumulative mortality by 3.0% (95% CI 1.6–6.4), while reducing cumulative incidence by 5.4% (95% CI 3.7– 8.9).
Conclusions: Risk-based vaccine targeting, particularly for individuals with low BMI, may yield greater reductions in TB incidence and mortality than geographic approaches. In practice, however, challenges in identifying and reaching high-risk populations – especially those with low BMI or DM – must be considered in implementation strategies.

EP60-1276-21 The potential epidemiological impact of TB screening among previously incarcerated individuals for TB in Brazil

L. O'Brien,[1] L. Goscé,[1] K. Horton,[1] A. Schwalb,[1] M. Harker,[1] E. Venero-Garcia,[1] A. Gun,[1] T. Sumner,[1] T. Prys-Jones,[1] R. Bakker,[1,2] R. White,[1] R. Houben,[1]
[1]LSHTM, Department of Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [2]KNCV Tuberculosis Foundation, KNCV Tuberculosis Foundation, South Holland, Netherlands
e-mail: lshlo3@lshtm.ac.uk

Background: Incarceration is a major driver of tuberculosis (TB) in Brazil (transmission population attributable fraction of 36.9% in 2019), and increasing. Incarcerated individuals face strongly increased risks of TB due to overcrowding, poorly ventilated facilities and high rates of re-incarceration, all contributing to high levels of repeated reinfection and progression- further increasing the risk of infection post-release. While prison-specific TB interventions are being studied, little focus has been given to previously incarcerated individuals, despite their potential role in transmission.
Design/Methods: We calibrated a deterministic TB infection transmission model to TB epidemiology and incarceration indicators in Brazil. We implemented a screening intervention where previously incarcerated individuals were screened with Xpert Ultra annually. Screening and treatment was held at 2025 levels for both currently incarcerated individuals and community individuals.
We assumed a five-year scale-up period for the screening intervention among previously incarcerated individuals (2025-2030) and a continuation until 2050. We modelled a range of hypothetical scenarios that assumed low (25%), medium (50%), and highly optimistic (80%) annual coverage.
Results: By 2050, TB prevalence in Brazil could drop by approximately 20%, 35%, and 45% under low, medium, and highly optimistic coverage scenarios, respectively. TB deaths could decline by approximately 15%, 25%, and 30%, respectively.
Conclusions: Screening for previously incarcerated individuals could be epidemiologically impactful, likely driven by high prevalence of recent (re-)infection among this population, and the high risk of re-incarceration. Given the epidemiological potential, it is worth investi-

gating approaches to overcome the logistical challenges of reaching this vulnerable population. Data is needed to better understand what levels of coverage are realistically achievable.

EP60-1277-21 The delivery of new TB vaccines to people living with HIV: When to vaccinate?

T. Sumner,[1] R. Clark,[1] T. Prys-Jones,[1] R. Bakker,[1,2] G. Churchyard,[3] R. White,[1] [1]London School of Hygiene and Tropical Medicine, Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [2]KNCV, KNCV, The Hague, Netherlands, [3]Aurum Institute, Aurum Institute, Johannesburg, South Africa
e-mail: tom.sumner@lshtm.ac.uk

Background: Tuberculosis (TB) remains a major cause of morbidity and mortality in people living with HIV (PLHIV). New TB vaccines may help reduce this burden. There is limited data on the response to new TB vaccines in PLHIV and how this may vary with levels of immunosuppression and anti-retroviral therapy (ART).
The potential interaction between vaccine efficacy and ART raises questions about the optimum timing of vaccination against TB in PLHIV.
Design/Methods: Using a simple cumulative risk model, we compared the impact of different TB vaccination strategies for PLHIV. We compared the impact of vaccinating at linkage to HIV care, to the impact of vaccinating at ART initiation. We explored how the optimum timing of vaccination depends on characteristics of the vaccine and the ART program at an individual and population level.
Results: For an individual, the optimum timing of vaccination against TB is at ART initiation unless the time to ART initiation is more than 6 months or if the reduction in vaccine efficacy when given prior to ART is small (see Figure 1).

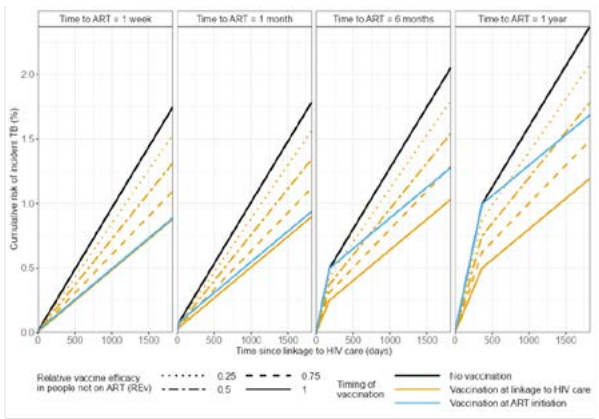

Figure 1. Cumulative risk of incident TB in individuals by time since linkage to HIV care. Colours show the different scenarios for the timing of vaccination. Line types show different relative vaccine efficacy in the absence of ART (compared to when on ART) (RE_v). Columns show different times to ART initiation (τ_{ART}).

At a population level, the proportion of PLHIV who initiate ART is a key determinant of the optimum strategy. If ART uptake is low, it would be better to vaccinate at linkage to HIV care, even if vaccine efficacy in ART naïve individuals is less than 50% of efficacy in individuals on ART.
Conclusions: Our results suggest that the optimum timing of new TB vaccination for PLHIV will depend on the relative efficacy of vaccination in ART-naïve individuals vs individuals on ART, and the uptake and timing of ART initiation.
If vaccine efficacy is lower among ART-naïve individuals, improvements in HIV programs may help maximize the impact of new TB vaccines.

EP60-1278-21 Impacts of diagnostic sensitivity on mortality in paediatric TB

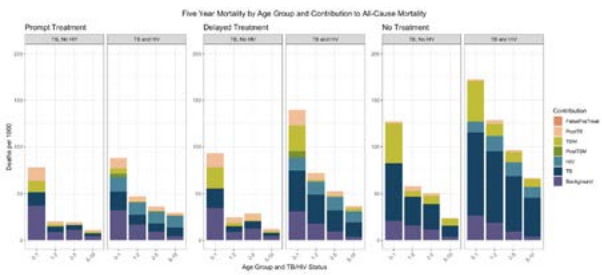
R.P. Tampi,[1,2] M.H. Can,[3] T. Cohen,[4,5] J.A. Seddon,[6,7] R. Song,[8] E. Bijker,[8] F. Basile,[8] N.A. Menzies,[3,2] [1]Harvard University, Interfaculty Initiative in Health Policy, Boston, United States of America, [2]Harvard University, Center for Health Decision Science, Boston, United States of America, [3]Harvard University, T.H. Chan School of Public Health, Global Health and Population, Boston, United States of America, [4]Yale University, Epidemiology of Microbial Diseases, New Haven, United States of America, [5]Yale University School of Public Health, Public Health Modeling Unit, New Haven, United States of America, [6]Imperial College London, Department of Infectious Disease, London, United Kingdom of Great Britain and Northern Ireland, [7]Stellenbosch University, Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Cape Town, South Africa, [8]University of Oxford, Department of Paediatrics, Oxford, United Kingdom of Great Britain and Northern Ireland
e-mail: rtampi@g.harvard.edu

Background: Early and accurate diagnosis of pediatric tuberculosis (TB) remains a major global challenge. Children with undiagnosed and untreated TB face increased risks of morbidity and mortality, including severe complications like tuberculous meningitis (TBM). We developed a microsimulation model to evaluate how changes in pediatric TB diagnostic sensitivity impact lifetime health outcomes.
Design/Methods: We simulated a cohort of 10,000 children (<10 years) undergoing pulmonary TB assessment at primary healthcare centers, tracking their lifetime health status, TB/HIV progression, and healthcare interactions, including loss to follow-up and return to care. Life expectancy was calculated for three diagnostic scenarios:
1. Prompt Treatment: As would result from a correct TB diagnosis at initial evaluation and receipt of timely treatment.
2. Delayed Treatment: As would result from TB diagnosis missed at initial evaluation. Some children would return for care as symptoms worsen.
3. No Treatment: Hypothetical scenario assuming no access to TB diagnosis and treatment.

Using the results of these scenarios, we assessed changes in five-year mortality from initial evaluation, causes of death, and life expectancy with incremental improvements in diagnostic sensitivity by TB/HIV status and age-group.

Results: Among children aged 0–1 with both TB and HIV, five-year mortality declined from 174 per 1,000 in the No Treatment scenario to 82 per 1,000 in the Prompt Treatment scenario (Figure).

Excess mortality due to TB and TBM were leading contributors to overall mortality in the No Treatment scenario, particularly in those with HIV. Each percentage point increase in diagnostic sensitivity raised life expectancy by 0.024 years in children with TB and 0.044 years in those with TB and HIV.



Conclusions: Enhancing pediatric TB diagnosis can substantially improve survival, particularly in high-risk groups such as infants and children with TB/HIV co-infection.

EP60-1279-21 Potential long-acting TB treatment for people with HIV in South Africa: Cost-effectiveness benchmarks

A. Zheng,[1] E. Pletner,[1] K. Middelkoop,[2,3] A.M. Neilan,[1,4,5] C.R. Horsburgh,[6] A.D. Paltiel,[7] K.A. Freedberg,[1,4,8] R. Wood,[2,3] K.P. Reddy,[1,4,9] [1]Massachusetts General Hospital, Medical Practice Evaluation Center, Boston, United States of America, [2]Desmond Tutu HIV Centre at the University of Cape Town, Institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa, [3]University of Cape Town, Department of Medicine, Cape Town, South Africa, [4]Harvard Medical School, N/A, Boston, United States of America, [5]Massachusetts General Hospital, Division of Infectious Diseases, Boston, United States of America, [6]Boston University School of Public Health and School of Medicine, Departments of Epidemiology, Biostatistics, Global Health and Medicine, Boston, United States of America, [7]Yale School of Public Health, Public Health Modeling Unit, New Haven, United States of America, [8]Massachusetts General Hospital, Division of General Internal Medicine, Boston, United States of America, [9]Massachusetts General Hospital, Division of Pulmonary and Critical Care Medicine, Boston, United States of America
e-mail: kpreddy@mgh.harvard.edu

Background: Long-acting tuberculosis drugs could improve tuberculosis treatment outcomes in South Africa, where there is high prevalence of HIV/tuberculosis co-infection and high attrition from standard tuberculosis treatment, but potential benefits must be weighed against costs.

We sought to identify scenarios where a long-acting tuberculosis treatment would provide clinical benefit and be cost-effective compared with standard tuberculosis treatment for people with HIV in South Africa.

Design/Methods: We used a validated microsimulation model to compare clinical and cost outcomes of:

1. Standard-of-care 6-month daily oral treatment (*SOC*);
2. A long-acting treatment regimen, entailing standard oral therapy for 2 months followed by a one-time injection (*LA*).

Base case parameters for *SOC/LA* included: efficacy, 97.6%/97.6%; disengagement while on oral therapy, 4%/month; and total regimen cost, USD 50/200. Parameters were varied in sensitivity analysis.

Outcomes included disengagement, mortality, tuberculosis relapses, life-years, and healthcare costs. We defined *LA* to be cost-effective compared to standard of care when its incremental cost-effectiveness ratio (ICER) was <USD 3,000 per year-of-life saved (YLS; opportunity cost-based threshold).

Results: In the base case, *LA* would produce less disengagement (10.9% vs. 17.7%) and lower all-cause mortality (10.7% vs. 10.9%) than *SOC* at 6m. Lower mortality would endure at 24m (17.6% vs. 21.7%). More tuberculosis relapses would occur in *LA* compared to *SOC* at 24m, due partly to higher survival. *LA* would be cost-effective

over 24m (ICER $2,580/YLS) and lifetime horizons (ICER $520/YLS) *(Table 1)*. In sensitivity analysis of the 24m horizon, *LA* would be cost-effective compared to *SOC* as long as *LA* efficacy is ≥97%, probability of disengagement on oral treatment in either strategy is ≥4%/month, or *LA* regimen cost is <USD 215.

Table 1. Base case model-projected clinical and economic outcomes of tuberculosis treatment strategies for people with HIV in South Africa.

	Disengagement from TB treatment, %	All-cause mortality, %	TB mortality, %	Life-months, undiscounted	Costs, undiscounted (USD)	ICER, USD/YLS*
24 months						
SOC	12.5	21.7	19.6	20.6	980	-
LA	5.8	17.6	15.5	21.2	1,080	2,580
Lifetime						
SOC	-	-	22.7	313.5	10,980	-
LA	-	-	18.6	329.7	11,640	520

SOC: standard of care; ***LA***: long-acting TB treatment strategy; **USD**: United States dollars; **ICER**: incremental cost-effectiveness ratio; **YLS**: year-of-life saved.

*ICERs were calculated using non-rounded discounted life-months and costs and are displayed as rounded values.

Conclusions: A long-acting injectable tuberculosis treatment regimen could be cost-effective if it maintains high efficacy at reasonable cost, especially when disengagement from standard oral treatment is high.

EP61 Bold actions advancing TB elimination

EP61-1280-21 Impact of person-centred care on treatment outcomes in drug-resistant TB: A case study from Mozambique a low-middle-income country

P. Zindoga,[1] A. Cassamo,[2] M. Jose,[1] M. Chachine,[1] A. Mugunhe,[2] B. Jose,[3] N. Guilovica,[1] [1]USAID, Integrated Health Office, Maputo, Mozambique, [2]Local TB Response, TB, Maputo, Mozambique, [3]NTP, TB, Maputo, Mozambique
e-mail: pereirazindoga1@gmail.com

Background and challenges to implementation: Drug-Resistant Tuberculosis (DR-TB) case management remains a significant challenge in Mozambique, characterized by low treatment success rates and high mortality and loss to follow-up rates. Contributing factors include poor social conditions such as unemployment, long distances to health facilities, limited knowledge about TB, delayed treatment seeking, incorrect medication intake or non-adherence, and insufficient clinical and laboratory follow-up. These challenges are further compounded by comorbidities, including malnutrition and HIV co-infection, which affect many DR-TB patients.
Intervention or response: The USAID TB project, implemented from 2019 to 2024 in 50 districts covering 54% of the country's population, provided a comprehensive care package, based on a patient-centered approach. This package included psychosocial support (mental health and counseling services), patient education, adherence support, infection control measures, monthly laboratory and clinical monitoring, patient follow-up, TB contact investigation, and Tuberculosis Preventive Therapy (TPT). Patients received pill boxes, cell phones for receiving SMS reminder and a monthly transport allowance of 540 meticais (~USD 8.4). All DR-TB patients were assigned CHCW to support treatment adherence, early detection of adverse drug reactions, and sample referrals for follow-ups tests. Healthcare providers at DR-TB sites were trained to provide individualized treatment plans that addressed the specific needs of each patient, including co-morbidities like HIV and diabetes and adjust the treatments according to the drug resistance profile.
Results/Impact: A total of 2,358 DR-TB patients were notified under the project. Of these, 51% (1198/2358) were female,10% (236/2358) were children under of 15 years old and 23% (542/2358) were HIV-positive. Treatment success increased from 51% (120/236) in 2019 to 82% (384/468) in 2024. The mortality rate decreased from 14% (32/236) in 2019 to 9% (43/468) in 2024.
Conclusions: The implementation of a patient-centered care package, combined with appropriate DR-TB treatment, significantly improved treatment outcomes. These strategies have been shown to enhance treatment adherence, improve outcomes in low-middle-income settings.

EP61-1282-21 Coach Mpilo: Men supporting men through TB and HIV treatment journeys in South Africa

K. Rutt,[1] A. Medina-Marino,[2] Z. Mhaleni,[3] M. Fosi,[3] L. de Vos,[4] K. Gala,[2] T. Njama,[2] J. Daniels,[5] [1]University of California Los Angeles, David Geffen School of Medicine, East London, South Africa, [2]Desmond Tutu Health Foundation, Eastern Cape, East London, South Africa, [3]Desmond Tutu Health Foundation, Eastern Cape, Mthatha, South Africa, [4]Desmond Tutu Health Foundation, Western Cape, Cape Town, South Africa, [5]Arizona State University, Edson College of Nursing and Health Innovation, Phoenix, United States of America
e-mail: kellyruttg@gmail.com

Background: The Coach Mpilo (CM) program, developed in South Africa, utilizes peer counselors (coaches) to support men's (players') journey in TB, TB/HIV, and HIV treatment. This study explored the experiences and perspectives of CM coaches to understand their successes and challenges and identify areas for improvement.
Design/Methods: We conducted a two-phased study with (n=20) coaches +18 years who were active in the program within the last three years. In phase one, we conducted interviews to understand coach self-efficacy, training application, challenges, masculinity, and personal transformation. In phase two, we used interview findings to guide a photovoice project with focus group discussions with coaches (n=10). Coaches used photography combined with narrative to document and reflect on their roles.
The analysis of the photovoice followed a four-part process: preview, review, cross-photo comparison, and theorizing. The transcripts and accompanying narratives were analyzed thematically.
Results: Coaches reported significant positive impacts on players' treatment adherence and well-being. Primary coach strategies with players included TB & HIV knowledge sharing, building trust, providing composed emotional support, motivating, and addressing stigma. Coaches leveraged personal experiences with TB/HIV and CM training concepts to create bonds with players.
Challenges included managing emotional boundaries, being unable to resolve resource scarcity for players, addressing health misconceptions, and collaborating with healthcare staff.
Coaches experienced personal growth, improved communication skills, and enhanced empathy. The program positively influenced coaches' perspectives on masculinity and related health-seeking behaviors.
Conclusions: The CM program demonstrates promise in improving TB and HIV treatment adherence through peer support. Coach and player shared experiences and cultural understanding contribute to program effectiveness. Future improvements should focus on providing emotional support to coaches, enhancing collaboration skills with healthcare staff, and addressing the impact of resource scarcity on treatment adherence. CM impact extends beyond players, positively transforming coaches and potentially influencing community attitudes toward TB/HIV treatment.

EP61-1283-21 Cash or calories: Preferences for nutritional support among persons with TB in South India

S.B. Cowan,[1] P. Babu Narasimhan,[2,3] M.R. Dauphinais,[1] K. Jain,[4] S. Prakash Babu,[4] C. Cintron,[1] L.L. Sabin,[5] S.K. Heysell,[6] L. Locks,[7,5] S. Mehta,[3,8,9,10] S. Lakshminarayanan,[4] P. Sinha,[1,11] [1]Boston Medical Center, Infectious Disease, Boston, United States of America, [2]MGMARI, Sri Balaji Vidyapeeth (Deemed to-be University), Clinical Immunology, Puducherry, India, [3]Cornell University, Cornell Joan Klein Jacobs Center for Precision Nutrition and Health, Ithaca, United States of America, [4]Jawaharlal Institute of Postgraduate Medical Education and Research, Department of Preventive and Social Medicine, Puducherry, India, [5]Boston University School of Public Health, Global Health, Boston, United States of America, [6]University of Virginia, Division of Infectious Diseases and International Health, Charlottesville, United States of America, [7]Boston University Sargent College of Health & Rehabilitation Sciences, Department of Health Sciences, Boston, United States of America, [8]St John's Research Institute, Infectious Disease, Indiabengaluru, India, [9]Cornell University, Program in International Nutrition, Division of Nutritional Sciences, Ithaca, United States of America, [10]Weill Cornell Medicine, Division of Epidemiology, Department of Population Health Sciences, New York, United States of America, [11]Boston University School of Medicine, Section of Infectious Diseases, Department of Medicine, Boston, United States of America
e-mail: sadie.cowan@fulbrightmail.org

Background: Undernutrition is a leading cause for Tuberculosis (TB) incidence in India, with some regions attributing nutrition to two-thirds of TB cases. Addressing food security can improve outcomes for people with tuberculosis (PWTB), but elimination efforts either overlook needs or face operational challenges. As part of the ongoing Learning Effect of Parasites and Reinforcing Diets on TB (TB LEOPARD) prospective cohort study (NCT05048485), we surveyed PWTB in South India about their nutritional needs and favored mechanisms of nutritional support.
Design/Methods: We enrolled adults with newly-diagnosed smear-positive pulmonary TB living in Puducherry and Tamil Nadu, India. 47 structured interviews explored PWTB's preferences for National Tuberculosis Elimination Programme (NTEP) support. We used descriptive statistics to understand average monetary requests and nutritional needs.
Results: Study participants preferred cash transfers to food baskets and other forms of nutritional support, when considered individually, but when considering cash

transfers compared to all types of nutritional support (including food baskets, ready to use foods, and prepared foods), participants appeared evenly divided as per their first choice (48.9% vs. 51.1%). Participants' responses also indicated that, if they were to receive monthly direct benefit transfers, approximately ₹2,000 per month would be their preference.

None of the participants, all interviewed two weeks after diagnosis, had received direct benefit transfer payments as part of the Nikshay Poshan Yojana, a social protection program that provides all Indian PWTB with cash transfers to defray food costs.

Conclusions: Our survey revealed that cash transfers were preferable to in-kind support. Our assessment demonstrates that while existing NTEP interventions are addressing the needs of PWTB, gaps remain in implementation. Going forward, a human-centered approach is necessary to address the operational challenges of the current structure.

Nutritional Support Options	Overall Frequency	Proportion of Participants' 1st Preference
Cash Transfer	2.40	48.9%
Food Basket	2.63	29.8%
Ready To Use Foods	2.85	12.8%
Vouchers (to purchase food)	2.89	8.5%
Prepared Foods	4.21	8.5%

Figure 1. Participants ranked the displayed forms of nutritional support on a scale of 1 to 5, with 1 being the most preferable option.

EP61-1284-21 Harnessing the power of private providers: Scaling up TB notification in Niger State

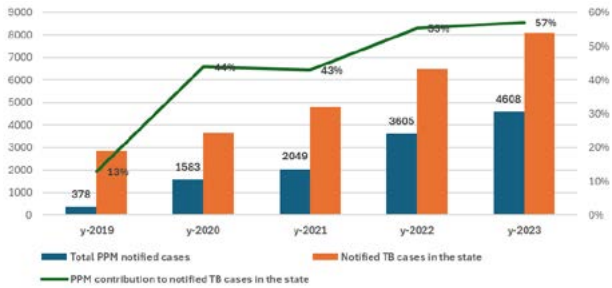
D. Philip,[1] I. Isah,[1] K. Ojobor,[2] D. Hananiya,[3] O. Chijioke-Akaniro,[4] O. Olarewaju,[4] [1]Niger State TB, Leprosy & Buruli Ulcer Control Program, Programs, Minna, Nigeria, [2]Project HOPE Nigeria, Programs, Minna, Nigeria, [3]World Health Organization, TB, Leprosy Programs, Minna, Nigeria, [4]NTBLCP Nigeria, M & E, FCT, Nigeria
e-mail: dphilip2007@gmail.com

Background and challenges to implementation: In Nigeria, approximately 60% of the population first seek healthcare from private providers, making the private sector a critical entry point for tuberculosis (TB) detection. Despite this, engagement of private providers in TB control has historically been suboptimal. In 2019, Niger State recorded only 13% of its TB case notifications through the Public-Private Mix (PPM) approach.

This abstract evaluates the impact of targeted PPM interventions and highlights the shift in private sector engagement between 2019 and 2023.

Intervention or response: A situation analysis, including a SWOT assessment, was conducted to determine the proportional contribution of PPM and identify operational gaps. Private health facilities were mapped and engaged using a hub-and-spoke model. Entry meetings were held with the Association of General Medical Practitioners of Nigeria (AGMPN) and Patent Medicine Vendors (PMVs) to foster collaboration. Capacity-building training was provided, and NTBLCP recording and reporting tools were distributed. Linkage Coordinators were trained and deployed to support referrals, documentation, and follow-up. Incentives were introduced based on national guidelines. PPM contributions were tracked quarterly using standardized NTBLCP tools.

Results/Impact: TB treatment coverage increased from 22% (2865 persons notified with TB) in 2019 to 64%(10,405 persons with TB notified) in 2024. PPM contribution to total TB case notification in Niger State increased from 13% in 2019 to 57% in 2023. The number of TB cases notified by PPM facilities rose from 378 in 2019 to 4,608 in 2023, representing over a 1100% increase. This trend corresponded with a consistent rise in the state's overall TB case notifications. Key enablers included improved private sector engagement, deployment of screening officers, use of incentives, and strengthened linkage systems.

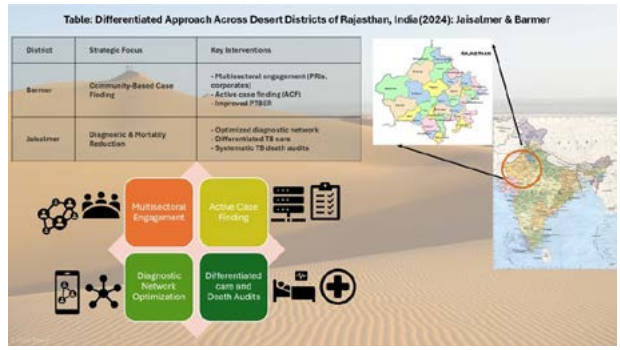


Conclusions: PPM interventions significantly improved TB case finding in Niger State. This approach demonstrates a scalable model for enhancing TB detection through strategic private sector engagement.

EP61-1285-21 TB-Free Desert Initiative in Rajasthan: A multi-sectoral and diagnostic network optimisation approach in the Thar region

P. Soni,[1] T. Patni,[2] R. Gupta,[3] A.K. Bhatt,[4] S. Rajvanshi,[5] P. Dhutraj,[3] S. Gupta,[3] A. Sharma,[3] A. Bhardwaj,[6] S. Chandra,[3] U. Singh,[7] [1]Directorate of Health and Family Welfare, Government of Rajasthan, Department of Health and Family Welfare, Government of Rajasthan, Jaipur, India, [2]Kamla Nehru State TB Training and Demonstration Centre, Ajmer, Rajasthan, Department of Health and Family Welfare, Government of Rajasthan, Ajmer, India, [3]Government of India-WHO Country Office for India, TB Technical Support Network, National TB Elimination Program, New Delhi, India, [4]Directorate of Health and Family Welfare, Government of Rajasthan, Department of Health and Family Welfare, Government of Rajasthan, Barmer, India, [5]Directorate of Health and Family Welfare, Government of Rajasthan, Department of Health and Family Welfare, Government of Rajasthan, Jaisalmer, India, [6]Maharishi Makandeshwar Medical College & Hospital, Kamarhati, Community Medicine, Solan, India, [7]Ministry of Health & Family Welfare, Govt. of India, Central TB Division, Delhi, India
e-mail: guptash@rntcp.org

Background and challenges to implementation: The Thar Desert (one of the largest hot sub-tropical deserts) in Rajasthan, India, face unique challenges due to region specific challenges, arid geography, and limited healthcare access. The TB-Free Desert Initiative aims to strengthen TB elimination through a multisectoral and diagnostic network optimization approach, evaluating its impact on case detection, diagnostic efficiency, mortality reduction, and the effectiveness of community-led advocacy and engagement in two desert districts of Rajasthan.
Intervention or response: In 2024, a differentiated approach was implemented across the two intervention districts. Barmer focused on active case finding through multisectoral engagement, while Jaisalmer prioritized diagnostic optimization and mortality reduction.
Data were extracted from *Ni-kshay*, (India's digital TB surveillance system), and analyzed using Microsoft Excel and R version 4.2.3. Key indicators assessed included Presumptive TB Examination Rate (PTBER), number needed to test (NNT), TB mortality, and progress in achieving TB-Free status based on a predefined six-point evaluation framework.
Results/Impact: From 2023 to 2024, Barmer recorded a 43% increase in PTBER and an 80% improvement in NNT; Jaisalmer saw a 20% rise in PTBER and 60% NNT improvement.
Notification rates declined by 4% in Barmer, indicating saturation of case finding, and rose by 8% in Jaisalmer due to better diagnostic access. TB mortality in Jaisalmer reduced from 5% to 4%, aided by optimized diagnostics and targeted care. These outcomes reflect the impact of tailored, district-specific strategies. Barmer achieved 31.5% and Jaisalmer 28.6% TB-Free Gram Panchayat certification underscoring the effectiveness of community-led governance in remote desert regions.



Conclusions: The TB-Free Desert Initiative demonstrates that governance-led, context-specific strategies can improve TB detection and reduce mortality in hard-to-reach desert regions. With proven diagnostic efficiency and community-driven action, the model offers a scalable path toward TB elimination in India's most challenging geographies.

EP61-1286-21 Current realities: Benefits of a diversified project portfolio and adaptive implementation for programme resiliency

M. Bajehson,[1] M. Tukur,[1] H. Baffa,[1] F. Babayo,[1] S. Kopa,[2] I. Umar,[2] A. Labaran,[3] S. Useni,[4] O. Chukwuogo,[4] B. Odume,[4] [1]KNCV Nigeria, Program, Kano, Nigeria, [2]Kano State Ministry of Health, Department of Public health, Kano, Nigeria, [3]Kano State Ministry of Health, Admin, Kano, Nigeria, [4]KNCV Nigeria, Program, Abuja, Nigeria
e-mail: mbajehson@kncvnigeria.org

Background and challenges to implementation: The January 20th executive order reverberated globally for donor funded programs. Nigeria with a Tuberculosis (TB) funding gap of 60%, has International funding accounting for 35% of the national TB budget. Kano state, the second most populous in Nigeria is supported for TB program implementation by KNCV Nigeria via two clearly demarcated grants for TB, funded by USAID and the Global Fund (GF) respectively. We share strategies, results and lessons learnt during the first quarter of 2025.
Intervention or response: USAID funded grant portfolio is more robust, supporting TB services across public and private facilities, having community components ensuring outreaches and contact investigation. The GF grant portfolio supports only community TB and Public private mix activities.
Emergency planning meeting was held between the two project teams and stakeholders. Mapping of public and private sector high burden facilities with communities that would be devoid of USAID funded support was

done. Transitioning to GF funded TB program support was facilitated where possible, or hub-spoke linkages established.
Monthly TB patient notification data was analysed from December 2024 to February 2025.
Results/Impact: In December, both programs cumulatively evaluated 26,091 persons found presumptive for TB (14% from GF funded arm) with 1,796 persons diagnosed with TB (11% from GF funded arm). In January, GF funded arm accounted for 30% and 27% of evaluated persons presumptive for TB and persons diagnosed with TB, respectively.
With solitary GF funded implementation In February, 15,542 persons were evaluated for TB (41% drop from average) of which 1,189 persons (36% drop from average) were diagnosed with TB.
Conclusions: Programs over dependent on external funding face dire consequences post executive order. Having a diversified funding portfolio is beneficial, enabling strategic program pivot at crucial times. This period provides a window for revamped domestic stakeholder engagement towards closing the funding gap and ensuring self reliance.

EP61-1287-21 Harnessing rural governance for TB elimination: Findings from a multi-tiered approach to achieving TB-free status in rural India

B. Singh,[1] M. Deka,[2] R. Rao,[1] S. Manjhi,[2] U. Singh,[1]
[1]Central TB Division, Ministry of Health and Family Welfare, Government of India, National TB Elimination Programme, New Delhi, India, [2]Government of India - WHO Country Office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India
e-mail: manjhis@rntcp.org

Background and challenges to implementation: Eliminating tuberculosis (TB) in India entails targeted action in rural regions, which account for 58% of TB cases and 68% of the population. Collaboration with rural governance structures is vital, as seen during India's polio elimination efforts. A multi-tiered collaborative approach was adopted spanning National to the community level through active engagement with Gram Panchayats (GPs), the foundational units of rural local self-governance.
This initiative institutionalized a structured mechanism for embedding TB elimination agenda in their curriculum to make 2.65 lakhs GPs TB free. A nationwide assessment was conducted in 2024 & 2025 to evaluate TB free status across GPs, guided by key programmatic indicators.
Intervention or response: MoHFW and MoPR signed an MoU to pursue TB-free Panchayats, backed by a joint action plan and directives for state, district, and sub-district authorities. Training were conducted for rural officials on TB prevention, management, and the TB-free GP initiative, aiming for a coordinated action. A National Scientific Committee developed a standardized methodology based on six indicators, with trained teams conducting field assessments to validate TB-free status. Segregated data from calendar years 2023 & 2024 were analysed to assess GPs TB free status.
Results/Impact: Of 2.65 lakhs GPs, 21,973 for 2023 and 50137 for 2024 were eligible for TB free status which further underwent verification. Post-verification, 18281 GPs were declared TB-free in 2023 and 46,118 GPs in 2024. Notably, 9,539 GPs maintained TB-free status for two consecutive years. States with higher presumptive examination and over 90% notification targets achievement in 2023 and 2024 had significantly more TB-free GPs ($p<0.05$), indicating strong programmatic impact.
Conclusions: The assessment signifies a whole-of-Government and community-centered approach towards TB elimination, leveraging rural governance structures. By fostering ownership at the grassroot level, the initiative holds significant promise in accelerating TB burden reduction and advancing TB elimination goals in rural India.

EP61-1288-21 Enhancing TB case-holding through effective pre-treatment and continuous counselling in Delta State, Nigeria

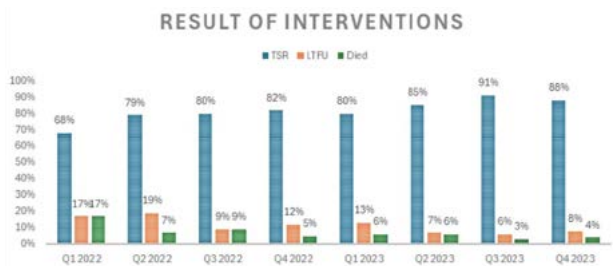
C. Ezeanya,[1] C. Osakwe,[1] M. Bathnna,[2] T. Adetiba,[1] O. Olupitan,[1] A. Agbaje,[3] C. Mensah,[4] P. Dakum,[3] O. Chijioke- Akaniro,[5] E. Ubochioma,[5] J. Ssekitooleko,[6] M. Zamzu,[6] Global Fund NTHRIP Team [1]Institute of Human Virology Nigeria (IHVN), Program Coordinating Unit (PCU), GF-NTHRIP, Abuja, Nigeria, [2]Institute of Human Virology Nigeria (IHVN), International Research Centre for Excellence, Abuja, Nigeria, [3]Institute of Human Virology Nigeria (IHVN), Office of the CEO, Abuja, Nigeria, [4]Institute of Human Virology Nigeria (IHVN), Office of the COO, Abuja, Nigeria, [5]National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Public Health Department, Abuja, Nigeria, [6]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Nigerian Country Team, Geneva, Switzerland
e-mail: cezeanya@ihvnigeria.org

Background and challenges to implementation: Case holding remains a persistent challenge in tuberculosis (TB) control, with pre-treatment loss to follow-up (LTFU) and poor adherence contributing to suboptimal treatment outcomes. Structured counseling has been shown to improve treatment initiation, adherence, and success. This study evaluates the effectiveness of targeted counseling interventions on case-holding and treatment outcomes among TB patients in Delta State, Nigeria.
Intervention or response: Following a baseline assessment of healthcare workers' knowledge and skills, a capacity-building initiative was implemented targeting linkage coordinators and Directly Observed Treatment

(DOT) officers. Training was delivered virtually and reinforced through mentorship during supervisory visits. Interventions included enhanced pre-treatment and ongoing counseling, facilitated patient linkage to nearby treatment centers, and medication home delivery for select patients.

Strengthened collaboration with hospital-based and standalone laboratories improved acid-fast bacilli (AFB) monitoring, while TB/HIV co-infected patients were promptly initiated on antiretroviral therapy (ART). Monthly line lists supported systematic follow-up of patients due for AFB testing. Defaulters were tracked via phone calls and home visits to ensure adherence.

Results/Impact: The results of the intervention showed TSR was 68% in Q1 2022 and increased to 79% in Q2 2022 and 80% and 82%, respectively in Q3 & Q4 2022. In 2023, TSR dropped to 80% in Q1 2023 due to the resignation of the linkage coordinators, and new ones were recruited, but it increased to 85% in Q2 2023, 91% in Q3 2023, and 88% in Q4 2023, with a corresponding drop in LTFU and death rates.



Conclusions: Structured counseling interventions and active follow-up significantly enhance TB treatment outcomes. Strengthening case-holding at the point of diagnosis through skilled counseling, adherence support, and timely tracking—can reduce LTFU, minimize TB transmission, and improve survival.

Sustained investment in human resources and patient-centered care strategies remains essential to achieving national TB control targets.

EP62 M. tuberculosis infection and preventive treatment

EP62-1289-21 High TB infection rates in two rural districts of Ethiopia: Implications for enhanced TB preventive treatment

O. Ali,[1] L. Wassie,[2] S.A. Abebe,[3] E.A. Abelti,[4] Y. Molla,[5] A. Gebreyohanes,[4] Z.G. Dememew,[6] D. Jerene,[7] D.G. Datiko,[5] K. Johnson,[8] C. Welch,[9] S. Konopka,[9,10] [1]KNCV Tuberculosis Foundation, Monitoring, Evaluation and Research, Addis Ababa, Ethiopia, [2]Armauer Hansen Research Institute, Mycobacterium unit, Addis Ababa, Ethiopia, [3]Management Sciences for Health, Data Management, Addis Ababa, Ethiopia, [4]KNCV Tuberculosis Foundation, Eliminate TB, Addis Ababa, Ethiopia, [5]Management Sciences for Health, Eliminate TB, Addis Ababa, Ethiopia, [6]Management Sciences for Health, Monitoring, Evaluation and Research, Addis Ababa, Ethiopia, [7]KNCV Tuberculosis Foundation, Epidemiology, Amsterdam, Netherlands, [8]Management Sciences for Health, Monitoring, Evaluation , Research and Learning, Arlington, United States of America, [9]Management Sciences for Health, Eliminate TB, Arlington, United States of America, [10]Management Sciences for Health, Infectious disease, Arlington, United States of America
e-mail: oumer.ali@kncvtbc.org

Background: Understanding tuberculosis (TB) infection (TBI) rates is important for designing and implementing TB elimination strategies. However, there is limited empirical data on community-based TB infection (TBI). Our aim was to determine the prevalence of TBI among predominantly agrarian communities in two regions of Ethiopia.

Design/Methods: Between December 2023 and March 2024, we conducted community-based cross-sectional surveys in two rural districts, one each in Oromia and South Ethiopia regions. The districts were selected based on their high TB notification rates from routine reports. Using a multi-stage sampling method, sub-districts were randomly selected and within each sub-district sample size was allocated proportionally. We then collected blood samples from randomly selected participants using QuantiFERON blood collection tubes. *Mycobacterium tuberculosis* antigens-specific IFN-γ responses were measured from overnight stimulated whole blood samples using QFT-TB Gold Plus ELISA Kit, following the manufacturer's instruction.

Then the result was interpreted qualitatively as IGRA positive or negative. Multivariable logistic regression was used to determine factors associated with the outcome variable.

Results: Of the 1,052 study participants enrolled to the study 54.9% were females, and 42.9% were 25 to 44 years of age with the median age of 35 years. The overall prevalence of TBI was 46.8% (95% CI: 43.8%, 49.9 %). The odds of having TBI were higher among individuals living in the

district from Oromia versus South Ethiopia (AOR = *1.60 (1.24-2.08*; p < 0.001), in those aged 25-44 (AOR = 1.60 (1.15-2.23; p = 0.005), and in those who were overweight versus normal (AOR = 1.42(1.04-1.95; p = 0.03). TBI rates did not differ by sex.

Conclusions: Our results confirm high TBI rates in two Ethiopian agrarian communities as compared to the global rate of 24.8%, underscoring the need for enhancing availability and access to community wide screening and provision of TB preventive treatment.

EP62-1290-21 Prevalence of TB infection among household contacts aged 18 years and above of persons with pulmonary TB: A secondary analysis of Cy-TB test data from West Bengal, India

A. Dey,[1] B. Sengupta,[1] S.K. Roy,[2] U.B. Singh,[3] S. Chandra,[1] D. Deka,[1] T.K. Saha,[2] B. Chaklader,[1]
[1]Government of India-WHO Country office for India-Technical Support Network, National TB Elimination Program, New Delhi, India, [2]Government of West Bengal, Department of Health and Family Welfare, Kolkata, India, [3]Government of India, Department of Health and Family Welfare, New Delhi, India
e-mail: chakladerb@rntcp.org

Background: The National TB Prevalence Survey in India (2019-2021) estimated a Tuberculosis Infection (TBI) prevalence of 21.7% in individuals aged 15 years and older. The prevalence rate among the household contacts of pulmonary TB is higher. A recent study reported that 71% HHCs in India are TBI positive. Based on this evidence the national guidelines suggested to treat HHC of pulmonary TB as TBI with (Test & Treat policy) or without (Treat only policy) confirming the TBI. Till early 2024 the state of West Bengal followed the treat only policy.

After availability of the novel TBI tests know as Cy-TB the state adopted test & treat policy. Anecdotal evidence suggested that TBI positivity in the state might be lower than the estimates reported by studies elsewhere.

The study aimed to estimate the prevalence of TBI among different demographic group as well as the factors associated with TBI, if any.

Design/Methods: This is an observational study. A secondary analysis was done on the Cy-TB data of West Bengal.

Results:

- Overall TBI prevalence among above 18yrs old HHC of pulmonary TB was 14.7% (95% CI 13.5%-15.9%).
- TBI prevalence among adults (18-59yrs) was 14.9% whereas among elderly (60yrs or above) it was 13.5%.
- The TBI prevalence among male, female & transgender was 13.3%, 15.7% and 16.7% respectively.

No significant socio-demographic association was found with of TBI **(Fig-1)**

Fig- 1: Prevalence of TB infection (TBI) among above 18 yrs household contacts of person with pulmonary TB and the correlation with the sociodemographic factors during January to December 2024 in West Bengal, India n= 3583, n1= 3056, n2= 527 [N= n1+n2]

Sociodemographic parameters	Total N (%*)	TBI negative n1 (%#)	TBI positive n2 (%#)	p-value
Age group				
Adult (18-59 yrs)	3175 (88.6)	2703 (85.1)	472 (14.9)	0.457
Elderly (60 yrs & above)	408 (11.4)	353 (86.5)	55 (13.5)	
Gender				
Male	1451 (40.5)	1258 (86.7)	193 (13.3)	0.146
Female	2126 (59.3)	1793 (84.3)	333 (15.7)	
Transgender	6 (0.2)	5 (83.3)	1 (16.7)	
Comorbidity Status				
No comorbidity	3576 (99.8)	3051 (85.3)	525 (14.7)	0.300
Had comorbidity (HIV &/Diabetes)	7 (0.2)	5 (71.4)	2 (28.6)	

Notes: * column percentage (within the category); # Row percentage; Proportions & p-Value calculated with Chi square test.

Conclusions: TBI positivity in the state is lower than the estimates mentioned in the national guidelines. No risk factor was identified for the TBI positivity. Larger & robust studies may be conducted to confirm lower TBI prevalence in West Bengal.

EP62-1291-21 TB infections among rifampicin-resistant TB household contacts: A multi-central prospective cohort study (TCCT study)

F. Zhou,[1] Y. Lan,[2] Q. Yang,[1] W. Zhang,[1] Q. Ruan,
[1]TCCT study group [1]Huashan Hospital, Fudan University, National Medical Center for Infectious Diseases, Shanghai, China, [2]Zunyi Medical University Affiliated Hospital, Department of Respiratory and Critical Care Medicine, Zunyi, China
e-mail: qlyang10@fudan.edu.cn

Background: Rifampicin-resistant tuberculosis (RR-TB) caused heavy burden on its patients and families. Aimed to prevent further transmission of RR-TB among families, this study monitored incidence and analyzed risk factors of tuberculosis infection of RR-TB household contact persons.

Design/Methods: This multi-central prospective cohort study (TCCT study, ClinicalTrials.gov: NCT04484129) recruited RR-TB close contact people with inclusion criteria as staying in the same house with index patients for more than 6 hours per week in 2 weeks preceding TB diagnosis. Interferon-gamma release assay (IGRA) or tuberculin skin test (TST) were implemented for tuberculosis infection (TBI) diagnosis. Sputum smear, culture, Xpert MTB/RIF and chest computed tomography (CT) examination were conducted for active TB (ATB) diagnosis. Generalized linear mixed models (GLMM) were established for infection risk factors analysis. All contact people would have an 18-month following-up observation of ATB development.

Results: Since May 2021, 435 RR-TB close contact people were enrolled. 219 were diagnosed with TB infections while 7 developed ATB (1 as RR-TB), with a TBI rate of 50.34% and ATB incidence of 1.35 per 100 person-years. The median time from index case RR-TB diagnosis to contact person ATB diagnosis was 57.5 days.

GLMM analysis showed male gender (*OR*=1.73, *95% CI* 1.03-2.91, *P*=0.038), low education level (*OR*=4.14, *95% CI* 1.40-12.26, *P*=0.033), abnormal chest CT (*OR*=2.01, *95% CI* 1.13-3.59, *P*=0.018), index patients with bilateral lung lesions (*OR*=3.42, *95% CI* 1.21-9.65, *P*=0.020) and positive sputum smear (*OR*=3.92, *95% CI* 1.42-10.85, *P*=0.023) increased TB infection risk.

Risk factors of TB infection among RR-TB close contact people.

Risk Factors	*Odds ratio (95% CI)*	*P* value
Contact Person Factors		
Male gender	1.73 (1.03-2.91)	0.038
Low education level		
(secondary education vs college degree or above)	2.33 (1.06-5.10)	0.033
(primary education vs college degree or above)	3.45 (1.42-8.39)	
(illiterate vs college degree or above)	4.14 (1.40-12.26)	
Abnormal chest CT	2.01 (1.13-3.59)	0.018
Index Case Factors		
Bilateral lung lesions vs unilateral lung lesions	3.42 (1.21-9.65)	0.020
Smear positive (1+ vs negative)	3.10 (1.23-7.78)	0.023
(2+ vs negative)	3.92 (1.42-10.85)	
(3+ vs negative)	3.29 (1.01-10.74)	
(4+ vs negative)	1.52 (0.53-4.32)	

Conclusions: RR-TB contact people had a high TB infection rate and developed ATB mostly within 3 months from index patient diagnosis. This study found TB infection risk factors for close contact people including male gender, low education level, abnormal chest CT, index patients with bilateral lung lesions and positive sputum smear, providing further preventive suggestions for RR-TB close contact people.

EP62-1292-21 Evaluation of TB infection prevention and control measures in China's designated medical institutions: A comparative analysis of 2014 and 2022

L. Zhang,[1] Y. Liu,[1] L. Li,[1] [1]Beijing Chest Hospital Affiliated to Capital Medical University / Beijing Tuberculosis and Thoracic Tumor Research Institute, Clinical center on TB, Beijing, China
e-mail: 88623953@qq.com

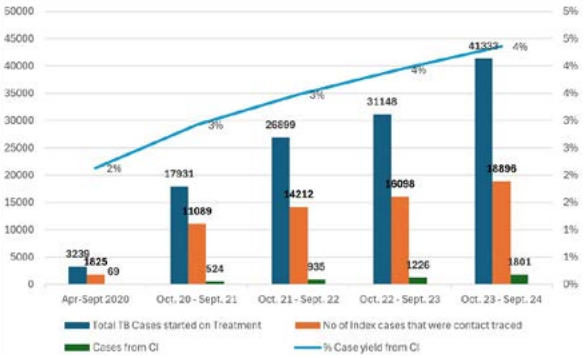
Background: To assess the implementation of tuberculosis (TB) infection prevention and control (TB-IPC) measures in prefecture and higher-level TB-designated medical institutions and provide insights for further improvements.
Design/Methods: This study compared TB-IPC measures in TB-designated medical institutions using data from 2 questionnaire surveys conducted by Clinical Center on TB, Chinese Center for Disease Control and Prevention in 2014 and 2022, and evaluated progress over time.
Results: A total of 47 TB-designated medical institutions were analyzed, including 20 provincial institutions (42.6%) and 27 municipal institutions (57.4%). By 2022, IPC measures had significantly improved, with high consistency observed across regions, institutional levels, and hospital grades. Compared to 2014, 2022 showed significant increases ($P < 0.05$) in the establishment of dedicated pathways for patients and staff, separate wards for smear-positive and smear-negative pulmonary TB patients, dedicated wards for drug-resistant pulmonary TB patients. The use of air purification/filtration increased significantly ($P < 0.001$), with over 90% of institutions adopting natural ventilation and ultraviolet germicidal irradiation. The use of N95 masks by medical staff also increased significantly ($P<0.05$).
Conclusions: Significant improvements were observed in TB-IPC at TB-designated medical institutions in China between 2014 and 2022, and demonstrated rigorous compliance with TB-IPC standards.

EP62-1293-21 Impact of household TB contact investigation on detecting TB: TB-LON 3 project experience

C. Uzoigwe,[1] O. Daniel,[1] A. Agbaje,[2] P. Dakum,[2] L. Shehu,[3] R. Eneogu,[4] M. Pedro,[5] A. Alege,[6] A. Okungbure,[1] [1]Institute of Human Virology Nigeria, Prevention, Care and Treatment, Lagos, Nigeria, [2]Institute of Human Virology Nigeria, Office of the CEO, Abuja, Nigeria, [3]Federal Ministry of Health, Public Health - National Tuberculosis, Leprosy and Buruli Ulcer Control Programme, Abuja, Nigeria, [4]United States Agency for International Development, TB-HIV Office, Abuja, Nigeria, [5]Institute of Human Virology Nigeria, Strategic Information, Lagos, Nigeria, [6]Society for Family Health, TB-HIV, Lagos, Nigeria
e-mail: cuzoigwe@ihvnigeria.org

Background and challenges to implementation: Tuberculosis (TB) remains a major public health concern in Nigeria, ranked 6th among high-burden TB countries. Despite its potential, TB contact investigation (CI) is underutilized. CI plays a crucial role in detecting missed undiagnosed TB cases and curbing transmission, though its implementation faces challenges due to significant TB knowledge gaps and limited resources.
This paper highlights the outcomes of the TB-LON 3 project's CI from April 2020 to September 2024, addressing key implementation challenges and utilizing available resources.
Intervention or response: CI is a strategic method involving the assessment of household or close contacts of TB patients, leading to appropriate treatment for newly diagnosed cases or TB Preventive Treatment (TPT). It is conducted for bacteriologically confirmed TB cases. To overcome implementation challenges, the project adopted a multifaceted approach, including comprehensive training for healthcare workers, adaptation of guidelines & protocols, and community engagement to boost awareness and involvement. TB-LON 3 project is implemented across Lagos, Ogun, Osun, and Oyo states in Southwest Nigeria.

Results/Impact: Between April 2020 and September 2024, 127,204 TB cases were diagnosed, with 120,550 initiated on treatment. Of these, 102,373 were bacteriologically confirmed, and 62,120 had their contacts traced.
Among 266,008 contacts identified, 265,749 were screened, yielding 4,555 TB cases (4,121 bacteriologically confirmed) and 4,380 began treatment consisting of 2,091 females and 2,289 males. CI cases rose from 69 in 2020 to 1,801 in 2024—a 2,600% increase—now contributing over 4% of all TB cases, despite tracing about 50% of index cases.
Additionally, 197,043 contacts were eligible for TPT, with 33% enrolled. Without CI, many cases would remain undiagnosed or detected late, increasing community spread.



Conclusions: CI remains a valuable yet underused strategy for TB detection in Nigeria. Addressing implementation barriers and optimizing resources can enhance early diagnosis and care, ultimately lowering TB-related illness and death. Programs should prioritize CI funding.

EP62-1294-21 Revisiting index contact households: Evidence for structured repeat testing among TB contacts in Khana LGA, Rivers state Nigeria

E. Ade,[1] B. Ukwuoma,[1] B. Nwaogu,[2] Q. Ogbuji,[2] T. Adetiba,[3] A. Adekunle,[4] E. Ubochioma,[5] O. Akaniro,[5] J. Ssekitoleko,[6] J. Kimeu,[7] T. Adoki,[8] D. Wikere,[8] [1]Association for Reproductive and Family Health (ARFH), GF TB/HIV Project, Port Harcourt, Nigeria, [2]Association for Reproductive and Family Health (ARFH), The GF N-THRIP Project, Abuja, Nigeria, [3]Institute of Human Virology Nigeria, The GF N-THRIP Project, Abuja, Nigeria, [4]Institute of Human Virology Nigeria, The GF N-THRIP Project, Port Harcourt, Nigeria, [5]National TB and Leprosy and Buruli Ulcer Control Programme Nigeria , GF PMU, Abuja, Nigeria, [6]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, PHME Specialist TB, Switzerland, Switzerland, [7]The Global Fund to Fight AIDS, Tuberculosis and Malaria, Global Health Campus, Health Products Management Specialist, Switzerland, Switzerland, [8]Rivers State TB and Leprosy and Buruli Ulcer Control Programme, Rivers State TB and Leprosy and Buruli Ulcer Control Programme, Port Harcourt, Nigeria

Background: Contact tracing is vital in tuberculosis (TB) control, yet a single round of testing may fail to capture cases that manifest later due to reactivation or reinfection. In Khana LGA, Rivers State, Nigeria, emerging TB cases within previously traced households years after initial investigations highlight the limitations of one-time screening, particularly in high-burden, resource-constrained settings.
Design/Methods: A retrospective analysis was conducted using TB registers, household interviews, and case reviews from 2020 to 2025. The study assessed initial contact tracing outcomes, follow-up gaps, and the timing and nature of newly diagnosed TB cases in previously screened households. Outcomes were benchmarked against WHO's evolving guidelines for systematic screening in TB-endemic regions.
Results: Among two index households traced in 2020 and 2022, five new TB cases were diagnosed between 2022 and 2025. Of 40 household contacts initially screened, only 12 (30%) underwent any follow-up before 2025.
Notably, 16 new cases emerged, with 40% identified only after symptom onset. Absence of structured re-screening, symptom normalization, and healthcare access barriers contributed to delayed diagnoses.
Importantly, no digital tracking or scheduled re-evaluations were employed.
Background and challenges to implementation: Contact tracing is vital in tuberculosis (TB) control, yet a single round of testing may fail to capture cases that manifest later due to reactivation or reinfection. A retrospective analysis was conducted using TB registers, household interviews, and case reviews from 2020 to 2025. The study assessed initial contact tracing outcomes, follow-up gaps.

Challenges that may arise can be attributed to lost- to follow up and migration of people from rural areas to urban and vice versa.

Results/Impact: Among two index households traced in 2020 and 2022, five new TB cases were diagnosed between 2022 and 2025. Of 40 household contacts initially screened, only 12 (30%) underwent any follow-up before 2025.

Notably, 16 new cases emerged, with 40% identified only after symptom onset. Absence of structured re-screening, symptom normalization, and healthcare access barriers contributed to delayed diagnoses.

Importantly, no digital tracking or scheduled re-evaluations were employed.

Conclusions: The findings underscore the critical need for repeat testing at 9 and 12 months post-exposure to capture delayed TB onset. This timing aligns with the completion of TB preventive therapy (TPT) and enables early detection among high-risk individuals.

To reduce household transmission and undiagnosed TB burden, national programs must institutionalize structured follow-up protocols, enhance TB awareness, and explore the integration of digital tools for longitudinal contact surveillance.

EP62-1295-21 Finding the missing people with TB through expanded public-private mix (PPM) engagement in Lagos State, Nigeria

V. Okafor,[1] C. Mgbemena,[2] D. Olugbenga,[1] B. Olaniyi,[1] N. Nwosu,[3] A. Agbaje,[4] M. Pedro,[5] C. Mensah,[6] R. Eneogu,[7] O. Sokoya,[8] S. Labaran,[9] P. Dakum,[4] [1]Institute of Human Virology Nigeria, Prevention, Care and Testing, Lagos, Nigeria, [2]Institute of Human Virology Nigeria, Pharmacy, Abuja, Nigeria, [3]Loving gaze, TB Intermediary Organization, Lagos, Nigeria, [4]Institute of Human Virology Nigeria, Office of CEO, Abuja, Nigeria, [5]Institute of Human Virology Nigeria, Strategic Information Unit, Lagos, Nigeria, [6]Institute of Human Virology Nigeria, Office of COO, Abuja, Nigeria, [7]USAID Nigeria, TB/HIV Division, Abuja, Nigeria, [8]Lagos TB, Leprosy and Buruli Ulcer Control Program, Public Health, Lagos, Nigeria, [9]National Tuberculosis, Leprosy and Buruli Ulcer Control, Public Health, Abuja, Nigeria
e-mail: vokafor@ihvnigeria.org

Background and challenges to implementation: Lagos State, one of the most densely populated cities in Nigeria, accounts for approximately 8.4% to 11% of the country's TB burden. The busy city has over 5,000 registered private healthcare facilities. Surveys show that between 50% and 70% of the population (Guy S., Hannah M.D., Madhukar P., 2021) seek healthcare services from private facilities. However, as of 2021, the number of private facilities engaged in TB care in Lagos was still limited compared to the total pool of private healthcare providers. This paper presents how Public-Private Mix (PPM) expansion efforts have helped to find missing TB cases in Lagos State between 2019 to 2024.

Intervention or response: In 2022, the TBLON 3 project, implemented by the Institute of Human Virology Nigeria (IHVN) through the intermediary organization Loving Gaze, expanded the scope of private healthcare facilities engagement and included informal care providers. Advocacy visits and stakeholders' engagement were conducted to reach out to facilities not previously involved in the TB program. On-the-job training was also provided for these facilities. Those not previously part of the TB program, referred to as 'linked facilities,' began referring their samples or cases to Lagos state tuberculosis and leprosy control program (LSTBLCP) facilities (hubs) for evaluation, data entry and treatment.

Results/Impact: Over 130 linked private facilities across 21 LGAs in Lagos state were brought into the TB program. Diagnosed TB cases rose from 3433 in 2019 to 4316 in 2024. The total cases from linked facilities within the period under review was 3659.

S/no	Year	Cases diagnosed from linked facilities	Cases diagnosed from LSTBLCP engaged facilities	Total
1	2019	0	3433	3433
2	2020	0	3113	3113
3	2021	0	3724	3724
4	2022	973	3076	4049
5	2023	1178	3218	4396
6	2024	1508	2808	4316

Conclusions: Private facilities should not be restricted to private hospitals and clinics but should also include patent proprietary medicine vendors, traditional birth attendants, community pharmacies, and standalone laboratories. Therefore, to achieve a high level of commitment to ending TB by 2030 requires scaling up comprehensive strategies to enhance the expansion and collaboration of the PPM network.

EP62-1296-21 Treatment uptake among people with TB infection detected by community-based screening in rural Vietnam

K. Luu,[1] ACT5 Study Team [1]Woolcock Institute of Medical Research, ACF Program, Ho Chi Minh, Viet Nam
e-mail: khanh.luuboi@sydney.edu.au

Background: The primary purpose of testing for, and treating, latent tuberculosis infection (LTBI) is secondary prevention of TB: that is, preventing progression to active TB in those who have been infected. If implemented as a community-wide intervention, it may accelerate progress towards TB elimination. The effectiveness of this intervention is, in part, dependent upon the willingness of people who are diagnosed with LBTI to accept treatment. Evidence from a previous study of mass-screening for latent TB infection found screened individuals complied poorly with preventive therapy, limiting the epidemiological impact of the intervention (1). We sought to establish whether higher levels of acceptance could be achieved in Ca Mau, Vietnam.
Design/Methods: We conducted a household survey of all adults living in 104 randomly selected villages in the rural province of Ca Mau in Vietnam and screened all consenting eligible people (age 5 and above). Those who were TST positive, in whom active TB was excluded, and who had no contraindications to treatment were recommended for treatment with isoniazid and rifapentine once weekly in twelve weeks (3HP). The medication was dispensed weekly by study staff who also used a symptom checklist for early detection of adverse drug reactions.
Results: *Progression from screening to commencing treatment for TBI*

Consented to screening	72, 341
TST Positive	24, 286 (33,6%)
Attended for further assessment	21, 084 (86.7% of those TST +ve)
Excluded (active TB)	224
Recommended to commence treatment for TBI	18, 745 (88.9% of those who complete assessment)
Received first dose of 3HP	13241 (70.6% of those recommended for treatment)
Complete TBI treatment (12 doses)	6321 (47.7% of those took first dose)

Conclusions: Overall, a high proportion of people diagnosed with TBI during community-wide screening commenced treatment for TBI. Failure to attend for further assessment was the major reason for non-commencement of treatment.

EP62-1297-21 Digital health interventions in improving initiation and completion of TB preventive treatment among household contacts: A systematic review and meta-analysis

G. Ayele,[1] M. Dalbo,[2] A. Tunje,[1] T. Belachew,[3] D. Jerene,[4] [1]Arba Minch University, Public Health, Arba Minch, Ethiopia, [2]Arba Minch College of Health Sciences, Midwifery, Arba Minch, Ethiopia, [3]Jimma University, Department of Population and Family Health, Jimma, Ethiopia, [4]KNCV Tuberculosis Foundation, Team lead, Hague, Netherlands
e-mail: ayelegistane@yahoo.com

Background: Tuberculosis preventive treatment is one of the key strategies to reduce TB transmission and disease progression to more advanced states. However, there is limited evidence on the effect of digital interventions on TB preventive treatment completion. Therefore, we aimed to investigate the current literature on the effectiveness of digital interventions in improving tuberculosis preventive treatment initiation and completion.
Design/Methods: A Systematic Review and Meta-analysis were conducted adhering to the Preferred Reporting Items for Systematic Reviews and meta-analysis guidelines. The eligible articles were; fulfilled population, intervention, comparison, and outcome criteria written in the English language starting from 1990, and which were conducted globally sourced from PubMed, Scopus, Cochrane, and Science Direct databases. Data were extracted based on Cochran's data collection recommendations. Two independent reviewers were assessed quality by the revised Cochrane risk of bias tool. Data synthesis and Meta-analysis were performed using Stata version 17. The random effect model was used to assess the effect of intervention as there was significant heterogeneity between the studies.
Results: Of 2214 articles identified 29 were included in full text screening after removing duplicates and irrelevant studies. Finally, 4 articles were included in systematic review and meta-analysis. A total of 1800 participants were included in this study. All studies assessed preventive therapy completion but none of them assessed its initiation. The pooled odds ratio was 0.74(95% CI: 0.43, 1.28) and there is substantial heterogeneity (I^2=66.14%) but had no publication bias (egger test=0.2612).
Conclusions: A limited number of studies explore the effect of digital interventions in improving TPT initiation and completion. The available evidence suggests the potential role of digital interventions in improving TPT initiation and completion when directly observed therapy was not feasible. This highlights the need for further studies of digital interventions to improve TPT initiation and completion rates.

EP62-1298-21 Strengthening TB diagnosis and preventive treatment from a global and Bangladesh perspective following UNHLM commitments

M.S. Alam,[1] P. Daru,[1] P.K. Modak,[1] M.M.-U. Alam,[2] J. Faruque,[2] PT-TEAM (Mostafizur Rahman, Md Shahadat Hossain) [1]Independent Public Health Consultant, Public Health and Development Sector, Dhaka, Bangladesh, [2]Public Health Consultant, Public Health and Development Sector, Dhaka, Bangladesh
e-mail: shamsher367@gmail.com

Background and challenges to implementation: Tuberculosis (TB) remains a major global health threat, responsible for approximately 1.25 million deaths annually, with low- and middle-income countries (LMICs) bearing the highest burden. A particularly vulnerable group includes household contacts of TB patients, especially children under five, among whom infection rates can reach 72% in high-burden settings.
A critical barrier to TB elimination is the management of tuberculosis infection (TBI)—a latent and asymptomatic condition affecting around 1.7 billion people worldwide. Without treatment, 5–10% of individuals with TBI may progress to active TB, making effective screening and timely tuberculosis preventive treatment (TPT) essential. Despite WHO guidelines, progress has been slow, with challenges such as limited diagnostic infrastructure, resource constraints, and disruptions from the COVID-19 pandemic impeding implementation.
Intervention or response: This study assessed the global and Bangladesh-specific progress toward TPT scale-up using secondary data from WHO and United Nations High-Level Meetings (UNHLM) on TB (2018 and 2023). It also reviewed innovative diagnostic tools, including Cy-Tb, a novel test piloted in Bangladesh by icddr,b, for their applicability in LMIC contexts.
Results/Impact: Globally, only 10% of the TPT target for household contacts was achieved by 2022. In Bangladesh, the National Tuberculosis Program (NTP) reached just 37% of its target, initiating TPT in 437,000 of 1.17 million identified contacts between 2018 and 2023. The gap underscores the pressing need for scalable, affordable, and accurate TBI diagnostic tools and better integration of TPT into routine health services.
Conclusions: To meet the 2023 UNHLM target of enrolling 30 million household contacts by 2027, countries like Bangladesh must accelerate TPT scale-up through enhanced surveillance, innovative diagnostics, and policy alignment. Sustained investment, operational research, and multi-sectoral collaboration are pivotal to achieving TB elimination goals by 2030.

EP63 TB uncovered: Advocacy and awareness in action

EP63-1299-21 Empowering mothers of children living with HIV to promote TB preventive therapy: A community-based approach in high-burden districts of Sindh, Pakistan

S. Sharaf Ali Shah,[1] W. Khattak,[2] [1]Bridge Consultants Foundation, Public Health, Karachi, Pakistan, [2]Bridge Consultants Foundation, Project Management, Karachi, Pakistan
e-mail: bridgeresearch_k@yahoo.com

Background and challenges to implementation: In Sindh province, Pakistan, HIV outbreaks in four high-burden districts exposed over 1,500 individuals, including a significant number of women and children, to co-infection risks. These communities face multiple layers of vulnerability, including poverty, low literacy, stigma, and limited access to healthcare services. Despite the known benefits of TB preventive therapy (TPT), particularly for children living with HIV, awareness and uptake of Isoniazid Preventive Therapy (INH) remained critically low. Social taboos, poor health-seeking behaviours, and lack of gender-responsive programming further hindered access to integrated TB-HIV care.
Intervention or response: Bridge Consultants Foundation (BCF) launched a project titled *„Fostering Participation and Empowerment of Women and Girls in TB Initiatives"* to strengthen community engagement and improve access to TB services through a gender-focused lens. One core activity involved the formation and training of support groups comprised of mothers and fathers of HIV-positive children. These groups were capacitated to understand the risks of TB, the benefits of TPT, and the importance of regular screening.
Special emphasis was placed on empowering mothers to take the lead in ensuring their children's TB-related healthcare needs were met.
Results/Impact: Support groups trained under the project actively mobilized over 600 HIV-affected families, leading to increased referrals for TB screening and a threefold rise in IPT uptake among children living with HIV. Women participants reported increased awareness, confidence, and engagement with local health services. The initiative also contributed to improved coordination between HIV and TB programs at the local level.
Conclusions: Empowering women—particularly mothers of HIV-positive children—is a powerful strategy to address TB-HIV co-infection risks in marginalized settings. Community-driven, gender-responsive models can transform health outcomes and ensure equitable access to TB prevention and care

EP63-1300-21 From villages to victory: Empowering PRIs to declare TB Mukt Gram Panchayats in Moga District, Punjab (A scalable model for India)

N.K. Sinha,[1] R. Gangula,[2] V. Joseph,[3] M. Sharma,[3] A. Das,[3] R. Dasari,[2] G.S. Sodhi,[4] R. Begum,[3] R. Bhaskar,[5] S.K. Mattoo,[6] B.S. Kushwaha,[6] U.B. Singh,[6] [1]TB Alert India, Program Management, Chandigarh, India, [2]TB Alert India, Program Management, Hyderabad, India, [3]KHPT, Programs, New Delhi, India, [4]Department of Health & Family Welfare Punjab, Health Department, Moga, India, [5]Office of Director Health Services, Government of Punjab, Chandigarh, India, [6]Central TB Division, Ministry of Health and Family Welfare, New Delhi, India
e-mail: rameshdasari@tbalertindia.org

Background and challenges to implementation: Panchayati Raj Institutions (PRIs) form the backbone of rural governance in India, with immense potential to influence and implement health interventions at the grassroots level. However, their role in tuberculosis (TB) elimination has been largely underutilized. To address this gap, the Integrated Measures for Prevention and Care in TB (IMPACT)-India Project, supported by The Global Fund, is being implemented by TB Alert India as a sub-recipient of KHPT in Moga district, Punjab, a Pradhan Mantri Aspirational District. The initiative aims to institutionalize PRI participation in the National TB Elimination Program (NTEP).
Intervention or response: The IMPACT-India project recruited seven dedicated Community Coordinators (CCs) for Moga and provided technical support across state of Punjab. Each CC has spearhead project initiatives across 45–50 Gram Panchayats (GPs), ensuring active participation from PRIs. By end of 2024, 175 (51% of 340 GPs) were oriented on TB awareness, early diagnosis, stigma reduction, and welfare schemes like Nikshay Poshan Yojana. PRI leaders organized campaigns, facilitated contact tracing, and collaborated with TB Champions and Ayushman Arogya Kendras. Special Gram Sabhas (village-level assemblies in India) on TB encouraged Panchayats to pass TB-Free resolutions
Results/Impact: By December 2024, Punjab's state average of TB-Free Gram Panchayats (GPs) rose significantly from 0.05% in 2023 to 4% (495 out of 13,052), a joint effort driven by NTEP and the IMPACT-India Project. In Moga, 77 GPs (23% out of 340) were declared TB-Free, which is six times higher than the state average, facilitated by localized political will, structured PRI training, community-driven action, and the efforts of Community Coordinators (CCs), enhancing TB awareness, referrals, and treatment adherence.
Conclusions: The Moga model demonstrates a scalable approach for integrating PRIs into NTEP. By empowering grassroots leadership with knowledge and resources, it accelerated TB elimination, offering a replicable strategy for high-burden districts and aspirational districts aiming for equitable health outcomes.

EP63-1301-21 HIV and TB are not the same: Rethinking how to tailor community engagement for TB

D. Trinh-Hoang,[1] M.S. Sivapuram,[2] N. James,[3] S. Bernays,[1] [1]University of Sydney, Public Health, Sydney, Australia, [2]The Union, Communications and Engagement, New Delhi, India, [3]Independent, Independent, London, United Kingdom of Great Britain and Northern Ireland
e-mail: duy.trinhhoang@sydney.edu.au

Background and challenges to implementation: Actively engaging communities in shaping discussions and decisions—known as community engagement (CE)—is increasingly seen as vital to support the acceptability, uptake, and effectiveness of public health responses. Yet Tuberculosis (TB) CE remains fragmented and underfunded. Unlike HIV, which has fostered strong community identities and sustained advocacy, TB CE is often transient, ending with treatment completion. Challenges include the absence of a unified TB community, an episodic disease trajectory, and historically lower investment.
Current upheavals in global health, including cuts to long-standing international aid, threaten emerging CE efforts and highlight the need to reimagine strategies that center communities and sustain their influence.
Intervention or response: To understand these challenges, we facilitated discussions with CE experts and practitioners to explore how HIV CE's success—driven by strong networks, advocacy, and community-led governance—could be adapted to meet TB affected communities' specific contextual conditions and inform approaches to TB CE.
Results/Impact: Historically, the emphasis on TB control has left little room for CE. Redressing this requires a strong commitment to affording TB affected communities, through CE, both more space and power to influence the strategic direction of TB efforts.
Findings underscore the need for CE strategies that extend beyond research-driven models to become integral to national TB programs.
While some elements of HIV CE, such as long-term advocacy and community leadership, can be adapted, its salience has been over-estimated, and TB CE requires context- and disease-specific approaches. CE initiatives in TB-affected communities demonstrated that nurturing the unique shared TB survivorship identity is key to enhancing long-term engagement and advocacy.
Conclusions: TB CE must move beyond short-term, project-based models to sustained, community-led engagement. National TB programs should integrate survivor networks and invest in long-term advocacy.
Future efforts must prioritize strengthening TB community identity, leadership structures, and embedding CE into TB policy and programs.

EP63-1302-21 Empowering TB survivor-led networks in India to adopt CRGS approaches

A. Srinivasan,[1] R. Ananthakrishnan,[1] A. Vyas,[2] A. Panda,[2] A. Versfeld,[3] J. Malar,[3] [1]Resource Group for Education and Advocacy for Community Health (REACH), TB, Chennai, India, [2]Resource Group for Education and Advocacy for Community Health (REACH), TB, New Delhi, India, [3]Stop TB Partnership, Country and Community Support for Impact, Geneva, Switzerland
e-mail: anupama@reachindia.org.in

Background and challenges to implementation: India's National Strategic Plan for TB elimination has incorporated several key dimensions of Communities, Rights, Gender and Stigma (CRGS). While understanding of CRGS principles is strong at the policy level, this is yet to percolate within communities, where both understanding and uptake remain more uneven.
In recent years, TB survivors and Champions have organised themselves as independent networks representing affected communities and advocating on their behalf. These networks are ideally positioned to adopt and promote CRGS strategies.
Intervention or response: The objective of this intervention was to build the capacity of TB survivor-led Networks on CRGS principles and tools and enhance their expertise to generate effective demand for equitable TB services. A comprehensive CRGS curriculum was developed, and network leaders from six state-level networks (Bihar, Chhattisgarh, Odisha, Uttar Pradesh, Uttarakhand, Tamil Nadu) were trained through in-person workshops.
Post training, trained network members undertook specific CRGS activities over a six-month period, focusing on different aspects of CRGS – outreach to transgender communities, mapping of local key and vulnerable populations (KVPs), stigma surveys in the community etc.
Results/Impact: Through this intervention, 108 network leaders from six states were trained and led the development of annual CRGS workplans for their respective networks, also sensitising over 1000 other members. They educated over 6000 individuals from KVPs - migrant poor, miners, urban slum dwellers, tribal and rural populations, construction workers, transmen and transwomen, prisoners etc. Based on the KVP prioritisation, they interviewed over 450 people from KVPs to understand specific barriers to health services.
Overall, network members sensitised 15,117 people on TB and CRGS through 1100 meetings.
Conclusions: While the TB Champion model is well entrenched in India, this intervention has established CRGS as a guiding principle for networks. In the long term, investment in building community-capacity on CRGS is essential to generate collective demand for more inclusive TB services.

EP63-1303-21 Coalition-driven advocacy to improve access to TB medicines in Canada: Using provider perspectives to create change

L. Faust,[1] C. Heffernan,[2] E. Rea,[3] T. Campbell,[4] M. Nash,[5] L. Raithby,[6] N. Bedingfield,[7,8] A. Houston,[9] P. Heitkamp,[10] Y. Tcholakov,[7] M. Brindamour,[11] [1]London School of Hygiene and Tropical Medicine, Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [2]University of Alberta, Medicine, Edmonton, Canada, [3]Toronto Public Health, Tuberculosis, Toronto, Canada, [4]Northern Inter-Tribal Health Authority, Tuberculosis, Price Albert, Canada, [5]Queen's University, Medicine, Kingston, Canada, [6]Results Canada, Policy, Ottawa, Canada, [7]McGill University, Medicine, Montreal, Canada, [8]York University, Medicine, Toronto, Canada, [9]University of Ottawa, Law, Ottawa, Canada, [10]TB PPM Learning Network, Community engagement, Montreal, Canada, [11]University of Saskatchewan, Medicine, Saskatoon, Canada
e-mail: yassentch@gmail.com

Background and challenges to implementation: Despite the recent development and availability of shorter, safer and all oral tuberculosis (TB) treatment regimens, key first and second line TB drugs remain difficult to access in Canada. Years of advocacy by the Canadian TB community have had little effect, indicating the need for new evidence-based strategies.
Intervention or response: In 2024, Stop TB Canada undertook a national survey of TB program staff and healthcare providers across 10 provinces and territories. The goal was to document access barriers, amplify provider experiences, and build a coalition for change. Using a mixed-methods design, the survey gathered quantitative data on drug availability and delays, alongside qualitative insights into clinical impacts.
The findings were compiled into a publicly released advocacy report. This report became a tool to convene a range of stakeholders, including the Public Health Agency of Canada, Indigenous Services Canada, and Health Canada.
Results/Impact: The survey received 71 responses and revealed systemic access delays, insufficient regulatory mechanisms, and lack of child-friendly TB drug formulations. The report's publication triggered a national conversation, resulting in a series of high-level meetings with government actors and regulators. The coalition broadened through engagement with affected communities and professional networks.
As a direct outcome of the advocacy, new pathways are now being explored to improve access to WHO-recommended TB medicines and pediatric formulations through streamlined regulatory approaches and centralized procurement.
Conclusions: This initiative demonstrates how provider-informed data, when combined with coalition-led advocacy, can generate policy momentum. It presents a scalable model for engaging health professionals, affected

communities, and policymakers in high-income countries facing similar access barriers. Ongoing collaboration is now focused on translating progress into sustained regulatory reform and improved equity in TB care.

EP63-1304-21 Eliminating barriers to TB care: Lessons from the 100-day intensified TB elimination campaign in remote tribal areas of Arunachal Pradesh, India (Dec 2024-Mar 2025)

M. Nyori,[1] O. Apang,[1] K. Bagang,[1] N. Sumnyan,[2] U. Singh,[3] S. Chandra,[2] D. Deka,[2] [1]National TB Elimination Programme, Government of Arunachal Pradesh, Department of Health and Family Welfare, Itanagar, India, [2]Government of India - WHO Country office for India, TB Technical Support Network, National TB Elimination Programme, New Delhi, India, [3]Central TB Division, Ministry of Health and Family Welfare, New Delhi, India

Background and challenges to implementation: The 100-Day Intensified TB Elimination Campaign in Kurung Kumey and Kra Daadi districts, Arunachal Pradesh, showcases a targeted approach to delivering equitable TB care to underserved, hard-to-reach areas. Despite challenges like landslides, inaccessible roads, and unreliable electricity and connectivity, the campaign reached vulnerable populations in the remotest regions.

Intervention or response: The state mobilized resources, including handheld X-rays, Nikshay Vahans (Mobile Medical Units), and additional NAAT (Nucleic Acid Amplification Test) machines, ensuring diagnostic capabilities in challenging terrains. Teams travelled at the break of dawn to reach villages like Kapu—one of the last hamlets near the Indo-China border—ensuring last-mile service delivery.

The campaign mapped vulnerabilities in a population of over 1.13 lacs, conducted 118 Nikshay Shivirs (integrated health camps) and screened 7,404 (100%) vulnerable individuals.

Alternate communication strategies and portable power solutions were deployed to address operational challenges. Collaborative efforts involved local government support, PRI member engagement, developmental partners, mobilization through women's self-help groups and schools to amplify awareness and participation.

Results/Impact: The campaign identified 3,140 persons with presumed TB, of whom 72% underwent X-ray screening, with 90% of the tests being NAAT-based, which detected 4 PwTB (Persons with Tuberculosis).

Key achievements included addressing TB determinants in tribal population, transitioning to 100% upfront NAAT testing, early detection of PwTB, and distribution of nutritional support through Nikshay Poshan Yojana (Financial support for nutritional needs) and Nutritional baskets. The success was reflected in increased TB Mukt Panchayat (TB-Free Village) claims and adoption of PwTB by Nikshay Mitras (Donors).

Conclusions: The 100-Day campaign in Arunachal Pradesh demonstrates that even in remote, resource-limited settings, strategic planning, innovative solutions, and strong ownership by community and public representatives can overcome barriers to TB care. It highlights the importance of integrating programmatic activities and fostering multi-sectoral collaboration, transforming campaign activities into sustainable practices and offering valuable insights for global replication.

EP63-1305-21 Evidence based advocacy to enhancing integrated TB and HIV service provision among persons with disabilities (PWDs) in Uganda

N. Namuyomba,[1] N. Carlo,[1] [1]ADPHA Uganda, Programs Department, Masaka city, Uganda
e-mail: nissynamuyomba176@gmail.com

Background and challenges to implementation: PWDs face significant barriers in accessing equitable HIV/TB services, leading to poorer health outcomes. In Uganda, an estimated 13.2 % of the population live with disability, and about 96,000 people fall ill to TB annually.

Intervention or response: To address this, ADPHA Uganda conducted an accessibility study in eight health facilities across Greater Masaka to identify barriers and promote disability-inclusive TB/HIV services. Using a mixed-methods approach, the study combined a literature review, stakeholder mapping, interviews, focus group discussions with quantitative methods. Findings were analysed and validated.

An advocacy strategy was formulated to promote disability-inclusive services, ensuring reasonable accommodations, and monitoring the physical accessibility of health facilities. This aimed to ensure PWDs. can confidently access services through the implementation of local legislation, training peer monitors, and advancing universal design principles in line with CRPD Article 25, SDG 3 and UNHLM targets.

Results/Impact: The study revealed that while all assessed facilities provide TB and HIV/AIDS services per national guidelines, none had institutionalised strategies to address the intersection of disability,TB, and HIV/AIDS. Disability rehabilitative services were not integrated, and essential assistive devices were excluded from care packages. Facilities lacked systematised reasonable accommodations, especially for people with invisible disabilities.
Poor infrastructure, inaccessible latrines, fragmented service points, and economic barriers further limited access, undermining CRPD Article 25, and efforts to achieve SDG 3. PWDs also faced stigma, inadequate service provision, awareness, exclusion from health promotion efforts and preventive services.
Conclusions: There is a critical need of strengthening integrated TB and HIV service provision for PWDs. This requires institutional reforms, budget allocations, inclusive planning, disability-sensitive data, and Multisectoral collaboration with OPDs to institutionalise reasonable accommodations and universal design.

EP63-1306-21 Empowering TB survivors as champions of change: A community-led approach to advancing TB elimination efforts in India

R. Begum,[1] A. Das,[1] V. Joseph,[1] R. Ranjan,[1] V.C. Rohit,[2] R. Gangula,[3] C. Joshi,[4] V. Nageswara Rao,[5] N. Kumar,[6] S. Kumar Mattoo,[6] U. B. Singh,[6] K. Karthikeyan,[2] [1]KHPT, TB, Delhi, India, [2]KHPT, TB, Bengaluru, India, [3]TB Alert India, TB, Hyderabad, India, [4]World Health Partners, TB, Delhi, India, [5]Piramal Swasthya Management and Research Institute, TB, Delhi, India, [6]Central TB Division, Ministry of Health and Family Welfare, TB, Delhi, India
e-mail: amitabh.das@khpt.org

Background and challenges to implementation: India has made substantial strides toward eliminating tuberculosis through sustained government initiatives. However, challenges such as limited awareness, delays in diagnosis, and challenges within the care continuum continue to impact progress.
Addressing stigma and enhancing community engagement remain critical to strengthening the response and accelerating TB elimination.
Intervention or response: The IMPACT India Project, supported by the Global Fund, addressed key challenges by empowering TB survivors to volunteer as advocates for TB prevention and care. Trained as "TB Vijetas" (Champions), they were placed at Ayushman Arogya Mandirs (AAMs)—the lowest-level health facilities serving ~5,000 people.
These Vijetas voluntarily led outreach, raised awareness, and provided peer support, integrating their advocacy within existing AAM infrastructure to promote early TB detection and treatment completion.
Results/Impact: October 2024 to March 2025, the project reached out to 19,249 TB survivors across 99 districts in 15 states, training 11,305 as Vijetas for voluntary community engagement activities in TB response. Of this over 70% (63% male, 37% female) were actively engaged in carrying out 19,305 community engagement activities. NTEP reported 14,611 more TB notifications in project districts compared to the same period last year. The project also strengthened community ownership, enhanced support mechanisms, and increased grassroots awareness.
Importantly, Female Vijetas (3,047) played a key role in raising awareness and promoting health-seeking behaviour, particularly in rural settings where TB stigma intersects with gender-related barriers. They led 6,704 engagement sessions at 3,593 AAMs, promoting inclusion and community support.
Conclusions: The IMPACT India Project illustrates how empowering TB survivors as volunteer champions can drive meaningful, community-led change. Their leadership in awareness, support, and stigma reduction reflects the transformative power of lived experience in advancing TB elimination.
This approach not only strengthens grassroots engagement but also lays the foundation for scalable, sustainable integration of survivor-led efforts into the broader health system.

EP63-1307-21 Utilising the 'Duare Sarkar' (Government at doorstep) camp for TB information, education and communication, as well as screening: Outputs of such a camp in a district of West Bengal, India

A. Dey,[1] S.K. Roy,[2] U.B. Singh,[3] S. Chandra,[1] T.K. Saha,[2] D. Deka,[1] B. Sengupta,[1] A. Biswas,[2] [1]Government of India-WHO Country office for India-Technical Support Network, National TB Elimination Program, New Delhi, India, [2]Government of West Bengal, Department of Health and Family Welfare, Kolkata, India, [3]Government of India, Department of Health and Family Welfare, New Delhi, India
e-mail: drabhijitdey@gmail.com

Background and challenges to implementation: 'Duare Sarkar' is an initiative of the Government of West Bengal, for delivery of services and welfare schemes at the doorsteps of the people through outreach camps. These camps are organized at the gram panchayat and municipal ward level. District Health authorities utilise these opportunities and arrange Health Camps to disseminate health related information, arrange screening and treatment camps for Communicable and non-communicable diseases including Tuberculosis.
Intervention or response: The Paschim Medinipur, a rural district having significant proportion of tribal population used this opportunity to organize IEC (Information Education and Communication) activities and health

camps for screening and treatment of Tuberculosis involving health care providers of the blocks and municipalities beyond the NTEP (National TB Elimination Programme) personnel. They established a collaboration with the general administration & panchayat raj institution to mobilize fund for additional nutrition of the Person with TB (PwTB).

Results/Impact:

- In 30 days, a total of 485 Duare Sakar camps arranged at Paschim Medinipur
- Total 16,221 people visited the health kiosk and received TB messages
- Total 10,214 people screened for TB
- 255 persons presumed to be TB & referred for Testing
- Four persons with TB diagnosed
- 50 existing PwTB received food basket through 11 identified Nikshay Mitras (donor) during the camp.
- People were also screened for diabetes, hypertension, cataract, oral cancer etc.

Conclusions: Arranging health camps especially TB screening & IEC activities during the Duare Sarkar Camp was a positive initiative in terms of diagnosis of additional number of PwTB and Nikshay Mitra (donors) for additional nutrition for the PwTBs.

EP63-1308-21 EduClowns for TB awareness: Creative community engagement for early detection and behavioural change in Tamil Nadu, India

M. Annapoorani,[1] [1]Blossom Trust, Senior Management, Virudhunagar, India

Background and challenges to implementation: Blossom Trust has implemented EduClowns an innovative approach aimed at identifying community members, particularly in marginalised and remote communities in rural Tamil Nadu, where under resourcing has led to misinformation, stigma and poor health-seeking behaviours that hinder the detection and care of Tuberculosis (TB). EduClowns uses theatre-based performances to engage communities, raising awareness on TB, sexual health, and universal health coverage.

Over three decades, more than 100 shows across Virudhunagar, Madurai, and Kanchipuram have supported TB awareness and community engagement.

Intervention or response: In 2024, the *EduClowns Campaign for the Prevention of Tuberculosis* (ECPT) was launched under the USAID-funded TIFA programme, in collaboration with NTEP and JSI. Aimed at bringing about behavioural change regarding TB and improve community detection and treatment adherence.

The campaign combined performances with on-site TB education, screening, and referrals. It aimed to reach 8,000 people, screen 1,800, and refer 90% of symptomatic individuals for testing. Planned outreach included 40 campaigns in 58 villages across Virudhunagar and Ramanathapuram. Although the campaign was suspended due to U.S. policy changes, the model showcased a community-led, stigma-reducing approach to TB detection and care.

Results/Impact: While ECPT was not fully implemented, Blossom Trust's previous EduClowns campaigns have successfully reached hundreds of thousands in communities across Tamil Nadu and demonstrated the potential for behaviour change. EduClowns have also drawn the attention of both local community and policymakers, influencing local and state-level health initiatives.

Conclusions: EduClowns is a scalable, culturally relevant strategy for TB advocacy, demonstrating how civil society can strengthen health systems and reduce health disparities in diverse communities. The model holds significant potential for adaptation to broader health interventions. Future implementation of the model can lead to increased TB awareness, early detection, and stronger referral pathways, improving overall TB care in target communities.

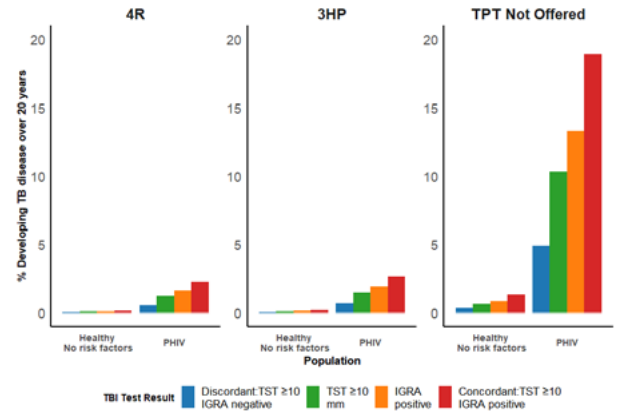
LATE BREAKER PRESENTATIONS

LB01 RIT/JATA Student Late Breaker Session on Lung Health

LB01-1300-18 Management of people with positive TB infection tests: Thinking in 4 dimensions

M. Lisboa Bastos,[1,2] R. Noseworthy,[2] J. R. Campbell,[2,3,4] D. Menzies,[2,3,4] [1]University of Manitoba, Family Medicine, Winnipeg, Canada, [2]McGill University, McGill TB Centre, Montreal, Canada, [3]McGill University, Department of Medicine, Faculty of Medicine and Health Sciences, Montreal, Canada, [4]McGill University, Respiratory Epidemiology and Clinical Research Unit, Research Institute, Montreal, Canada
e-mail: mayara_bastos@yahoo.com.br

Background: When managing a positive TB infection (TBI) test, providers often focus solely on the test result. Yet individual benefit also depends on clinical context, age, and the preventive regimen. We used a Markov microsimulation model to evaluate 20-year risks and benefits of TPT in numerous populations and age groups with at least one positive TBI test.
Design/Methods: We considered four dimensions: (1) population risk group (20 groups, including healthy individuals and persons with HIV [PHIV]); (2) TPT regimen (3HP, 3HR, 4R, 9H, or no treatment); (3) age group; and (4) test result: TST ≥10 mm only, IGRA-positive only, TST ≥10 mm & IGRA-negative, or TST ≥10 mm & IGRA-positive. For each group, a cohort of 10,000 persons was simulated 1,000 times to generate 95% uncertainty intervals. Outcomes included TB-incidence, TB-related mortality and disability, TPT-related adverse events, and QALYs.
Results: We present findings for two risk groups (PHIV and healthy individuals), one age group (18–34 years), and three TPT scenarios (no treatment, 3HP, 4R) (Figure). Among untreated PHIV and healthy persons, TB risk was 10.3% (0.4–31.7) and 0.8% (0–3.0) for TST ≥10 mm only, respectively. 4R substantially reduced TB risk across test categories and had the lowest adverse event rates (1.7%–4.1%).
While TB risk decreased with discordant tests, and increased with concordant positive tests, differences between tests were modest compared to differences between risk groups. For example, among untreated PHIV, risk was 13.3% (0.5–40.9) for IGRA-positive only and 18.9% (17.8–20.0) for dual-positive, compared to 0.8% and 1.3%, respectively, among healthy individuals. Among adults >65 years, TB risk was lower, but TB-related mortality higher, resulting in larger QALY gains from TPT.



Conclusions: Individual risk factors—such as age and underlying condition—are more important than test type in determining TB risk and TPT benefit and should guide provider decision-making.

LB01-1301-18 Improving M. tuberculosis DNA detection from urine and non-sputum sample using the QuickConc method: Preliminary results from a spike-in experiment

M. Hikone,[1] N. Saito,[1] [1]Nagasaki University, Institute of Tropical Medicine, Kenya Research Station, Nagasaki, Japan
e-mail: mayu.hikone@nagasaki-u.ac.jp

Background: Urine- and other non-sputum (e.g., pleural fluid, cerebrospinal fluid)-based molecular diagnostics offer potentially more effective alternative to conventional methods; however, detecting *Mycobacterium tuberculosis* (MTB) DNA remains challenging due to its low concentration. QuickConc (AdvanSentinel, Japan), a novel concentration method originally developed for environmental DNA research and wastewater surveillance, utilizes silica-glass fibers and a cationic surfactant to capture nucleic acids and improve downstream molecular detection.
While QuickConc has demonstrated efficacy in concentrating nucleic acids from environmental samples, its application to MTB detection or clinical sample has not yet been explored. This study aimed to evaluate the analytical performance of QuickConc for enhancing MTB DNA detection in urine.
Design/Methods: DNA was extracted from the H37Rv strain of MTB cultured in Löwenstein–Jensen medium using DNeasy Blood & Tissue Kit (QIAGEN) and subsequently spiked into urine samples from healthy individuals. A spike-in experiment was performed using MTB DNA at two concentration levels (10^8 and 10^7 copies/mL). Samples were either processed using the QuickConc concentration method or left unprocessed as controls. Conventional PCR targeting the IS6110 gene (123 bp amplicon) was performed, and PCR products were analyzed via agarose gel electrophoresis.

Results: QuickConc-treated samples showed PCR amplification at 10^8 copies/mL, and detectable though weaker band at 10^7copies/mL.
In contrast, unprocessed samples produced only faint bands at 10^8 copies/mL and no detectable band at 10^7copies/mL (Figure). The QuickConc method improved the limit of detection and the amplification band intensity.

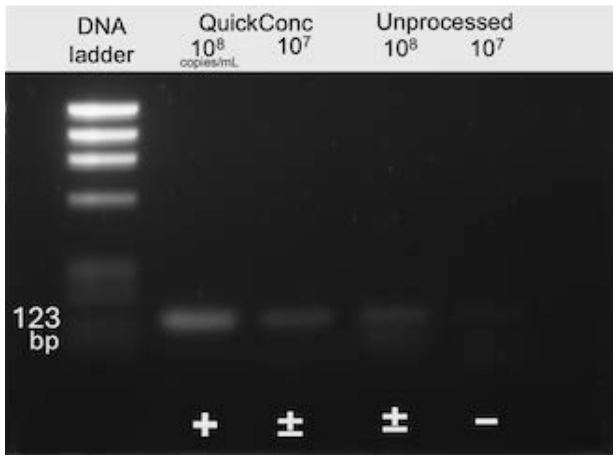


Figure.

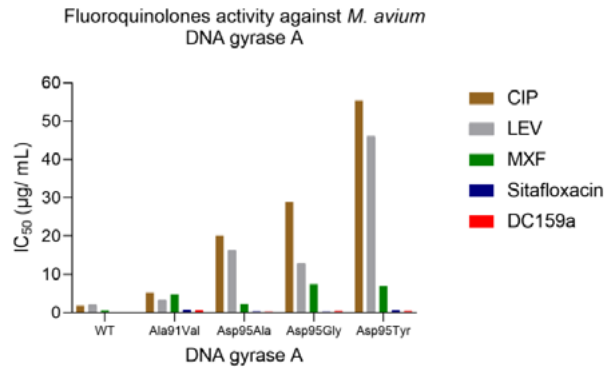
Conclusions: Under preliminary conditions, the QuickConc method enhanced MTB DNA detection from urine by effectively concentrating target DNA, highlighting its potential as a sample preparation step for molecular diagnostics using urine and non-sputum sample. Further optimization and validation using clinical samples are currently underway.

LB01-1302-18 Potent inhibition of wild-type and fluoroquinolone-resistant *M.avium* DNA gyrase by sitafloxacin and DC159a

S. Jayaweera,[1] J. Thapa,[1] C. Nakajima,[1] Y. Suzuki,[1,2]
[1]Hokkaido University, Division of Bioresources, Sapporo, Japan, [2]Hokkaido University, Institute for Vaccine Research and Development, Sapporo, Japan
e-mail: muhandiramgesasini.jayaweera.v9@elms.hokudai.ac.jp

Background: *Mycobacterium avium* is an opportunistic pathogen belonging to the *Mycobacterium avium* complex (MAC) that causes chronic pulmonary infections. Moxifloxacin, a fluoroquinolone, is a recommended second-line treatment for MAC infections. Resistance to moxifloxacin is becoming more widespread. Sitafloxacin is a therapeutically accessible fluoroquinolone in Japan, while DC159a is a new experimental fluoroquinolone with strong potency against resistant bacteria. However, studies regarding their activity against *M. avium* are rare.
Design/Methods: We investigated the inhibitory effects of sitafloxacin and DC159a on recombinant *M. avium* DNA gyrase A and B wild-type (WT) and gyrase A mutants Ala91Val, Asp95Ala, Asp95Gly, and Asp95Tyr, using a DNA supercoiling inhibitory assay to calculate the half inhibitory concentration (IC_{50}).
The minimum inhibitory concentration (MIC) of DC159a and sitafloxacin was determined for 11 clinical isolates (7WT, 2Asp95Gly, 2Asp95Tyr) and compared with previously tested MICs of moxifloxacin, ciprofloxacin, and levofloxacin.
Results: Sitafloxacin and DC159a inhibited both WT and mutant DNA gyrase A in a dose-dependent manner. The IC_{50} values of sitafloxacin against DNA gyrase A were 0.132 ± 0.02 μg/mL for WT and 1.061 ± 0.3, 0.738 ± 0.06, 0.597 ± 0.08, and 1.123 ± 0.13 μg/mL for Ala91Val, Asp95Ala, Asp95Gly, and Asp95Tyr, respectively. For DC159a, the IC_{50} values were 0.229 ± 0.03 μg/mL for WT and 0.831 ± 0.4, 0.539 ± 0.08, 0.870 ± 0.03, and 0.887 ± 0.09 μg/mL for the respective mutants.
All mutants showed higher IC_{50} values than the WT (4.52-8.51-fold for sitafloxacin and 2.35-3.87-fold for DC159a), indicating that DC159a retains greater inhibitory activity against mutated gyrase A.
The minimum inhibitory concentrations of sitafloxacin and DC159a were observed to be half that of moxifloxacin for the WT. DC159a showed the lowest MIC values in mutant strains compared to moxifloxacin (8-64-fold).



Conclusions: The results indicate that DC159a and sitafloxacin have a strong inhibitory profile against *M. avium* DNA gyrase A, suggesting that they may be used as a promising treatment.

LB01-1303-18 Finding TB post-treatment in India: Cost-effectiveness of phone compared to home-based screening

S. Wasunkar,[1] D. Kim,[2] S. Cox,[3] A. Kadam,[4] R. Thompson,[5] V. Damale,[6] G. Lele,[4] E. Kendall,[7,8] J. Golub,[3,7] V. Mave,[3,4] H. Sohn,[2] [1]Seoul National University, Human Systems Medicine, Seoul, Republic of Korea, [2]Seoul National University, Preventive medicine, Seoul, Republic of Korea, [3]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States of America, International Health, Baltimore, United States of America, [4]Johns Hopkins India, Center for Infectious Diseases in India (CIDI), Pune, India, Infectious Diseases, Pune, India, [5]Harvard T H Chan School of Public Health, Global health and population, Boston, United States of America, [6]DY Patil Medical College, Hospital and Research center, Medicine, Pune, India, [7]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States of America, Infectious Diseases, Baltimore, United States of America, [8]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States of America, Epidemiology, BaltimoreUnited, United States of America
e-mail: wasu_magicseoul@snu.ac.kr

Background: Despite successful tuberculosis (TB) treatment, survivors and their household members remain at elevated risk for TB. Active case finding (ACF) targeting the index and associated household members can address the importance of case finding gaps; however, evidence on resource implications and cost-effectiveness of different ACF approaches for these risk groups remains limited.
Design/Methods: As part of the TB Aftermath - a hybrid effectiveness-implementation trial comparing home versus phone-based screening among TB survivors and their HHCs in Pune, India , we conducted cost and cost-effectiveness analysis from the health service provider perspective. Total costs per arm and average cost per household visit were estimated and proportioned according to the time taken to conduct the activities. The Incremental Cost-Effectiveness Ratio (ICER) was defined as the incremental cost per additional TB case detected through home-based screening relative to phone screening. Costs were calculated for an initial design phase of 8 months and a 40-month implementation period.All costs were assessed from the health service provider perspective and annuitized over 5 years at a 3% discount rate.
Results: The total programmatic cost was $4941.96 for the home-based arm and $661.10 for the phone arm, reaching the households of 537 and 539 index participants enrolled in the respective arms of the trial.When accounting for all households assessed, the total cumulative cost was $9.16 and $1.23 per household in the home and phone-based ACF strategy. With a total of 58 and 37 people with TB detected in the home-phone-based strategies, the cost per TB case detected was $85.20 and $17.39 for the respective strategies. The incremental cost-effectiveness ratio (ICER) was $203.85 per additional TB case detected.

Study Arm	Total no of household enrolled	Cumulative cost per household	Total cost	Incremental cost	Total no of TB cases detected	Incremental TB case detected	Cost per TB case detected	ICER
Home Based Arm	539	$9.16	$4941.96		58		$85.20	
				$4280.86		21		$203.85
Phone Based Arm	537	$1.23	$661.10		37		$17.39	

Conclusions: Despite higher resource needs, home-based ACF approach for post-TB case finding was able to detect more people with TB amongst the index participants' households, allowing for earlier case detection.

LB01-1304-18 Diagnostic and predictive accuracy of a 3-gene *M. tuberculosis* Host Response Cartridge in household contacts – Updated results from the multi-centre prospective ERASE-TB study

A.-L. Behnke,[1,2,3] I.-D. Olaru,[4] L. Larsson,[4,1] A. Mfinanga,[5,1] E. Marambire,[6,1] D. Banze,[7,1] C. Nhamuave,[7] L.T. Minja,[5] C. Khosa,[7] K. Held,[1,2] N. Heinrich,[1,2] K. Kranzer,[4,1,2,6] ERASE-TB Consortium [1]LMU Hospital, Institute of Infectious Diseases and Tropical Medicine, Munich, Germany, [2]German Centre for Infection Research (DZIF), Partner site Munich, Munich, Germany, [3]Charité - University Medicine Berlin, Berlin School of Public Health, Berlin, Germany, [4]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom of Great Britain and Northern Ireland, [5]National Institute for Medical Research, Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, [6]Biomedical Research and Training Institute, The Health Research Unit Zimbabwe, Harare, Zimbabwe, [7]Instituto Nacional de Saúde, INS, Marracuene, Mozambique
e-mail: anna-lisa.behnke@med.uni-muenchen.de

Background: WHO recommends TB screening for household contacts (HHCs). Non-sputum diagnostics based on mRNA expression show promise.
Design/Methods: We evaluated the diagnostic and predictive accuracy of the Cepheid Xpert *Mycobacterium tuberculosis* Host Response (MTB-HR) prototype for TB in the context of HHC screening. 2,079 HHCs (≥10 years) from Mozambique, Tanzania, and Zimbabwe were included. TB screening (clinical, radiological, microbiological) was conducted every 6 months over 24 months. We analysed MTB-HR scores and area under the receiver operating curves (AUROC) stratified by symptom and HIV status. Optimal MTB-HR score thresholds were identified using the Youden method. Sensitivity, specificity, and positive/negative predictive values were calculated with 95% confidence intervals (95%CI) using the Wilson method.
Results: The median MTB-HR score was -0.9 (IQR -1.3 – -0.60) in HHCs without TB and -2.6 (IQR -3.1 – -1.7) in HHCs with TB. Symptomatic HHCs with TB had low-

er MTB-HR scores than asymptomatic HHCs: -2.6 (IQR -3.1 – -1.9) vs. -1.2 (IQR -1.7 – -0.84, p=0.006). Analysis of diagnostic accuracy included 41 HHCs with MTB-HR results within 30 days of TB diagnosis. AUROC was 0.86 (95%CI 0.79–0.92). At a cut-off of -1.475, sensitivity was 81% (95%CI 66–90) and specificity 81% (95%CI 79–83). Sensitivity was higher in HIV-negative and symptomatic HHCs, while specificity was higher in HIV-positive and asymptomatic HHCs. Negative predictive value exceeded 98% across subgroups; positive predictive value was low.
Prediction analysis included 21 and 14 people with incident TB at 6 and 12 months, respectively. AUROC was 0.77 (95%CI 0.65–0.89) at 6 months, and 0.56 (95%CI 0.41–0.71) at 12 months. At 6 months, a -1.675 cut-off yielded 62% sensitivity (95%CI 41–79) and 87% specificity (95%CI 86–89).

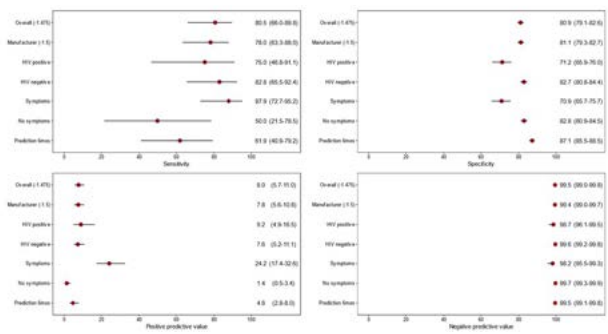


Figure. Accuracy of the MTB-HR assay for TB diagnosis and prediction: sensitivity (a); specificity (b); positive (c) and negative predictive values (d).

Conclusions: Our results indicate that the MTB-HR might be useful in identifying HHCs who need further testing or closer follow-up for the detection and management of TB.

LB01-1305-18 Impact of sequencing and analysis artefacts on the performance of the WHO mutation catalogue for genotypic drug susceptibility testing of *M. tuberculosis*

N. Hermans,[1,2] J. Phelan,[3] C. Köser,[4,5] P. Miotto,[5] D. Cirillo,[5] A. Iskakova,[6,7] A. Slyzkyi,[1] K. Kremer,[1] R. Anthony,[2]
[1]KNCV Tuberculosis foundation, Diagnostics Team, Division of TB Elimination & Health Systems Innovations, The Hague, Netherlands, [2]National institute for public health (RIVM), Department of Bacterial Surveillance and Response, Bilthoven, Netherlands, [3]London School of Hygiene & Tropical Medicine, Department of Infection Biology, London, United Kingdom of Great Britain and Northern Ireland, [4]Cambridge University, Department of Genetics, Cambridge, United Kingdom of Great Britain and Northern Ireland, [5]IRCCS San Raffaele Scientific Institute, Emerging Bacterial Pathogens Unit, Milan, Italy, [6]KNCV Tuberculosis Foundation, Country office, Bishkek, Kyrgyzstan, [7]National Center, for Phthisiology, Bishkek, Kyrgyzstan
e-mail: noud.hermans@kncvtbc.org

Background: The WHO *Mycobacterium tuberculosis* complex mutation catalogue has become the reference standard for interpreting genotypic drug susceptibility (DST) results. To boost the sensitivity of the catalogue, it includes a set of additional grading rules to classify novel or rare mutations with limited phenotypic and genotypic DST data as markers of resistance. If triggered incorrectly, however, these rules may overcall resistance.
Design/Methods: We investigated the root-causes of unexpectedly high levels of genotypic resistance to rifampicin and pretomanid/delamanid.
Results: During an external quality control assessment, two of the fifteen participating laboratories reported a low-frequency *rpoB* variant (~5% at position 1346 in codon 449) that triggered the additional grading rule for rifampicin. Phenotypic DST, additional data analyses, and use of alternative sequencing reagents suggested these variants were sequencing artefacts.
The end of *fbiC* overlaps 2.7 repeats in the *M. tuberculosis* H37Rv reference genome. The deletion of one or more of these repeats inappropriately triggered the loss-of-function additional grading rule, resulting in the false prediction of delamanid and pretomanid cross-resistance, even though the end of *fbiC* remained unchanged. In the Dutch reference laboratory database, this phenomenon was observed in >30% of 7400 isolates in a lineage-dependent manner.
Conclusions: The additional grading rules inferring drug resistance were erroneously triggered because of sequencing and analysis artefacts. Our findings underline the importance of quality control of both laboratory and computer-assisted data analysis procedures, as well as the rapid communication of exceptions and adjustments to the WHO catalogue rules. Indeed, the second edition of the mutation catalogue already acknowledged the *rpoB* exception and the third edition is due to include the *fbiC*

exception. The latter issue has already been addressed in v6.3.0 of TB Profiler, an open source tool for genotypic DST using the second edition of the WHO mutation catalogue.

LB01-1306-18 Estimating the global financial burden of TB: Updated forecasts and funding scenarios, including a PEPFAR withdrawal scenario analysis

N. Mzizi,[1,2] S. Ndabezitha,[3] A. Zwerling,[4] [1]University of Texas Health Science Center in Houston, Management, Policy, and Community Health, Houston, United States of America, [2]Baylor College of Medicine, Global TB Program, Houston, United States of America, [3]University of Texas Health Science Center in Houston, Biostatistics, Houston, United States of America, [4]University of Ottawa, School of Epidemiology and Public Health, Ottawa, Canada
e-mail: nompumelelo.mzizi@bcm.edu

Background: Tuberculosis (TB) remains a leading infectious killer, with 10.8M cases and 1.3M deaths in 2023, imposing a $81.5B financial burden. Stagnant incidence and a $16.3B funding gap (vs. $22B need) undermine WHO's End TB targets. This analysis updates TB's financial burden and models a 50% PEPFAR cut's impact on 2025 TB outcomes and financial burden.
Design/Methods: We developed a financial model using WHO TB incidence and mortality data (2015-2023), Global Fund financing reports, and TB patient cost surveys. Forecasts for 2024-2025 were produced using ARIMA time series models. Economic burden components included health system costs, household expenditures, and productivity losses (valued at US$50,000 per TB death). Three funding scenarios for 2025 were modeled:
- **Status Quo** (US$6B/year),
- **Increased Global Fund allocation** (US$8B/year),
- **PEPFAR Withdrawal** (-US$1B donor funding).

Sensitivity analysis varied household costs (US$500 -1,500) and mortality loss (US$25,000 - 75,000). A regression model estimated deaths averted per US$1B invested (0.415 million).
Results: In the Status Quo ($6.5B), 2025 projects 10.6M cases, 1.3M deaths, and an $84.5B burden ($6.5B health, $10.6B household, $67.5B mortality). Increased Funding ($8.0B) averts ~312,000 deaths (1.2M deaths), reducing the burden to $78.6B. The PEPFAR Cut ($7.25B) increases deaths by ~312,000 (1.512M), raising the burden to $93.45B ($7.25B health, $10.6B household, $75.6B mortality). Sensitivity analysis shows burdens of $47.6B-$108.7B across cost ranges. Each $1B in funding averts ~$8B in economic losses.
Conclusions: TB's $81.5B-$93.45B annual burden, driven by mortality, demands urgent funding. Increased investment could save 312,000 lives and $14.85B, while PEPFAR cuts risk setbacks, especially in TB/HIV regions. Sustained Global Fund and bilateral support are critical to meet 2030 End TB goals.

LB01-1307-18 Assessing the economic viability of introducing new shorter TB drug regimens in Ethiopia

E. Fekadu,[1] [1]Addis Ababa University, Health Systems Management & Health Policy Department/Health Economics, Addis ababa, Ethiopia
e-mail: enda.pharm@gmail.com

Background: The Ethiopian national TB program dedicates millions of dollars yearly for the programmatic management as well as for the procurement of life-saving medications. This research evaluates the economic viability of shorter-duration DRTB regimens through an assessment of their cost-effectiveness and potential advantage with longer and individualize treatments.
The research investigates more affordable and efficient treatment options to improve health system efficiency and effectiveness.
Design/Methods: A cross-sectional study design was used to evaluate the economic feasibility of introducing new shorter TB drug regimens in Ethiopia. The research design combined quantitative and qualitative methods to gather complete economic and healthcare data during a particular time period.
The cost benefits (CBA) analysis evaluates the economic and health outcomes of shortening TB regimens against the longer TB regimen and Indvidualized Longer TB regimens. The cost data includes both medical expenses for drugs and diagnostic tests and doctor visits and patient travel expenses that are not medical in nature.
A thorough literature review combined with data collection from all hospitals and randomly selected facilities used to compile comprehensive expenditures.
Results: A total of 271 DR-TB patients from 13 regions of Ethiopia were included in this study, F (3, 271) =10.695, p= 0.000001, η^2 = 0.107 (large effect size), The ILTR group had significantly higher OOP than the LTR (Mean diff=24.213, p=0.000079, 95% CI [10.1, 38.33], and the OOP of LTR had significant difference with the STR (Mean diff=-28.471, p=0.000002, 95% CI [-42.47, -14.47].
The Cost-Utility Analysis (CUA) result indicates, Short-Term Regimen (STR) provided the lowest cost per QALY at $1296.72 followed by the Long-Term Regimen (LTR) at $2301.71 and the Individualized Long-Term Regimen (ILTR) at $4750.1 per QALY gained.
Conclusions: A shorter regimen offers the ability to decrease financial costs through reduced direct treatment expenses and decreased healthcare facility congestion and better patient compliance.

LB01-1308-18 TB and cytomegalovirus co-pathogenicity amongst adults with cryptococcal meningitis: A prospective cohort study

J. Ellis,[1] G. Hale,[1] L.J. Nsangi,[2] A. Wele,[3] E. Kigozi,[2] N. Feasey,[4] K. Kranzer,[1] D.A.J. Moore,[1] K. Fielding,[1] D.B. Meya,[2] D.R. Boulware,[5] J.N. Jarvis,[1] Infectious Diseases Institute Clinical Meningitis Research Group [1]London School of Hygiene and Tropical Medicine (LSHTM), Clinical Research Department, London, United Kingdom of Great Britain and Northern Ireland, [2]Infectious Diseases Institute, Meningitis research group, Kampala, Uganda, [3]University of Minnesota, Division of Biostatistics and Health Data Science, Minneapolis, United States of America, [4]University of St Andrews, The School of Medicine, St Andrews, United Kingdom of Great Britain and Northern Ireland, [5]University of Minnesota, Division of Infectious Diseases, Minneapolis, United States of America
e-mail: jayne.ellis1@lshtm.ac.uk

Background: Case fatality amongst adults with HIV-associated cryptococcal meningitis is 24-45% at 10-weeks. Co-prevalent tuberculosis (TB), cytomegalovirus (CMV) and bloodstream infections (BSI) may contribute to poor outcomes.
Design/Methods: We prospectively enrolled adults with cryptococcal meningitis from three tertiary referral hospitals in Uganda. Participants underwent enhanced screening for TB disease (urine TB-LAM and Xpert MTB/Rif Ultra testing, Myco/F blood cultures, chest radiography), CMV viremia (quantitative polymerase chain reaction), and bacteremia (blood cultures at baseline and day-7). Prevalence of co-infections and associations with mortality were determined; adjusted for age, sex, site, CD4 and anti-retroviral therapy.

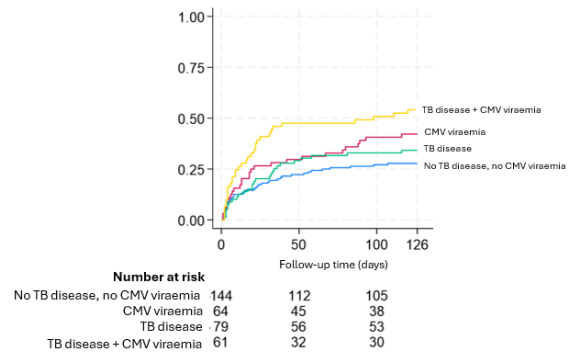

Figure 1. Cumulative all-cause mortality over time amongst Ugandan adults diagnosed with HIV-associated cryptococcal meningitis, stratified by CMV and TB disease co-infection sub-group.

Results: We enrolled 450 adults, median age 36 (IQR 30-42) years, median CD4 count 29 (IQR 11-75) cells/mm^3. Overall, 45% (204/450) had TB disease diagnosed: 18% (79/450) were receiving anti-tuberculous therapy at enrolment, and 28% (125/450) were diagnosed with TB during hospitalization (n=74 with microbiologically-confirmed TB); 34% (144/417) had CMV viremia and 3% (12/422) had a significant bacterial BSI.
Participants with TB disease had higher 18-week mortality vs. participants without TB disease (44% vs. 33%; adjusted Odds Ratio (aOR) 1.70; 95%CI, 1.09-2.63).
Participants with CMV viremia had two-fold higher mortality at both 2-weeks (21% vs. 11%, aOR 2.19; 95%CI 1.24-3.86), and 18-weeks (48% vs. 30%; aOR 2.20; 95%CI, 1.37-3.53) vs. participants without CMV viremia. Bacteremia was not associated with mortality. Amongst participants with CMV viremia, TB and cryptococcosis, 18-week mortality was 54% (33/61) vs. 28% (40/144) among participants with cryptococcosis alone (aOR 3.30; 95%CI 1.74-6.27).
Conclusions: Co-infections amongst adults with cryptococcosis are highly prevalent; TB and/or CMV viremia occurred in >50% of participants. 18-week mortality was highest amongst participants with both TB disease and CMV viremia indicating co-pathogenicity in the context of HIV-associated cryptococcal meningitis. Empirical TB treatment and/or targeted anti-CMV therapy may be a potential therapeutic intervention to improve overall survival outcomes amongst this high-risk population.

LB01-1309-18 Pre-existing isoniazid resistance selects for acquired rifampicin-resistant TB: A combined prospective cohort and case-control study in Ho Chi Minh City, Viet Nam

R. Spies,[1,2] H. Nguyễn Hồng,[1] P. Phan Triệu,[1] Q. Nguyễn Lê,[1] T. Đỗ Đặng Anh,[1] T. Trịnh Thị Bích,[1] H. Vũ Thị Ngọc,[1] M.H. Đặng Thị,[3] G. Thwaites,[1,2] T. Nguyễn Thụy Thương,[1,2] T. Walker,[1,2] [1]Oxford University Clinical Research Unit, Tuberculosis Group, Ho Chi Minh City, Viet Nam, [2]University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom of Great Britain and Northern Ireland, [3]Pham Ngoc Thach Hospital, Tuberculosis, Ho Chi Minh City, Viet Nam
e-mail: ruan.spies@ndm.ox.ac.uk

Background: Isoniazid resistance is present in ~20% of tuberculosis (TB) cases in Vietnam. The national TB programme (NTP) uses Xpert (Ultra) MTB/RIF for routine diagnostics, however, these platforms do not detect pre-existing isoniazid resistance.
Design/Methods: We conducted two complementary studies in Ho Chi Minh City between March 2020 and April 2024. First, we prospectively enrolled all adults routinely diagnosed with rifampicin-resistant (RR) TB by Xpert, cultured and sequenced their sputum samples, and analysed whole-genome sequencing data alongside publicly available genomes. We combined clinical history and phylogenetic criteria to define whether resistance was likely transmitted or acquired, estimating the contribu-

tion of each to overall RR-TB burden. Second, among adults with initially rifampicin-susceptible (RS) TB who developed recurrence, we compared controls, who remained RS at recurrence, to cases, who developed RR-TB. Paired isolates from initial and recurrent episodes underwent WGS to exclude reinfection and identify bacterial predictors of RR acquisition.

Results: In the prospective cohort, we enrolled, sequenced and confirmed RR-TB in 1,369/2,336 cases (59%) reported to the NTP. Overall, 82% (80.3–84.3) of RR-TB was attributed to transmission and 15% (13.5–17.3) to acquisition. Paired WGS data were available for 174/525 controls and 138/211 cases. Of these, 13 controls (7%) and 8 cases (6%) were excluded after identifying non-tuberculous mycobacteria as the major species during their initial episode. New infections were responsible for 29% (n=46) and 40% (n=52) of recurrences for controls and cases, respectively. Among 115 controls and 78 cases with confirmed relapse or treatment failure, pre-existing isoniazid resistance was the strongest predictor of RR acquisition (OR 100,19-1882).

Conclusions: Acquired resistance comprises ~15% of the RR-TB burden in Ho Chi Minh City and almost invariably follows pre-existing isoniazid resistance. These findings supporting expanding routine diagnostics to include rapid detection of isoniazid resistance, enabling timely treatment modification which may prevent acquired RR-TB.

LB01-1310-18 Causal links between gut microbiota and the risk of TB and type 2 diabetes: A Mendelian randomisation meta-analysis

A. Chauhan,[1] A. Rangrez,[2] S. Chauhan,[3] S. Pati,[4]
[1]South Asian Institute of Health Promotion, Health Promotion, Delhi, India, [2]University Hospital Heidelberg,, Department of Cardiology, Angiology and Pneumology, Heidelberg, Germany, [3]GOI-WHO TB Technical Support Network, Central TB Division, New Delhi, India, [4]Indian Council of Medical Research, ICMR, New Delhi, India
e-mail: arohi_285@yahoo.co.in

Background: The global syndemic of tuberculosis (TB) and type 2 diabetes mellitus (T2DM) is increasingly recognized as being shaped by shared immunometabolic dysfunctions. The gut microbiota, a central regulator of immune and metabolic pathways, is implicated in both diseases, yet the causal underpinnings remain unresolved. Mendelian Randomization (MR) enables evaluation of microbiota-disease associations while minimizing confounding and reverse causation.

Design/Methods: We systematically reviewed and meta-analyzed MR studies published between January, 2000 - April 2025 that investigated genetically predicted gut microbial taxa in relation to TB and T2DM risk. Databases searched included Medline, Embase, Scopus, Web of Science, and Cochrane Central. Study quality was assessed using the STROBE-MR checklist. Summary odds ratios were calculated using random-effects models where appropriate.

Results:

Fourteen MR studies (n > 5 million individuals) were included, with outcome data predominantly from European ancestry cohorts. Several microbial taxa demonstrated consistent causal associations. *Dorea*, *Alistipes*, and members of the *Lachnospiraceae* family were linked to increased susceptibility to both TB and T2DM, likely via pro-inflammatory and metabolic endotoxemic pathways. In contrast, *Ruminococcaceae UCG003* and *UCG010* exhibited protective effects in T2DM but not TB. *Akkermansia muciniphila* showed a paradoxical role, protective against T2DM by enhancing gut barrier integrity, but associated with increased TB risk, potentially via mucin degradation and immune overstimulation. *Bacteroides* was consistently associated with heightened risk for both conditions, particularly extrapulmonary TB and metabolic dysregulation.

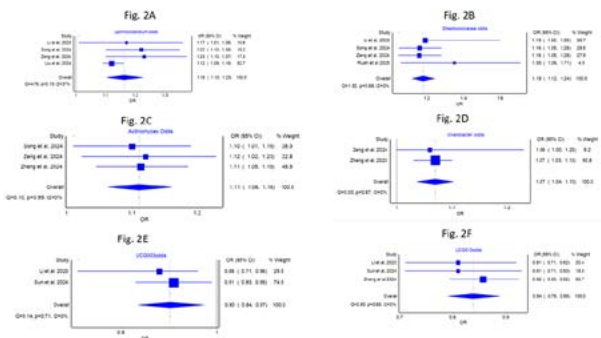

Figure: Association of Gut microbiota and T2DM.

Conclusions: Our findings support a causal role of gut microbial composition in modulating susceptibility to TB and T2DM. Several taxa exhibit disease-specific or dual associations, revealing convergent pathways along the gut–lung–metabolic axis. These insights underscore the potential for microbiota-targeted diagnostics and therapeutics, particularly in TB-DM comorbidity. Future research should prioritize species-level resolution, multi-ancestry analyses, and longitudinal studies in TBDM populations.

LB01-1311-18 Linezolid-associated adverse events and outcomes in the treatment of multidrug/rifampicin-resistant TB: A systematic review and meta-analysis of randomised controlled trials

M. Restinia,[1,2] J.-Y. Wu,[1,3] F. Gafar,[4,5,6] W. Hou,[7,8,9,10] C.-Y. Li,[1,11,12]
[1]National Cheng Kung University, Department of Public Health, College of Medicine, Tainan, Taiwan, [2]Universitas Islam Negeri Syarif Hidayatullah Jakarta, Department of Pharmacy, Faculty of Health Sciences, Tangerang Selatan, Indonesia, [3]Chi Mei Medical Center, Department of Nutrition, Tainan, Taiwan, [4]Research Institute of the McGill University Health Centre, Respiratory Epidemiology and Clinical Research Unit, Centre for Outcomes Research & Evaluation, Montreal, Quebec, Canada, [5]McGill University, McGill International TB Centre, Montreal, Quebecca, Canada, [6]Universitas Padjadjaran, Department of Biomedical Sciences, Faculty of Medicine, Bandungi, Indonesia, [7]Taipei Medical University Hospital, Department of Physical Medicine and Rehabilitation, Taipei, Taiwan, [8]Taipei Medical University, Department of Physical Medicine and RehabilitationGeriatrics and Gerontology, School of Medicine, College of Nursing,, Taipei, Taiwan, [9]Taipei Medical University, School of Gerontology and Long Term Care, College of Nursing, Taipei, Taiwan, [10]Taipei Medical University, Cochran Taiwan, Taipei, Taiwan, [11]China Medical University, Department of Public Health, College of Public Health, Taichung, Taiwan, [12]Asia University, Department of Healthcare Administration, College of Medical and Health Science, TaichungTa, Taiwan
e-mail: mitarestinia1@gmail.com

Background: Linezolid is widely used for multidrug/rifampicin-resistant tuberculosis (MDR/RR-TB) treatment, but its optimal dosing and treatment duration remain uncertain, particularly concerning safety and efficacy profiles. This study was conducted to systematically evaluate the safety and efficacy of linezolid-containing regimens for adults and children with MDR/RR-TB focusing on the effects of dose and treatment duration.

Design/Methods: A comprehensive literature search was performed in PubMed, Embase, Scopus, Web of Science, Cochrane Library, CINAHL, and ClinicalTrials.gov for randomized controlled trials (RCTs) published between January 1, 2001 and July 20, 2025. Eligible RCTs assessed adverse events, treatment discontinuation, sputum culture conversion, and unfavorable outcomes in individuals receiving linezolid-containing regimens versus standard of care (SOC). Pooled risk differences (RDs) were calculated using random-effects models, with subgroup analyses by dose (≤600 mg/day vs 1200 mg/day) and treatment duration (≤6 months vs 9 months and >9 months). The combined results were examined for heterogeneity, sensitivity, and publication bias.

Results: Twelve RCTs (n=3,581) were included. Linezolid did not significantly increase the risk of anemia, thrombocytopenia, leukopenia, neutropenia, optic neuritis, or gastrointestinal, renal, and hepatic disorders. However, the risk of peripheral neuropathy (RD 0.04; 95% CI 0.00-0.08; P=0.03; I^2 79%) was higher compared to SOC. Lower daily dose (≤600 mg/day) and shorter durations (≤9 months) of linezolid were associated with improved safety. Unfavorable outcomes were reduced (RD −0.15; 95% CI −0.21 to −0.09; P<0.00001) and sputum culture conversion were increased (RD 0.05; 95% CI 0.00-0.09; P=0.04) in the linezolid groups. While, treatment discontinuation did not differ significantly between the two groups.

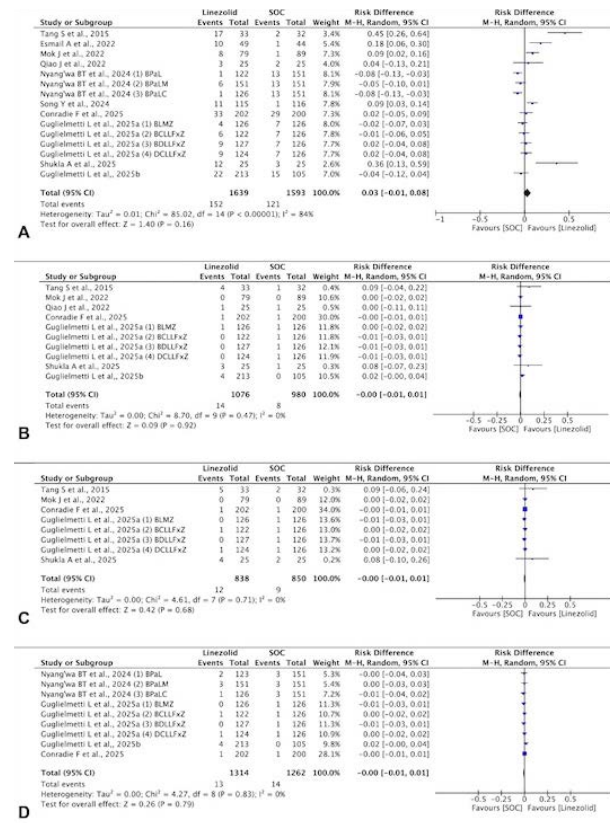

Figure: Forest plot of reported myelosuppression (A) anemia (B) thrombocytopenia (C) leukopenia (D) neutropenia.

Conclusions: Linezolid-containing regimens demonstrated acceptable safety and efficacy for the treatment of MDR/RR-TB. Lower doses and shorter durations improved tolerability without compromising treatment outcomes. These findings support current WHO-recommended regimens and highlight the potential of linezolid as a key component of shorter, effective MDR/RR-TB treatment strategies.

LB01-1312-18 Impact beyond the lungs: Evidence of muscle power deficits and functional impairment in severe pulmonary TB

E.T. Marambire,[1,2] A. De Wilton,[3,4] J. Stanely,[1,4] C. Calderwood,[1,5,4] K. Mattick,[1,6] W. Samuriwo,[1] M. Paradza,[1] G. Gwaze,[1] F. Kowo-Nyakoko,[3,7] K. Ward,[8,7] C. Gregson,[1,4] K. Kranzer,[1,9,5] [1]Biomedical Research and Training Institute, The Health Research Unit, Harare, Zimbabwe, [2]University Hospital, LMU Munich, CIHLMU Center for International Health, Munich, Germany, [3]Biomedical Research and Training Institute, The Health Research Unit Zimbabwe, Harare, Zimbabwe, [4]University of Bristol, Bristol Medical School, Bristol, Bristol, United Kingdom of Great Britain and Northern Ireland, [5]London School of Hygiene & Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom of Great Britain and Northern Ireland, [6]Brighton and Sussex Medical School, Global Health and Infection Department, Bristol, United Kingdom of Great Britain and Northern Ireland, [7]University of Southampton, MRC Lifecourse Epidemiology Centre, Human Development & Health, Southampton, United Kingdom of Great Britain and Northern Ireland, [8]London School of Hygiene & Tropical Medicine, MRC Unit The Gambia, Banjul, Gambia (Republic of The), [9]LMU University Hospital, LMU Munich, Institute of Infectious Diseases and Tropical Medicine, Munich, Germany
e-mail: angus.dewilton@bristol.ac.uk

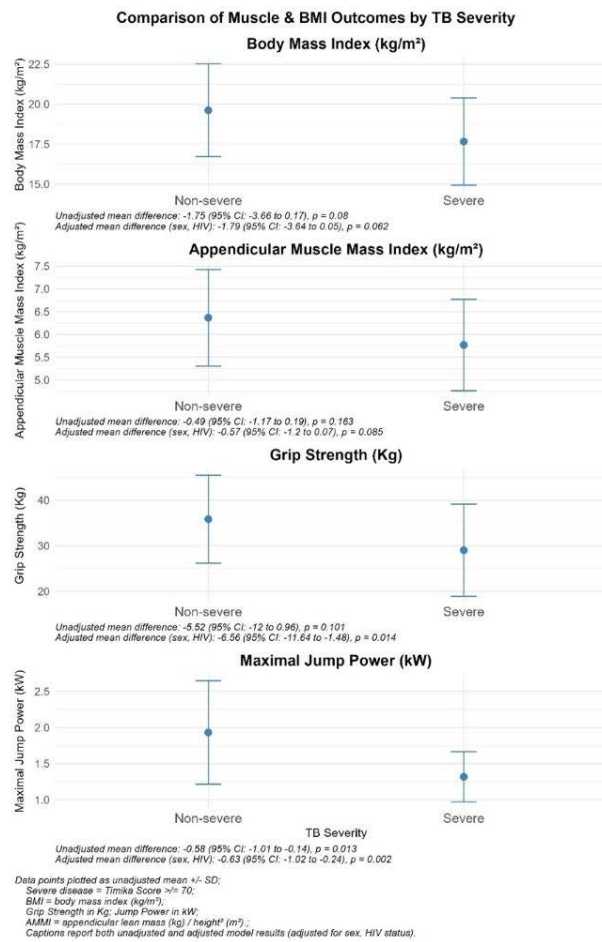
Background: Pulmonary tuberculosis is associated with cachexia but associations with muscle power and functional impairments are poorly defined. We aimed to assess the relationship between tuberculosis disease severity, muscle measurements and functional impairment.

Design/Methods: Seventy-five adults with Xpert-confirmed pulmonary tuberculosis in Harare, Zimbabwe, completed work and disability questionnaires (WHO-DAS), anthropometry, Jamar dynamometry (hand-grip strength), jumping mechanography (peak muscle power) and Short Physical Performance Battery (lower-limb strength and balance assessment; SPPB). Severe tuberculosis disease was defined as chest radiograph Timika score≥70 (range 0-140).

Appendicular Muscle Mass Index (AMMI, kg/m^2) was computed from Dual-energy X-ray Absorptiometry (DXA). Measures of functional impairment were by WHODAS>35, SPPB<12, or >50% workdays missed. Univariable and multivariable linear and logistic regression examined associations between disease severity and (a) muscle indices or (b) functional measures and adjusted for age and HIV status.

Results: All participants completed all assessments, except for jumping mechanography which 19/75 (25.0%) felt too unwell to perform. Overall, 22 (29.3%) were categorised as having severe tuberculosis. Mean age was 37.9 years (SD 8.5); 22 (29.3%) were female, 33 (44%) were underweight (BMI<18.5kg/m2) and 36 (48.0%) were living with HIV. 49 (65.3%) had a SPPB<12, indicating objective functional impairment. Participants with severe tuberculosis had lower muscle strength (mean difference -6.56kg, CI -11.64kg to -1.48kg) and power (mean difference -0.63kW, CI -1.02kW to -0.24kW) (Figure 1).

BMI and muscle mass were lower, but not significantly. Those with severe tuberculosis also had greater odds of impairment in two domains: SPPB<12 (OR 4.93 [95%CI 1.23–33.16]) and WHODAS>35 (OR 49.0 [1.25–15.65]) but were not significantly more likely to have missed >50% workdays (OR 1.64 [0.38–7.59]).



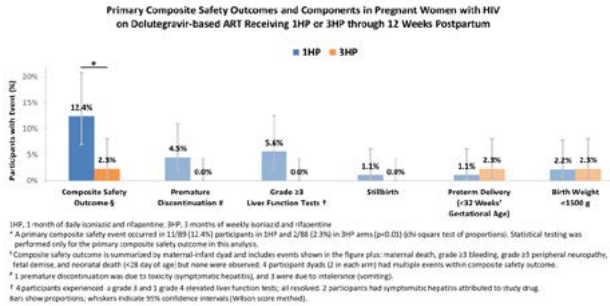
Conclusions: Severe pulmonary tuberculosis is associated with reduced muscle mass and function, potentially resulting in functional impairment through mechanisms other than lung pathology. Persistence of these findings post-treatment remains to be determined.

LB02 The Union/CDC Late-Breaker Session - Clinical Trial Advances in TB: HIV Co-Infection, Pediatric Meningitis, and New Drugs

LB02-1313-19 Safety of rifapentine-based TB prevention in pregnant women with HIV on dolutegravir: DOLPHIN-Moms trial

S. LaCourse,[1] J. Mathad,[2] L. Varughese,[3] B.A.S. Nonyane,[4] S. Kim,[5] J. Moodley,[6] T. Beattie,[7] V. Govender,[8] T. Moloantoa,[9] M. Van Schalkwyk,[10] G. Churchyard,[8] R. Chaisson,[3] on behalf of the DOLPHIN Moms Study team
[1]University of Washington, Department of Medicine, Division of Allergy and Infectious Diseases, Seattle, United States of America, [2]Weill Cornell Medicine, Department of Medicine, New York, United States of America, [3]Johns Hopkins University, Department of Medicine, Baltimore, United States of America, [4]Johns Hopkins, Department of Medicine, Baltimore, United States of America, [5]Frontier Science Foundation, Biostatistics, Brookline, United States of America, [6]The Aurum Institute NPC, Clinical Research Department, Durban, South Africa, [7]The Aurum Institute NPC, Clinical Trials, Johannesburg, South Africa, [8]The Aurum Institute NPC, Clinical Research Division, Johannesburg, South Africa, [9]University of Witwatersrand, Perinatal HIV Research Unit (PHRU), Klerksdorp, South Africa, [10]Family Centre for Research with Ubuntu (FAMCRU), Department of Medicine, Cape Town, South Africa
e-mail: sylvial2@uw.edu

Background: WHO endorses 3-month weekly isoniazid-rifapentine (3HP) for TB prevention for people with HIV (PWH) in general. For pregnant PWH, 6-month daily isoniazid is recommended due to limited safety data of rifapentine in pregnancy. DOLPHIN-Moms is an open-label phase II trial in South Africa evaluating safety of 3HP and 1-month daily isoniazid-rifapentine (1HP) in pregnant PWH on dolutegravir-based antiretroviral therapy (DTG-ART).
Design/Methods: Pregnant PWH with HIV viral suppression at 20-34 weeks gestation were randomized to 1HP or 3HP with twice-daily DTG. Primary outcome was a composite of maternal mortality, premature discontinuation (intolerance or toxicity), targeted maternal, pregnancy, and neonatal adverse events (AEs) by 12 weeks postpartum (12wkPP).
Results: Among 177 randomized participants (n_{1HP}=89; n_{3HP}=88), median (interquartile range) age was 32 years (27-36), gestational age 26 weeks (23-30), and CD4 689 cells/mm^3 (529-828). A primary composite safety event was experienced by 11/89 (12.4%) participants in 1HP and 2/88 (2.3%) in 3HP arms (p<0.01) *(Figure)*.
All maternal grade ≥3 liver enzyme elevations occurred in the 1HP arm (5/89 [5.6%]); all resolved. Grade ≥3 AEs occurred in 24/89 (27.0%) maternal participants in 1HP and 15/88 (17.0%) in 3HP arms. Treatment completion was similar for both arms (1HP: 83/89 [93%]; 3HP: 87/88 [99%]). One infant death (non-treatment related due to bacterial pneumonia) occurred in the 1HP arm. No maternal deaths, infant HIV infection, or maternal or infant TB disease occurred. 95% of participants with viral load data through 12wkPP remained consistently virally suppressed (1HP: 85/88 [97%]; 3HP: 79/87 [91%]). All but 1/11 participants with detectable viral load at any time before 12wkPP had subsequent viral suppression.



Conclusions: Among pregnant PWH on twice daily DTG-ART, those receiving 3HP had fewer adverse composite safety events than 1HP. High rates of treatment completion and viral suppression were observed with both regimens, supporting expanded TB prevention options in pregnancy.

LB02-1314-19 Six-month mortality in ATLAS trial of immediate and/or high-dose anti-TB therapy for adults with HIV-related sepsis

S. Mpagama,[1] S. Heysell,[2] M. Null,[2] B. Said,[1] E. Nuwagira,[3] T. Thomas,[2] D. Boulware,[4] M. Conaway,[5] C. Moore,[2] C. Muzoora,[3] [1]Kibong'oto Infectious Diseases Hospital, Research and Innovation, Siha, United Republic of Tanzania, [2]University of Virginia, Infectious Diseases and International Health, Charlottesville, United States of America, [3]Mbarara University Science Technology, Medicine, Mbarara, Uganda, [4]University of Minnesota, Infectious Diseases, Minneapolis, United States of America, [5]University of Virginia, Public Health Sciences, Charlottesville, United States of America
e-mail: sempagama@yahoo.com

Background: The greatest burden of sepsis is found in persons living with HIV (PLWH) in Africa, where the risk of death is greatest from tuberculosis (TB) compared to other non-TB pathogens. The ATLAS trial recently found immediate conventional-dose anti-TB therapy improved 28-day mortality for PLWH admitted with sepsis and later found to have TB (11.8% versus 38.4% for diagnosis-dependent treatment, standard-of-care).
Design/Methods: We now report on the 6-month outcomes of the phase 3, multisite, open-label, randomised controlled 2×2 factorial superiority trial of (1) immediate and (2) high-dose anti-TB therapy in addition to stan-

dard of care (ceftriaxone for seven days) for adult PLWH admitted with sepsis at four hospitals in Tanzania and Uganda. The intervention was continued for 28 days, after which a non-study clinician determined the need for continuation of anti-TB therapy.

Results: Among 395 participants, we assigned 99 to immediate conventional-dose, 99 to immediate high-dose, 100 to diagnosis-dependent high-dose, and 97 to diagnosis-dependent conventional-dose (standard-of-care) therapy. We confirmed TB in 204 (51.6%) participants. The 6-month mortality was 38.9% for the immediate conventional-dose group, 44.4% for the immediate high-dose group, 35.5% for the diagnosis-dependent high-dose group, and 41.8% for the diagnosis-dependent conventional-dose group (not statistically significant). In participants with later confirmed TB, the adjusted hazard ratio (95%CI) for 6-month mortality relative to the standard of care was 0.47 (95%CI, 0.24-0.90; p=0.02) for the immediate conventional-dose group; 0.61 (95%CI, 0.32-1.13; p=0.12) for the immediate high-dose group; and 0.56 (95%CI, 0.31-1.01; p=0.06) for the diagnosis-dependent high-dose group. No significant differences in adverse events occurred among treatment groups.

Conclusions: Immediate conventional-dose anti-TB therapy significantly reduced 6-month mortality in those later confirmed to have TB, comprising the majority of the population. Further studies should consider the optimal timing of anti-TB discontinuation in those that survive sepsis without later diagnostic confirmation of TB.

LB02-1315-19 In pursuit of an improved oxazolidinone for TB: A phase 1 trial evaluating safety, tolerability, pharmacokinetics, and food effect of TBD09 (MK-7762) in healthy adults

D. Holtzman,[1] C. Vinnard,[1] A. Anderson,[1] A. Yeakey,[1] L. Daglish,[1] E. McIntyre,[1] J. Nussbaum,[2] L. Stamm,[3] J. Alexander,[4] S. Rasmussen,[5] M. Levi,[1] C. Wells,[1]
[1]Gates Medical Research Institute, Clinical Development, Cambridge, United States of America, [2]Merck, Translational Medicine, South San Francisco, United States of America, [3]Merck, Infectious Disease Clinical Research, San Francisco, United States of America, [4]Alexander Pharma Consulting LLC, Clinical Development, Cary, United States of America, [5]Celerion, Clinical Research, Lincoln, United States of America
e-mail: christopher.vinnard@gatesmri.org

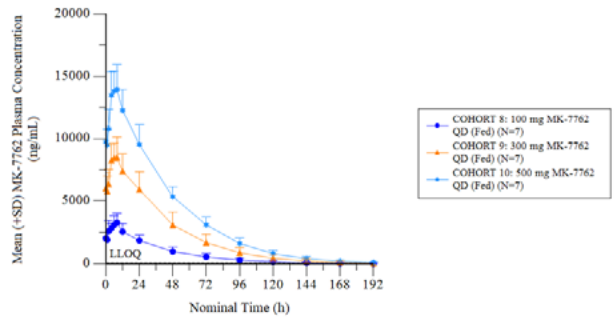
Background: The drug candidate TBD09 (previously MK-7762) is a novel oxazolidinone with similar or better potency than linezolid in pre-clinical tuberculosis (TB) models and a potentially improved safety profile with less off-target mitochondrial protein synthesis inhibition. A first-in-human trial characterized the safety and pharmacokinetics (PK) of TBD09 in healthy adults.

Design/Methods: Gates MRI-TBD09-101 was a randomized, double-blind, placebo-controlled clinical trial. Part 1 included 5 cohorts evaluating single ascending doses (SAD) of oral TBD09 (50, 150, 300, 600, or 1200 mg) or placebo in fasted participants, and a cross-over food effect (FE) cohort with TBD09 (300 mg) in fasted and fed (high-fat, high-calorie) states.

Part 2 included a 3-period FE cohort (600 mg: fasted; standard meal; high-fat, high-calorie meal) and 3 multiple ascending dose (MAD) cohorts (100, 300, 500 mg, or placebo) in fasted or fed states (28 days).

Results: Forty-eight participants (n=40, SAD Cohorts 1-5; n=8, FE Cohort 6) were dosed in Part 1 and 71 participants (n=11, FE Cohort 7; n=60, MAD Cohorts 8-10) were dosed in Part 2. TBD09 was well-tolerated with no safety concern identified at exposures that exceeded the PK target. TBD09 did not impact hematologic safety lab values over 28 days in MAD cohort participants. The observed half-life of TBD09 in plasma (geometric mean) on Day 28 in the MAD cohorts ranged between 24.0 - 26.3 hours (Figure).

TBD09 C_{max} and AUC increases were dose-proportional after single doses through 300 mg, and less than dose-proportional above 300 mg. In Cohort 7, TBD09 AUC_{0-24} and C_{max} increased by approximately 1.4 to 1.6-fold in the fed state, compared to fasted, following a 600 mg dose.



Conclusions: The results of Gates MRI-TBD09-101 support continued development of TBD09. Additional clinical trials with longer dosing durations and in participants with TB are planned to further characterize the safety and efficacy of TBD09.

LB02-1316-19 Shortened intensive anti-TB treatment and aspirin for African and Asian children with TB meningitis: The 48-week results from the phase-3 factorial randomised SURE trial

D.M Gibb,[1] & the SURE Trial Team,[2] [1]University College London, Medical Research Council Clinical Trials Unit, London, United Kingdom of Great Britain and Northern Ireland, [2]University College London, Medical REsearch Council Clinical Trials Unit, London, United Kingdom of Great Britain and Northern Ireland
e-mail: diana.gibb@ucl.ac.uk

Background: Tuberculous meningitis (TBM) has high mortality (~20%) and neurological sequelae (~50%), particularly in young children. Standard WHO-recommended 12-month standard-of-care anti-tuberculosis treatment (SOC-ATT) (2m HRZE;10m HR) for TBM follows pulmonary TB treatment, but CNS penetration is suboptimal. Inflammation plays a major role in TBM, but data on aspirin in children are sparse.
Design/Methods: We randomised children with TBM to 24-week intensive ATT [isoniazid (20mg/kg), rifampicin (30mg/kg), pyrazinamide (40mg/kg), levofloxacin (20mg/kg)] versus SOC-ATT (10% non-inferiority margin), and factorially, to aspirin (20mg/kg) versus placebo as adjuvant anti-inflammatory therapy (superiority); all children received corticosteroids (standard care). The primary 48-week efficacy endpoints were mortality and modified Rankin Scale (mRS) respectively.
Results: 369 children were enrolled from 9 hospitals (4 Vietnam, 2 India, 1 Zambia, 1 Zimbabwe, 1 Uganda) between 03/2021-07/2024. Median age was 4.8 years (2m-18y), 53% male, 4% living with HIV, 77% definite/probable TBM (Marais criteria); TBM stage I/II/III were 46%/40%/14%. 48-week vital status was ascertained for 99% and mRS for 95% of the modified-intent-to-treat population (excluding 6 with alternative diagnoses).
Preliminary results showed non-inferiority of intensive-ATT was **NOT** demonstrated: 29(16%) intensive-ATT versus 21(12%) SOC-ATT died: adjusted risk difference=5.1% (95%CI -1.7% to +12.0%; p=0.14). There was a trend towards an interaction (p=0.13), with numerically higher mortality risk in each of the SOC-ATT-aspirin (adjusted hazard ratio(aHR) vs SOC-ATT-placebo=2.81 (1.09-7.28) p=0.03), intensive-ATT-placebo vs SOC-ATT-placebo (aHR=2.52 (0.97-6.59) p=0.06), and intensive-ATT-aspirin vs SOC-ATT-placebo (aHR=2.85 (1.10-7.38) p=0.03) (unadjusted for multiple testing). 38/176(22%) aspirin versus 25/170(15%) placebo had mRS scores 5/6 (severe disability/died) (adjusted odds ratio=1.80, (95%CI 0.95-3.41; p=0.07). 100/186(54%) intensive-ATT versus 79/183(43%) SOC-ATT experienced ≥1 grade 3/4 adverse events (p=0.04), and 103/185(56%) vs 76/184(41%) on aspirin versus placebo respectively (p=0.006). Among week-48 survivors, 238/296(80%) had no symptoms/disability (mRS=0/1), 76% with aspirin versus 85% with placebo (adjusted p=0.02).

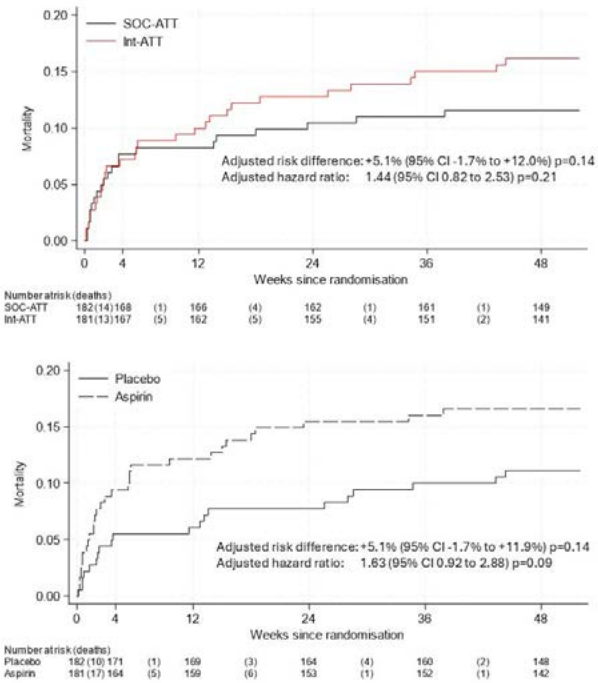


Figure: Mortality through 48 weeks by (A) Intensive-ATT vs SOC-ATT and (B) aspirin vs placebo.

Conclusions: Neither shortened intensive-ATT nor aspirin showed any benefit for children with TBM. Post-treatment follow-up to week-72 is ongoing.

LB02-1317-19 DA-7801: Cost-effective anti-TB drug with strong efficacy and low toxicity

J. Choi,[1] [1]Dong-A ST, R&D Center, Seoul, Republic of Korea

Background: Global tuberculosis (TB) treatment heavily relies on international aid, yet less than half of the $13 billion required annually is secured. To improve treatment access in low-income countries, there is an urgent need for new TB drugs with high efficacy and drastically reduced production costs.
Design/Methods: DA-7801, developed by Dong-A ST, represents a novel anti-TB agent engineered through AI-based molecular modeling to optimize drug properties, including simple chemical synthesis and scalable, cost-efficient mass production. The compound's antimicrobial efficacy was rigorously evaluated in vivo using well-established murine TB infection models to simulate human disease.
Safety assessments were conducted through repeated-dose toxicity studies in rats, with particular attention to the no-observed-adverse-effect level (NOAEL) to define therapeutic windows and safety margins.
Results: DA-7801 exhibited potent in vitro antibacterial activity against *Mycobacterium tuberculosis*, with a minimum inhibitory concentration (MIC) of ≤0.016 μg/mL,

indicating strong potency. In vivo efficacy studies demonstrated significant reduction of bacterial loads in lung tissue, outperforming existing reference drugs by over fourfold. Toxicity studies revealed an excellent safety profile, with a NOAEL exceeding 300 mg/kg in rats, approximately one-third of the toxicity observed with current TB therapies. These data collectively highlight DA-7801's promising therapeutic potential and favorable safety margins.

	Vehicle	Pretomanid (40)	DA-7801 (10)	DA-7801 (20)	DA-7801 (40)

In Vivo Efficacy Evaluation.

Conclusions: DA-7801 meets key preclinical requirements for anti-TB drug development and is poised to enter clinical trials. It has demonstrated broad-spectrum activity from drug-susceptible (DS) to multidrug-resistant (MDR) TB. A combination regimen with bedaquiline is also under investigation to shorten MDR treatment duration. With its simple synthesis and low-cost scalability, DA-7801 holds promise for enhancing global TB treatment accessibility.

LB02-1318-19 IMPAACT 2034: Phase 1 study of the pharmacokinetics (PK), safety/tolerability and acceptability of a single dose of pretomanid in female children with rifampicin-resistant TB

P. Howell,[1] Y. Zou,[2] A. Garcia-Prats,[3] G. Montepiedra,[4] L. Aaron,[4] J. Nedelman,[5] E. Svensson,[2] M. Beumont,[5] E. Sun,[5] S. Nachman,[6] A. Hesseling,[7] E. Weld,[8] [1]University of Witwatersrand, Clinical HIV Research Unit, Johannesburg, South Africa, [2]Uppsala University, Department of Pharmacy; Pharmacometrics; Global Health Pharmacometrics, Uppsala, Sweden, [3]University of Wisconsin-Madison, Division of General Pediatrics and Adolescent Medicine, Division of Global Pediatrics, Madison, United States of America, [4]Harvard School of Public Health, Statistical and Data Analysis Center, Boston, United States of America, [5]TB Alliance, Research and Development, New York, United States of America, [6]Stony Brook University, Renaissance School of Medicine, Stony Brook, United States of America, [7]Stellenbosch University, Paediatric Research, Stellenbosch, South Africa, [8]Johns Hopkins University, Infectious Diseases, Baltimore, United States of America
e-mail: eweld@jhmi.edu

Background: Pretomanid is approved in adults for the treatment of tuberculosis (TB) resistant to isoniazid, rifamycins, a fluoroquinolone and a second-line injectable antibacterial drug. Ten and 50mg dispersible tablet formulations were developed for pediatric use and shown in healthy adults to achieve exposures similar to the adult marketed formulation. IMPAACT 2034 investigated the pharmacokinetics, safety/tolerability, and acceptability of a single dose of pretomanid in female children with rifampicin-resistant TB (RR-TB).

Design/Methods: 28 female children with RR-TB, 6 with HIV, on an optimized background TB regimen (OBR), were enrolled in South Africa (N=26) and Thailand (N=2) into 4 weight cohorts: 1 (≥31 kg, N=8); 2 (20-<31 kg, N=2); 3 (12-<20 kg, N=8); 4 (4-<12 kg, N=9). All received a single dose of pretomanid based on weight, ranging between 20 and 200mg, using the marketed tablet or the scored, pediatric formulations. The primary objective was to confirm modeled weight-based doses of pretomanid for future evaluation in a multiple-dose (MD) study. Participants were followed up for 2 weeks post-dosing. We conducted an interim PK analysis in 27 PK-evaluable participants. A previously developed population PK model based on data from 3 pretomanid studies in adults with TB was used as starting point.

Results: Median age was 5 years (range 0.6-17.6 years), median weight 15.1 kg (range 6.9-56.8 kg). The PK of pretomanid was characterized with sufficient precision and power across cohorts to predict doses in the MD study for all cohorts. Study doses achieved exposures (C_{max} and AUC) that were comparable to those in healthy and TB-infected adults. The overall safety for a single dose of pretomanid was acceptable across ages and weight cohorts.

PK Parameter	Statistics	All (N=27)	Cohort 1 (N=8)	Cohort 2 (N=2)	Cohort 3 (N=8)	Cohort 4 (N=9)
Cmax (ng/mL)	Median (Range)	2275 (1341-3562)	2124 (1399-3850)	2272 (2207-2338)	2295 (2060-2520)	2243 (1354-3562)
	Mean (SD)	2260 (570)	2175 (530)	2272 (93)	2317 (570)	2285 (720)
	Geometric Mean (GSD)	2188 (1.3)	2113 (1.3)	2272 (1)		2182 (1.4)
AUC_{0-48} (hg*h/mL)	Median (Range)	51.4 (25.5-82.7)	51.5 (34.9-73.5)	50.4 (49.4-51.4)	50.6 (41.1-71.1)	52.4 (25.5-82.7)
	Mean (SD)	53.2 (14)	54.2 (14)	50.4 (1.5)	52.5 (11)	53.5 (20)
	Geometric Mean (GSD)	51.2 (1.3)	52.6 (1.3)	50.4 (1)	51.6 (1.2)	49.8 (1.5)
$AUC_{0-\infty}$ (hg*h/mL) (model)	Median (Range)	59.6 (28-95.9)	66.2 (45.9-94)	58.6 (58.1-59.1)	57.5 (46.8-85.5)	59.8 (28-95.9)
	Mean (SD)	63.5 (1.8)	68.6 (1.9)	58.6 (1.5)	60.9 (1.3)	62.4 (24)
	Geometric Mean (GSD)	60.9 (1.4)	66.3 (1.3)	58.6 (1)	59.8 (1.2)	57.9 (1.5)

SD, standard deviation; GSD, geometric SD
Cohort 1 (weight ≥31 kg); Cohort 2 (weight 20 – <31 kg); Cohort 3 (weight 12 – <12 kg) – Cohort 4 (weight <12 kg)

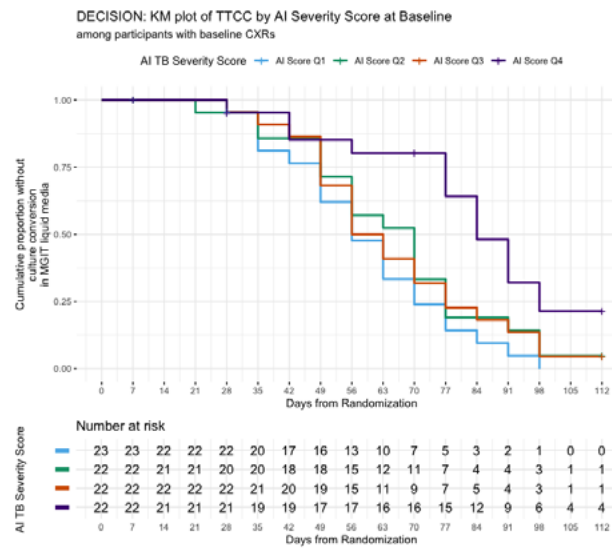
Table. Summary of PK Parameters for Participants in IMPAACT 2034.

Conclusions: The interim PK data provided sufficient power to select doses for a future MD study. A single dose of pretomanid was safe and tolerated in female children.

LB02-1319-19 An AI chest X-ray severity score is prognostic of time to culture conversion in a pulmonary TB clinical trial

E. Basson,[1,2] B.H. Aldana,[3] M. McClean,[4] M. van Erp,[5] E.T.M. Klinkenberg,[5] P. Phillips,[3] N. Heinrich,[1,2,6] M. Hoelscher,[1,2,4,6] [1]LMU University Hospital, Institute of Infectious Diseases and Tropical Medicine, Munich, Germany, [2]German Centre for Infection Research (DZIF), Munich Partner Site, Munich, Germany, [3]University of California San Francisco, UCSF Centre for Tuberculosis, San Francisco, United States of America, [4]Helmholtz Zentrum München, German Research Centre for Environmental Health, Munich, Germany, [5]Delft Imaging Systems B.V., X-ray, Ten Bos, Netherlands, [6]Fraunhofer Institute, Translational Medicine and Pharmacology ITMP, Immunology, Infection, and Pandemic Research, Munich, Germany
e-mail: erlandy.basson@med.uni-muenchen.de

Background: Computer-aided detection (CAD) systems have demonstrated value in tuberculosis (TB) screening frameworks, but their value in describing disease severity and predicting treatment response remains unexplored. Our study evaluated the associations between a novel AI-generated chest X-ray (CXR) score, measured at baseline, and early microbiological response, measured as time to culture conversion (TTCC) in liquid media.
Design/Methods: We performed a secondary analysis of CXRs from participants enrolled in DECISION, a 16-week phase 2 dose-finding clinical trial conducted at four sites. Cox proportional hazards models were used to assess the relationship between baseline AI-generated severity score and TTCC, both unadjusted and adjusted for baseline covariates: age, sex, HIV status, and BMI. Since trial results have not been publicly presented, all analyses aggregated data across treatment arms.
Results: Of 92 enrolled individuals, 89 had baseline CXRs available. Novel severity scores were generated by quantifying size and probability of active TB from heat maps from CAD4TB v7.0, an existing CAD screening tool. The median baseline severity score was 36.3 (range 7.1-66.1). In unadjusted analyses, the severity score was strongly associated with TTCC, with a hazard ratio of 0.77 per 10 unit increase in score (CI: 0.66-0.89, $p < 0.0001$); results were similar in the adjusted analysis (HR: 0.69 CI: 0.57-0.83, $p < 0.001$). When split into quartiles, participants with the highest 25% of scores converted more slowly than the least severe group, with a median difference in TTCC of 28 days (HR 0.32, CI: 0.16-0.62, $p < 0.0001$).



Conclusions: An AI-generated CXR severity score at baseline offers a potentially powerful tool to identify patients at risk of delayed culture conversion. These findings, collected in a trial setting, highlight the tool's potential for early risk stratification in treatment of pulmonary TB, with the additional benefit of improving consistency in data collection within multi-site studies.

LB02-1320-19 Missed opportunities: High yield of universal TB testing in people and their companions in the emergency department in South Africa

R. Berhanu,[1] L. Mlambo,[2] N. Mofokeng,[3] P. Abraham,[4] L. Anova,[5] L. Genade,[2] D. Evans,[6] N. Martinson,[2]
[1]Vanderbilt University Medical Center, Department of Medicine, Division of Infectious Diseases, Johannesburg, South Africa, [2]University of the Witwatersrand, Perinatal HIV Research Unit, Johannesburg, South Africa, [3]University of the Witwatersrand, Perinatal HIV Research Unit, Botshabelo, South Africa, [4]University of the Witwatersrand, Perinatal HIV Research Unit, Klerksdorp, South Africa, [5]Vanderbilt University Medical Center, Department of Medicine, Division of Infectious Diseases, Nashville, United States of America, [6]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa
e-mail: rebecca.h.berhanu@vumc.org

Background: Emergency departments (EDs) serve high-risk populations who may not access other healthcare, representing unique opportunities for tuberculosis (TB) screening. We performed an observational study examining sputum TB PCR testing yield among ED patients and companions in a large South African township.
Design/Methods: Adult patients and companions at the Botshabelo hospital ED in the Free State, South Africa were offered HIV and sputum TB PCR testing irrespective of TB symptoms or risk factors after individual informed consent. Sputum specimens were tested in the hospital laboratory using the BD Max MDRTB system per standard of care.
Results: Of 568 assessed individuals, 217 were ineligible (24 on TB treatment, 108 unable to consent due to illness severity or intoxication, 76 declined, 9 other). All 362 enrolled participants provided sputum. Of 308/362 with valid sputum TB PCR results: 124 (40%) were ED patients and 184 (60%) companions.
Participants were 87% male, median age 36 years (IQR 27-43), 22% living with HIV, and 18% WHO symptom screen positive. TB risk factors included smoking (58%), alcohol misuse (AUDIT-C score >= 3 for women and >= 4 for men) (56%), incarceration history (29%), mining history (8%), and close TB contact (8%).

Characteristic	Overall n = 308	Sputum TB PCR negative n = 294	Sputum TB PCR positive n = 14	p-value
Attending as patient (vs companion)	184/308 (40%)	177/294 (60%)	7/14 (50%)	0.6
Male sex	269 /308 (87%)	256/294 (87%)	13/14 (93%)	>0.9
Age (median, IQR)	36.0 (26.9, 43.2)	35.8 (27.9, 42.8)	41.6 (25.9, 51.4)	0.4
WHO symptom screen positive	55/308 (18%)	53/294 (18%)	2/14 (14%)	>0.9
Living with HIV	64/286 (22%)	60/272 (22%)	4/14 (29%)	0.5
Alcohol misuse	134/241 (56%)	127/230 (55%)	7/11 (64%)	0.8
Current smoker	179/308 (58%)	171/294 (58%)	8/14 (57%)	0.9
History of incarceration	88/308 (29%)	84/294 (29%)	4/14 (29%)	> 0.9

Table.

Overall, 14/308 (4.5%, 95% CI 2.6% - 7.7%) had a positive sputum TB PCR with no significant difference between ED patients (5.6%) and companions (3.8%, p=0.6). Among 14 individuals with TB, half were companions, 7% reported cough, 14% were WHO symptom screen positive, 70% were HIV-negative, and 60% had no identifiable TB risk factors.
Conclusions: High TB testing yield (4.5%) among unselected[TS1] ED patients and companions –most asymptomatic and without identifiable risk factors – demonstrates significant missed opportunities for TB detection in South African emergency department settings in South Africa. These findings support further exploring universal TB testing approaches in EDs within high TB prevalence settings.

LB02-1321-19 Bedaquiline long-acting formulation: Interim results of a phase 1 pharmacokinetic and safety study for single-dose TB preventive treatment

M. Zeitlinger,[1] M. Prager,[1] C. Guinard-Azadian,[2] B. Remmerie,[3] E. Birmingham,[4] N. Bakare,[5] L. Ballell,[3] C. Diba,[3] R. Savic,[6] B. Solans,[6] I. Eshun-Wilsonova,[7] V. Cox,[5] [1]Medical University of Vienna, Department of Clinical Pharmacology, Vienna, Austria, [2]Johnson & Johnson, TB Research & Development, Issy-les-Moulineaux, France, [3]Johnson & Johnson, TB Research & Development, Beerse, Belgium, [4]Johnson & Johnson, TB Research & Development, Raritan, United States of America, [5]Johnson & Johnson, TB Research & Development, Titusville, United States of America, [6]UCSF School of Pharmacology, San Francisco, United States of America, [7]Johnson & Johnson, TB Research & Development, Cape Town, South Africa
e-mail: vcox@its.jnj.com

Background: A long-acting injectable (LAI) formulation is being evaluated in healthy volunteers in this first-in-human safety/pharmacokinetics (PK) study to support dose selection of bedaquiline (BDQ) LAI for TB preventive treatment (TPT).
Design/Methods: TMC207TBC1006 is a Phase 1, open-label, parallel-group, single ascending dose study assessing the PK, safety, and tolerability of an IM injection of BDQ LAI at three doses: low-dose, 2.5mL (Group A); medium-dose, 5mL (Group B); and high-dose, 2 x 5mL (Group C). Primary endpoints include PK parameters of BDQ and M2 metabolite, adverse events (AEs) including injection site reactions (ISRs), adverse events of special interest and ECG parameters. Secondary endpoints include a pain scale and preference evaluation. PK and safety are assessed for 52 weeks after administration. This interim analysis was performed 3 months after enrolling the last participant in Group C, based on available PK and safety data from all 3 groups. A new modelling and simulation framework was developed for dose selection.

Results: 32 participants were enrolled: 4 in Group A, 8 in Group B and 20 in Group C. Interim PK analyses showed robust BDQ release, resulting in less-than-dose proportional BDQ C_{max} and AUC_{3month}. Target human BDQ exposure for TPT, as determined based on translational PK/PD, is achieved with a single BDQ LAI medium-dose, 5mL injection. Injections were generally well-tolerated. All participants experienced ISRs, which were manageable with counseling and/or minimal analgesics. ISRs were mostly pain and tenderness of grade 1 and 2 severity. Grade 3 injection-associated events include pain, tenderness and erythema in 3 participants and hypotension in 1 participant. There were no drug-related serious or grade 4 AEs.
Conclusions: Interim analyses showed robust BDQ release with no major safety concern. This first clinical study of a long-acting TB formulation informs dose selection for future investigation of BDQ LAI as potential single-dose TPT.

LB03 The Union/CDC late-breaker - TB Detection and Transmission: New Diagnostic Approaches and Study Insights

LB03-1322-21 Asymptomatic ≠ less infectious: School-based study highlights critical role of asymptomatic TB in transmission

S. Ge,[1] Q. Ruan,[1] F. Li,[2] Y. Ren,[3] L. Fei,[1] Y. Yang,[1] J. Li,[2] W. Zhang,[1] TB YOUTH study group [1]National Medical Center for Infectious Diseases, Huashan Hospital, Fudan University, Department of Infectious Diseases, Shanghai, China, [2]Guizhou Center for Disease Control and Prevention, Institute for Tuberculosis Prenvention and Control, Guiyang, China, [3]Shanghai Sci-Tech Inno Center forInfection & Immunity, Clinical Research Departement, Shanghai, China
e-mail: yoko9714@163.com

Background: Asymptomatic tuberculosis (TB), a crucial part of the disease spectrum, has received increasing attention. The research on its infectiousness remains insufficient. This work compared the infectiousness of asymptomatic and symptomatic TB cases in school settings.
Design/Methods: Active TB index in schools were classified into symptomatic and asymptomatic cases based on the presence or absence of cough, fever, night sweats, weight loss, or hemoptysis. Close contacts were screened using interferon-γ release assay (IGRA) in Guizhou Province, China from September 2023 to June 2025 (TB-YOUTH screening study: NCT06033807). Contacts with positive IGRA were regarded as *M. tuberculosis* infected. A multilevel logistic regression model incorporating random intercepts for index cases, with adjustment for contact-level covariates, was employed to compare the risk of IGRA positivity between contacts of asymptomatic and symptomatic cases. Index-level confounding variables were balanced through stabilized inverse probability weighting (IPW).
Results: A total of 18,501 close contacts were included in the study, among which 9,056 (48.9%) were contacts of asymptomatic TB patients. The overall IGRA positivity rate was 10.1%. After adjusting for the smear status of index cases and contacts' characteristics (age, gender, BCG scar, other TB contact history), there was no significant difference in the risk of IGRA positivity between contacts of asymptomatic TB patients and those of symptomatic TB patients (adjusted odds ratio [aOR]: 0.90, 95% confidence interval [95% CI]: 0.76–1.07, $P = 0.23$). Subgroup analysis excluding the contacts whose index cases were clinically diagnosed cases showed similar result (aOR: 1.04, 95% CI: 0.90–1.19, $P = 0.59$).
Conclusions: Asymptomatic TB is not less infectious than symptomatic TB, and may play an important role in the transmission of *M. tuberculosis*. To achieve the goal of ending TB, it is necessary to pay attention to the early detection of asymptomatic TB and the medical evaluation of their contacts.

LB03-1323-21 Evaluation of MultNAT and PortNAT swab-based assays for Mycobacterium tuberculosis detection in Nigeria: A comparative study with Xpert MTB/RIF Ultra and Culture

A. Babayi,[1] T.T. Eliya,[1] Z. Liang,[2] T. Garg,[3] J. Creswell,[3] J. Bimba,[1] [1]Bingham University, Zankli Research Centre, Karu, Nigeria, [2]Ustar Biotechnologies (Hangzhou) Ltd, Business Development, Hangzhou, China, [3]Stop TB Partnership, Innovations and Grants, Geneva, Switzerland
e-mail: babayipwa@gmail.com

Background: The Global TB Report estimates that 10.8 million people fell ill with TB in 2023, however only 8.2 million case notifications were recorded. Despite global and national progress post-COVID, the TB notification gap persists—particularly in Nigeria with a 25% gap in 2023. This study evaluated two novel tongue swab-based TB assays to enhance point-of-care screening and strengthen surveillance, to improve case notification.
Design/Methods: 124 participants (54% men) and had their sputum and tongue swab specimens collected and processed according to the manufacturer's protocol, from February to June 2025. The study participants included individuals aged 15 years and older presenting with symptoms suggestive of TB, as well as people living with HIV who exhibited elevated C-reactive protein levels. All specimens were subjected to the novel tests, Xpert MTB/Rif and Liquid Culture (MGIT) Assays.
Results: A summary of the findings are seen in the table below. Both novel diagnostics were compared with Xpert MTB/Rif Ultra, and culture separately. PortNAT showed exceptional specificity (99 - 100%) and a Positive Predictive Value (94-100%), meaning almost all positive results are truly MTB-positive. Its lower sensitivity may however lead to more missed cases. MultNAT on the other hand, showed high sensitivity (87-88%), and a strong Negative Predictive Value (NPV) of 96-97%.

N - 124		Based on Xpert MTB	Based on Culture
PortNAT	Sensitivity	58%	56%
	Specificity	100%	99%
	PPV	100%	94%
	NPV	88%	88%
MultNAT	Sensitivity	87%	88%
	Specificity	99%	98%
	PPV	96%	92%
	NPV	96%	97%

Conclusions: PortNAT may play a significant role in confirmatory diagnosis, especially where overdiagnosis may be of concern, as in clinically diagnosed children, while MultNAT may be more suited for active case finding in the communities. The duality of both assays presents a strategic opportunity to phase TB diagnosis.

LB03-1324-21 Diagnostic accuracy of Pluslife MiniDock MTB using sputum and tongue swabs

G. Theron,[1] D.J. Christopher,[2] J.S. Bimba,[3] H. Phan,[4] W. Worodria,[5] M. Muyoyeta,[6] C. Yu,[7] C.M. Denkinger,[8] R2D2 TB Network [1]Stellenbosch University, DSI-NRF Centre of Excellence for Biomedical Tuberculosis Research, South African Medical Research Council Centre for Tuberculosis Research, Division of Molecular Biology and Human Genetics, Faculty of Medicine and Health Sciences, Cape Town, South Africa, [2]Christian Medical College, Department of Pulmonary Medicine, Vellore, India, [3]Bingham University, Zankli Research Center, Karu, Nigeria, [4]Hanoi Lung Hospital, Center for Promotion of Advancement of Society, Hanoi, Viet Nam, [5]Makerere University, College of Health Sciences, Kampala, Uganda, [6]Centre for Infectious Disease Research in Zambia, TB Programmes, Lusaka, Zambia, [7]De La Salle Medical and Health Sciences Institute, Research Services, Dasmariñas City, Philippines, [8]Heidelberg University, Department of Infectious Diseases and Tropical Medicine, Heidelberg University Hospital and Faculty of Medicine, Heidelberg, Germany
e-mail: Claudia.Denkinger@uni-heidelberg.de

Background: Improved diagnostic tests are critical to identifying tuberculosis (TB) in high-burden countries. The MiniDock MTB Test (Guangzhou Pluslife Biotech Co., Ltd., China) is an automated molecular test that can process both sputum and tongue swab samples. We evaluated the diagnostic accuracy of the MiniDock MTB Test and compared to existing tests, sputum smear microscopy and Xpert MTB/RIF Ultra (Xpert).
Design/Methods: From September 2024 to March 2025, we consecutively enrolled people ≥12 years with presumed pulmonary TB in India, Nigeria, the Philippines, South Africa, Uganda, Vietnam, and Zambia.
Participants provided sputum samples for TB testing (smear, Xpert x1, liquid culture x2), and a tongue swab sample was collected. MiniDock was performed on tongue swabs and swabs dipped in sputum. Mycobacterial culture served as the reference standard. Sensitivity and specificity were calculated and compared with smear microscopy and Xpert using McNemar's test.
Results: Among 1380 enrolled participants, 603 (43.7%) were female, 255 (18.6%) were living with HIV, and 226 (17.4%) had culture-confirmed TB.
Sensitivity of sputum swabs tested on MiniDock was 85.7% (95% CI: 80.4–90.0), and specificity was 97.6% (95% CI: 96.4–98.4). With tongue swabs, sensitivity was 79.6% (95% CI: 73.8–84.7), and specificity was 99.5% (95% CI: 98.9-99.8).
Among those with valid results for MiniDock and Xpert, sensitivity of sputum swabs was similar to Xpert (86.7% vs. 89.4%, p=0.11).
Sensitivity of tongue swabs exceeded sputum smear (80.7% vs. 62.4%, p<0.001), and sensitivity was high among people requiring sputum induction (84.6%, 95% CI: 54.6–98.1).

Conclusions: The MiniDock MTB Test met WHO targets for both sputum and non-sputum based diagnostic tests. Sensitivity of both sample types exceeded smear, still widely used in many high-burden settings, and the sensitivity of sputum swab was comparable to sputum Xpert. Swab-based testing with MiniDock MTB Test shows promise as a near point-of-care method for TB detection.

LB03-1325-21 Evaluating the performance of computer-aided detection systems for pediatric tuberculosis: Results from the CAPTURE consortium

M. Kohli,[1] M. Palmer,[2] S. Kik,[3] A. Mace,[4] A. Penn-Nicholson,[5] J. Seddon,[6] D. Jaganath on behalf of the CAPTURE Consortium,[7] [1]FIND, Evidence and Policy, Geneva, Switzerland, [2]Stellenbosch Univerity, TB, Cape Town, South Africa, [3]Independent Consultant, independent Consultant, Den Haag, Netherlands, [4]FIND, Digital Health, Geneva, Switzerland, [5]FIND, TB, Geneva, Switzerland, [6]Imperial College, TB, London, United Kingdom of Great Britain and Northern Ireland, [7]UCSF, Pediatric Infectious Disease, San Fransisco, United States of America
e-mail: mikashmi.kohli@finddx.org

Background: Computer-aided detection (CAD) systems are approved and used to interpret chest x-rays (CXRs) for tuberculosis (TB) screening in adults. However, their performance in pediatric populations remains under-evaluated, despite the unique radiographic and clinical presentation of TB in children.

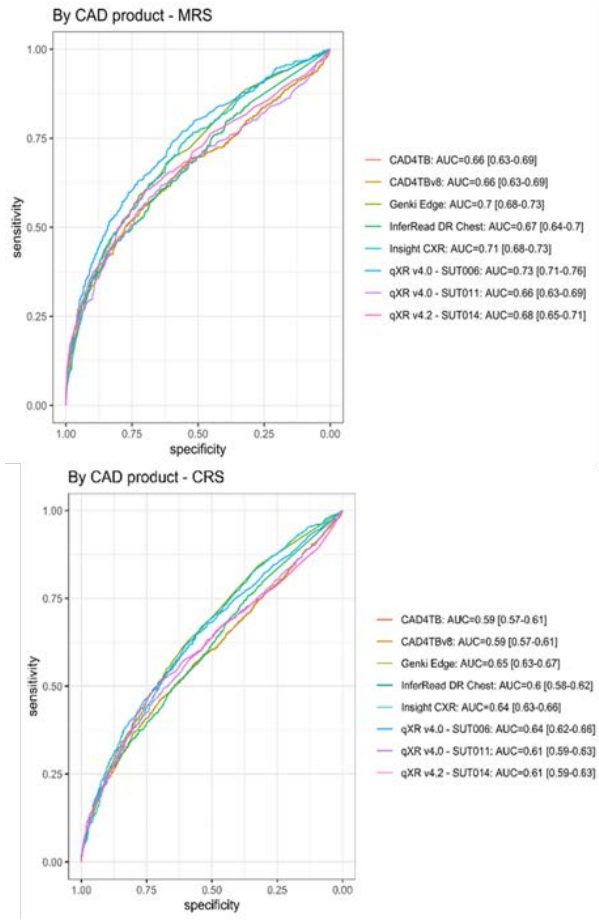
We aimed to evaluate the diagnostic accuracy of eight CAD products in children aged 0-14 year across diverse clinical settings

Design/Methods: We collected de-identified CXRs from children who were previously enrolled in TB diagnostic studies across ten high-burden countries. These CXRs were read by eight commercially available CAD products , and their TB prediction scores were compared against a microbiological and composite reference standard (MRS and CRS, respectively) according to the NIH TB classifications.

We calculated the area under the receiver operating characteristic curve (AUC), overall and by subgroups of age group, HIV status, and underweight status.

Results: We assessed 4760 CXRs from children with a median age of 2.5 years, 12% with HIV, and 24% who were underweight. Against the MRS, CAD systems were able to classify TB in children, with AUC (95% CIs) ranging from 0.65 (0.63-0.68) to 0.71(0.69-0.74). AUCs against the CRS ranged from 0.59 (0.58-0.61) to 0.64 (0.63-0.66).

Better performance was seen in age group 10-14 years than in younger age groups when compared to MRS-(AUC ranges: 0.75-0.80). CAD performance was similar by HIV status, but AUCs were higher in underweight children (AUC ranges 0.67-0.73).



Conclusions: Current CAD systems have suboptimal performance in children compared to adults, although they may have utility for adolescents and underweight children. These analyses underscore the importance of CAD systems being trained with pediatric images and child-specific thresholds to improve accuracy.

LB03-1326-21 Towards child-friendly TB diagnosis: An interim diagnostic accuracy analysis of SMaRT-PCR: A noninvasive mask-based TB diagnostic workflow

A. Shaikh,[1] K. Sriraman,[1] S. Vaswani,[1] A. Mitra,[1] R. Coutinho,[1] N. Mistry,[1] I. Shah,[2] K.K. Singhal,[3] S. Mane,[4] V. Singh,[3] V. Oswal,[5] SMaRT-PCR Study Team
[1]The Foundation for Medical Research, Tuberculosis, Mumbai, India, [2]Bai Jerbai Wadia Hospital for Children, Department of Pediatric Gastroenterology & Infectious Disease, Mumbai, India, [3]Lady Hardinge Medical College and Kalawati Saran Children's Hospital, Pediatrics, New Delhi, India, [4]Grant Government Medical College & Sir J.J. Group of Hospitals, Pediatrics, Mumbai, India, [5]Vikas Nursing Home, Tuberculosis, Mumbai, India
e-mail: ambreen.m.shaikh@gmail.com

Background: Tuberculosis diagnosis in children is challenging, as current diagnostic methods are predominantly invasive and suboptimal. Herein, we present interim results from our ongoing study evaluating diagnostic accuracy of SMaRT-PCR, a novel workflow integrating noninvasive mask-based aerosol sampling with reverse transcriptase-PCR (RT-PCR), for pulmonary tuberculosis (PTB) detection in children.

Design/Methods: The SMaRT-PCR diagnostic study aims to enroll 1200 children aged 1-14 years with presumptive TB from urban and rural settings. Currently, for the urban phase, children are being enrolled from tertiary hospitals and a TB clinic in Mumbai and Delhi, India.

Participants undergo a 10-minute mask sampling that captures bioaerosols using modified KN94-mask combined with RT-PCR for *Mycobacterium tuberculosis* (MTB)-specific gene transcripts and a conventional TB test involving gastric lavage/sputum/induced sputum collection, assessed using GeneXpert Ultra (Xpert-Ultra) and MTB culture.

We evaluated the diagnostic performance of SMaRT-PCR, Xpert-Ultra, and culture in comparison to composite reference standard (CRS), which includes microbiological and/or clinically confirmed TB with treatment initiation.

Results: Of 316 enrolled children, 97 with complete data were included for interim analysis. Among 27 children diagnosed with PTB, only 17 received microbiological confirmation.

In comparison of all three methods against CRS, SMaRT-PCR exhibited significantly higher sensitivity (30%, p=0.019) than Xpert-Ultra and 18.5% higher than culture (Table 1).

SMaRT-PCR had 95.3% specificity against CRS. The PTB diagnostic yield of SMaRT-PCR was 21%, compared to 13.6% for Xpert-Ultra, whereas by combining both test results, the diagnostic yield increased to 24.7%.

A - Analysis based on Diagnostic Classification

Diagnostic classification	SMaRT-PCR positive (Mask samples)	Xpert-Ultra Positive (Gastric Lavage/ Sputum/Induced Sputum)	Culture Positive (Gastric-lavage/ Sputum/Induced Sputum)
Pulmonary tuberculosis[1] (n=27)	21	13	16
Extrapulmonary tuberculosis[1] (n=23)	6	1	0
Latent tuberculosis[2] (n=2)	2	0	0
Disseminated tuberculosis (n=2)	0	0	0
Unlikely tuberculosis (n=43)	2	0	0

B - Diagnostic performance of novel and conventional tests for detecting pediatric pulmonary tuberculosis

Reference	Diagnostic Tests	Sensitivity (with 95% CI[3])	Specificity (with 95% CI[3])
Composite Reference standard	SMaRT-PCR	77.78% (58.6% - 90.9%)	95.35% (84.2% - 99.4%)
	Xpert-Ultra	48.15% (31.5% - 65.3%)	100.00% (91.8% - 100.0%)
	MTB Culture	59.26% (42.4% - 74.5%)	100.00% (91.8% - 100.0%)

[1] – Includes confirmed and probable TB cases
[2] – Children initiated on preventive TB treatment
[3] – 95% confidence interval calculated using Wilson's Score Interval

Table 1 - Diagnostic performance of SMaRT-PCR.

Conclusions: Preliminary results suggest that SMaRT-PCR has better sensitivity than conventional diagnostic tests, making it a promising noninvasive approach for pediatric TB detection. The complete sample size analysis will provide more accurate estimations of SMaRT-PCR's diagnostic accuracy across diverse settings.

A higher combined sensitivity of the two diagnostic tests suggests that SMaRT-PCR may serve as a beneficial complement to current diagnostic strategies, potentially improving detection rates.

LB03-1327-21 Pooling sputum specimens of people at high risk of TB reduces costs of Xpert Ultra TB testing without compromising concordance (TUTTPlus Study)

S.V. Omar,[1] B.A.S. Nonyane,[2] L. Genade,[3] A. David,[4] A. Bulane,[5] S.-A. Meehan,[6] M.P. Mohlomonyane,[7] R. Berhanu,[8] L. Scott,[4] L. Lebina,[9] D. Evans,[10] N. Martinson,[3,11] [1]National Institute for Communicable Diseases, Centre for Tuberculosis, Johannesburg, South Africa, [2]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, South Africa, [3]University of the Witwatersrand, Perinatal HIV Research Unit, Soweto, South Africa, [4]University of the Witwatersrand, Wits Diagnostic Innovation Hub, Johannesburg, South Africa, [5]National Instutute of Communicable Diseases, Centre for TB, Johannesburg, South Africa, [6]Stellenbosch Universty, Desmond Tutu TB Centre, Department of Pediatrics and Child Health, Cape Town, South Africa, [7]University of the Witwatersrand, Perinatal HIV Research Unit, Polokwane, South Africa, [8]Vanderbilt University Medical Center, Department of Medicine, Division of Infectious Diseases,, Nashville, United States of America, [9]Africa Health Research Institute, Clinical Trials Unit, Mtubatuba, South Africa, [10]University of the Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [11]Johns Hopkins University, Division of Infectious Diseases, School of Medicine, Baltimore, United States of America

Background: Scaling-up TB testing is critical to ending TB, but costs of molecular tests limit widespread use. Testing pooled sputum samples may reduce costs. We evaluated the concordance, and cost-efficiency of sputum pooling versus individual testing using Xpert MTB/RIF Ultra.

Design/Methods: We recruited 3,161 adult outpatients at high TB risk who donated a 3ml sputum specimen, split into two aliquots after processing: one tested individually and the other in pooled groups. If a pool tested positive constituent participant's individual results were reviewed. Pool sizes varied—initially 4 per pool; then 3 for samples from people living with HIV (PLWH); 5 for HIV-negative; and based on symptoms, pools of 4 for asymptomatic and 5 for symptomatic people, regardless of HIV status. Concordance and accuracy of pooled versus individual testing were analyzed considering "trace" results as positive, then, as negative for Mycobacterium tuberculosis (Mtb), and stratifying each pool by their constituent participants' majority HIV and symptom status. Time-motion studies and test costs informed cost comparisons, assuming only individual retesting of specimens from positive pools.

Results: Of 2,888 participants specimens included, median age was 40 years, 71% female, 76% PLWH, and 23.2% symptomatic for TB. Individually tested samples were positive for Mtb in 3.1% and "trace" positive in 1.1%. Concordance between pooled and individual tests ranged from 98.1% (95.3–99.3%) in pools of 3 to 88.5% (71.0–96.0%) in pools of 5, which had lower concordance than pools of 4. Assuming "trace" as positive increased concordance. Pools of 4 for PLWH and asymptomatic individuals yielded high concordance and reduced test costs compared to individual testing (Table).

	Unstratified	PLWH		Asympto-matic	Sympto-matic
Pool size (number of constituent participant specimens)	All pools combined	3	4	4	4
Specimens included (n)	2888	732	824	792	508
Pooling yield (%) (assuming trace as positive)	27.4	18.7	22.1	25.0	21.6
Concordance (95%CI) of pooling strategy to individual sputum testing. All Ultra tested	97.3 (95.4,98.5)	97.8 (94.6,99.2)	97.8 (95.5,98.92)	99.5 (97.0,99.9)	95.5 (92.2,97.4)
Cost (2025 USD)					
Pooled tested – Cost per person tested (Cost per TB positive diagnosis)	$5.59 ($142.80)	$6.21 ($324.46)	$5.35 ($191.93)	$5.36 ($169.65)	$6.02 ($161.00)
Individual tested – Cost per person tested (Cost per TB positive diagnosis)	$14.18 ($362.53)	$14.18 ($741.66)	$14.18 ($508.19)	$14.18 ($449.38)	$14.18 ($379.26)
Cost difference (%)	-60.6%	-62.1%	-62.2%	-62.2%	-57.5%

Table: Accuracy and modelled costs of a pooling strategy; testing pools of split participants' single sputum specimens – one aliquot tested individually and the other tested in the pool with varying pool sizes, and modelled costs of pooling assuming only positive pools were individually tested v. individually tested specimens.

Conclusions: Ultra-testing pooled sputum specimens is a cost-effective, accurate strategy for TB diagnosis, particularly pool sizes of 4 for PLWH and asymptomatic individuals. This approach could facilitate scalable TB testing in resource-limited settings, dependant on laboratory processes.

LB03-1328-21 Smarter screening, lower costs: A seven-country mixed-methods evaluation of novel TB diagnostic strategies from the Start4All consortium

R. Byrne,[1] M. Henrion,[2,3] A. McCoy,[1] S. Banu,[4] V. Santos,[5] M. Sander,[6] S. Wandiga,[7] A. Choko,[8] J. Bimba,[9] S. John,[10] L. Vo,[11] T. e-mail: tom.wingfield@lstmed.ac.uk

Background: Globally, one-in-four people with tuberculosis (TB) are missed. In Bangladesh, Brazil, Cameroon, Kenya, Malawi, Nigeria, and Vietnam, "Start4All" is evaluating diagnostic algorithms using commercially-available tools to enhance early TB diagnosis and care-linkage at primary healthcare (PHC).

Design/Methods: We recruited 4409 adults presenting to PHC with TB symptoms.

All participants had: capillary-blood C-reactive protein (CRP); sputum Xpert-Ultra (individual and pooled); and chest X-rays with computer-aided detection (CAD-CXR). Microbiological reference standard was sputum culture.

We compared costs and effectiveness of concurrent and sequential positive serial algorithms including CRP, CAD-CXR, and pooled and individual Xpert-Ultra.

We used Bayesian analysis to estimate diagnostic accuracy including sensitivity, specificity, positive/negative predictive values, and proportions of positive results.

Provider-perspective cost analysis included commodity and implementation costs. A decision-tree model estimated cost-per-person with TB detected, complemented by probabilistic sensitivity analysis.

Test feasibility and acceptability were evaluated through 38 interviews and 18 focus-groups with people with TB, healthcare workers, and policymakers across all countries.

Results: Ten diagnostic algorithms demonstrated promising performance, with >80% sensitivity and >95% specificity.

Of these, five offered substantial cost savings with only modest reductions in people confirmed with TB, when compared to individual Xpert-Ultra (Table).

CAD-CXR followed by pooled Xpert-Ultra, and CAD-CXR followed by individual Xpert-Ultra reduced costs by 69% and 67%, while detecting only 13% and 11% fewer individuals with confirmed TB, respectively.

Pooled Xpert-Ultra detected 2% fewer people with confirmed TB and reduced costs by 29%.

Sub-analysis by HIV status showed similar findings.

Stakeholders perceived all five algorithms to have moderate or high feasibility and acceptability, with adaptations suggested for scale-up.

	Xpert	CAD-CXR ->Xpert	Pooled Xpert ->Xpert	CAD-CXR or CRP ->Xpert	CAD-CXR -> Pooled Xpert ->Xpert	CAD-CXR or CRP -> Pooled Xpert ->Xpert
Performance analysis compared to sputum culture MRS						
Sensitivity % (95%CI)	89.6 (85.1, 93.1)	82.3 (77.3, 86.7)	86.7 (82.1, 90.5)	64.5 (79.7, 88.6)	80.1 (74.9, 84.8)	82.3 (77.2, 86.8)
Specificity % (95%CI)	97.2 (96.5, 97.7)	98.3 (97.8, 98.6)	98.0 (97.6, 98.4)	98.2 (97.8, 98.5)	98.6 (98.2, 98.9)	98.6 (98.2, 98.9)
PPV % (95%CI)	66.5 (60.8, 71.9)	74.9 (69.6, 79.7)	73.4 (68.2, 78.2)	74.9 (69.7, 79.7)	78.3 (73.1, 83.0)	78.3 (73.1, 83.0)
NPV % (95%CI)	99.3 (99.0, 99.6)	98.9 (98.5, 99.2)	99.2 (98.8, 99.4)	99.0 (98.7, 99.3)	98.8 (98.4, 99.1)	98.9 (98.5, 99.2)
DYT % (95%CI)	8.0 (7.2, 8.8)	6.5 (5.8, 7.3)	7.0 (6.3, 7.8)	5.7 (6.0, 7.4)	6.1 (5.4, 6.8)	6.2 (5.5, 7.0)
Modelled percentage cost savings and people with TB detected compared to individual Xpert						
Percentage reduction in cost relative to individual Xpert (%)	NA	66.5	25.3	20.3	69.1	27.5
Percentage reduction in people with TB detected relative to individual Xpert (%)	NA	11.2	1.9	5.9	13.4	8.9

Legend: Xpert = Xpert-Ultra. MRS = Microbiological reference standard. PPV = positive predictive value; NPV = negative predictive value; DYT = diagnostic yield amongst those tested ie. the proportion of individuals for whom the algorithm successfully identified they had TB among all individuals tested. Arrows between tests in an algorithm indicate the preceding test or tests were positive. For example, CAD-CXR or CRP -> Pooled Xpert -> Xpert is a modelled algorithm consisting of a first step of CAD-CXR or CRP and, if either or both of these tests are positive, a next step of pooled Xpert and, if the pooled Xpert is positive, a final step of individual Xpert. Cost model outputs were based on 100,000 simulations with 10,000 iterations each in a hypothetical cohort of 1,000 individuals.

Table. Modelled performance and cost savings of the most promising TB diagnostic algorithms at primary healthcare level.

Conclusions: In the multi-country Start4All study, low-cost, low-complexity diagnostic algorithms appeared feasible, acceptable, and able to maintain high diagnostic accuracy and yield, while reducing the cost-per-person with TB detected at PHC.
These findings support broader evaluation of algorithmic TB diagnostic approaches in high-burden, resource-limited settings.

LB03-1329-21 The diagnostic TB overture: Deep listening to hear what CXR can and can't see

N.L. Jumbe,[1] D. Marcelo,[2] D.J. Christopher,[3] H. Phan,[4] G. Theron,[5] W. Worodria,[6] R. Savic,[7] D. Jaganath,[8] R2D2 TB Network [1]Level 42 AI, Level 42 AI, Mountain View, United States of America, [2]De La Salle Medical Health Sciences Institute, Center for Tuberculosis Research, Dasmariñas City, Philippines, [3]CMC Vellore, Pulmonology, Vellore, India, [4]National Lung Hospital, National Lung Hospital, Hanoi, Viet Nam, [5]Stellenbosch University, Department of Science and Technology, Cape Town, South Africa, [6]Makerere University, College of Health Sciences, Kampala, Uganda, [7]University of California San Francisco, Department of Bioengineering and Therapeutic Sciences, San Francisco, United States of America, [8]University of California San Francisco, Pediatrics, San Francisco, United States of America
e-mail: devan.jaganath@ucsf.edu

Background: Chest X-rays (CXRs) are valuable for TB screening and diagnosis but face major barriers to scale in primary care and resource-limited settings. Using an artificial intelligence (AI)-embedded point-of-need stethoscope, we developed a foundational TB diagnostic model to capture, classify and visualize audible and inaudible pulmonary abnormalities — vibrome biosignatures — mirroring the diagnostic patterns of CXR without the need for radiation or imaging infrastructure.
Design/Methods: We prospectively enrolled individuals aged ≥12 years with presumptive TB across Uganda, South Africa, India, Vietnam, and the Philippines. Each received a chest X-ray (CXR) and a 3-minute anterior-only vibroacoustic recording at six chest sites. A foundational model was developed using vibroacoustic data from 6,800 individuals with COVID-19, RSV, Influenza A/B, TB, or were healthy, paired with 21,000 multi-disease CXRs.
This model was then optimized to detect lung field abnormalities in enrolled individuals in reference to the CXR read by a radiologist or CAD software. Performance was evaluated on a 25% held-out dataset using five-fold cross-validation to compute AUROC, sensitivity, and specificity.
Results: We included 400 participants (median age 39 [IQR 29–52]; 45% female; 12% living with HIV). The 4,000 Hz vibrome biosignature alone classified abnormal CXRs with an AUROC of 0.779 (sensitivity 0.777; specificity 0.582). When combined with routine clinical covariates, performance improved to an AUROC of 0.836 (sensitivity 0.821; specificity 0.656). Prediction accuracy was higher when all six chest sites were used as compared to site-level accuracy. Notably, the model identified TB cases missed by CXR and resolved all indeterminate microbiologic reference standard (MRS) outcomes.

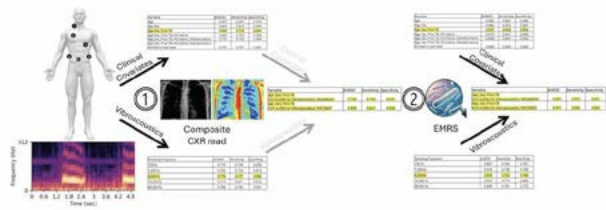

Figure 1: Music-of-the-body foundational model. Integrating clinical covariates (i.e., instrument shape such as age, sex, and prior TB) with inaudible and audible vibroacoustic signals to predict CXR findings and Extended Microbiologic Reference Standard (EMRS) outcomes. AUROC: Area Under the Receiver Operating Characteristic Curve. Yellow highlight=best performing algorithm. Just as music recognition systems identify full songs more accurately than isolated song segments, our vibrome biosignature-based approach demonstrates stronger performance at the patient level, capturing complex and distributed disease patterns that mirror the harmonic structure of the body's internal physiology.

Conclusions: Vibrome biosignatures technology decodes the "music of the body" and is able to identify and visualize lung abnormalities with high sensitivity and moderate specificity. This innovation has the potential to support TB screening and diagnosis without radiation, sputum, or facility infrastructure.

LB03-1330-21 Intensive screening reduces tuberculosis transmission over time in prisons

J. Bampi,[1] E. Jung,[2] A.D. Salindri,[2,3] A.M. Silva,[1] Y. Liu,[2,4] D.H. Tsuha,[1] A.d.S. Santos,[5] R.D. de Oliveira,[6] J. Andrews,[2] J. Croda,[7,8,9] [1]Federal University of Mato Grosso do Sul, Post Graduate Program in Infectious Diseases and Parasitology, Campo Grande, Brazil, [2]Stanford University School of Medicine, Division of Infectious Diseases and Geographic Medicine, Stanford, United States of America, [3]Universitas Padjadjaran, Research Center for Care and Control of Infectious Disease, Bandung, Indonesia, [4]Yale University School of Medicine, SEICHE Center for Health and Justice, New Haven, United States of America, [5]Federal University of Grande Dourados, Post Graduate Program in Health Sciences, Dourados, Brazil, [6]State University of Mato Grosso do Sul, Nursing Course, Dourados, Brazil, [7]Federal University of Mato Grosso do Sul, Medicine Department, Campo Grande, Brazil, [8]Yale University School of Public Health, Department of Epidemiology of Microbial Diseases, New Haven, United States of America, [9]Oswaldo Cruz Foundation, FIOCRUZ-MS, Campo Grande, Brazil
e-mail: bampijvb@gmail.com

Background: Few studies have prospectively evaluated the impact of intensified screening on Mtb transmission in high-risk settings. We leveraged serial QuantiFERON-TB Gold Plus (QFT) testing to estimate risk of infection over time in a longitudinal cohort undergoing intensive active case finding.

Design/Methods: In a prospective cohort of incarcerated adults (≥18 years) from two high-burden Brazilian prisons starting February 2023, participants underwent symptom screening, sputum testing with Xpert MTB/RIF and culture, and chest radiography every four months, with annual testing by interferon-gamma release assay (IGRA) using QFT. Individuals with negative QFT at baseline formed a subcohort.

The primary outcome was conversion to positive QFT during follow-up. Conversion rates and 95% confidence intervals were calculated using exact binomial tests. We fit a Poisson regression with fixed effects for prison to evaluate the association between time since study initiation (in years) and risk of QFT conversion.

Results: Among 614 individuals with a negative QFT at baseline and at least one follow-up result, 246 (40%) converted to positive (Figure 1).

Conversion risk declined from 48.8% (169/346) in the first year of the study to 28.9% (55/208) in the second year (p<0.001). Risk of conversion decreased by 41% per additional year of follow-up (RR: 0.59, 95% CI: 0.45-0.78). This decline was observed both among participants enrolled at study initiation and followed for two years, and among those newly enrolled and followed in the second year, suggesting that temporal trends in transmission, rather than cohort effects, were responsible for the reduction in QFT conversion.

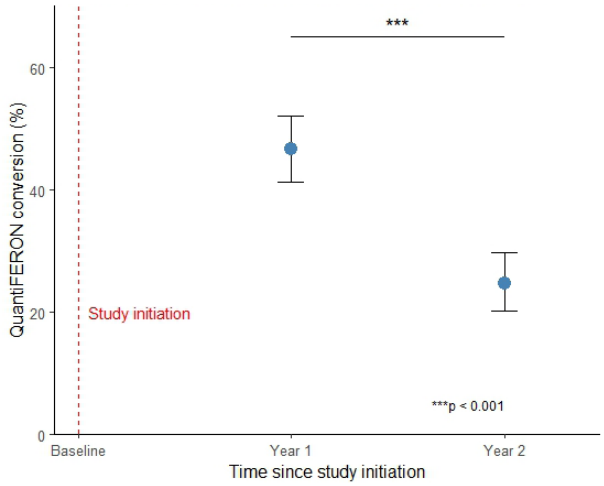

Figure 1. QuantiFERON conversion over time since study initiation.

Conclusions: These findings offer early evidence that intensified screening can reduce Mtb transmission in high-burden prison settings. Longitudinal monitoring of Mtb infection status in serial active case finding enables continuous evaluation of transmission impacts and identification of individuals eligible for preventive therapy.

TBSCIENCE ORAL PRESENTATIONS

TBS02-05 Clinical and transcriptomic risk factors for post-tuberculosis lung disease (PTLD) phenotypes in Kenyan adults

J.S. Zifodya,[1] L.A. Kijaro,[2] V. Nduba,[2] M.S. Khatun,[1] K. Crothers,[3,4] T.R. Hawn,[3] J.K. Kolls,[1] D.J. Horne,[3]
[1]Tulane University School of Medicine, New Orleans, United States of America, [2]Kenya Medical Research Institute CRDR, Nairobi, Kenya, [3]University of Washington School of Medicine, Seattle, United States of America, [4]Veterans Affairs Puget Sound Health Care System, Seattle, United States of America
e-mail: jzifodya@tulane.edu

Background: Post-tuberculosis lung disease (PTLD) affects half of pulmonary tuberculosis survivors, yet mechanisms remain unclear. We sought to identify clinical and host-response transcriptomic risk factors for PTLD restrictive and obstructive phenotypes.
Methods: In an observational, prospective, cohort study, we enrolled treatment naïve adults with pulmonary tuberculosis in Nairobi, Kenya. Participants completed 6 months of oral anti-tuberculosis treatment, blood draws at diagnosis and at treatment completion, and spirometry 6 months after treatment completion. PTLD was phenotyped as restrictive (low FVC) or obstructive based on spirometry.
Results: We enrolled 205 participants of whom 103 (50.2%) developed PTLD, 60 with restrictive-PTLD and 43 with obstructive-PTLD. Median age and proportion of women was similar amongst those with PTLD compared to those with normal lung function (34.2 years vs. 35.6 years and 22.3% vs. 24.5%, respectively). Clinically, at baseline those who developed PTLD had lower BMI, lower mid-upper arm circumference, and lower peak flow than those with normal lung function. In multivariable analyses, more quadrants involved on CXR at diagnosis was associated with both restrictive-PTLD (aOR 1.9, p<0.001) and obstructive-PTLD (aOR 2.2, p<0.001). Prior TB was associated with obstructive-PTLD (aOR 5.4, p<0.001). Clinical risk factors were otherwise similar. In transcriptomic analyses, those with restrictive-PTLD had upregulation of pro-fibrotic pathways including IL-6/JAK/STAT3 and TNF-α at baseline (FDR<0.2, Figure). This was no longer present at treatment completion. Those who had obstructive-PTLD had no differential gene expression at baseline but had ongoing inflammation at treatment completion including IFN-α and IFN-γ response (FDR<0.2, Figure).
Conclusions: PTLD is common and PTLD phenotypes have similar baseline clinical risk factors. However, PTLD-phenotypes have unique endotypes. Restrictive-PTLD was marked by early pro-fibrotic inflammation. Whereas those with obstructive-PTLD had ongoing inflammation at treatment completion. Our findings support the role of differential host response in the development of PTLD phenotypes.

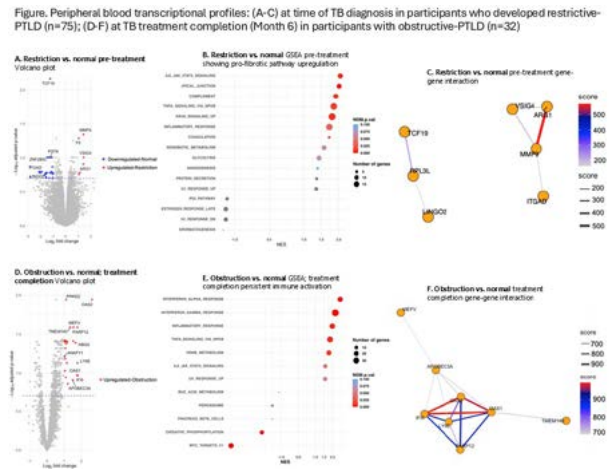

Figure. Peripheral blood transcriptional profiles: (A-C) at time of TB diagnosis in participants who developed restrictive-PTLD (n=75); (D-F) at TB treatment completion (Month 6) in participants with obstructive-PTLD (n=32)

TBS02-10 Integrative proteogenomics illuminates molecular drivers of *M. tuberculosis* virulence

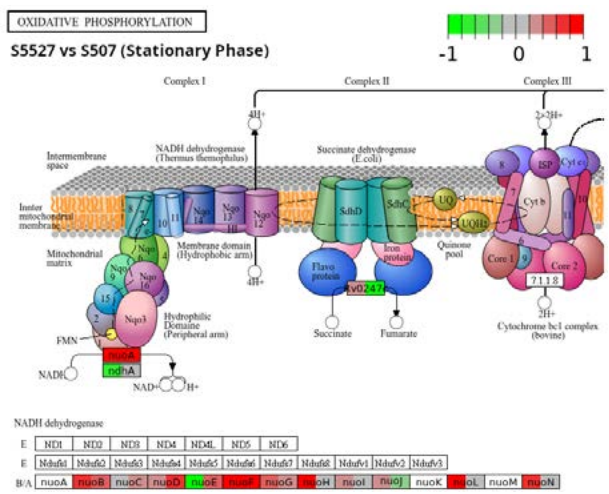
M.G. Potgieter,[1,2,3] S. Fortuin,[2] J. Ambler,[1] N. Soares,[4,5] M. Klopper,[6] M. Grobbelaar,[6] M. De Vos,[6] S. Sampson,[6] R. Warren,[6] J. Blackburn,[2] N. Mulder,[1] [1]Computational Biology Division, Department of Integrative Biomedical Sciences, University of Cape Town, Cape Town, South Africa, [2]Division of Chemical and Systems Biology, Department of Integrative Biomedical Sciences, IDM, University of Cape Town, Cape Town, South Africa, [3]EPCON, Cape Town, South Africa, [4]Center for Applied and Translational Genomics (CATG), Mohammed Bin Rashid University Medicine and Health Sciences (MBRU), Dubai Health, Dubai, United Arab Emirates, [5]College of Medicine, Mohammed Bin Rashid University of Medicine and Health Sciences (MBRU), Dubai Health, Dubai, United Arab Emirates, [6]Stellenbosch University, Cape Town, South Africa
e-mail: thys@epcon.ai

Background: Tuberculosis (TB) remains a leading cause of infectious mortality, where subtle molecular variations among *Mycobacterium tuberculosis* strains determine trajectories from latent infection to active disease. Integrative proteogenomics combining high-resolution mass spectrometry with genomic data can resolve these virulence determinants. We applied Progenio, a multi-strain proteogenomic pipeline, to two epidemiologically linked W/Beijing isolates with contrasting virulence to delineate molecular drivers of pathogenicity.
Methods: Hypervirulent S5527 and hypovirulent S507 strains of *M. tuberculosis* were cultured under mid-log, oxidative-stress, and stationary-phase conditions. Orbitrap LC–MS/MS spectra were searched with MaxQuant against six-frame ORF databases generated by Progenio,

which maps genomic peptides, annotates novel open reading frames (ORFs), alternative N-terminal translation start sites, interrupted coding sequences (ICDSs), and N-terminal acetylation events, then performs differential-abundance and gene-set enrichment analyses.

Results: From 818 580 submitted spectra, 346 305 (42.3%) were identified, yielding 21 652 unique peptides and 2 327 protein groups. Progenio revealed 7 novel coding regions, 17 alternative translation start sites, and 5 ICDSs. N-terminal acetylation mapping identified 110 proteins, with 17 unique to S5527 and 11 unique to S507, indicating altered post-translation regulation.

Stationary-phase analysis showed significant upregulation of the nuo operon (MT3233–MT3246) in S5527 (q = 0.089), implicating enhanced respiratory Complex I activity and suggesting NDH-1 inhibitors as candidate therapeutics. The mce1 operon (MT0172–MT0187) was downregulated in S507 (q = 0.065), indicating reduced lipid import, while the ESX-1 secretion system was enriched in S5527. Differential N-terminal acetylation of cell-wall enzymes (KasA and Pks13) highlights strain-specific post-translational regulation that may influence clinical trajectories.



Conclusions: Progenio's integrated ORF discovery, start-site variation, ICDS detection, and acetylation profiling identify proteogenomic signatures driving *M. tuberculosis* virulence. Enhanced Complex I expression, modulation of lipid-transport, and differential acetylation of cell-wall biosynthetic enzymes represent actionable targets for diagnostics and therapies, illuminating the microscopic frontiers of TB pathology.

TBS02-15 Impact of diabetes on macrophage and *Mycobacterium tuberculosis* interaction: Insights from dual RNA-seq

J. Brake,[1] V. Koeken,[2] N. Sumpter,[1] J. Schildkraut,[1] E. Terschluesen,[1] E. Ardiansyah,[3] J. van Ingen,[1] R. van Crevel,[1] [1]Radboud University Medical Centre, Nijmegen, Netherlands, [2]Hogeschool Rotterdam, Rotterdam, Netherlands, [3]Universitas Padjadjaran, Bandund, Indonesia
e-mail: julia.brake@radboudumc.nl

Diabetes mellitus (DM) increases susceptibility to tuberculosis (TB), though the specific immune dysregulations contributing to this risk remain unclear.

We performed dual RNA-sequencing to capture transcriptional profiles of both host and pathogen. Human monocyte-derived macrophages (hMDMs) from individuals with type 1 diabetes (T1DM) (n = 12) and healthy controls (HC) (n = 12) were infected with *Mycobacterium tuberculosis* (*Mtb)* strain H37Rv, followed by gene expression and secreted cytokine level (T1DM; n = 17, HC; n = 17) analysis.

Our findings reveal that infected hMDMs from both T1DM and HC groups significantly upregulate genes linked to immune responses against bacterial pathogens. Despite comparable overall transcriptional responses, T1DM hMDMs showed a higher baseline activation of IFNγ but lower upregulation upon infection, with smaller fold changes of several pro-inflammatory genes compared to HCs. Secreted cytokine levels revealed only minimal differences between groups.

However, also on cytokine level, IFNγ concentration was lower for T1DM hMDMs compared to HC hMDMs upon infection. RNA-sequencing analysis of *Mtb* showed substantial transcriptional shifts when intracellular but no distinct differences between *Mtb* being intracellular in T1DM and HC macrophages. Upon infection, strong correlations between hMDM genes and *Mtb* genes were found.

This study demonstrates that while hMDMs from individuals with T1DM exhibit small transcriptional disparities, their response to *Mtb* infection largely mirrors that of HCs. Notably, both IFNγ gene expression and cytokine secretion were lower in T1DM hMDMs, which may contribute to the increased susceptibility to TB in individuals with T1DM. Our dual RNA-sequencing approach provides valuable insights into macrophage-*Mtb* interactions in both healthy and T1DM context.

TBS02-20 Proteins associated with neutrophil degranulation result in lung damage in symptomatic TB patients

M.D. Naicker,[1] T. Naidoo,[2,1] G. Wells,[1] K. Lumamba,[1] K. Nargan,[1] A. Govender,[1] J. Jones,[3] M. Pang,[3] M. Roukes,[3] T.-F. Chou,[3] D. Chen,[4] A. Steyn,[1,4] [1]Africa Health Research Institute, Durban, South Africa, [2]Walter Sisulu University, Eastern Cape, South Africa, [3]Caltech, Pasadena, United States of America, [4]University of Alabama at Birmingham, Birmingham, United States of America
e-mail: Delon.Naicker@ahri.org

TB immunopathology is complex and multifactorial; however, neutrophils have recently emerged as crucial contributors to severe lung tissue damage. Over the past two decades, proteomics has provided critical insights into host–pathogen interactions. A significant knowledge gap remains regarding the proteomic landscape of TB lesions, which represent the primary site of infection and critical interface of host-pathogen interaction. Recent advances in proteomic technologies, coupled with access to human lung tissue, now offer a unique opportunity to characterize the proteome at the primary site of TB infection and to elucidate what drives lung damage in advanced TB disease.

We hypothesize that proteins associated with neutrophil degranulation contribute to lung damage in necrotic granulomata.

Thirty necrotic granulomas, representative of advanced symptomatic TB, were collected from resected diseased lung tissue from eighteen patients from KwaZulu-Natal, South Africa. The granulomata were precisely dissected using laser capture microdissection and analyzed by liquid chromatography-tandem mass spectrometry (LC/MS-MS) to identify host proteins.

LC/MS-MS analysis identified approximately 4,700 host proteins with high confidence across thirty necrotic granulomata. Among these, 2,290 proteins exhibited significantly altered abundance relative to healthy control tissue. Ingenuity Pathway Analysis identified neutrophil degranulation as the highest-ranked canonical pathway. Notably, proteins associated with neutrophil degranulation, namely, the cytochrome b558 subunits, CY24A and CY24B, critical components for reactive oxygen species production, along with myeloperoxidase, neutrophil elastase, cathepsin G, proteinase 3, and azurocidin-1, were in significantly higher abundance in necrotic granulomata compared to healthy controls.

Animal models have suggested neutrophil-mediated lung damage; however, direct evidence of this in human lung tissue has been lacking. Our findings demonstrate that proteins associated with neutrophil degranulation contribute to lung damage in human pulmonary TB. These proteins may serve as potential therapeutic targets for host-directed therapies aimed at modulating neutrophil-driven pathology in symptomatic TB.

TBS02-25 Studying the Influence of host Iron genotypes, iron supplementation and iron chelators on *Mycobacterium tuberculosis* complex infections in vitro

N. Top,[1] S. Campino,[2] C. Cerami,[1] L. Tientcheu,[1] [1]Medical Research Council Unit the Gambia, Banjul, Gambia (Republic of The), [2]London School of Hygiene and Tropical Medicine, London, United Kingdom of Great Britain and Northern Ireland
e-mail: lshnt2@lshtm.ac.uk

Background: Tuberculosis (TB), driven by *Mycobacterium tuberculosis* complex (MTBC), remains a major global health threat. Iron is essential for MTBC survival and virulence, and the host tightly regulates iron availability to limit infection. However, common genetic variants in iron metabolism genes may alter this balance, influencing bacterial growth, immune responses, and therapeutic efficacy of iron modulation.

Objective: To determine how host iron-related genetic variants affect MTBC intracellular growth and the cellular response to iron supplementation and chelation, across key MTBC lineages circulating in West Africa.

Methods: We isolated monocytes from 60 healthy Gambian adults with known genotypes: ferroportin Q248H (n=17), TFR2 rs7385804 (n=29), and wild-type controls (n=12). Cells were infected with GFP-tagged clinical strains of Mtb Lineage 2 (L2), Lineage 4 (L4), or *M. africanum* Lineage 6 (L6), then treated with 100 μM $FeSO_4$ or 250 μM deferoxamine (DFO). Intracellular bacterial growth was measured over 7 days via GFP fluorescence. Oxidative stress (CellROX™) and GPX4 expression were assessed as markers of ferroptosis.

Results: Monocytes with the ferroportin Q248H variant exhibited significantly reduced bacterial growth across all MTBC lineages (L2: p=0.0008; L4: p=0.0005; L6: p=0.0025), while TFR2 variant cells supported higher growth, particularly of L4 strains. Iron supplementation promoted MTBC replication, especially in Q248H cells, but this was consistently reversed by DFO treatment. Iron loading increased intracellular ROS and reduced GPX4 levels, indicating ferroptosis activation.

These effects were most pronounced in TFR2 monocytes, which exhibited heightened oxidative stress and ferroptotic susceptibility. Both DFO and ferrostatin-1 significantly alleviated bacterial burden and restored redox balance.

Conclusion: Host genetic variation in iron metabolism modulates susceptibility to MTBC infection and response to iron-targeted therapy. Iron chelation reverses the pro-infective effects of iron loading across genotypes, supporting its use as a host-directed therapy in TB particularly where iron-loading genotypes and virulent lineages co-circulate.

TBS02-30 Unmasking hidden diversity: Direct sputum sequencing reveals extensive mixed-lineage TB infections missed by culture in a high-burden setting

B.C. Mann,[1] A. Shaik,[2] S. Mulaudzi,[3] K.R. Jacobson,[4] R.M. Warren,[1] M.R. Farhat,[3] [1]Stellenbosch Univeristy, Cape Town, South Africa, [2]Texas A&M University, Texas, United States of America, [3]Harvard Medical School, Boston, United States of America, [4]Boston Medical Centre, Boston, United States of America
e-mail: bcmann@sun.ac.za

Background: Worcester, South Africa, has one of the highest tuberculosis (TB) incidence rates globally, with high rates of problem alcohol use (>50%) and HIV infection (~30%) among patients. In such settings, individuals are likely to harbour mixed infections or exhibit significant within-host *Mycobacterium tuberculosis* (Mtb) genetic diversity. Culture-based whole genome sequencing (WGS) may underestimate diversity due to selective outgrowth of dominant clones. We applied direct-from-sputum WGS to better capture within-host Mtb diversity in this high-transmission context.
Methods: We performed WGS directly from sputum and after culture in a prospective cohort of patients with drug-susceptible TB assessing Mtb diversity prior to antibiotic exposure. Low-frequency variants were identified using FreeBayes, a tool we identified in simulations to be top performing. We masked regions prone to contamination, homology, or low-confidence calls. A no-template and two H37Rv controls were processed alongside patient samples to monitor for contamination.
We identified mixed lineage infections and examined associations with clinical indicators such as time to culture conversion and time to positivity.
Results: We sequenced sputum and culture samples from 200 patients, of which 139 yielded high-quality data. Reduced diversity was observed in 42%, where mixed lineages in sputum resolved to a single lineage in culture. Concordant single lineages were seen in 37%, while 8% had single but discordant lineages between sample types.
Another 8% showed mixes in sputum and a non-matching lineage in culture. Only 5% had concordant mixed infections.

Description	Number of pairs
Complete Concordance Single	52
Completely Concordant Mix	7
Discrepant Single Lineages	11
Discrepant Multiple Lineages	11
Reduced Diversity	58
Total	139

Table 1: Counts of samples categorized by lineage diversity and concordance status.

These findings indicate frequent mixed lineage infection and loss or distortion of within-host diversity during culture. No evidence of contamination was detected in the no-template or H37Rv controls
Conclusions: In a high-burden setting, direct-from-sputum WGS revealed extensive within-host Mtb diversity and mixed infections missed by culture. These findings underscore limitations of conventional workflows and support integrating culture-free sequencing for accurate drug-resistance and transmission surveillance in this setting.

TBS02-35 Latent *Mycobacterium tuberculosis* infection is associated with increased inflammatory cytokines with dysregulation of antigen presentation pathways and innate immunity in diabetic individuals

Z. Hasan,[1] K. Masood,[1] M. Yameen,[1] J. Ashraf,[1] N. Ram,[1] N. Saifullah,[2] B. Jamil,[1] M. Irfan,[1] A. Ajmal,[1] R. Hussain,[1] M. Rottenberg,[3] J. Cliff,[4] [1]Aga Khan University, Karachi, Pakistan, [2]Jinnah Postgraduate Medical Center, Karachi, Pakistan, [3]Karolinska Institutet, Stockholm, Sweden, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom of Great Britain and Northern Ireland
e-mail: zahra.hasan@aku.edu

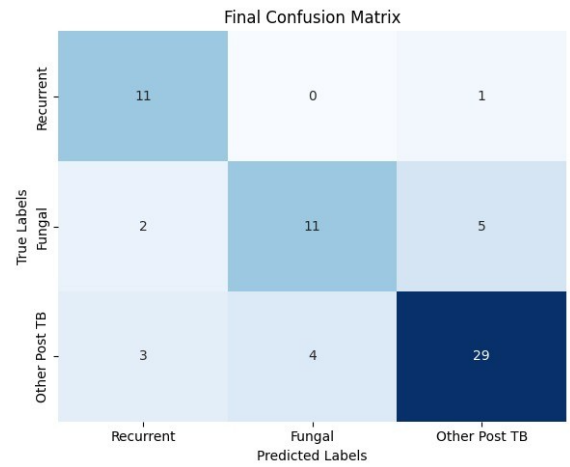
Background: Diabetes mellitus (DM) is a comorbid associated with worsened tuberculosis (TB) outcomes with less known about DM and latent TB (LTBI). We investigated the concomitant effects of LTBI and DM on the host through analysis of TB-antigen stimulated cytokines and host blood transcriptomes.
Methods: Participants included healthy individuals, those with DM, and all were tested for LTBI using IGRA testing. Therefore we studied healthy controls (EC, n=22), LTBI (n=29), DM (n=30) and DM-LTBI (n=19) groups. HbA1c > 6.5% g/dL was used to identify DM. Th1/Th2 cytokines were measured using the Bioplex assay. Blood RNA transcripts were investigated using microarrays. Transcriptome data was analyzed using GO pathways.
Results: TB-antigen stimulated IFN-g and IL-2 responses were raised in those with LTBI as compared with EC, and in DM-LTBI as compared with DM groups. The DM-LTBI group participants displayed raised levels of TNF-a (compared with LTBI), GM-CSF and IL-13 (compared with EC and DM). Host blood transcriptome analysis of study groups revealed 359 differentially expressed genes (DEGs): 187 DEGs between LTBI and EC; 182 DEGs between DM and EC, with 12 DEGs between DM-LTBI and EC groups.
In LTBI, there was downregulation of antigen presentation pathways (HLA-DQA1, HLADRB5). Comparing LTBI-DM and LTBI groups revealed upregulation of host adaptive, innate immunity and inflammatory (MMP9,

TLRs) pathways. GSE analysis of Wikipathways revealed upregulation of SARS-CoV-2 associated signaling pathways as well as IL-1-related inflammation associated with obesity.
Further investigation of transcripts in those who had DM-LTBI, comparing individuals with uncontrolled (HDM) as compared with controlled (CDM) diabetes revealed 488 DEGs, with upregulation of cell signaling and motility processes and downregulation of ribosome biogenesis.
Conclusions: We show that LTBI and DM synergistically increase host inflammatory and metabolic processes whilst reducing innate immunity, likely increasing susceptibility to pathogens.

TBS02-40 An imaging-based artificial intelligence (AI) system for diagnosing recurrent pulmonary tuberculosis

P.T. Palani,[1] N. Wig,[1] S. Sinha,[1] S. Vyas,[1] N. Nischal,[1] P. Sethi,[1] V.P. Meena,[1] A. Singh,[1] S. Spalkit,[1] A. Singh,[2] A. Ray,[1] [1]All India Institute of Medical Sciences (AIIMS), New Delhi, India, [2]Indian Institute of Technology, Delhi, India
e-mail: premt2499@gmail.com

Introduction: Recurrent pulmonary tuberculosis (rPTB) poses diagnostic challenges due to considerable overlap with post-TB lung disease (PTLD) including chronic pulmonary aspergillosis (CPA) and poor microbiological yield. Computed tomography (CT) scans provide better accuracy than conventional chest X-rays at differentiating healed lesions from active disease; however, they require trained radiologists for interpretation. Training AI models to interpret CT scans can combine accuracy with faster diagnosis.
Objective: To develop and validate a computed tomography (CT)-based artificial intelligence (AI) model for differentiating rPTB, PTLD and CPA.
Methods: 66 patients with a history of past TB and new respiratory symptoms were studied. A convoluted neural network (CNN) model was trained on CT scans from these patients, using radiologist input and clinical/microbiological data. The scans were labelled by an experienced user, segmented using 3D Slicer (an open-source, medical image editing software), pre-processed and classified based on labels.
Classification was done using DenseNet Architecture, which utiilizes a deep learning model and Pyradiomics, an open-source Python package for extracting medical imaging data. The scans were then divided into 5 folds; each fold consisted of a training set and a validation set. The results of the 5 folds were combined to yield a final pooled confusion matrix.
Results: rPTB, PTLD and CPA was diagnosed in 12, 36 and 18 patients respectively.



The model's ROC achieved an AUC of 0.93 for diagnosing rPTB, with a sensitivity, specificity and accuracy of 91.67%, 90.74% and 90.91 % respectively. The final confusion matrix shows the actual diagnoses on the y-axis and the model's predictions on the x-axis.
Conclusion: The AI model reliably diagnosed rPTB and differentiated it from close clinical mimics. Further training and validation of this model might enable its use in communities with a high burden of rPTB.

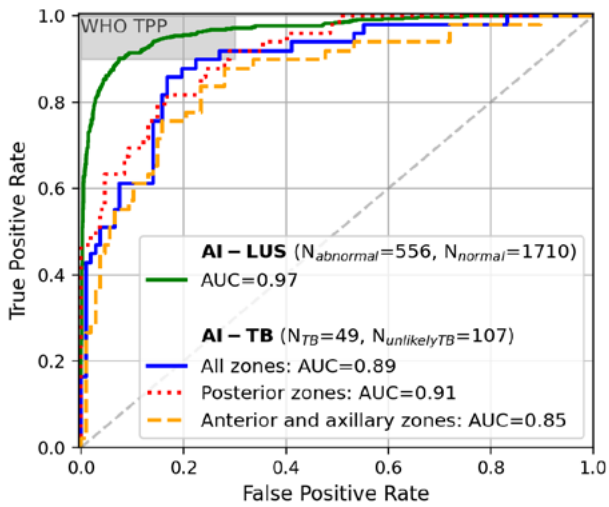
TBS02-45 Expanding TB screening and triage through standardised sweep ultrasound and AI: Findings from a pilot study in Zambia

E. Swinkels,[1] C. Bresges,[2] K. Mateyo,[3,4,5] M. Fentress,[6] S. Lungu,[7] R. Chimfwembe,[7] K. Shanaube,[3] H. Ayles,[3,5] [1]Eindhoven University of Technology, Eindhoven, Netherlands, [2]University Hospitals Sussex NHS Trust, Brighton, United Kingdom of Great Britain and Northern Ireland, [3]Zambart, Lusaka, Zambia, [4]University Teaching Hospital, Lusaka, Zambia, [5]London School of Hygiene and Tropical Medicine, London, United Kingdom of Great Britain and Northern Ireland, [6]University of California, San Francisco, United States of America, [7]Kanyama General Hospital, Lusaka, Zambia
e-mail: e.j.s.swinkels@tue.nl

Background: Despite being preventable and treatable, tuberculosis (TB) remains underdiagnosed, with one-third of people with TB missed globally. There is a pressing need for scalable, cost-effective tools accessible in community and primary care. Handheld ultrasound offers a promising solution: it is portable, relatively affordable, radiation-free, and suitable for bedside use. Combined with artificial intelligence (AI) and a standardised sweep protocol, lung ultrasound (LUS) may enable TB screening without requiring specialised expertise.
Design/Methods: From March to December 2023, radiographers collected and interpreted LUS videos using a 5- or 16-zone sweeping protocol at a primary health

facility in Lusaka, Zambia. 809 symptomatic adults were enrolled (mean age 37.6±13.4 years; 61% male; 150/750 [20%] living with HIV; 110/679 [16%] with pulmonary TB) and received LUS. Blinded expert clinician and radiographer interpretations showed substantial agreement (Cohen's Kappa=0.68; 386 videos from 23 participants). An AI model optimised for mobile deployment was trained on 16-zone data to distinguish normal from abnormal LUS and predict TB using a composite reference of Xpert Ultra, urine lipoarabinomannan, and clinical diagnosis. Performance was evaluated on 2266 videos from 198 participants excluded from training (TB diagnosis for 156; 49 positive), comprising unseen 16-zone and all 5-zone data, at zone (AI-LUS) and participant (AI-TB) level.

Results: AI-LUS achieved an AUC-ROC of 0.97. AI-TB met WHO's screening target product profile (sensitivity>0.90 at specificity>0.70), using either a full-thorax or posterior-only protocol (see Figure). The latter significantly reduced scan time from 12.0±3.4 to 2.0±1.7 minutes. Incorporating TB diagnosis labels into training yielded marginal gain in AUC-ROC.



Conclusions: The findings demonstrate that a simple, standardised lung sweep protocol, combined with AI and integrated into a mobile application, is feasible and potentially effective. By bringing TB screening closer to the point of need, this tool may help identify people who would otherwise remain undetected.

TBS04-10 Widespread preexisting resistance to new and repurposed anti-tuberculosis drugs through loss-of-function

D. Conkle-Gutierrez,[1] F. Valafar,[1] [1]San Diego State University, San Diego, United States of America
e-mail: dconklegutierrez@sdsu.edu

Five New and Repurposed Drugs (NRDs) were approved in the last decade for treatment of multi-drug resistant tuberculosis: bedaquiline, clofazimine, linezolid, delamanid, and pretomanid. Unfortunately, resistance to these drugs emerged faster than anticipated, partly from preexisting resistance in naïve strains. Previous investigations into the rapid emergence mostly used short variants.

For the first time, we utilize *de novo*-assembled genomes, and systematically include Structural Variations (SV) and heterogeneity to comprehensively study this rapid emergence.

First, a systematic literature review revealed 313 NRD resistance variants in 13 genes.

Next, 409 globally diverse clinical isolates collected prior to the drugs' programmatic use (308 were MDR, 106 had *de novo* assembled genomes) were utilized to study the 13 genes comprehensively for conventional, structural, and heterogeneous variants. We identified 5 previously reported and 67 novel putative NRD resistance variants.

These variants were 2 promoter mutations (in 8/409 isolates), 13 frameshifts (21/409), 6 SVs (9/409), 35 heterogeneous frameshifts (32/409) and 11 heterogeneous SVs (12/106).

Delamanid and pretomanid resistance mutations were most prevalent (48/409), while linezolid resistance mutations were least prevalent (8/409).

Preexisting NRD resistance was highly prevalent in these strains (85/409, 21%), primarily through loss-of-function mutations in genes responsible for prodrug activation and efflux pump regulation. Loss-of-function mutations were similarly frequent throughout the genome, suggesting a wide bet-hedging strategy.

Hence, any future drugs resistible through loss-of-function in non-essential genes may similarly suffer from preexisting resistance, which will then spread rapidly upon programmatic use. This effect might be mitigated at early-stage drug design through comprehensive preexisting-resistance assessment.

TBS04-15 Safety and pharmacokinetics of bedaquiline in children aged ≥2<5 years with MDR-TB: 24-week results from Cohort 3 of the TMC207-C211 study

M. Khan,[1] J. van de Logt,[2] B. Remmerie,[3] N. Lounis,[3] E. Birmingham,[4] I. Leipoldt,[5] N. Bakare,[6] [1]Tuberculosis & HIV Investigative Network (THINK), Durban, South Africa, [2]Johnson & Johnson, Leiden, Netherlands, [3]Johnson & Johnson, Beerse, Belgium, [4]Johnson & Johnson, Raritan, United States of America, [5]Johnson & Johnson, Durban, South Africa, [6]Johnson & Johnson, Titusville, United States of America
e-mail: nbakare@its.jnj.com

Background: The TMC207-C211 study is a phase 2, open-label, multicenter, single-arm study to evaluate pharmacokinetics, safety, tolerability and anti-mycobacterial activity of bedaquiline in combination with a background regimen of multidrug resistant tuberculosis (MDR-TB) medications for the treatment of children and adolescents 0 months to <18 Years of age with confirmed or probable pulmonary MDR-TB. Data for ≥5 to <18-year-olds (cohorts 1 & 2) have been reported previously.
Methods: Children aged ≥2 to <5 years received bedaquiline (dosed at 8 mg/kg qd for 14 days, followed by 4 mg/kg tiw for 22 weeks) in combination with an individualized MDR-TB treatment regimen, with follow-up until 120 weeks. Primary objectives were safety, tolerability and PK of bedaquiline over a 24-week treatment period to inform on dosing recommendations. Safety parameters were analyzed descriptively. BDQ and M2 PK parameters were derived using noncompartmental (AUC24h, Cmax, tmax, and Cmin at Weeks 2 and 12; Cmin and t1/2 at Week 24) or popPK models (AUC168h at Wk12 and Wk24).
Results: 15 participants from Phillippines and South Africa, median age 3.8 years (range: 2 to 4.9 yrs), with confirmed (N=3) or probable (N=12) MDR-TB, were treated. No deaths, SAEs, or AEs leading to permanent discontinuation or temporary interruption of bedaquiline were reported. Two participants experienced a grade 3 AE, considered not related to bedaquiline. There were no occurrences of QTcF >460 ms. Individual bedaquiline AUC168h at Week 12 and Week 24 were within the 95% prediction interval of AUC168h in adults receiving the standard adult bedaquilne dose. GM AUC168s were within pre-specified target (60-140% of adult AUC168h, ss)

Pharmacokinetic parameters*	Day 14	Week 12	Week 24
AUC24h (ng.h/mL)	47,800 +/-27,000a	26,700+/-7,270b	-
AUC168h (ng.h/mL)	-	123,000+/-43,700	136,000+/-51,500
Cmax (ng/mL)	3690 +/- 2640	1810 +/- 872	-

* GM AUC168s were within pre-specified target (60-140% of adult AUC168h,ss)
Note: Expressed as mean +- standard deviation
a N=14 for AUC24h at Day 14
b N=10 for AUC24h at Week 12

Table: Pharmacokinetics of bedaquiline in Cohort 3 (≥2 to <5 Years of Age) TMC207-C211 study (N=15)

Conclusion: In children aged ≥2 to <5 years old with MDR-TB, 24 weeks of bedaquiline provided a comparable safety and pharmacokinetic profile to adults. This data will inform bedaquiline dosing recommendations, including children aged ≥2 to <5 years old.

TBS04-20 Decoding the role of ATF4 in pediatric tuberculosis by single-cell transcriptomics and metabolomics

X. Yu,[1] J. Liu,[2] [1]The Fifth People's Hospital of Suzhou, Department of Tuberculosis, Suzhou, China, [2]The Fifth People's Hospital of Suzhou, Suzhou, China
e-mail: xinxin810104@126.com

Background: Pediatric tuberculosis (TB) poses diagnostic challenges due to immature immune responses and non-specific clinical manifestations. Current diagnostic tools lack sufficient sensitivity. Activating transcription factor 4 (ATF4) has been implicated in immune regulation via amino acid metabolism; however, its role in pediatric TB remains unclear. This study aims to elucidate the ATF4-mediated metabolic-immune network using single-cell transcriptomics.
Design/Methods: Peripheral blood samples were collected from children with active TB (ATB), latent TB infection (LTBI), and healthy controls (HC). Single-cell RNA sequencing (scRNA-seq) was employed to profile immune cell subsets, and plasma amino acid metabolites were analyzed via LC-MS/MS. ATF4-deficient immune cell models were generated to assess its impact on Mycobacterium tuberculosis clearance in vitro.
Results: scRNA-seq revealed significant upregulation of ATF4 in monocytes and neutrophils of pediatric ATB patients, with co-expression of metabolic enzymes and immunosuppressive genes (PD-L1, IL-10). Metabolomic analysis identified abnormal levels of glutamine and tryptophan, which, combined with ATF4 expression, effectively distinguished ATB from LTBI. Functional assays demonstrated that ATF4 inhibition enhanced macrophage bactericidal activity and promoted $CD8^+$T cell proliferation and IFN-γ production.
Conclusion: ATF4 drives immune suppression in pediatric TB via metabolic reprogramming of monocytes and neutrophils. Its expression and associated metabolites may serve as novel biomarkers for early diagnosis. This study offers a new perspective on metabolism-immune crosstalk, providing a foundation for precision diagnostics and therapeutics in pediatric TB.
Summary: ATF4 regulates immune suppression through metabolic reprogramming in pediatric TB, with its expression and metabolites serving as potential biomarkers for early diagnosis and treatment, offering insights into metabolism-immune interactions for precision therapeutics.

TBS04-25 A machine-learning model of sequence, biochemical, and structural features to predict bedaquiline resistance in *Mycobacterium tuberculosis*

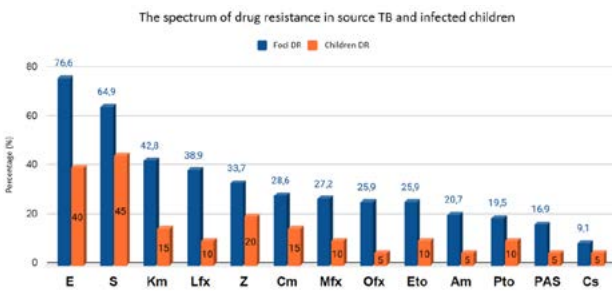
W. Quispe Rojas,[1] M. De Diego Fuertes,[1] M. Safarpour,[1] V. Rennie,[1] A. Van Rie,[1]
[1]Antwerpen University, Antwerpen, Belgium
e-mail: wilma.quisperojas@student.uantwerpen.be

Background: Bedaquiline (BDQ) is a core drug for rifampicin-resistant TB treatment.BDQ resistance is primarily caused by variants in the *Rv0678* gene.The WHO mutation catalogue classifies 97% of all missense variants in *Rv0678* as „*of uncertain significance*," limiting the clinical use of NGS diagnostics.
Methods: We performed a literature review to identify isolates with *Rv0678* missense variants that had corresponding MGIT phenotype data. After quantification of 13 sequence, biochemical, and structural features for each identified variant, we used AI methods (binary random forest classifier) to predict the BDQ phenotype. Hyperparameter tuning was implemented using Grid Search, and overfitting addressed using 5-fold cross-validation. Performance was assessed using Area Under the Curve (AUC) and F1 score. Clinical value was estimated by calculating the model's sensitivity and specificity, the proportion of variants classified as high, moderate and low probability of resistance, and the net reclassification improvement (NRI).
Results: The final model contained 5 features: evolutionary conservation, shortest atomic distance to key functional sites, biochemical differences between amino acids, impact on protein stability and dynamics in the ligand state, and effect on protein–protein interaction affinities in the DNA binding state. The final model achieved an AUC of 0.848 and F1-score of 0.853. For the 58 unique missense variants identified by the literature review, the model sensitivity was 91.6% and specificity 81.8%. Of the 159 variants classified in the WHO catalogue as 'uncertain significance', the model could classify 73 (45.9%) variants: 35 as high and 38 as having a low probability of BDQ resistance, with uncertainty remaining for 76 (47.7%) variants (moderate probability of resistance). For 149 variants listed in the catalogue, the NRI was +23.2%.
Conclusion: Using five sequence, biochemical, and structural features a machine learning model can characterize the impact of *Rv0678* missense variants and improve prediction of the BDQ phenotype.

TBS04-30 Evaluation of the drug resistance spectrum of *M. tuberculosis* in children from foci of multidrug-resistant tuberculosis

A. Prikhodko,[1] A. Kazakov,[2,1] N. Klevno,[2] A. Pakhlavonova,[2] E. Sokolskaya,[2] [1]Federal State Autonomous Educational Institution of Higher Education «N.I. Pirogov Russian National Research Medical University» of the Ministry of Health of the Russian Federation, Moscow, Russian Federation, [2]National Medical Research Center for Phthisiopulmonology and Infectious Diseases of the Ministry of Health of the Russian Federation, Moscow, Russian Federation
e-mail: alexeykazakov1982@yandex.ru

Introduction: According to the WHO Global tuberculosis (TB) Report, in 2023 only 37% of household contacts of smear-positive TB patients in the European Region received preventive TB treatment. In the Russian Federation in 2023, a high proportion of multidrug-resistant (MDR) strains was identified among children with bacteriologically confirmed TB: 37,3% in the 0–14 age group and 41,6% among adolescents aged 15–17 years.
Objective: To assess the spectrum of drug resistance in children from MDR-TB foci.
Methods: A retrospective analysis was performed on 406 medical records of children aged 0–17 years with respiratory tuberculosis treated at the National Medical Research Center for Phthisiopulmonology and Infectious Diseases of the Ministry of Health of Russia from January 2023 to May 2025.
Results: Among the 406 children, 166 (40,99%; 95% CI: 36,3–45,84) had known contact with TB patients. In total 89 cases (53,61%; 95% CI: 46,03–61,03) were exposed to MDR or pre-extensively drug-resistant (pre-XDR) TB strains. Resistance to more than four anti-TB drugs was documented in 67 cases (75,28%; 95% CI: 65,4–83,07). High resistance rates were found against levofloxacin in 30 cases (33,71%; 95% CI: 24,74–44,02). In 17 instances (85%; 95% CI: 63,96–94,76), the resistance profile matched in the source of infection and children with tuberculosis from MDR-TB foci. Preventive therapy following contact with MDR or pre-XDR TB patients was documented in only 18 cases (20,22%; 95% CI: 13,19–29,72).



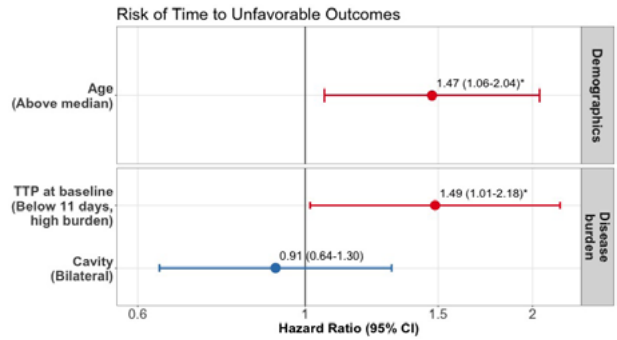
Conclusions: Levofloxacin resistance in MDR-TB households reached 33,7%. A high concordance (85%) was found between drug resistance in source TB and infected children. Preventive treatment for children in MDR and

pre-XDR TB households was not given in 79,2% of cases. Empiric regimens were ineffective due to broad resistance, including to fluoroquinolones. There is an urgent practical need for effective preventive treatment protocols with new anti-TB drugs.

TBS04-35 Risk factors for unfavorable outcomes in four trials of bedaquiline and pretomanid-based regimens

S. Hwang,[1] B. P.Solans,[1] G. E. Velásquez,[2,3] P. P. J. Phillips,[2,4] P. Van Brantegem,[1] R. Savic,[1,2] [1]Department of Bioengineering and Therapeutics, Schools of Pharmacy and Medicine, University of California, San Francisco, San Francisco, United States of America, [2]UCSF Center for Tuberculosis, University of California, San Francisco, San Francisco, United States of America, [3]Division of HIV, Infectious Diseases, and Global Medicine, University of California, San Francisco, San Francisco, United States of America, [4]Division of Pulmonary and Critical Care Medicine, University of California, San Francisco, San Francisco, United States of America
e-mail: sejung.hwang@ucsf.edu

Tuberculosis (TB) remains one of the leading causes of death from an infectious disease. Bedaquiline (B) and pretomanid (Pa)-based regimens have been newly developed as promising regimens for TB; regimens containing BPa plus linezolid with or without moxifloxacin are recommended for the treatment of drug-resistant TB. Identification of risk factors related to TB-related unfavorable outcomes is a crucial first step to support the stratification of participants for future novel interventions.
We aimed to evaluate baseline risk factors for TB-related unfavorable outcomes in clinical trial participants treated with BPa-based regimens.
We compiled data from 4 phase 2–3 clinical trials (Nix-TB, ZeNix, TB-PRACTECAL, and SimpliciTB). Each clinical trial included BPa-based regimens combined with different drugs: clofazimine, linezolid, moxifloxacin, or pyrazinamide. Unfavorable outcome was defined according to the criteria specified in each trial including treatment failure and treatment discontinuation. We constructed univariate and multivariate Cox proportional hazards models to identify risk factors for time to TB-related and non TB-related unfavorable outcomes.
We considered the following baseline characteristics: age, sex, weight, height, BMI, HIV status, sputum smear grade, sputum culture time to positivity (TTP), *M. tuberculosis* (*Mtb*) drug resistance, and cavitary disease.
A total of 1,119 participants were included in the analysis. Age, smear grade, baseline TTP, *Mtb* drug resistance, and regimen composition were identified as potential independent risk factors from univariate analysis. Age and baseline TTP were retained in the final multivariate model of time to unfavorable outcomes after adjusting for the study and regimen. The hazard ratios (HR) (95% confidence intervals, CIs) of age above a median 35 years and baseline TTP below 11 days were 1.47 (1.06–2.04) and 1.46 (1.01–2.18).
This analysis demonstrated that older age and higher baseline burden of disease were associated with an increased hazard of unfavorable outcome in clinical trial participants receiving BPa-based regimens.



TBS08-10 Innovating TB diagnosis: A model-based evaluation of tongue swab molecular testing across four high-burden countries

A.J.D. Barrameda,[1] P. Papadopoulou,[2] C. Yu,[1] H. Phan,[3] M. Muyoyeta,[4] A.K. de Villiers,[2,5] H. Le,[3] S. Muzazu,[4] A. Cattamanchi,[6,7] C.M. Denkinger,[2] A. Andama,[8] F.M. Marx,[2,5] [1]Tuberculosis Research Laboratory, Research Services, De La Salle Medical and Health Sciences Institute, Dasmariñas City, Philippines, [2]Department of Infectious Disease and Tropical Medicine, Heidelberg University Hospital, Heidelberg, Germany, [3]Center for Promotion of Advancement of Society, Hanoi, Viet Nam, [4]Centre for Infectious Diseases Research in Zambia, Lusaka, Zambia, [5]South African Centre for Epidemiological Modelling and Analysis (SACEMA), Center for Epidemic Response and Innovation, School of Data Science, Stellenbosch University, Stellenbosch, South Africa, [6]Center for Tuberculosis, University of California, San Francisco, United States of America, [7]Department of Medicine, Division of Pulmonary Diseases and Critical Care Medicine, University of California Irvine, Irvine, United States of America, [8]Makerere University College of Health Sciences, Kampala, Uganda
e-mail: florian.marx@uni-heidelberg.de

Background: Tongue swab (TS)-based molecular testing is an innovative, non-sputum sampling approach for tuberculosis (TB) diagnosis. With promising accuracy demonstrated in recent studies, TS testing has the potential to overcome key biological and operational barriers in current diagnostic pathways. We estimated the health impact and cost-effectiveness of TS-based testing strategies using MiniDock MTB (Guangzhou Pluslife Biotech), a near-point-of-care molecular platform, across four TB high-burden countries.

Methods: As part of the Tongue Swab Yield (TSwaY) study, we collected site-level cost data from primary care facilities in the Philippines, Uganda, Vietnam, and Zambia. A probabilistic decision-analytic model was developed to simulate three diagnostic strategies in settings with onsite Xpert MTB/RIF Ultra (Ultra): (1) replacement of sputum Ultra with TS MiniDock, (2) complementary TS testing for individuals unable to produce sputum, and (3) dual testing for individuals with a negative or no sputum Ultra result. Outcomes included disability-adjusted life years (DALYs) averted and incremental net monetary benefits (iNMB) across a range of willingness-to-pay (WTP) thresholds.
Results: TS-based replacement testing reduced diagnostic costs but led to fewer DALYs averted than the current standard in three of four countries. Complementary TS testing averted 24–54 additional DALYs per 1,000 individuals tested at an incremental cost of USD 242–955 per DALY averted compared to replacement. Dual testing conferred further health gains (8–14 DALYs/1,000) at incremental costs of USD 399–1,592 per DALY averted compared to complementary testing. iNMB analyses (Figure) identified dual testing as optimal at WTP thresholds ≥USD 500 (Philippines), ≥USD 750 (Uganda, Vietnam), and ≥USD 1,250 (Zambia).

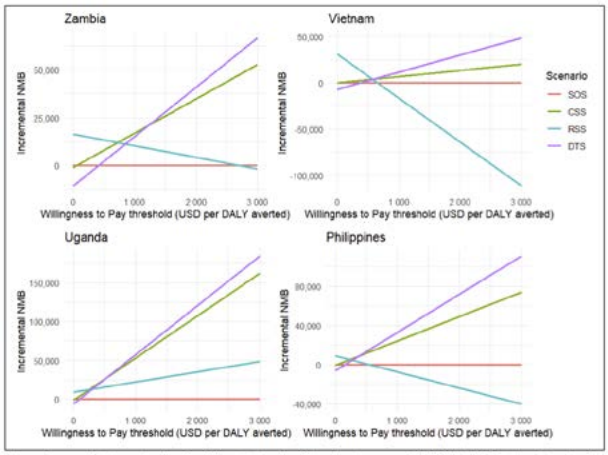


Figure: Incremental net monetary benefits of different strategies of integrating tongue swab (TS) MiniDock MTB testing into routine TB diagnostic algorithms in four TB high-burden countries: SOS = Sputum only scenario (base-case); CSS = Complementary testing scenario: TS is offered to people who are unable to produce sputum; RSS = Replacement scenario: TS replaces sputum-based testing; DTS = Dual test scenario: both samples are collected if possible, and TS-based molecular testing is processed for individuals with negative or no sputum Xpert Ultra result.

Conclusions: A combination of sputum-based and TS-based molecular testing, through complementary or dual testing strategies, can yield considerable health benefits at reasonable additional cost compared with sputum-based testing alone. These findings support the future integration of TS-based testing into TB diagnostic algorithms in high-burden settings.

TBS08-15 Nutritional markers and poor weight gain during tuberculosis treatment are associated with persistent inflammation and post-tuberculosis lung disease

P. Sinha,[1] M. Karoly,[1] S. Gaikwad,[2] L.E. Hanna,[3] V. Mave,[4] A. Gupta,[5] C. Padmapriyadarsini,[6] A.N. Gupte,[7]
[1]Boston Medical Center, Boston, United States of America, [2]Byramjee Jeejeebhoy Government Medical College and Sassoon General Hospital, Pune, India, [3]National Institute for Research in Tuberculosis (NIRT) Central Biorepository, Chennai, India, [4]Byramjee Jeejeebhoy Government Medical College (BJGMC)/Johns Hopkins University (JHU) Clinical Research Site (CRS), Pune, India, [5]Johns Hopkins University (JHU), Baltimore, United States of America, [6]National Institute for Research in Tuberculosis, Chennai, United States of America, [7]Boston University School of Public Health, Department of Global Health, Boston, United States of America
e-mail: agupte1@bu.edu

Background: Nearly half of persons with pulmonary tuberculosis (PTB) have ventilatory defects despite successful treatment. While undernutrition has been linked to an increased risk of poor treatment outcomes, its association with post-treatment lung function has not been investigated.
Methods: We enrolled adults with drug-sensitive PTB within 7 days of treatment initiation at clinics in Pune and Chennai, India. Plasma collected at enrolment and 2 months of treatment underwent multiplex ELISA for interferon gamma (IFN-g), tumor necrosis factor alpha (TNF-a), interleukin (IL)-1b, IL-6, IL-17, and IL-18 quantification. Spirometry was performed at successful treatment completion according to ATS/ERS standards. We measured associations of body mass index (BMI) and mid-upper arm circumference (MUAC) measured at enrolment, premorbid BMI estimated at the time of PTB symptom onset, and weight gain during treatment, with systemic inflammation and post-treatment lung function.
Results: Of 163 participants (57% male; median age 32 years), 72 (48%) had ventilatory defects – 52 (32%) had airflow obstruction and 27 (17%) had restrictive spirometry. The median (IQR) premorbid BMI, enrolment BMI and MUAC were 19 (17-21) kg/m$_2$, 18 (16-10) kg/m$_2$ and 22 (20-24) cm, respectively. After adjusting for potential confounders, higher premorbid BMI (aOR 0.79 per unit increment, 95%CI 0.68-0.91), enrolment BMI (aOR 0.81 per unit increment, 95%CI 0.70-0.91), enrolment MUAC (aOR 0.81 per cm increment, 95%CI 0.71-0.92), and a 10% or greater weight gain during 6 months of PTB treatment (aOR 0.41, 95%CI 0.18-0.91) were independently associated with lower odds of any post-treatment ventilatory defects. Conversely, lower BMI, MUAC, and <10% weight gain were associated with higher baseline levels and slower resolution of IL-6. Persistently elevated IL-6 levels were associated with higher odds of post-treatment ventilatory defects ($p<0.01$ for all).

Nutritional Metrics	Ventilatory defects	Baseline IL-6 levels	Month 2 IL-6 levels	Change[1] in IL-6 levels
	OR[2] (95% CI[3])	β[4] (95% CI)	β[4] (95% CI)	β[4] (95% CI)
Baseline BMI[5]	0.81 (0.70, 0.91)	-0.54 (-0.80, -0.29)	-0.15 (-0.42, 0.12)	-0.37 (-0.68, -0.07)
Baseline Premorbid BMI[5]	0.79 (0.68, 0.91)	-0.38 (-0.66, -0.11)	-0.15 (-0.42, 0.16)	-0.23 (-0.55, 0.09)
Baseline MUAC[6]	0.81 (0.71, 0.92)	-0.51 (-0.76, -0.24)	-0.06 (-0.34, 0.20)	-0.41 (-0.72, -0.11)
5 % 2 months bodyweight gain[7]	0.53 (0.23, 1.16)	0.11 (-1.83, 2.06)	-1.36 (-3.31, 0.57)	1.63 (-0.56, 3.83)
10 % 6 months bodyweight gain[8]	0.41 (0.18, 0.91)	0.38 (-1.53, 2.30)	-1.85 (-3.77, 0.06)	2.54 (0.29, 4.61)

Adjusted for sex, age, symptom duration (< 1 month or 1 month+), disease severity, ever-smoker, alcohol misuse, and diabetes.
1. IL-6 levels change from baseline to 2 months; 2. OR: odds ratio; 3. CI: Confidence Interval 4. β: linear regression coefficient; 5. BMI: Body mass index kg/m^2; 6. MUAC: mid-upper arm circumference kg/m^2; 7. 5% bodyweight gain after 2 months of PTB treatment; 8. 10% of bodyweight gain after 6 months of PTB treatment

Table 1: Adjusted association of nutritional metrics with post-treatment ventilatory defects and IL-6 levels (log transformed).

Conclusion: Undernutrition and poor weight gain are associated with increased and persistent systemic inflammation which may mediate risk of post-tuberculosis lung disease.

TBS08-20 Detection of aerosolised *Mycobacterium tuberculosis* DNA from adults with presumed pulmonary tuberculosis using an electrostatic sampler in a South African primary care setting

J. Achar,[1,2] R. Venter,[2] J. van Schalkwyk,[2] Z. Booi,[2] Z. Mahlobo,[2] Z. Palmer,[2] N. Rufino de Sousa,[1] K. Lönnroth,[1] J. Seddon,[2,3] A. Rothfuchs,[1] G. Theron,[2] [1]Karolinska Institutet, Stockholm, Sweden, [2]Stellenbosch University, Cape Town, South Africa, [3]Imperial College London, London, United Kingdom of Great Britain and Northern Ireland
e-mail: jay.achar@ki.se

Background: Non-sputum-based diagnosis of tuberculosis (TB) is a public health priority. Little is known about the feasibility of detecting Mycobacterium tuberculosis (*Mtb*) in respiratory aerosols in primary care, its diagnostic value, and the clinical and microbiological characteristics associated with detection.
Methods: We recruited symptomatic adults self-presenting to South African primary care clinics with a sputum Xpert MTB/RIF Ultra (Ultra) result. Two cough aerosol samples were collected from each participant using THOR, a novel electrostatic aerosol sampler, combined in the laboratory and tested by Ultra. Samples were collected at each clinic by participants coughing inside a dedicated booth with an internal volume of 1.9m^3 for 5 mins. Predictors of aerosol *Mtb* DNA (AMD) detection were assessed.
Results: Amongst 137 participants, 71 (52%) had medium or high and 34 (25%) had negative Ultra semi-quantitative results. Compared to sputum Ultra positivity, sensitivity of AMD detection in people with sputum Ultra high results was 56.9% (95%CI: 51.1-62.7) and specificity was 76.5% (95%CI: 70.4-82.5). Overall, AMD was detected from 56 (41%) participants. Factors associated with AMD detection were male sex with sputum Ultra semi-quantitative result greater than medium (aRR 3.26; 95%CI: 1.11-9.55; p=0.024) and reported fever (aRR 0.58; 95%CI: 0.29-1.07; p=0.099). AMD was detected in 8 (24%) people with negative sputum Ultra. Sputum-to-aerosol IS1081/6110 cycle threshold ratios in three participants was ≥0.75 suggesting a higher capacity to expel *Mtb* DNA. Despite rigorous decontamination, AMD was detected from 30% of environmental samples highlighting THOR's potent sampling capability and the risk to healthcare staff.

	aRR[1]	95% CI[2]	p-value
Sex: Sputum Ultra semi-quantitative result			
Female: ≤ low/negative	-	-	-
Female: ≥ medium	1.89	0.53, 6.7	0.571
Male: ≤ low/negative	1.13	0.3, 4.26	0.996
Male: ≥ medium	3.26	1.11, 9.55	0.024
Reported fever			
No	-	-	-
Yes	0.58	0.29, 1.07	0.099

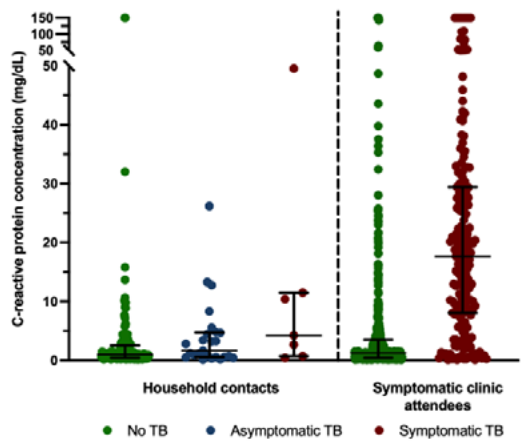
[1]aRR = adjusted risk ratio;
[2]CI = Confidence Interval calculated with robust Standard Errors

Conclusions: Electrostatic aerosol sampling is feasible in primary care to detect people with infectious TB. More widespread use of aerosol sampling to detect TB might help to characterise predictors of transmission.

TBS08-25 Universal screening for asymptomatic TB among adults with household exposure to a patient with pulmonary TB

S.C. Mendelsohn,[1] H. Mulenga,[1] M. Tameris,[1] T. Moloantoa,[2] S.T Malherbe,[3] G. Walzl,[3] T.J. Scriba,[1] T.R. Sterling,[4] M. Hatherill,[1] RePORT South Africa Study Team [1]South African Tuberculosis Vaccine Initiative, Institute of Infectious Disease and Molecular Medicine, University of Cape Town, Cape Town, South Africa, [2]Perinatal HIV Research Unit, University of Witwatersrand, Johannesburg, South Africa, [3]DST/NRF Centre of Excellence for Biomedical TB Research; South African Medical Research Council Centre for TB Research; Division of Immunology, Department of Biomedical Sciences, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa, [4]Vanderbilt Tuberculosis Center, Vanderbilt University Medical Center, Nashville, United States of America
e-mail: simon.mendelsohn@uct.ac.za

Background: More than half of TB detected by community prevalence surveys is classified as asymptomatic. We evaluated the yield of universal sputum bacteriological screening for asymptomatic TB among household contacts (HHC) in South Africa.
Methods: Adults (≥18 years) with household exposure to pulmonary TB patients were enrolled at three sites. Systematic screening of TB symptoms (any duration), chest radiograph (CXR; any abnormality), and sputum microscopy, Xpert Ultra, and liquid culture were performed. Serum C-reactive protein (CRP) was measured by multiplex bead array. Prevalent TB was microbiologically confirmed (Xpert Ultra or culture). Symptomatic and asymptomatic TB were defined as prevalent TB with and without reported symptoms, respectively.
Results: Between March 2021-December 2022, 979 HHC were enrolled; 185 (18.9%) living with HIV and 187 (19.1%) with previous TB. Prevalent TB occurred in 51 (5.2%) and was asymptomatic in 42/51 (82.4%). Only 13/42 (31.0%) asymptomatic TB cases were smear-positive [8/13 (61.5%) scanty or 1+]. CRP did not discriminate healthy HHC from those with asymptomatic TB (AUC 0.60; 95%CI 0.47–0.73; *Figure*).



An abnormal CXR was observed in 23/41 asymptomatic (sensitivity 56.1%, 95%CI 41.0–70.1%) versus 8/9 symptomatic (88.9%, 95%CI 56.5–98.0%) TB cases. Sensitivity of CXR with symptom screening was 64.0% (32/50, 95%CI 50.1–75.9%) for all prevalent TB.
Conclusions: More than 80% of TB cases among HHC were asymptomatic; CXR screening missed 40% of these. Community prevalence surveys reliant on symptom- and CXR-based approaches may significantly underestimate asymptomatic TB prevalence in endemic countries. CRP did not significantly differentiate asymptomatic TB from asymptomatic HHC without TB, suggesting CRP is not appropriate as a screening test in community settings.
These findings support the hypothesis that asymptomatic TB in the community, among persons not presenting for healthcare, is associated with less severe disease and less systemic inflammation than symptomatic TB among clinic attendees.

TBS08-30 Integration of ELISA and LAMP in a Novel urine-based assay: A visual, rapid, and non-invasive approach for diagnosing pediatric tuberculosis

I. Verma,[1] A. Kashwal,[1] S. Sharma,[2] M.S. Singh,[3] J. Mathew,[1] P.C. Vaidya,[1] S. Sethi,[1] [1]Postgraduate Institute of Medical Education and Research, Chandigarh, India, [2]All India Institute of Medical Sciences, Bilaspur, India, [3]All India Institute of Medical Sciences, Rishikesh, India
e-mail: induvermabio@gmail.com

Background: Diagnosing pediatric TB is challenging due to its pauci-bacillary nature and difficulty in obtaining invasive samples.We aimed to identify *in vivo* expressed mycobacterial proteins in urine samples for the development of a rapid antigen detection assay for pediatric TB using a novel approach of integrating immunological and molecular techniques.
Methods: In this study, 210 pediatric pulmonary TB suspects were enrolled. Urine samples from culture-confirmed pulmonary TB cases (n = 8) and non-tuberculous controls (n = 8) were analysed using shotgun mass spectrometry. Selected TB-specific mycobacterial proteins were produced in recombinant form to develop an indirect antigen detection ELISA in urine.
Additionally, ELISA-LAMP assay was designed by conjugating an amino-modified reporter oligonucleotide to the secondary antibody, followed by isothermal amplification using LAMP primers and visual colour change detection.
Results: Thirty eight mycobacterial proteins were identified in urine, of which 17 were exclusively detected in TB. Two mycobacterial protein (DNA binding/ intermediary metabolism) were identified in maximum number of TB samples and evaluated for antigen detection ELISA development in urine samples both from TB and non-TB

subjects (n=25). ROC analysis to determine the optimal concentration-based cut-off providing maximum specificity showed promising results only for one mycobacterial protein (DNA binding). Cutoff for this protein was subsequently applied to blinded samples from a validation cohort comprising 156 pediatric pulmonary TB suspects. Decoding of results against a composite reference standard (CRS) comprising clinical, radiological, and microbiological findings, showed 75.0% sensitivity and 90.4% specificity for ELISA and 79% sensitivity and 89% specificity for ELISA-LAMP based on visual detection of colour change.

Conclusion: Mycobacterial proteins identified in urine samples show potential for non-invasive diagnosis of pediatric pulmonary TB. ELISA integrated with LAMP allows equipment-free, colorimetric detection suited for low-resource settings, though specificity need to be improved to meet WHO target product profiles for new tuberculosis diagnostics.

TBS11-10 Immunogenicity and efficacy of replication-limited or irradiation-inactivated BCG delivered intravenously to rhesus macaques

P. Darrah,[1] C. Lehman,[1] M. Robertson,[1] A. Bucsan,[1] A. Smith,[2] C. Scanga,[2] P. Maiello,[2] P. Lin,[2] J. Flynn,[2] R. Seder,[1] [1]NIH Vaccine Research Center, Bethesda, MD, United States of America, [2]University of Pittsburgh, Pittsburgh, United States of America
e-mail: tdarrah@nih.gov

Novel vaccines that prevent pulmonary TB in adults are urgently needed. Intravenous (IV) BCG vaccination protects against TB in highly susceptible rhesus macaques. Protection in this model correlates with antigen-specific CD4 T cells and NK cells in the bronchoalveolar lavage (BAL), among other immune features. Depletion studies in IV BCG-immunized macaques substantiate the requirement for CD4 T cells and CD8a-expressing cells in protection.

Given BCG is a live bacterial vaccine, its persistence in vivo is likely related to its protective efficacy. Non-replicating BCG might be better suited for IV delivery but its efficacy in this model is unknown. To address this, we vaccinated macaques with a live, replication-limited pantothenate BCG auxotroph (AUX), a non-live, irradiation-inactivated BCG (IRD), wild-type BCG (WT), or no vaccine (Unvax). Immune responses in the BAL and PBMC were measured longitudinally. Six months after BCG, animals were challenged with Mtb and bacterial burdens were quantified at endpoint.

Compared to Unvax (~5.6 log CFU), WT BCG mediated >4-log reduction in CFU (2 of 4 animals protected) while AUX BCG conferred a 1.8-log reduction (3 of 7 protected). In contrast, IRD BCG animals had similar burdens to Unvax (1 of 7 protected, ~5.5 log CFU). Together, these data indicate a hierarchy of protection related to the viability and replicative capacity of BCG. To look for immune features correlating with protection, we compared protected vs unprotected animals across all vaccine groups. In BAL, protected animals had a pronounced influx of lymphocytes after BCG with a significantly higher frequency antigen-specific CD4 T cell producing Th1/Th17 cytokines. Of note, unprotected animals had higher proportions of IL-17 in BAL and PBMC--driven largely by the IRD macaques. Ongoing transcriptional analysis in blood and BAL will provide further insight into the immune features defining protection and how it is influenced by BCG attenuation.

TBS11-15 Immunogenicity of the novel TB vaccine H107e/CAF®10b in BCG exposed, Mtb-uninfected adults in South Africa

C. Lindestam Arlehamn,[1] E. Nemes,[2] A.-M. Winther,[1] A. Gela,[2] M. Mlotshwa,[3] V. Govender,[3] G. Churchyard,[3] R. Mortensen,[1] [1]Statens Serum Institut, Copenhagen, Denmark, [2]University of Cape Town, Cape Town, South Africa, [3]The Aurum Institute NPC, Johannesburg, South Africa
e-mail: cela@ssi.dk

An effective vaccination strategy is urgently needed to combat tuberculosis (TB). We evaluated the immunogenicity of a protein subunit vaccine, H107e, adjuvanted with the novel liposomal adjuvant CAF®10b, in BCG-exposed, Mtb-uninfected adults from South Africa.

The H107e subunit protein consists of eight Mtb-specific antigens, not shared with BCG to broaden the antigenic repertoire. CAF®10b is designed to increase the magnitude of Th1, confer robust Th17-induction, a novel target for vaccine optimization, and promote mucosal homing of T cells.

A phase Ia open-label trial (nTB-01) was conducted. Healthy IGRA negative adults aged 18-45 years were enrolled into one of four study arms to receive two intramuscular injections 28-days apart; Arm 1-H107e antigen (n=5), Arm 2-CAF®10b adjuvant (full dose; n=5), Arm 3-H107e+low-dose CAF®10b (n=15), or Arm 4-H107e+full-dose CAF®10b (n=15).

Immunogenicity was measured using whole blood intracellular cytokine staining, dual IFNγ/IL-17 ELISpot, and IgG ELISA. After the second dose of H107e with CAF®10b at either dose, participants had significantly increased frequencies of H107e-specific CD4 T cells expressing IFNγ/TNFα/IL-2/IL-17 (median% of CD4 T cells 0.76% (95% CI 0.63-1.02%)) at day 43 compared with pre-vaccination ($p<0.0001$).

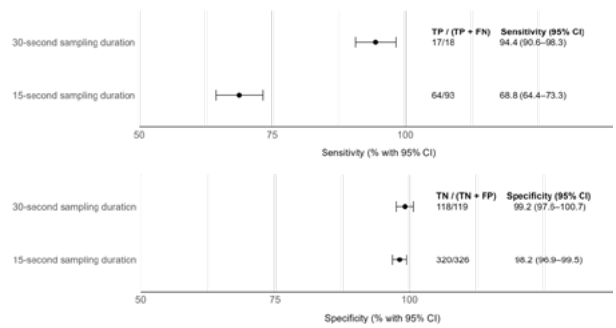
H107e-specific IL-17-producing T cells were significantly higher following vaccination at either dose compared to pre-vaccination (5.6-fold (95% CI, 2.0-12.4)), and H107e-

specific IgG responses were significantly higher in H107e/CAF®10b recipients (median units/mL, 95% CI; 41.1 (36.1-74.4) Arm 3, 104.8 (44.6-255.6) Arm 4) than H107e or CAF®10b alone (27.0 (6.2-78.2), and 3.5 (3.2-8.0)). Day 43 IGRA conversion, H107e contains ESAT-6, was observed in 70% adults receiving H107e/CAF®10b, and 53% of Arm 4 remained positive at day 85.
Thus, the H107e antigen and CAF®10b at two doses induces vaccine-specific Th1 and Th17 cytokine-expressing CD4 T cell responses, as well as antigen-specific IgGs in a cohort of BCG-exposed, Mtb-uninfected adults from South Africa.

TBS11-20 Diagnostic performance of tongue swabs for tuberculosis using two sampling durations with the Pluslife MTBC platform

S. Hartati,[1] R.C. Koesoemadinata,[1] L. Chaidir,[1,2] D.N. Pascapurnama,[1] B.A.P. Wilopo,[1,2] S.M. Graham,[3] P.C. Hill,[4] B. Alisjahbana,[1,5] [1]Research Center for Care and Control of Infectious Disease, Universitas Padjadjaran, Bandung, Indonesia, [2]Department of Biomedical Sciences, Faculty of Medicine, Universitas Padjadjaran, Bandung, Indonesia, [3]Centre for International Child Health, The University of Melbourne Department of Paediatrics, Melbourne, Australia, [4]Centre for International Health, Division of Health Sciences, University of Otago, Dunedin, New Zealand, [5]Hasan Sadikin Hospital, Department Internal Medicine, Faculty of Medicine, Universitas Padjadjaran, Bandung, Indonesia
e-mail: sri.harta88@gmail.com

Background: Tongue swabbing is an emerging, non-invasive method for detecting tuberculosis (TB), particularly useful in low-resource and high-burden settings. Swabbing technique, including sampling duration, may influence diagnostic performance, but optimal parameters are still under evaluation. This study aimed to evaluate the diagnostic accuracy of tongue swabs using two different sampling durations -15 seconds and 30 seconds- on the Pluslife MTBC platform.
Design/Methods: From August 2024 to April 2025, we consecutively enrolled presumptive TB patients aged >28 days from a lung hospital, lung clinic, and seven community health centers in Bandung, Indonesia. Tongue swabs were initially collected by swabbing the dorsum for 15 seconds before sputum collection and processed using the Pluslife MTBC instructions for use (IFU). Midway through, the swabbing duration was extended to 30 seconds. Diagnostic accuracy -sensitivity, specificity, and 95% confidence intervals- was assessed against liquid culture.
Results: Among 419 participants in the 15-second swabbing group (58.0% male, median age 42 years), Pluslife tongue swab testing showed a sensitivity of 68.8% (95% CI: 64.4–73.3) and specificity of 98.2% (95% CI: 96.9–99.5) compared to liquid culture. In the 30-second group (n=137; 51.8% male, median age 13 years), sensitivity improved to 94.4% (95% CI: 90.6–98.3) with specificity of 99.2% (95% CI: 97.6–100.7). Of the seven patients who were Pluslife positive but culture negative, five were Xpert positive, two had a chest X-ray suggestive of TB.



Conclusion: Pluslife tongue swab testing demonstrated variable sensitivity related to sampling duration. The 30-second protocol met WHO minimum sensitivity and specificity thresholds for non-sputum, point-of-care TB tests. 'False positive' Pluslife cases were likely to have TB. Further research with larger populations is needed to validate these findings and inform standardized protocols for tongue swab-based TB diagnosis.

TBS11-25 Novel aptamer-based immunoassay targeting gastric lavage antigens for pediatric pulmonary tuberculosis diagnosis

A. Kashwal,[1] I. Verma,[1] J. Mathew,[1] P.C Vaidya,[1] S. Sethi,[1] M.S. Singh,[2] T.S.K. Prasad,[3] [1]Postgraduate Institute of Medical Education and Research, Chandigarh, India, [2]All India Institute of Medical Sciences, Rishikesh, India, [3]Center for Systems Biology and Molecular Medicine, Yenepoya Research Centre, Yenepoya (Deemed to be University), Mangalore, India
e-mail: kashwalanjali777@gmail.com

Background: Diagnosis of pediatric pulmonary tuberculosis remains challenging due to its paucibacillary nature. Infants and young children often swallow the sputum, thus making gastric lavage (GL) a valuable alternative for biomarker discovery. We aimed to identify *in-vivo* expressed mycobacterial proteins in GL samples from pediatric pulmonary tuberculosis and develop a rapid aptamer-based antigen detection assay.
Methodology: In this study, 200 pediatric pulmonary tuberculosis suspects were enrolled. GL samples from culture-confirmed TB cases (n = 8) and non-TB controls (n = 8) were processed for mass spectrometry via data-independent acquisition to identify Mtb specific antigens. Selected mycobacterial protein was produced in recombi-

nant form for the aptamers generation by SELEX process. The final-round aptamer pool was cloned and sequenced, followed by sequence alignment and structural prediction using Clustal Omega and Mfold, respectively. Aptamer candidates with the lowest predicted ΔG values were docked in silico with the target protein to assess binding affinity and interaction sites.
The affinity and specificity of selected aptamers were evaluated using immunoblotting and Aptamer-Linked Immunosorbent Assay (ALISA).
Results: Total 681 mycobacterial proteins were identified, among which 98 were uniquely detected in GL samples of confirmed TB subjects. A mycobacterial protein exhibiting the highest detection frequency in TB samples was selected for aptamer generation. The ALISA was initially developed using GL samples from 10 pediatric subjects each from the confirmed TB, probable TB, and non-TB groups, using selected aptamers.
ROC analysis of the data led to optimal concentration-based cut-off providing maximum specificity which was subsequently applied to blinded samples from a validation cohort of 150 pediatric pulmonary TB suspects. Result interpretation against a composite reference standard (CRS) incorporating clinical, radiological, and microbiological findings indicated 89% sensitivity and 90% specificity.
Conclusion: This study demonstrates the potential of a rapid, aptamer-based immunoassay for pediatric pulmonary tuberculosis diagnosis, especially valuable in high-burden settings.

TBS11-30 Boosting immunity: Screening immunomodulators for enhanced antimicrobial therapy in tuberculosis

T. Lawrence,[1,2] T. Mpotje,[1,2] P. Majozi,[1,2]
K. Rajkumar-Bugheloo,[1,2] D. Moodley,[1] M.J. Marakalala,[1,3,4,5,2]
[1]Africa Health Research Institute, Durban, South Africa,
[2]University of KwaZulu-Natal, Durban, South Africa,
[3]University College London, London, United Kingdom of Great Britain and Northern Ireland, [4]SAMRC Centre for Tuberculosis Research, Cape Town, South Africa,
[5]Stellenbosch University, Cape Town, South Africa
e-mail: tamialawrence073@gmail.com

Tuberculosis (TB), caused by the pathogen *Mycobacterium tuberculosis* (*Mtb*), remains a global health threat due to drug resistance, poor treatment adherence, and high mortality rates. Host-directed therapies (HDTs) offer a novel approach to improve TB treatment outcomes by enhancing the host's immune defence, controlling inflammation, reducing post-TB complications and mortality. This study aimed to assess the potential of immunomodulatory compounds targeting Toll-like receptors (TLRs) 7/8, as adjunctive HDTs for TB.
For this study screening of the effects of immunomodulatory agents in THP-1 cells infected with the luminescent H37Rv *Mtb* LUX, was performed. The effects on the pro-inflammatory cytokines, TNF-α, IL-1β and IL-6 were quantified using ELISA.
Luminometry was used to analyse the effects of TLR modulation on bacterial clearance. A promising compound, TLR M, a TLR7/8 agonist, was identified as an activator of macrophage pro-inflammatory responses and underwent further evaluation using an in vitro 3D biomimetic TB granuloma model.
The effects on inflammation were measured using ELISA and antimycobacterial effects using luminometry. H&E-stained and immunofluorescent labelled slides were imaged using confocal microscopy to spatially analyse the association of TLR M's protein target, TLR7/8, with TB-induced inflammation and granuloma formation in resected TB-diseased lung tissue.
This study identified TLR7/8 as potential targets for adjunctive HDTs, revealing their potential to enhance the immune response response to *Mtb* infection and improve antimycobacterial properties. From TB diseased participants, we observed that alveolar macrophages contribute to TLR7/8 mediated signalling, potentially amplifying effector functions and aiding in *Mtb* clearance.
Taken together, TLR M represents a potential adjuvant HDT for TB treatment. The ability of this TLR7/8 agonist to modulate the inflammatory immune response and enhance antimycobacterial activity suggests that it can improve treatment outcomes and mitigate TB-related morbidity and mortality. Further research into TLR7/8-targeted therapies may therefore lead to enhanced strategies for combating TB.

TBS-EP05 Distinct immune profiles in tobacco and biomass smoke-induced COPD: A comparative study across two populations

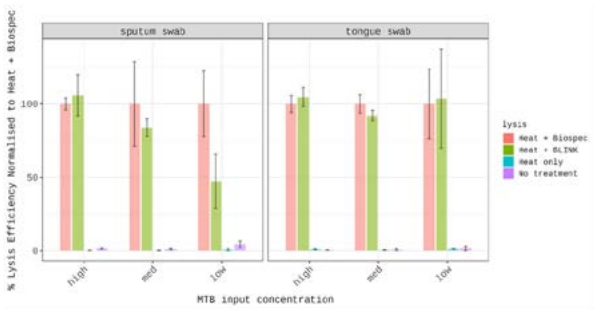
C. Rush,[1] T. Gilstrom,[2] U. Schmitz,[3] J. Warner,[1]
[1]College of Medicine and Dentistry and Australian Institute of Tropical Health and Medicine, James Cook University, Townsville, Australia, [2]James Cook University, Cairns, Australia, [3]College of Science and Engineering, James Cook University, Townsville, Australia
e-mail: catherine.rush@jcu.edu.au

Background: Chronic Obstructive Pulmonary Disease (COPD) is a major global health issue and the third leading cause of death worldwide. While tobacco smoke is the primary risk factor in high-income countries, biomass smoke (BS) from indoor cooking and heating is a key contributor in low- and middle-income countries (LMICs). Emerging evidence suggests that COPD driven by these exposures may constitute distinct disease phenotypes, but the immunological mechanisms underpinning this heterogeneity remain unclear.
Methods: This study compared two COPD-affected cohorts:
1. Well-characterised Australian patients hospitalised with tobacco smoke-induced COPD (TS-COPD), and;
2. A rural Papua New Guinea (PNG) population chronically exposed to biomass smoke.
Peripheral blood samples were analysed using flow cytometry and transcriptomics to identify immune cell phenotypes, cytokine profiles, and gene expression changes.
Results: In TS-COPD, CD4+ and CD8+ T-cells exhibited activated and exhausted phenotypes, with reduced expression of transcription factors linked to T-cell differentiation.
Mucosal-associated invariant T-cells (MAITs) showed high expression of exhaustion markers (CTLA4, PD1, TIM3). In the PNG BS-exposed cohort, symptomatic individuals demonstrated elevated Th17-related plasma cytokines and impaired T-cell function on stimulation.
Transcriptomic profiling revealed reduced expression of IL7R, CD96, and ITK in symptomatic BS-COPD individuals, in contrast to increased expression of these markers in TS-COPD. Gene enrichment analyses showed enhanced innate immune activity and reduced adaptive T-cell signals in BS-COPD.
Conclusion: Distinct immunological pathways underpin COPD in tobacco- versus biomass-smoke-exposed individuals. TS-COPD is characterised by T-cell exhaustion, while BS-COPD shows dysregulated Th17 inflammation and suppressed T-cell responsiveness.
These findings highlight the need for phenotype-specific approaches to COPD treatment, particularly in LMICs where biomass exposure is prevalent.

TBS-EP08 LyseTB - Comparative analysis of lysis devices for molecular testing of tuberculosis

S. Jain,[1] A. Ball,[2] C. Anderson,[2] A. Cattamanchi,[3,4] C. Denkinger,[1] S. Yerlikaya,[1] A. Steadman,[2] [1]Department of Infectious Diseases and Tropical Medicine, Heidelberg University Hospital, Heidelberg, Germany, [2]Global Health Labs, Research and Product Development, Bellevue, United States of America, [3]Center for Tuberculosis, University of California San Francisco, San Francisco, United States of America, [4]Division of Pulmonary Diseases and Critical Care Medicine, University of California Irvine, Irvine, United States of America
e-mail: sonal.jain@uni-heidelberg.de

Background: Robust sample preparation, particularly lysis, of *Mycobacterium tuberculosis* (MTB) remains essential to maximizing sensitivity of swab-based molecular tests. Diagnostic companies are developing proprietary lysis devices, each employing distinct lysis mechanisms. However, there are limited comparative data on their performance for TB diagnosis.
This study aims to evaluate the performance of several devices, selected through systematic technology scouting, in processing tongue swabs and sputum-dipped swabs.
Methods: For each lysis device, we evaluate lysis efficiency across three clinically-relevant mycobacterial loads, nuclease inactivation, and biosafety. We benchmark performance against a reference method of 10-minute heat inactivation at 95°C followed by bead beating using the Biospec Mini-Beadbeater-16. Experiments are conducted on contrived tongue swabs and sputum swabs (*i.e.,* swabs swirled in sputum) spiked with known quantities of MTB H37Ra cells. We use qPCR to measure DNA recovery from the lysates.



Results: We have generated preliminary results for the BLINK X Shaker (BLINK AG, Germany), a portable, compact bead beater with capacity to process up to three samples. It showed lysis efficiency comparable to the ref-

erence method across high, medium, and low MTB loads in tongue swab samples (Fig1, right). However, in sputum swabs, performance dropped at low input levels (Fig1, left).

Conclusion: These findings highlight the BLINK X Shaker as a promising device for MTB lysis from tongue swabs, with further optimization needed for more complex matrices like sputum, particularly at lower bacterial loads. Evaluation of four additional devices is ongoing, with final results to be presented at the conference. Findings from this study will provide insights into optimizing sample preparation protocols, ultimately enhancing the accuracy and reliability of TB diagnostics.

TBS-EP11 Growth phase-specific DNA methylation bias manifesting as intercellular mosaic methylation in *Mycobacterium tuberculosis* clinical isolates

S. Modlin,[1] F. Valafar,[1] [1]San Diego State University, San Diego, United States of America
e-mail: faramarz@sdsu.edu

DNA methylation plays diverse regulatory roles in bacterial pathogens, yet its dynamics remain poorly understood in *Mycobacterium tuberculosis* (*Mtb*). Here, we report intercellular mosaic methylation (IMM) by the orphan Type I methyltransferase MamC in a subset of fast-growing clinical isolates despite having wild-type mamC. Through PacBio long-read sequencing, we identified four *Mtb* complex isolates with anomalous hypomethylation at MamC-targeted sequence motifs. These "MamC-anomalous" isolates exhibited unique methylation heterogeneity, distinct from phase variation, indicating IMM, a phenomenon rarely documented for Type I methyltransferases.

We found that hypomethylation patterns in these isolates were linked to chromosomal replication dynamics. MamC methylation efficiency decreased progressively with distance from the origin of replication, with this positional bias markedly intensified in MamC-anomalous strains. By contrast, other *Mtb* methyltransferases (MamA, MamB) showed strand-specific but less pronounced positional methylation effects.

Using a refined peak-to-trough ratio (PTR) metric adapted for long-read sequencing, we show that MamC-anomalous isolates exhibit elevated and highly stable replication-linked coverage bias, consistent with unusually rapid and synchronized growth. These growth dynamics were not reflected in methylation patterns of MamA or MamB, suggesting a unique sensitivity of MamC activity to bacterial growth phase.

Together, our results uncover a growth phase-associated modulation of methylation efficiency, manifesting as intercellular mosaic methylation, a previously unknown relationship in *Mtb* epigenetics. This advances our understanding of *Mtb* DNA methylation systems and suggests functional links between replication state and epigenetic heterogeneity in clinical *Mtb* isolates with potential implications for adaptive diversification during rapid growth.

TBS-EP14 Potential pediatric tuberculosis incidence and deaths resulting from interruption in programmes supported by international health aid, 2025-2034: A mathematical modelling study

N. Menzies,[1] T. Brown,[2] J. Imai-Eaton,[1,3] P. Dodd,[4] T. Cohen,[5] L. Martinez,[6] [1]Harvard TH Chan School of Public Health, Boston, United States of America, [2]Boston University Chobanian & Avedisian School of Medicine, Boston, United States of America, [3]MRC Centre for Global Infectious Disease Analysis, Imperial College London, London, United Kingdom of Great Britain and Northern Ireland, [4]School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom of Great Britain and Northern Ireland, [5]Yale School of Public Health, New Haven, United States of America, [6]Boston University School of Public Health, Boston, United States of America
e-mail: nmenzies@hsph.harvard.edu

Background: Children experience elevated risks of developing and dying from tuberculosis (TB). We estimated the additional pediatric TB deaths that could occur over 2025-2034 if programmes supported by United States bilateral health aid and the Global Fund to Fight AIDS, Tuberculosis, and Malaria (Global Fund) are discontinued.

Methods: We collated data on funding sources for TB and HIV programs in low- and middle-income countries and constructed scenarios representing reductions in health aid from 2025. Using calibrated transmission-dynamic models for 130 countries, we projected the discontinuation of TB and HIV treatment services under several funding reduction scenarios, and how this would affect pediatric TB exposure and treatment access. We projected pediatric TB incidence and mortality over 2025-2034 to calculate the impact of funding reductions.

Findings: Compared to maintenance of pre-2025 service levels, withdrawal of services currently supported by US bilateral health aid was projected to result in an additional 2.5 million (95% uncertainty interval: 1.8–3.3) pediatric TB cases and 340,000 (240,000–460,000) deaths over 2025-2034. Withdrawal of US support to the Global Fund and reduction in non-US contributions was projected to result in an additional million 8.9 (6.9–11.5) pediatric TB cases and 1.5 million (1.1–2.0) deaths, more than double the number expected with continued service levels. Impacts were greatest in Sub-Saharan Africa and South-East Asia (Figure). Restoration of services in 2026 led to a substantially smaller number of additional deaths.

Interpretation: Without actions to restore discontinued services, cuts to health aid for TB and HIV programs could result in large numbers of childhood TB deaths over the next decade.

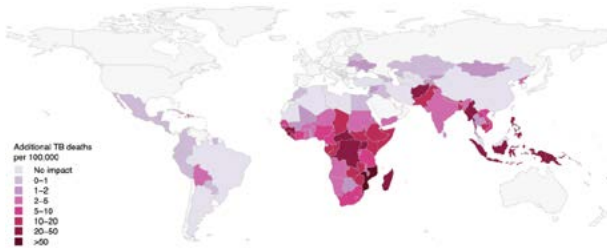


Figure: Additional childhood TB deaths over 2025-2034 with funding reductions, as compared to continued funding.
Scenario represents 100% of U.S. bilateral funding cut in 2025, plus 100% of U.S. and 50% of non-U.S. Global Fund contributions cut in 2026.

TBS-EP17 Spontaneous control of early Mycobacterium tuberculosis infection in children exposed to M. tuberculosis without standard treatment

M. Ahmed*,[1,2] A. Razid*,[1,2] H. Zar,[3] N. Ntinginya,[4] C. Khosa,[5] M. Nliwasa,[6] V. Verghese,[7] C. Geldmacher*,[1,2,8] L. Olbrich*,[1,2,8] RaPaed-AIDA-TB consortium [1]Institute of Infectious Diseases and Tropical Medicine, LMU University Hospital, LMU Munich, Munich, Germany, [2]German Center for Infection Research (DZIF), partner site Munich, Munich, Germany, [3]Department of Paediatrics and Child Health, and South African Medical Research Council Unit on Child and Adolescent Health, University of Cape Town, Cape Town, South Africa, [4]National Institute for Medical Research, Mbeya Medical Research Centre, Mbeya, United Republic of Tanzania, [5]Instituto Nacional de Saúde (INS), Centro de Investigação e Treino em Saúde da Polana Caniço (CISPOC), Maputo, Mozambique, [6]Helse Nord Tuberculosis Initiative, Kamuzu University of Health Sciences, Blantyre, Malawi, [7]Pediatric Infectious Diseases, Department of Pediatrics, Christian Medical College (CMC), Vellore, India, [8]Fraunhofer Institute ITMP, Immunology, Infection and Pandemic Research, Munich, Germany
e-mail: alia.razid@med.uni-muenchen.de

Mycobacterium tuberculosis (Mtb) infection in exposed children can progress to tuberculosis (TB) disease or be self-contained without treatment. Distinguishing exposed children who will control incipient *Mtb* infection from those who develop TB disease could reduce over-treatment but remains challenging. The T-cell activation marker (TAM)-TB flow cytometry assay has shown potential for diagnosing TB disease.
Here, we explore its use in children considered unlikely to have TB disease.

RaPaed-TB is a prospective TB diagnostic accuracy study in five low-middle income countries. The TAM-TB is based on *Mtb*-specific IFNγ$^+$CD4$^+$ T-cells expressing CD38 after ESAT6/CFP10 stimulation in children with suspected TB <15 years using predefined CD38 cut-offs.
Whole blood samples were collected at baseline and for up to six months post-treatment initiation. TAM-TB results were classified as positive (TAM$^+$), latent (TAM^{lat}), or negative (TAM$^-$). Participants were classified as confirmed TB (TB$^+$), unconfirmed TB(TB$^?$), or unlikely TB (TB$^-$) following adapted NIH guidelines.
Of 203 children classified as TB$^-$, 30 (15%) were TAM$^+$ at baseline, suggestive of active TB infection. 90% (27/30) had a positive Tuberculin Skin Test (TST) and 93% (28/30) reported recent TB contact, mostly household members.
Within these 30 TB$^-$TAM$^+$children, a significant decline in median IFNγ$^+$ CD38-expression was observed (59.4% vs 37.5%, p<0.002) at month 1, where 30% (9/30) had converted to TAM^{lat} and 3.3% (1/30) to TAM$^-$, which was comparable to TB$^+$ on treatment reflecting an induced decline of MTB-specific T-cell activation.
Compared to children considered TB$^-$TAM$^-$, this TB$^-$TAM$^+$ group was significantly more likely to have a positive TST (p<0.001) and recent TB contact (p<0.001). 33.3% (10/30) were initiated on TB preventive treatment (p<0.003), while 66.7% (20/30) had not received any treatment for TB disease.
These findings suggest spontaneous control of active *Mtb* infection in children considered TB$^-$, but with immunological evidence of *Mtb* exposure and TB disease at baseline.

TBS-EP20 The Treatment Recommender: An AI-powered decision aid for a stratified precision medicine approach to rifampicin resistant tuberculosis treatment

A. Van Rie,[1] L. Verboven,[1] G. Maartens,[2] V. Rennie,[1] F. Conradie,[3] A. Reuter,[4] K.E Dooley,[5] [1]University of Antwerp, Antwerp, Belgium, [2]University of Cape Town, Cape Town, South Africa, [3]University of Witwatersrand, Johannesburg, South Africa, [4]University of Stellenbosch, Cape Town, South Africa, [5]Vanderbilt University Medical Center, Nashville, United States of America
e-mail: annelies.vanrie@uantwerpen.be

Introduction: The BPaLM regimen revolutionized rifampicin-resistant tuberculosis (RR-TB) treatment. Linezolid toxicity and bedaquiline resistance increasingly requires doctors to design individualized rescue regimens. The endTB-Q trial demonstrated that fluoroquinolone-resistant TB (FQ^R-TB) treatment should be stratified by disease severity and that extensive FQ^R-TB disease may require individualized treatment regimens.

Methods: We developed a Treatment Recommender for stratified precision medicine using targeted next generation sequencing (tNGS) or whole genome sequencing (WGS) data. International expert opinion was gathered to define optimal treatment strategies. Within each strategy, the recommender model selects the optimal regimen composition based on individual drug features and regimen features. The recommender model was developed using AI-methods to analyze 1,972 feedback datapoints from 21 global RR-TB experts during 5 training rounds. Success was defined as the majority of experts accepting the recommended regimen.
Results: The Treatment Recommender version 2 was built to be conform to recent guidelines, emerging data, and adheres to 7 principles: [1] administer BPaLM whenever tNGS or WGS classifies all 4 drugs as susceptible, independent of prior exposure, [2] include B, Pa/DLM and L whenever these drugs are possibly effective, [3] limit the use of the BDLC (bedaquiline/delamanid/linezolid/clofazimine) regimen to FQ^R-TB with limited disease, [4] strengthen the BDLC regimen in case of extensive FQ^R-TB disease, [5] strengthen regimens in case of possible resistance to B, Pa , D or L, [6] compose individualized regimens with six drugs, and [7] prioritize oral drugs when a sufficiently strong all-oral regimen can be designed. After 5 training rounds, the Treatment Recommender model achieved an overall 83% success rate, 100% for 5-drug strengthening regimens and 76% for 6-drug individualized regimens.
Conclusion: AI-based clinical decision aids can facilitate the implementation of NGS-guided precision medicine in high burden settings and guide doctors to implement stratified and personalized treatment for patients suffering from complex RR-TB disease.

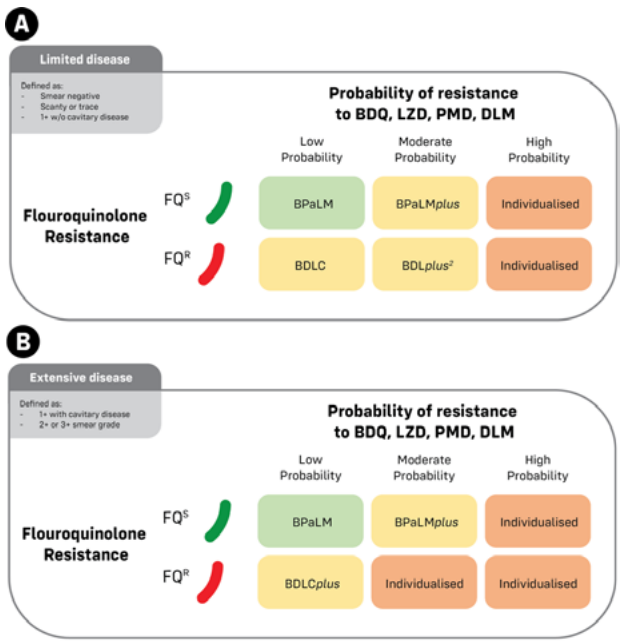

Figure 1: Daigram illustrating the regimen strategies employed by the Treatment Recommender, stratified by whether the patient is suffering from (A) limited disease or (B) extensive disease

TBS-EP23 Interred mechanisms of resistance and host immune evasion revealed through network-connectivity analysis of *M. tuberculosis* complex graph pangenome

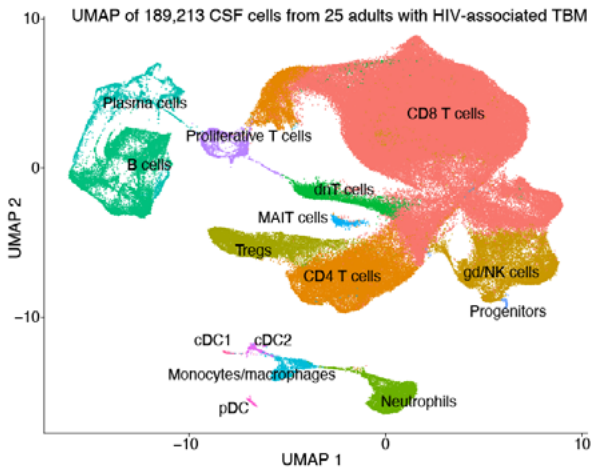
M. Espinoza,[1] A. Swing,[2] F. Valafar,[2] [1]Dartmouth College, Hannover, United States of America, [2]San Diego State University, San Diego, United States of America
e-mail: mespinoza5@sdsu.edu

Mycobacterium tuberculosis complex successfully survives environmental pressures through mechanisms of rapid adaptation which remain poorly understood despite knowledge gained through decades of research.
In this study, we used 110 reference-quality, complete *de novo* assembled, long-read sequenced clinical genomes to study patterns of structural adaptation through a graph-based pangenome analysis, elucidating rarely studied mechanisms that enable enhanced clinical phenotypes offering a novel perspective to the species‘ adaptation.
Across isolates, we identified a pangenome of 4,325 genes (3,767 core and 558 accessory), revealing 290 novel genes, and a substantially more complete account of difficult-to-sequence *esx/pe/pgrs/ppe* genes.
Seventy-four percent of core genes were deemed non-essential *in vitro*, 38% of which support the pathogen‘s survival *in vivo*, suggesting a need to broaden current perspectives on essentiality. Through information-theoretic analysis, we reveal the *ppe* genes that contribute most to the species‘ diversity-several with known consequences for antigenic variation and immune evasion.
Construction of a graph pangenome revealed topological variations that implicate genes known to modulate host immunity (*Rv0071-73, Rv2817c, cas2*), defense against phages/viruses (*cas2, csm6,* and *Rv2817c-2821c*), and others associated with host tissue colonization.
Here, the prominent trehalose transport pathway stands out for its involvement in caseous granuloma catabolism and the development of post-primary disease.
We show paralogous duplications of genes implicated in bedaquiline (*mmpL5* in all L1 isolates) and ethambutol (*embC-A*) resistance, with a paralogous duplication of its regulator (*embR*) in 96 isolates. We provide hypotheses for novel mechanisms of immune evasion and antibiotic resistance through gene dosing that can escape detection by molecular diagnostics.

TBS-EP26 Single-cell RNA sequencing of cerebrospinal fluid in HIV-associated tuberculous meningitis

J.R Barnacle,[1,2,3] N. Bangani,[3] H. Slawinski,[2] K.A Wilkinson,[2] C.J Stek,[3] D. Barber,[4] A. O'Garra,[2,5] R.J Wilkinson,[2,1,3]
[1]Imperial College London, London, United Kingdom of Great Britain and Northern Ireland, [2]Francis Crick Institute, London, United Kingdom of Great Britain and Northern Ireland, [3]University of Cape Town, Cape Town, South Africa, [4]National Institute of Allergy and Infectious Diseases, Bethesda, United States of America, [5]National Heart and Lung Institute, Imperial College London, London, United Kingdom of Great Britain and Northern Ireland
e-mail: barnacj@crick.ac.uk

Tuberculous meningitis (TBM) causes death in a quarter of cases, and a third of survivors suffer persistent neurological disability. In people living with HIV, mortality exceeds 50%. Death and disability are contributed to by immune dysregulation, and adjunctive host-directed therapies aim to modulate this response to improve outcome. Developing such therapies relies on improved understanding of the immune response during TBM.
To investigate this response, we performed single cell RNA sequencing on 25 cerebrospinal fluid (CSF) samples from adult TBM patients living with HIV in Cape Town enrolled into a clinical trial. Lumbar CSF was taken seven days following enrolment. The median age, CD4 count and viral load at enrolment were 37 years, 115 cells/mm³, and 59,389 copies/ml respectively. 10/25 (40%) had a reduced Glasgow coma score or focal neurology at enrolment. 14/25 (56%) were microbiologically confirmed with a positive *M. tuberculosis* culture or GeneXpert Ultra result.



189,213 cells were analysed following quality control and doublet removal. Results reveal a CD8 T cell predominance with abundant granzyme and perforin expression and great heterogeneity in cell type proportions between patients. We identified a significant population of neutrophils, which associate with mortality in TBM, and are rarely captured by single cell RNA sequencing. We will report correlations between cell type proportions, cellular phenotypes, microbiological confirmation and clinical severity, and relate these findings in a larger cohort investigated by untargeted and targeted CSF proteomics.
This is the first single cell RNA sequencing study to examine the immune response to TBM in people living with HIV, and the largest to investigate an infectious aetiology of any type in the CSF. These data help us to understand the immune state of the CSF during *M. tuberculosis* infection at a resolution never before seen and generate novel hypotheses for future host-directed therapies.

TBS-EP29 *In vitro* characterization of GSK2556286 activity in combination with bedaquiline and pretomanid against *M. tuberculosis*

J. Galizia,[1] M.S. Rabodoarivelo,[1] D. Recchia,[2] M. Dal Molin,[3,4] E. Hoffman,[5] O. Sanz,[6] M.R. Pasca,[2] S. Ramón García,[1,7,8]
[1]Department of Microbiology, Pediatrics, Radiology and Public Health, Faculty of Medicine, University of Zaragoza, Zaragoza, Spain, [2]Department of Biology and Biotechnology Lazzaro Spallanzani, University of Pavia, Pavia, Italy, [3]Department of Internal Medicine, Division of Infectious Diseases, University of Cologne, Cologne, Germany, [4]Faculty of Medicine, Center for Molecular Medicine Cologne (CMMC), University of Cologne, Cologne, Germany, [5]Center for Infection and Immunity of Lille, Institut Pasteur de Lille, Lille, France, [6]Diseases of the Developing World, GlaxoSmithKline, Tres Cantos, Spain, [7]IBER Enfermedades Respiratorias (CIBERES), Instituto de Salud Carlos III, Madrid, Spain, [8]Research & Development Agency of Aragon Foundation (Fundación ARAID), Zaragozaspain, Spain
e-mail: jgalizia@unizar.es

The search for improved chemotherapy with drugs having different mechanisms of action remains crucial for the complete eradication of *Mycobacterium tuberculosis* (Mtb). GSK2556286 (GSK286), a novel drug candidate, combined with bedaquiline (B) and pretomanid (Pa) has shown promise in improving tuberculosis treatment.
In this work, the main aim was to explore, in an *in vitro* manner, the interaction between GSK286 and the core BPa backbone and the individual contribution of each compound or pairwise combination to the general combination.
Dose-response time kill assays (TKA) with different concentrations of GSK286 used alone or in combination with BPa at matching EC10 and EC50 against Mtb H37Rv were carried out. Overall, the combination of GSK286 + BPa exhibited maximal killing effect when BPa was applied at its EC50. However, the interaction was primarily influenced by the BPa backbone. Reducing concentrations of B and Pa revealed that the pairwise GSK286 + B com-

bination exerted a more favorable interaction compared to both GSK286 + BPa and BPa combination. Moreover, these results were confirmed with a THP-1 intracellular kinetic assay, verifying the intracellular activity against Mtb for the combination GSK286 + B + Pa, as well as the favourable interaction of the pairwise GSK286 + B.
These findings provide valuable insights into the synergies and limitations of these drug combinations, paving the way for further investigations and development of an optimal approach to treat tuberculosis.
This work has received support from the Innovative Medicines Initiatives 2 Joint Undertaking (grant No 853989). This work reflects only the author's views, and the JU is not responsible for any use that may be made of the information it contains.

TBS-EP32 Machine learning model for community-based tuberculosis screening: A proof-of-principle study

H. Loharja,[1,2] K.F. Muchie,[1] K. Karimi,[1] A. Zimmer,[1] M.R. Opata,[2] J. Rocklöv,[2] C. Denkinger,[1] [1]University Hospital Heidelberg, Department of Infectious Diseases and Tropical Medicine, Heidelberg, Germany, [2]Interdisciplinary Center for Scientific Computing (IWR), Heidelberg, Germany
e-mail: alexandra.zimmer@uni-heidelberg.de

Case detection for Tuberculosis (TB) remains a challenge, with millions of new cases remaining undetected each year, a phenomenon known as the diagnostic gap. The WHO-4-symptoms screening (W4SS) is widely utilized for screening, but excludes contextual information (e.g. comorbidities) and proves not sufficiently accurate.
We aimed to address the current limitations of TB screening algorithms by leveraging machine learning (ML) to develop a TB risk prediction model for community based TB screening.
For model development, three datasets were harmonized: two prevalence surveys (PS) and one community-randomized study, all conducted in South Africa and Zambia (N= 118808). The merged harmonized dataset was split for model training (80%) and internal validation (20%). A fourth PS dataset from South Africa was set aside for external validation (N= 27350).
A composite reference, based on microbiological results and prolonged cough, was used to define the "Possible TB" category. Missing data were handled using multiple imputation separately for the internal and external datasets. Relevant input variables were selected based on domain knowledge.
The model was developed using Extreme Gradient Boosting (XGBoost), and to address class imbalance, inverse class weighting was applied. Model performance was evaluated on the internal and external validation datasets using precision, recall, F1-score, balanced accuracy, and AUC. For comparison, W4SS was assessed in parallel on the same datasets. The ML model outperformed W4SS to predict 'Possible TB' cases with higher sensitivity in both internal (73% vs. 52%) and external validation (69% vs. 17%), and demonstrated more robustness across the datasets.

	Internal Validation				External Validation			
	Precision	Recall (Sensitivity)	F1-score	Balanced Accuracy	Precision	Recall (Sensitivity)	F1-score	Balanced Accuracy
Unlikely	0.95	0.83	0.88		0.92	0.74	0.82	
Possible TB	0.40	0.73	0.52	0.78	0.35	0.69	0.47	0.72
Average	0.68	0.78	0.70		0.64	0.72	0.65	

Table 1. Key performance metrics of the XGBoost model in the internal and external validations.

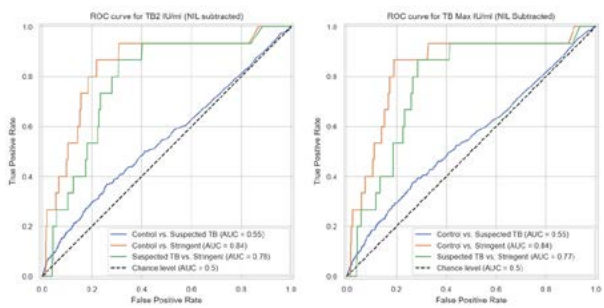
Further exploration of state-of-the-art machine learning approaches, and incorporating additional, diverse datasets are planned, with the ultimate goal of meeting the WHO target product profile for TB screening and integrating the model into an accessible screening app.

TBS-EP35 Quantitative IFNγ Responses from QuantiFERON-TB Gold Plus Predict Progression to Active Tuberculosis in Global High-Burden Settings

J. Sunshine,[1] M. Shaffer,[1] A. Dagnew,[1] A. Schmidt,[1] N. Frahm,[1] [1]Gates Medical Research Institute, Cambridge, United States of America
e-mail: justine.sunshine@gatesmri.org

Introduction: A predictive biomarker for tuberculosis (TB) progression would transform targeted prevention efforts and clinical trial design. Although interferon-gamma release assays (IGRAs), including QuantiFERON® TB-Gold Plus (QFT-Plus), have been studied for this purpose, systematic evaluation of quantitative IFNγ responses to the QFT-Plus TB1 and TB2 antigens remains limited, particularly in high burden settings.
Methods: An exploratory analysis was conducted within a large, prospective study of 5,259 participants from TB-endemic regions. QFT-Plus TB1 and TB2 IFNγ concentrations were assessed at baseline and analyzed in relation to subsequent TB outcomes over ≥12 months follow-up. Participants were classified as controls (no TB), suspected TB (no microbiological confirmation), or laboratory-confirmed TB, including a subset meeting a stringent case definition (≥2 positive microbiologic tests). Associations between baseline IFNγ concentrations and TB progression were assessed using non-parametric statistics and Receiver Operating Characteristic (ROC) analysis.
Results: Independent of IGRA status, baseline TB2 and maximum IFNγ concentrations (highest of TB1 or TB2) were significantly higher among participants who later

were suspected of TB, had laboratory-confirmed TB, or met the stringent TB case definition. Associations with baseline TB1 IFNγ concentrations and disease progression were observed only when considering QFT-Plus as a continuous variable (including IGRA+/-) and in participants meeting the stringent case definition. Under this stringent definition, TB2 and maximum values achieved an Area Under the Curve of 0.84, with sensitivity of 80% and specificity of 78–81% (Fig 1). However, positive predictive values (PPV) for TB progression within two years were low across measures (1.0–1.3%).



Conclusion: In high-burden settings, QFT-Plus TB2 and maximum TB1/TB2 IFNγ concentrations were associated with progression to TB disease. Although limited by a relatively short follow-up and few TB cases potentially impacting the observed PPV, these markers show promise as risk stratification tools or components of composite biomarkers in future research applications.

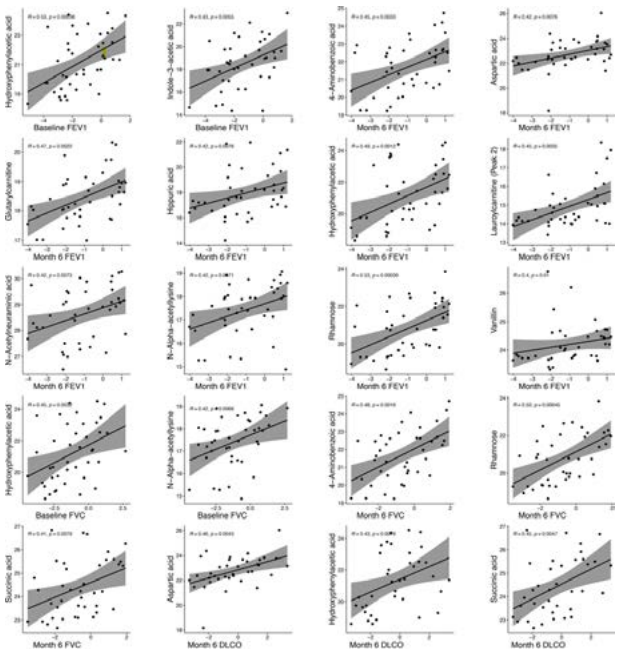
TBS-EP38 Sputum metabolites correlated with lung function during and after TB treatment

J. Lyles,[1] A. Queiroz,[2] G. Collins,[1] M. Aldeco,[1] R. Tirouvanziam,[1] P. Maenetje,[3] D. Masilela,[3] R.R. Malemela,[3] J. Chandler,[1] G. Bisson,[4] S. Auld,[1] [1]Emory University, Atlanta, United States of America, [2]FIOTEC, Salvador, Brazil, [3]The Aurum Institute, Johannesburg, South Africa, [4]University of Pennsylvania, Philadelphia, United States of America
e-mail: joshua.chandler@emory.edu

Introduction: Although post-TB lung disease (PTLD) is a major contributor to TB-associated morbidity, biological pathways that drive lung damage remain poorly characterized. We leveraged metabolomics of sputum to characterize pathways associated with lung health and disease during and after TB treatment.

Methods: We collected induced sputum from adults with and without HIV who were newly diagnosed with drug-susceptible pulmonary TB in Johannesburg, South Africa and enrolled in a longitudinal cohort study within 2 weeks of TB treatment initiation. Metabolomics was performed on sputum supernatants using hydrophilic interaction liquid chromatography coupled to an Orbitrap mass spectrometer. Pulmonary function testing was performed at baseline and 6 months (end of TB treatment). Spearman's correlation was calculated between metabolites and pulmonary variables (p-value < 0.05, FDR < 0.05).

Results: Among 40 participants, 7 (18%) were female, the median age was 37 (IQR 32-49), and 12 (30%) had HIV coinfection. At baseline, 22 (55%) had a reduced forced expiratory volume in 1 second (FEV1) and 16 (40%) had a reduced forced vital capacity (FVC) (z-score ≤ 1.65). Among 177 known metabolites, 16 were significantly positively correlated with lung function parameters (FEV1, FVC, or DLCO) at baseline or 6 months, including benzenoids (p-hydroxyphenylacetate [PHPA], p-aminobenzoate, hippuric acid, and vanillin), carnitines (lauroyl- and glutaryl-), amino acids (aspartic acid and N-alpha-acetyllysine), bile acids (GCDA and GCA), and lysolipids (LPC 16:0 and LPC 18:0), as well as rhamnose, N-acetylneuraminic acid, and succinate (Figure).



Conclusion: Among individuals with pulmonary TB, sputum metabolites reflecting a variety of pathways were correlated with lung function, both at diagnosis and after TB treatment completion. Robust associations of PHPA and lung function suggest a role for altered tyrosine metabolism in lung health. Future work will extend these analyses to a larger cohort, validating potential biomarkers of PTLD, with additional mechanistic analysis of key metabolic pathways.

TBS-EP41 Longitudinal immune cell profiling reveals distinct immunophenotypes associated with treatment response in pulmonary tuberculosis

J. Eggeling,[1,2,3,4,5] M. Reimann,[1,2,3] J. Heyckendorf,[2,6] B. Kalsdorf,[1,2,3] D. Lewinsohn,[7] D. Schaub,[1,2,3] T. Schmidt,[8] E. Tolosa,[9] M. Sester,[8] C. Lange,[1,2,3] P. Sánchez Carballo,[1,2,3] DZIF-TB cohort study group [1]Research Center Borstel, Clinical Infectious Diseases, Borstel, Germany, [2]German Center for Infection Research, Tuberculosis Unit, Partner Site Hamburg-Lübeck-Borstel-Riems, Germany, [3]Lübeck University, Respiratory Medicine & International Health, Lübeck, Germany, [4]Schleswig-Holstein University Hospital, Pediatric Oncology and Rheumatology, Kiel, Germany, [5]Schleswig-Holstein University Hospital, Neonatology, Pediatric Pneumology and Neuropediatrics, Kiel, Germany, [6]Schleswig-Holstein University Hospital, Internal Medicine I, Kiel, Germany, [7]Oregon Health and Science University, Pulmonary, Allergy and Critical Care Medicine, Portland, United States of America, [8]Saarland University, Transplant and Infection Immunology, Homburg, Germany, [9]University Medical Center Hamburg-Eppendorf, Institute of Immunology, Hamburg, Germany
e-mail: jeggeling@fz-borstel.de

Inflammation is a hallmark of tuberculosis (TB), a leading cause of morbidity and mortality worldwide. While hyperinflammation can cause tissue damage, hypoinflammation may prevent effective pathogen clearance. Stratifying TB patients by immunophenotypes using flow-cytometry may guide future host-directed immunetherapies.

We conducted a two-step prospective observational cohort study among healthy controls and pulmonary TB patients in Germany to explore immune cell populations and their changes during treatment and their association with clinical data, cytokine assays and gene enrichment analysis.

At baseline (T0), individuals were grouped into three immune clusters. Cluster A, mainly healthy controls, showed a functional immune profile with less differentiated T cells and antigen-presenting cells (APCs) lacking exhaustion markers. Clusters B and C, primarily TB patients, displayed terminally differentiated T cells, PD-L1 on APC, and activated MAIT cells – which are indicative of an inflammatory and exhausted immune state.

After two weeks of therapy (T1), many patients transitioned towards cluster A, and by the end of therapy (Te), only two clusters remained, suggesting partial recovery of immune function.

Despite these shifts, markers such as CD27, CD28, and PD-L1 remained key in distinguishing clusters. Consistently, cluster C patients presented elevated levels of inflammatory cytokines (e.g., IFN, IP10, TNF, IL-6), IL-1RA, and soluble PD-L1, reflecting severe immune dysfunction. Gene expression analysis revealed increased T-cell differentiation and activation in dysfunctional clusters, alongside downregulated inflammation- and interferon-related genes. The end-of-treatment clusters showed differences in B-cell and platelet-related genes. Patients in clusters B and C had higher mycobacterial loads (shorter TTP) and slower clinical recovery (longer TTCC), especially those in cluster C.

TB patients showed variable changes in immune profiles during therapy. Severe immune dysfunction characterized by T-cell exhaustion and MAIT activation was linked to increased mycobacterial burden and delayed recovery, pointing towards biomarkers for guiding host-directed TB therapy.

TBS-EP44 Whole genome sequencing-guided patient management – A pragmatic clinical trial of a precision medicine strategy to shorten treatment for rifampicin-resistant tuberculosis

A. Van Rie,[1] E. Costa Conceicao,[2] F. Ndebele,[3] S. Charalambous,[3] B. Fanampe,[4] S. Abrams,[1] G. Churchyard,[3] R. Warren,[2] SMARTT Trial Group [1]Global Health Institute, Faculty of Medicine, University of Antwerp, Antwerp, Belgium, [2]Department of Molecular Biology and Human Genetics, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa, [3]Aurum institute, Johannesburg, South Africa, [4]Free State Department of Health, Bloemfontein, South Africa
e-mail: annelies.vanrie@uantwerpen.be

Background: All patients with rifampicin-resistant tuberculosis (RR-TB) should have access to a short, safe and effective regimen. We evaluated a novel RR individualization strategy guided by whole genome sequencing (WGS) complemented with an AI-based treatment recommendation decision aid.

Methods: We conducted a randomized, pragmatic medical device trial in South Africa. Adult participants with pulmonary RR-TB, including those with fluoroquinolone resistance, were randomized to the South African 9- or 18-month regimen or a 6-month individualized WGS-guided regimen. Feasibility, acceptability, accuracy, treatment shortening, bacteriological effectiveness (change in half-life mycobacterial load and stable culture conversion at 8, 12 and 24 weeks), clinical effectiveness [risk difference (RD) for unfavourable treatment outcome with a 10% non-inferiority margin] and safety (severe adverse events) were evaluated.

Results: Of the 203 participants randomized, 162 were included in the mITT analysis (78 SOC and 84 WGS group) which consisted of culture positive participants. WGS results were accurate (99% specificity compared to phenotypic DST) and available for all participants in the WGS group. Overall, 81% of participants initiated the WGS-guided treatment after a median of 48 days (IQR 40,

62) following RR-TB treatment initiation. The WGS strategy resulted in treatment shortening of a median of 2.6 months. All surrogate markers of bacteriological response were in favor of the WGS strategy, but none of the differences were statistically significant. Unfavorable treatment outcomes were observed in 24% in the WGS group and 42% in the SOC group (RD -17.2% non-inferiority p <0.0001, superiority p=0.021) (figure). The proportion of patients experiencing a serious adverse event was similar in both groups (33% in SOC and 27% in WGS group, RD -6%, 95% CI -8, 20; p=0.41).

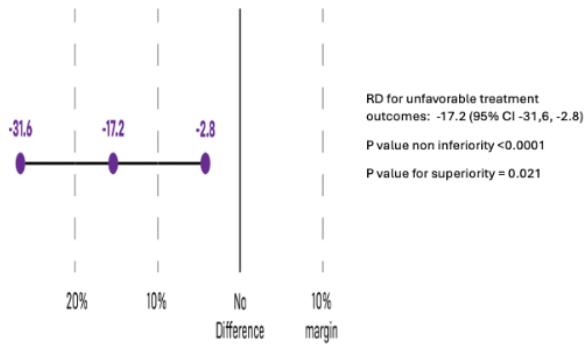


Figure. Clinical efficiency analysis shows non-inferiority (10 percentage point margin) and superiority of whole genome sequencing guided individualized treatment for rifampicin resistant TB in th modified intention-to-treat population.

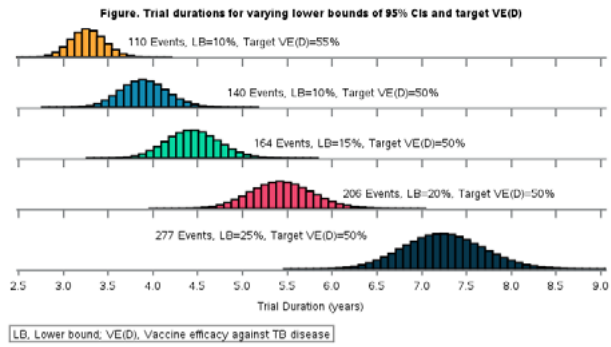
Interpretation: The WGS-guided treatment strategy was feasible, acceptable, accurate, safe, demonstrated similar bacteriological efficacy and superior clinical effectiveness compared to the South African SOC strategy for RR-TB.

TBS-EP47 Design optimization for a global phase 3 trial of the M72/AS01$_{E-4}$ Mycobacterium tuberculosis (Mtb) vaccine

M. Curran,[1] R. Noble,[1] A. Cinar,[1] A.C. Schmidt,[1] A.F. Dagnew,[1] [1]Gates Medical Research Institute, Cambridge, MA, United States of America
e-mail: amy.cinar@gatesmri.org

Background: Vaccine efficacy (VE) trials for tuberculosis (TB) are challenging in low incidence settings when timely evidence is needed. A phase 3 trial (NCT06062238) is underway to assess the VE of M72/AS01$_{E-4}$ against bacteriologically-confirmed pulmonary TB (VE[D]) among IGRA-positive/HIV-negative participants (primary objective) and in IGRA-negative and HIV-positive participants (secondary objectives).
Methods: Trial simulations were conducted for adults (15–44 years) in high-burden TB settings. Design features including trial duration, lower bound of 95% confidence interval (CI), and event count were modeled to assess feasibility under different VE assumptions based on phase 2b results (NCT01755598). Key assumptions included 3% annual IGRA conversion rate, 5% annual dropout, 2-year enrollment period, and pulmonary TB incidence of 200 to 500/100,000 person-years.
Results: Simulations revealed that in an all-comer population with 67% IGRA prevalence at enrollment, >90% of TB events would occur in baseline IGRA-positive participants, rendering the trial underpowered to evaluate VE(D) in IGRA-negative participants. A feasible trial design was determined to enroll 18,000 IGRA-positive, HIV-negative participants with 1:1 randomization of M72/AS01$_{E-4}$ or placebo.
Assuming pulmonary TB incidence rate of 400/100,000 person-years, a target VE(D) of 55%, power >90%, and a lower margin of 95% CI of 10%, this design would have a 90% probability of accruing 110 events in the per-protocol population and detecting a VE(D) of 55% within 4 years of enrollment initiation (Figure).
This timeframe will mitigate the impact of a lower-than-expected incidence rate and allow assessment of protection duration. The primary objective will be met if the null hypothesis H0: VE(D)≤10% is rejected, i.e., the lower bound of the 95% CI for VE(D) exceeds 10%.



Conclusions: Simulation-based trial design modeling informed the design of a feasible phase 3 TB vaccine trial. These findings underscore the value of rigorous trial simulations for optimizing trial designs, particularly for low-incidence disease contexts.

TBS-EP50 What is the potential impact of vaccinating younger (9–14 year old) adolescents with new TB vaccines?

R.A. Clark,[1] L. Martinez,[2] A. Fiore-Gartland,[3] F. Cobelens,[4] R.G. White,[1] M. Hatherill,[5] [1]LSHTM, Department of Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [2]Boston University Medical Center, Massachusetts, United States of America, [3]Fred Hutchinson Cancer Research Center, Seattle, United States of America, [4]Amsterdam University Medical Center, University of Amsterdam, Amsterdam, Netherlands, [5]University of Cape Town, South African Tuberculosis Vaccine Initiative, Institute of Infectious Disease and Molecular Medicine and Department of Pathology, Cape Town, South Africa
e-mail: rebecca.clark@lshtm.ac.uk

Background: New tuberculosis (TB) vaccines may be available soon. However, efficacy results will only be available for IGRA-positive individuals aged ~15+. In reality, countries may decide to introduce the vaccine routinely to adolescents younger than aged 15 with higher school attendance, e.g., alongside HPV vaccination. Most adolescents younger than aged 15 are IGRA-negative and have low TB incidence. We estimated the health impact of introducing new TB vaccines to 9–14 year olds in India and South Africa.
Methods: We used previously developed and calibrated TB infection transmission models to estimate the impact of introducing a vaccine with 50% efficacy to prevent disease in India and South Africa over 2030–50. We delivered the vaccine routinely to those aged 9 years and as one mass campaign for ages 10–14 years. The vaccine was assumed to be effective in either IGRA-positives only or irrespective of IGRA status.
Results: Modelling suggested that the health impact of vaccines effective only in IGRA-positive individuals was considerably smaller than for vaccines effective irrespective of IGRA status (India: 1.9 vs 6.1, South Africa: 0.2 vs 0.6, millions of averted TB episodes, respectively). The cost per disability adjusted life year (DALY) averted for vaccines effective only in IGRA-positives was larger than for vaccines effective irrespective of IGRA status (India: 412 vs 116, South Africa: 290 vs 75, USD per DALY averted).

Table Epidemiological and cost-effectiveness results with 95% uncertainty intervals

Country	The vaccine works in…	Cumulative TB cases averted	Cumulative TB deaths averted	Cumulative DALYs averted	Cumulative costs in USD	ICER (USD/DALY averted)
India	IGRA+ only	1.9m (1.6, 2.2)	0.3m (0.3, 0.4)	7.7m (6.8, 8.8)	3.2b (3.1, 3.3)	412 (358, 479)
	IGRA+ and IGRA-	6.1m (5.3, 6.9)	1.0m (0.9, 1.2)	22.5m (19.8, 25.8)	2.6b (2.5, 2.8)	116 (96, 135)
South Africa	IGRA+ only	0.2m (0.2, 0.2)	14.0k (10.9, 16.1)	0.6m (0.4, 0.6)	161m (102, 231)	290 (189, 456)
	IGRA+ and IGRA-	0.6m (0.6, 0.7)	41.1k (36.4, 48.3)	1.7m (1.5, 1.9)	129m (86, 187)	75 (51, 112)

Cumulative cases, deaths, and DALYs averted, and cumulative costs are measured between 2030–2050 and are compared to the scenario with no vaccine. Costs and ICERs (cost/DALY averted) are calculated from the health-system perspective. Abbreviations: b=billions, DALY=disability adjusted life-years, ICER = incremental cost-effectiveness ratio, k=thousands, m=millions, USD=United States dollars

Conclusions: If new TB vaccines only work in IGRA-positive individuals, and initial delivery is only to adolescents aged 9–14, impact is likely to be low, with much vaccine wastage.
Further, given the low TB incidence in this population, the lack of efficacy in IGRA-negative individuals would take many years to detect. We need to include younger adolescents in the development of new TB vaccines and plan to measure efficacy in this key group.

TBS-EP53 Immunometabolic profiling of *Mycobacterium tuberculosis* infected human lung tissue

W. Manjeese,[1] B. Cumming,[1] S. Nadeem,[2] K. Nargan,[1] T. Naidoo,[1] B. Truebody,[1] A. Steyn,[1,2] [1]Africa Health Research Institute, Durban, South Africa, [2]University of Alabama at Birmingham, Birmingham, United States of America
e-mail: barry.truebody@ahri.org

The early immune response to *Mycobacterium tuberculosis* (*Mtb*) infection is mediated by immune cells that work in synergy to phagocytose *Mtb* and illicit effector responses. *Mtb* activated macrophages mount a pro-inflammatory response and they rely on glycolysis and pentose phosphate pathway for metabolism. Immune cell metabolism is dictated by the available substrates in their microenvironment, and it can be rewired by *Mtb* for its survival. This reprogramming regulates the cell's effector functions that could contribute to tuberculosis (TB) disease progression.
Previously, we have shown that metabolic reprogramming and compromised mitochondrial function contribute to the breakdown of CD8+ T cell immunity during *Mtb* infection. In the present study, we hypothesise that metabolic reprogramming of host immunity in the lung by *Mtb* contributes to TB disease.
Notably, our carbon tracing studies with stable isotope-labeled substrates, combined with analysis of freshly resected human TB tissue, indicate that both the human tuberculous lung and *Mtb* infected monocyte-derived macrophages preferentially metabolize lactate over glucose.
We also found that the use of lactate as a substrate reduced the secretion of IL-1β, IL-6, IL-12, TNF-α, IFN-γ, IL-4 by *Mtb* infected human monocyte-derived macrophages. Immunohistochemical analysis of the human tuberculous lung revealed the differential production of GLUT 2, 3, 4 and 5, in addition to monocarboxylate transporters, MCT1 and 4, which transport lactate, across the spectrum of lesions. Lactate dehydrogenase B that preferentially catalyses the conversion of lactate into pyruvate was also differentially produced across the spectrum of lesions.
Currently, we are employing multiplex immunofluorescence (mIF; Lunaphore platform) to allow a better understanding of the complex interaction between immune

cells, bacilli, and metabolism in the tuberculous lung. These findings lay the foundation for future studies that will explore the potential of immunometabolic markers as biomarkers of TB disease progression and potentially leading to host directed therapeutic strategies.

TBS-EP56 Investigation into the peripheral localization, morphology and host/pathogen interaction of MDSCs during stages human tuberculosis lymph nodes granuloma evolution

S.O. Adebiyi,[1] T. Jooste,[1] G. Walzl,[1] N. Du Plessis Burger,[1]
[1]Stellenbosch University, Cape Town, South Africa
e-mail: sadebiyi@sun.ac.za

Tuberculosis (TB) granulomas exist along a spectrum of phenotypes, ranging from protective, sterile granulomas that contain the infection to permissive granulomas that allow uncontrolled growth and dissemination of Mycobacterium tuberculosis (M.tb). These heterogeneous granulomas can coexist within a single host, with TB clinical and treatment outcomes determined locally by the cumulative effect of this granuloma heterogeneity.
However, the factors driving the formation and persistence of distinct granuloma phenotypes remain largely unclear. Myeloid suppressor cells (MDSCs), known for their immunosuppressive and immunomodulatory roles, were hypothesized in this study to play a major role in granuloma heterogeneity.
To test this hypothesis, the study employed the 10x Genomics Visium spatial transcriptomics platform, combined with routine histological staining, to characterize the immune landscape of four granulomas (necrotic and non-necrotic) across eight tissue sections from archived lymph nodes of children who underwent excision surgery for lymphadenitis.
Findings from this study indicate that pediatric lymph node granulomas exhibit compartment-specific structures distinct from those observed in pulmonary granulomas.
Notably, they lack the characteristic lymphocytic cuffs and B-cell islands commonly seen in pulmonary granulomas.
Additionally, MDSCs in the granulomas were found to colocalize more with M2 macrophages and neutrophils, rather than T cells, suggesting that these interactions likely support granuloma polarization and promote immunosuppression in both necrotic and non-necrotic granulomas.
Widespread immunosuppression characterized by TGFB1 and IDO expression was observed in all granulomas. However, in certain microenvironments, the presence of pro-inflammatory cytokines such as IFN-Y counteracted these suppressive signals, creating protective microenvironments. Both protective and suppressive microenvironments were present in varying proportions across all granulomas, with the dominant microenvironment determining the overall phenotype of each granuloma. These findings suggest the presence of distinct, spatially coordinated immunoregulatory programs within different TB granuloma types during active disease.

TBS-EP59 Improving collaboration through access: A scoping review of TB clinical trial repositories

M. McClean,[1,2] N. Heinrich,[2,3,4] F. Jones,[5] C. Lienhardt,[6]
[1]Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Munich, Germany, [2]Division of Infectious Diseases and Tropical Medicine, University Hospital Ludwig Maximilian University (LMU), LMU Munich, Munich, Germany, [3]Center for International Health, University Hospital Ludwig Maximilian University, Munich, Germany, [4]Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Immunology, Infection and Pandemic Research, Munich, Germany, [5]Laboratory & Clinical Sciences Branch, National Institute of Allergy and Infectious Diseases, National Institutes of Health (NIH), Rockville, United States of America, [6]Unité Mixte Internationale TransVIHMI (UMI 233 IRD–U1175 INSERM, Université de Montpellier), Institut de Recherche pour le Développement (IRD), Montpellier, France
e-mail: mairi.mcclean@helmholtz-munich.de

Background: Better biomarkers for treatment response could help in making trials faster, less costly and more meaningful; and allow individualised treatment on a programmatic level. Validation of new biomarkers is hampered by access to sufficient numbers of patients with relapse; a usually rare outcome in trials.
To address this, as part of the Facilitating Accelerated Science and Translation for TB Regimen Development (FAST-TB) consortium, we undertook a scoping project to identify biobanks and data repositories that hold clinical trial data and biobanked samples, and to assess the extent to which these resources are available for potential secondary use.
Methods: We developed and distributed electronically a structured questionnaire targeting TB clinical trial repositories throughout the globe. The survey aimed to characterize repository contents, metadata, access frameworks, and openness to further engagement.
Results: Of the 23 organisations contacted we received 9 responses, describing data from 33 studies, including >23,500 patients from Asia, Africa and Europe. Of these, 4 organisations reported data and/or samples from persons who experienced disease recurrence. A total of 13 studies were observational, primarily in adults (22/33) and focused on pulmonary TB (15/33). Samples and data types were varied (Figure 1).

Notably, repository representatives showed strong interest in follow-up discussions on data access and sample specifications. FAST-TB will be able to establish contact between biobanks and researchers upon request.

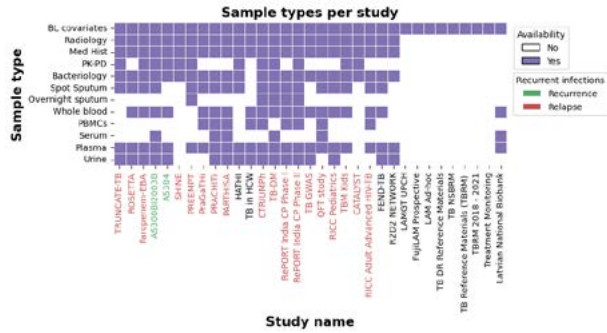


Figure 1. Sample availability by study. Red: recurrence samples; green: relapse samples identified by sequencing.

Conclusion: This openness presents a key opportunity: by systematically mapping available resources and engaging stakeholders, FAST-TB aims to facilitate new research collaborations and improve the efficiency of treatment development and evaluation pipelines.

While preliminary, this effort aims to improve the visibility and utility of existing clinical trial assets, thereby supporting broader efforts to accelerate the development, evaluation, and implementation of novel TB treatment biomarkers.

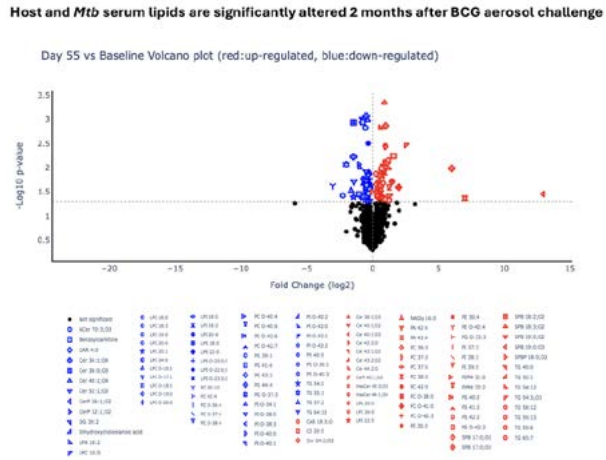
TBS-EP62 Phosphatidylcholine alterations correlate with natural and M. tuberculosis-specific antibody responses in a primate model

S. Santiago Torres,[1] N. Rout,[1] L. Morici,[1]
E. Otoupalova,[1] [1]Tulane University School of Medicine, New Orleans, United States of America
e-mail: ssantiagotorres@tulane.edu

Background: *Mycobacterium tuberculosis* (Mtb) manipulates host lipid metabolism to support its survival and immune evasion. Phosphatidylcholine (PC), a key membrane phospholipid, is elevated in tuberculosis (TB) patients and promotes Mtb growth in macrophages, while its precursor lipids, lysophosphatidylcholines (LPCs), are decreased. Natural antibodies, such as anti-P1 and anti-Apolipoprotein B100 immune complex (anti-ApoB100 IC) antibodies, recognize various phospholipids including phosphatidylcholine and can inhibit their uptake by macrophages. This study explores the relationship between PC metabolism and both Mtb-specific and natural antibody responses in a non-human primate model of TB.

Methods: Longitudinal serum samples from Rhesus macaques exposed to aerosolized Bacillus Calmette-Guérin (BCG) were collected at Days 0, 36, and 55 post-challenge. ELISAs quantified IgA and IgM responses to Mtb-specific antigens (lipoarabinomannan [LAM], mycolic acid) and IgA and IgM natural antibody responses (anti-P1, anti-ApoB100 IC). Lipidomics profiled changes in host and bacterial lipids. Data were analyzed using Mann-Whitney U tests, ANOVA, and Spearman correlation.

Results: Serum levels of PC derivatives (e.g., PC42:0, PC48:2, PC-O 41:0, PC-O 42:3) significantly increased, while LPCs (e.g., LPC16:0, LPC20:1, LPC24:0) significantly decreased at Days 36 and 55 ($p < 0.05$). IgA responses to LAM and ApoB100 IC showed strong correlations with PC species such as PC42:2 (R = 0.61, R=0.67) and PC-O 33:3 (R = 0.57, R=0.69; $p < 0.01$), respectively. Anti-LAM IgM and anti-P1 IgA responses correlated with an Mtb cell wall phospholipid, phosphatidylinositol mannoside 4 33:2 (R = 0.56, R=0.59; $p < 0.015$).



Conclusions: BCG exposure induced sustained changes in lipid metabolism, including PC elevation and LPC depletion, mirroring patterns seen in human TB. Specific PC derivatives correlated with both Mtb-specific and natural antibodies, particularly of IgA and IgM isotypes. These results suggest a link between host lipid remodeling and immune responses, with potential cross-reactivity between altered host lipids, Mtb antigens and natural antibodies.

TBS-EP65 Baseline Sputum Gene Expression and Its Association with Pulmonary Fibrosis and Post-TB Lung Function

H. Hong,[1] B. Dobosh,[2] A. Queiroz,[3] Y. Li,[1] D.M. Moncada Giraldo,[2] J.D. Chandler,[2] Y.J. Kang,[1] P. Maenetje,[4] J. Choene,[4] R.M. Tirouvanziam,[2] S. Auld,[2] G.P. Bisson,[1] [1]University of Pennsylvania, Philadelphia, United States of America, [2]Emory University, Atlanta, United States of America, [3]Owaldo Cruz Foundation (FIOCRUZ), Salvador, Brazil, [4]Aurum Institute, Johannesburg, South Africa
e-mail: hjhong@upenn.edu

Post-tuberculosis lung disease (PTLD) is an important contributor to morbidity and mortality following tuberculosis (TB), yet its underlying mechanisms are poorly understood. Lung structural involvement and impaired pulmonary function at presentation are associated with PTLD, but biomarkers of these conditions are lacking. We hypothesized that sputum gene expression would be associated with radiographic and functional measures of respiratory severity at baseline and after treatment completion.

Adults (≥18 years) in South Africa with Xpert-positive pulmonary TB (n=63) provided sputum samples within 2 weeks of treatment initiation. Sputum cell pellets were profiled using a 96-gene custom Fluidigm panel, with RT-qPCR data normalized to ACTB. Fibrosis and consolidation were scored on high-resolution computed tomography using a 0–5 scale, and lung function was assessed by spirometry (FEV_1 and FVC z-scores). Linear regression models adjusted for age, sex, and HIV status (HIV only for lung function given z-score use) using a false discovery rate < 0.2.

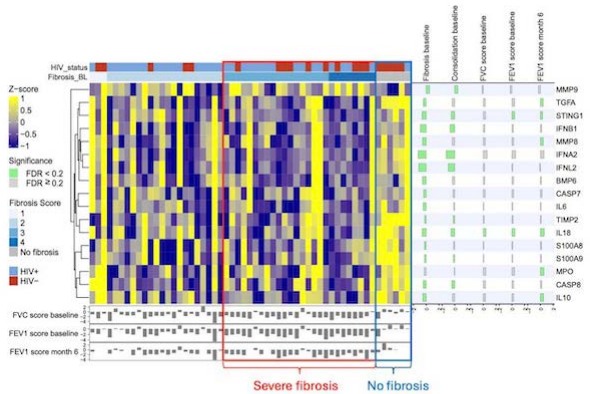


Figure. Baseline sputum gene expression stratified by pulmonary fibrosis severity. Heatmap of normalized gene expression (−ΔCt) in baseline sputum samples from adults with pulmonary TB, shown across fibrosis scores (0–4) on high-resolution CT. A marked contrast in gene expression was observed between participants with no fibrosis (score 0) and those with severe fibrosis (scores 3–4). Individuals without fibrosis—mostly people without HIV and with better lung function at baseline and 6 months—exhibited higher expression of *BMP6, CASP7, CASP8, IFNA2, IFNB1, IFNL2, IL10, IL18, IL6, S100A8, S100A9, STING1, TGFA,* and *TIMP2,* while *MMP9* expression was elevated in severe fibrosis. These patterns reflect distinct transcriptional profiles associated with fibrosis severity at TB treatment initiation.

Higher baseline expression of BMP6, CASP7/8, IFNA2, IFNB1, IFNL2, IL10, IL18, IL6, S100A8/9, STING1, TGFA, and TIMP2 was associated with less baseline pulmonary fibrosis, while higher MMP9 expression was associated with greater fibrosis. Greater expression of IL18 and STING1 were associated with higher FEV_1 at baseline and 6 months; IL18 was also associated with higher FVC at baseline. Several immune mediators previously associated with baseline fibrosis (TGFA, IL10) were also associated with higher 6-month FEV_1.

Our preliminary findings suggest that upregulation of immune mediators—some with anti-fibrotic properties—may lower risk of fibrotic progression. IL18, interferons, and BMP6 may suppress TGF-β signaling, while STING1, IL10, and TGFA may exert immune regulation and epithelial repair. IL18 showed consistent protective associations across all outcomes, highlighting its potential as a biomarker and possible therapeutic target in PTLD. These encouraging pilot data warrant further validation.

TBS-EP68 Use of tuberculosis molecular bacterial load assay in sputum samples to characterize tuberculosis treatment response over 12 weeks

T. Vongjarudech,[1,2] I. Noreña,[3] F. Njeleka,[4] B. Mtafya,[4] L. Minja,[4,5,6] C. Manyama,[4] N. Heinrich,[3] E. Svensson,[2,1] [1]Department of Pharmacy, Pharmacology and Toxicology, Radboud University Medical Center, Nijmegen, Netherlands, [2]Department of Pharmacy, Uppsala, Sweden, [3]Institute of Infectious Diseases and Tropical Medicine, LMU Munich University Hospital, Munich, Germany, [4]National Institute for Medical Research (NIMR-MMRC) Tanzanian National, Mbeya, United Republic of Tanzania, [5]Swiss Tropical and Public Health Institute, Allschwil, Switzerland, [6]University of Basel, Basel, Switzerland
e-mail: Thanakorn.Vongjarudech@radboudumc.nl

Introduction: Tuberculosis Molecular Bacterial Load Assay (TB-MBLA, LifeArc) quantifies viable *Mycobacterium tuberculosis* (Mtb) RNA and offers a faster readout of treatment response than Mycobacterial Growth Indicator Tube time-to-positivity (MGIT-TTP). We characterized treatment response in the SUDOCU and DECODE studies using longitudinal TB-MBLA data and compared it with MGIT-TTP, a gold standard.

Method: Sputum samples collected weekly over 12 weeks from 148 adults with drug-sensitive pulmonary TB. Participants were randomized to sutezolid- or delpazolid-containing regimens (with background bedaquiline, delamanid, and moxifloxacin) or control, were utilized. Batch-specific standard curves converted quantification cycle values (Cq) to copies-per-reaction (c/rxn). Both TB-MBLA and MGIT-TTP values were $\log_{10}$-transformed.

Result: We analyzed 4,864 TB-MBLA measurements of Mtb 16S rRNA (Figure 1). Log_{10} TB-MBLA showed a moderate negative correlation with $\log_{10}$ MGIT-TTP (Pearson's r = –0.59, 95% CI: –0.64 to –0.54). At week 6,

30.6% of TB-MBLA observations were below the limit of detection (LOD of 2.11 $\log_{10}$ c/rxn) compared with 39.5% of MGIT-TTP that had reached the upper LOD (1008 h). By week 12, these proportions increased to 68.8% for TB-MBLA and 95.2% for MGIT-TTP. While MGIT-TTP reaches the LOD earlier and shows a larger proportion of undetectable observations later in the treatment period, TB-MBLA provides a more continuous and quantitative measure of bacterial load and treatment response. Correlations between baseline biomarker values and time to sputum culture conversion (TSCC) were r = 0.24 (95% CI: 0.13 to 0.34) for $\log_{10}$ TB-MBLA, and r = –0.21 (95% CI: –0.32 to –0.10) for $\log_{10}$ TTP, showing similar strengths.

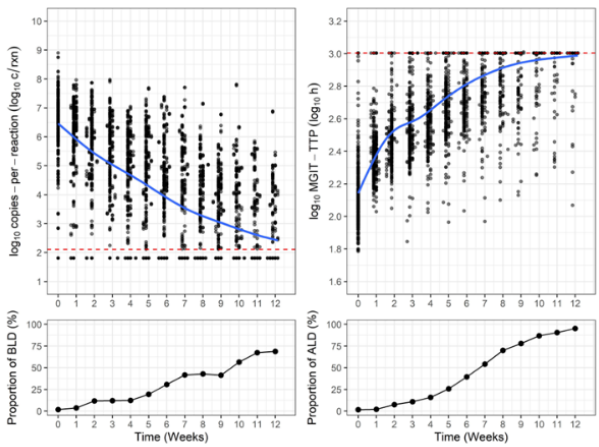

Figure 1: Observed $\log_{10}$ copies-per-reaction ($\log_{10}$ c/rxn) from Tuberculosis Molecular Bacterial Load Assay (TB-MBLA, LifeArc) (top-left panel) and observed $\log_{10}$ MGIT-TTP ($\log_{10}$ h) (top-right panel) over time during treatment. The top panels show individual observations as dots, with blue solid lines representing locally estimated scatterplot smoothing (LOESS) regression. The red dashed line indicates the limit of detection (LOD). The bottom-left panel displays the proportion of $\log_{10}$ c/rxn observations below the LOD (BLD), while the bottom-right panel shows the proportion of $\log_{10}$ TTP observations above the LOD (ALD).

Conclusion: TB-MBLA aligns with MGIT-TTP while shortening analytical turnaround times, underscoring its utility for monitoring TB treatment response. Ongoing work using non-linear mixed-effects models will further investigate the dynamics of TB-MBLA, the link to MGIT-TTP and clinical outcomes and evaluate performance in drug-exposure-response analysis to support dose optimization.

TBS-EP71 *Mycobacterium tuberculosis* curli pili reduces oxygen consumption rate of THP-1 macrophages during early infection

S. Ashokcoomar,[1] T. Naidoo,[2] B. Cumming,[3] Z. Baig,[3] B. Truebody,[3] J. Mackenzie,[3] A. Steyn,[3] M. Pillay,[1]
[1]University of KwaZulu-Natal, Durban, South Africa, [2]University of Cape Town, Cape Town, South Africa, [3]Africa Health Research Institute (AHRI), Durban, South Africa
e-mail: shineseashokcoomar@gmail.com

Background: The development of improved anti-tuberculosis (TB) strategies to address drug-resistance and ineffectual TB treatment regimens should focus on interrupting the initial host-pathogen interaction.
This study aimed to elucidate the effect of surface-located adhesin, *Mycobacterium tuberculosis* (*Mtb*) curli pili (MTP), on the bioenergetic and metabolomic profiles of THP-1 macrophages during initial stages of infection.
Methodology: Differentiated THP-1 macrophages were infected for 4 hours with wildtype (WT), Δ*mtp*, or *mtp*-complement strains of *Mtb*. Bioenergetic profiles and metabolic flux were determined through cell mitochondrial stress test (CMST) and glycolytic rate assay (GRA) performed in an extracellular flux analyzer. The metabolic flux of uninfected and *Mtb* infected THP-1 macrophages were determined through $^{13}C_6$-glucose tracing liquid chromatography with tandem mass spectrometry. Statistical analysis highlighted differences/similarities amongst the THP-1 macrophage groups.
Results: The Δ*mtp* infected THP-1 macrophages mimicked the higher oxygen consumption rate (OCR) for basal respiration, ATP production, maximal respiration and spare respiratory capacity of the uninfected THP-1 macrophages, relative to the WT and *mtp*-complement infected THP-1 macrophages. The Δ*mtp* infected THP-1 macrophages displayed the highest compensatory glycolytic rate. *Mtb* infection caused the redirection of carbon from the tricarboxylic acid cycle to glycolysis, in addition to an increased flux through the pentose phosphate pathway. However, in the Δ*mtp* infected THP-1 macrophages, the total metabolite abundance was lower, similar to the uninfected THP-1 macrophages.
Conclusion: Data indicates that the absence of MTP facilitates prompt clearance of the intracellular pathogen before it establishes a successful infection. This implies that the presence of MTP facilitates the survival of the pathogen during the early stages until infection is established.
These findings support the growing evidence that the MTP adhesin is an important virulence factor and interruption of the interaction between pathogen and host, will facilitate swift clearance of the infection by the host.

TBS-EP74 Non-sputum biomarkers for on-treatment prediction of TB disease recurrence

M. McClean,[1,2] O. Baranov,[1,3,4] M. Ahmed,[1,3] C. Geldmacher,[1,3,4] F.P. Casale,[2] N. Heinrich,[1,3,4] K. Held,[1,3,4] [1]Division of Infectious Diseases and Tropical Medicine, University Hospital Ludwig Maximilian University (LMU), LMU Munich, Munich, Germany, [2]Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Munich, Germany, [3]German Center for Infection Research (DIZF), Partner Site Munich, Munich, Germany, [4]Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Immunology, Infection and Pandemic Research, Munich, Germany
e-mail: mairi.mcclean@helmholtz-munich.de

Introduction: TB disease recurrence represents a significant burden to persons on treatment and incurs long follow-up periods in clinical trials. On-treatment identification of individuals at greater risk of recurrence could guide alternative treatment and follow-up strategies.
Methods: From the PanACEA multi-arm, multi-stage trial, we identified 8 persons who experienced disease recurrence within 1 year of treatment initiation, and 8 controls with sustained cure, matched for biological sex, age, treatment arm, and baseline disease severity. We generated bulk RNA-sequencing from whole blood samples at weeks 0,1,2,4,9,14, and 26, and paired with clinical covariate data. We performed cross-sectional univariate analysis using t-tests and Kruskal-Wallis tests, and used linear mixed models and repeated measures correlation for longitudinal data, with Bonferroni correction. Model selection was performed with likelihood ratio tests (LRT). We validated the predictive performance of multiple transcriptomic signature scores using area under the receiver operating characteristic curve (AUROC) values.

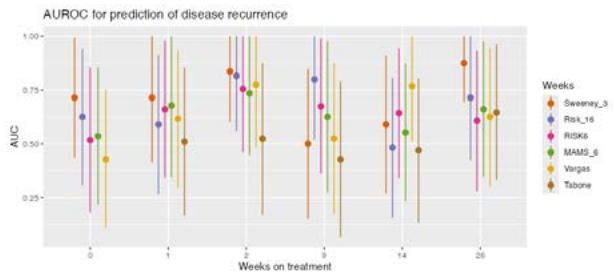

Figure 1. AUROC curves of transcriptomic signature scores across treatment weeks.

Results: Median time-to-negativity was significantly different between recurrence vs controls (adjusted P = 2.0 x 10-2). Longitudinally, we also found significantly different temporal changes in body mass index (BMI) (adjusted P=3.82 x10-4) and heart rate (adjusted P=6.71x10-5) between outcome groups. Sweeney-3, Risk-6, MAMS6 and Tabone27 signatures were correlated with BMI over time, and MAMS6 and Risk-16 with neutrophil counts. At week 26, Sweeney-3 showed highest performance [AUROC = 0.87 (0.68-1 CI); Figure 1]. Interestingly, for 4 signatures, the highest AUC values were observed at Week 2 into treatment.
Conclusions: The Sweeney-3 signature shows promise for treatment outcome prediction at week 26. Temporal biomarkers may be more informative than cross-sectional observations for treatment monitoring, and HR and BMI could represent informative and easily measurable markers of treatment response. Ongoing work is focused on integrative modeling combining transcriptomic and clinical features to optimize early risk stratification.

TBS-EP77 On the replacement of smear microscopy: Decontamination has a negative impact on GeneXpert Ultra

D. Augustinsson,[1,2] M. Jonsson Nordvall,[1] S.-P. Von,[3] K. Niward,[1,2] T. Schön,[1,2] [1]Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection, Linköping University, Linköping, Sweden, [2]Department of Infectious Diseases, Region Östergötland, Linköping, Sweden, [3]Department of Clinical Microbiology, Kalmar Hospital, Kalmar, Sweden
e-mail: daniel.augustinsson@liu.se

Background: WHO recommends replacing smear microscopy (SM) with molecular tests, such as GeneXpert MTB/RIF Ultra (GX), for detection of Mtb in pulmonary tuberculosis (PTB). GX is used both on decontaminated samples in TB laboratories and directly on sputum as a point-of-care test (POCT). A direct comparison between these strategies in relation to SM is needed before GX can replace SM for the evaluation of contagiousness.
Method: For direct comparison on identical samples, pooled Mtb-negative sputum samples were spiked with Mtb H37Rv at 2500 CFU/ml and 250 000 CFU/ml and analysed directly (POCT) and after NaOH-based decontamination and concentration of the sample. Baseline Cycle threshold (Ct) value of IS6110 and semi-quantiative result from the first POCT clinical sputum sample were compared to highest SM (auramine stained after concentration) from culture confirmed PTB patients in Sweden.
Results: In spiked sputum samples, median Ct-values were significantly lower in POCT sputum samples (20.8 (IQR 17.9-22.9) vs 23.2 (IQR 22.4-25.3), p<0.05, n=22) at 2 500 CFU/mL (Figure 1A). The median POCT Ct-value was significantly higher in SM negative patients (19.8 (IQR 16.8-24.4) vs 16.2 (IQR 16.1-17.4), p<0.001, n=44) and decreased with higher SM grade (rho=-0.57, p<0.001). All GX negative patients were SM negative and 94% (30/32) of SM positive patients had a semi-quantitative GX result of Low or higher (Fig 1B). Both POCT Ct-value and SM grade correlated significantly to time to positive culture (TTP) (rho=0.77 and 0.72, p<0.001).

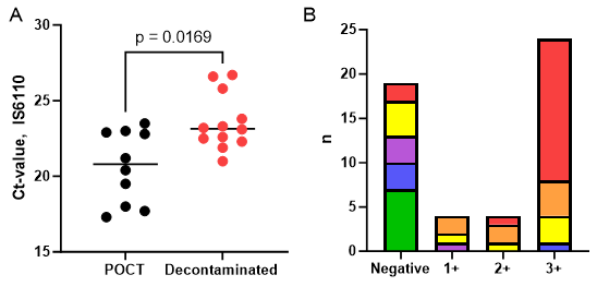

Figure 1A: GeneXpert MTB/RIF Ultra performed on pooled Mtb-negative sputum samples spiked with Mtb H37Rv at 2 500 CFU/ml analysed with (red dots) and without prior decontamination (POCT, black dots), n=22. No statistical difference was seen at 250 000 CFU/ml (data not shown). **1B**: Semiquantiative GX result of the first clinical sputum sample analyzed with POCT (n=51) and highest smear grade. Trace outlier in 3+ category had a second POCT with "Low" result. Negative=Green, Trace=Blue, Very Low=Purple, Low=Yellow, Medium=Orange, High=Red.

Conclusions: Sputum samples analysed directly by GX (POCT) showed a higher bacterial yield than decontaminated samples. In clinical sputum samples from culture confirmed PTB patients, there was a strong correlation between POCT and SM as well as to TTP. Our results suggests that GX performed directly on the sputum sample, rather than after decontamination, may replace SM both for diagnosis and evaluation of contagiousness.

TBS-EP80 Persistent immune alterations following TB treatment: Longitudinal profiling and possible association with microbiota

L. Shipingana,[1,2] C. Naidoo,[1,2] T. Webber,[1] T. Chiyaka,[1,2] L. Kleynhans,[3] G. Theron,[1,2] [1]Stellenbosch University, Cape Town, South Africa, [2]African Microbiome Institute, Cape Town, South Africa, [3]Mater Research Institute, Brisbane, Australia
e-mail: lshipingana@sun.ac.za

Background: *Mycobacterium tuberculosis (M.tb)* infection drives systemic immune activation. However, immune perturbations and their resolution following tuberculosis (TB) treatment remain unclear. We hypothesise that *M.tb* induced inflammation persists post treatment with possible microbial modulation, affecting disease severity, treatment outcomes, and immune recovery.
Methods: We profiled serum inflammatory markers using Luminex assays paired with stool and sputum microbiome (16S rRNA gene sequencing analysis) in people with TB and their household contacts (HHCs) at baseline, 6 months (end of treatment) and 18 months post treatment. Associations between immune markers and microbial composition were examined over time to identify potential drivers of immune activation or suppression.
Results: Systemic inflammatory markers were elevated and heterogenous in people with TB compared to lower and more uniform inflammatory marker expression in HHCs. Longitudinally, elevated inflammatory markers declined with treatment but remained altered post-treatment. Distinct immune correlations and trajectories suggest dynamic immune remodelling. Post-treatment, distinct microbial communities emerged in both the lungs and gut. Preliminary findings suggest links between specific microbes and immune profiles.
Conclusion: Our findings highlight TB associated heightened and variable immune activation that partially resolves post-treatment, potentially contributing to post-TB complications. Anaerobe-driven inflammation may underlie these effects, highlighting the importance of host-microbiome interactions in TB susceptibility, recovery and targets for host-directed therapy.

TBS-EP83 Blood RNA biomarkers to predict treatment failure or relapse after truncated treatment of pulmonary tuberculosis

R. Gupta,[1] I. Sari,[2] J. Jiang,[1] E. Burhan,[3] J. Greenan-Barrett,[1] V. Balanag,[4] M. Noursadeghi,[1] N. Paton,[5] TRUNCATE-TB Trial Team [1]University College London, London, United Kingdom of Great Britain and Northern Ireland, [2]National University Hospital, Singapore, Singapore, [3]Persahabatan Hospital, Jakarta, Indonesia, [4]Lung Centre of Philippines, Quezon, Philippines, [5]National University of Singapore, Singapore, Singapore
e-mail: r.gupta@ucl.ac.uk

Background: Biomarkers indicating cure at end of treatment could optimise implementation of shorter treatment strategies. We assessed candidate blood RNA biomarkers to predict treatment failure or relapse (TFR) following 8 weeks' treatment in the TRUNCATE-TB trial.
Methods: TRUNCATE-TB randomised adults (18–65 years) with rifampicin-susceptible pulmonary TB (NCT03474198) to either 24-week standard treatment; or to the TRUNCATE strategy, comprising initial 8-week treatment with re-treatment where needed. We performed blood RNA sequencing of samples from baseline, weeks 4/8, end of treatment (if treatment was extended), and week 24. We evaluated the accuracy of 12 candidate RNA biomarkers (from systematic review) for 96-week TFR.
Results: RNA data were available from 166 standard treatment and 446 TRUNCATE strategy participants (median 4 samples per participant). TRUNCATE strategy participants included 80 experiencing TFR and 309 without TFR. Candidate RNA biomarkers were highly correlated (Spearman ρ 0.76-0.98). FCGR1A showed the highest mean area under the receiver operating characteristic curve (AUROC) for TFR across sampling timepoints. Biomarker scores were highest at baseline. These resolved over time with similar trajectory by treatment strategy (Figure), but median scores remained >2 standard deviations above the mean of a healthy control population after 8 weeks' treatment. Biomarker scores continued to decline after treatment cessation in TRUNCATE strategy participants. Discrimination of FCGR1A

for TFR among TRUNCATE strategy participants was moderate from baseline to end of treatment (AUROCs 0.65-0.67); but improved at week 24 (AUROC 0.71; 95% CI 0.65-0.78).

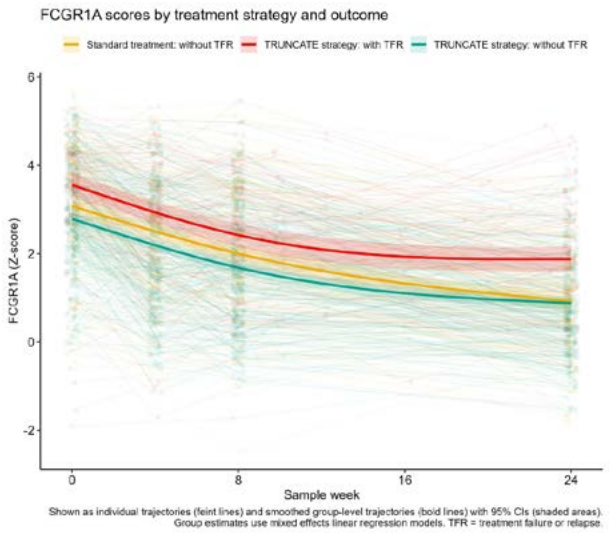

Figure.

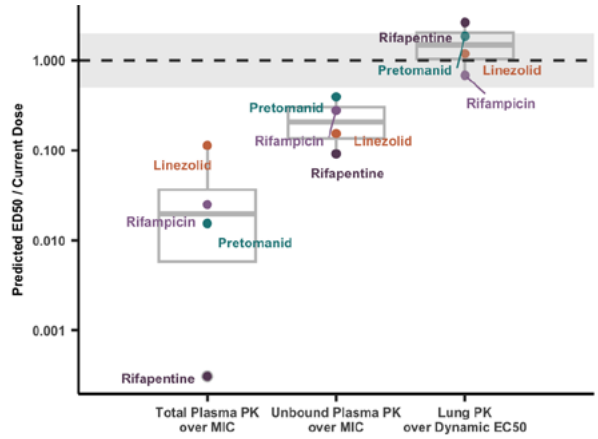
Conclusions: Residual elevation of RNA biomarkers at 8-weeks and similar trajectories among those receiving truncated or standard treatment suggests ongoing bacterial clearance or gradual immune homeostasis after 8 weeks. Among TRUNCATE strategy participants, RNA biomarkers provide limited prediction of long-term TFR when measured at baseline through treatment end. Divergent biomarker trajectories thereafter suggests a potential role in predicting TFR after treatment cessation.

TBS-EP86 Proposing a framework for human dose prediction of anti-tuberculosis drug candidates

A. Patel,[1] B. Pérez Solans,[1] R. Savic,[1] [1]University of California San Francisco, San Francisco, United States of America
e-mail: anu.patel@ucsf.edu

Background: Having a standardized approach for human dose prediction (HDP) early in discovery and development is transformative for increasing the likelihood of a compound's success. In the tuberculosis (TB) field, plasma exposure over the minimum inhibitory concentration (MIC) has been used as a pharmacokinetic-pharmacodynamic (PK-PD) target to inform efficacious dose, but this has not aligned with clinical results. By performing a back-translational PK-PD analysis of approved anti-TB drugs, we aim to identify best methods for HDP.
Methods: Potency assay data, as well as translational and clinical PK models, were collected for ten anti-TB drugs, including four that underwent clinical dose-finding studies. Exposures in various matrices (plasma, lung, lesions, cavitary caseum) based on a rabbit-to-human translational tool were simulated across doses up to 10000 mg using NONMEM. Coverage over relevant PD targets, including MIC, intramacrophage IC_{90}, caseum MBC_{90}, and *in vivo* EC_{50}, was simulated and an effective dose quantified, defined as achieving coverage over 50% of the steady-state dosing interval (ED_{50}). This ED_{50} was then compared to the currently known efficacious dose of each drug.
Results: Generally, plasma PK over MIC underpredicted the clinical efficacious dose across drugs, even after protein binding corrections. Lung PK over EC_{50}, a dynamic metric quantified from *in vivo* PK-PD studies, resulted in predictions within approximately two-fold of efficacious dose for clinically dose-optimized drugs. Assessing caseum PK-PD is essential for identifying efficacy in hard-to-treat patient phenotypes and could accurately identify penetrating drugs.



Conclusions: Efficacious dose prediction relies on the attainment of an accurate PK-PD target. Coverage defined by site-of-disease exposures over a dynamic potency target has been shown to be most predictive of clinical efficacious dose. This approach has the potential to reduce the time needed for a drug to reach clinical stages with an acceptable dose range and minimize costly dose-finding studies.

TBS-EP89 Evaluating the association between baseline neutrophil counts and pulmonary tuberculosis outcomes: Baseline and post-treatment lung function and high-resolution CT findings

Y. Kang,[1] Y. Li,[1] P. Maenetje,[2] N. Mofokeng,[2] L. Mngomezulu,[2] H. Hong,[1] A. Rajaratnam,[3] M. Marll,[3] F. Willis,[3] R. Tirouvanziam,[3] S. Auld,[3] G.P. Bisson,[1]
[1]University of Pennsylvania, Philadelphia, United States of America, [2]Aurum Institute, Johannesburg, South Africa, [3]Emory University, Atlanta, United States of America
e-mail: yjnkng88@gmail.com

Background: Nearly two-thirds of pulmonary tuberculosis (TB) patients have respiratory sequelae after treatment. Neutrophils are associated with TB pathology, but the relevance to post-TB lung disease is unknown. We hypothesized that higher baseline blood neutrophil counts would be associated with worse lung function and imaging in adults even after treatment for pulmonary TB.
Design/Methods: We conducted a longitudinal cohort study of 259 TB patients initiating standard four-drug therapy for rifampin-susceptible pulmonary TB in Johannesburg, South Africa.
We used Wilcoxon rank-sum testing to compare neutrophil groups with respect to forced expiratory volume in 1 second (FEV_1), forced vital capacity (FVC), total lung capacity (TLC), and diffusing capacity of the lung for carbon monoxide (DLCO), and high-resolution CT (HRCT) scores for lung abnormality, consolidation and fibrosis. These were assessed at baseline (within 2 weeks of treatment), month 6 (end of treatment), and month 12. Race-neutral Global Lung Initiative reference standards measured lung function, which adjust for age, gender, and height. Linear regression adjusted for HIV, antiretroviral therapy, smoking and alcohol.
Results: Table 1 shows that participants in the baseline top neutrophil tertile cohort had lower baseline FEV_1, FVC, and DLCO z-scores ($p<0.05$), indicating worse lung function and gas exchange, and more consolidation and fibrosis on HRCT ($p<0.05$). Imaging differences persisted at 12 months ($p<0.05$), but lung function differences did not.

Table 1. Comparison of Lung Function and High-Resolution CT (HRCT) Imaging by Neutrophil Tertiles at Initiation and Post-Tuberculosis Treatment

Baseline (first two weeks of TB Treatment)					Month 12 (6 months after TB Treatment)				
Lung Characteristics	Top 33% Neutrophils (N=85)	Bottom 67% Neutrophils (N=171)	P-value	Adjusted P-value	Lung Characteristics	Top 33% Neutrophils (N=85)	Bottom 67% Neutrophils (N=171)	P-value	Adjusted P-value
FEV1 z-score median (IQR) N=248	-1.9 (-2.8, -1.0)	-1.2 (-2.3, -0.3)	**0.002**	**0.027**	FEV1 z-score median (IQR) N=86	-1.1 (-2.4, -0.4)	-0.9 (-1.9, 0.3)	0.246	0.114
FVC z-score median (IQR) N=248	-1.7 (-2.6, -0.6)	-1.2 (-1.9, -0.3)	**0.005**	**0.049**	FVC Z-score median (IQR) N=86	-0.7 (-1.7, 0.1)	-0.4 (-1.4, 0.4)	0.274	0.239
TLC z-score median (IQR) N=127	-1.3 (-2.7, -0.3)	-1.2 (-2.2, -0.0)	0.462	0.757	TLC Z-score median (IQR) N=60	0.1 (-0.4, 0.6)	-0.4 (-1.5, 0.4)	0.186	0.558
DLCO z-score median (IQR) N=205	-1.0 (-2.1, 0.4)	0.5 (-1.7, 0.6)	0.126	**0.047**	DLCO Z-score median (IQR) N=85	-0.1 (-1.9, 1.5)	-0.1 (-1.2, 1.0)	0.882	0.593
Overall HRCT lung abnormality median (IQR) N=206	14.0 (11.0, 19.0)	14.0 (9.0, 17.0)	0.281	0.273	Overall HRCT lung abnormality median (IQR) N=113	9.5 (5.0, 14.0)	7.0 (5.0, 10.0)	0.070	0.139
HRCT Consolidation median (IQR) N=206	6.0 (4.0, 10.0)	4.0 (2.0, 7.0)	**<0.001**	**<0.001**	HRCT Consolidation median (IQR) N=113	0.0 (0.0, 0.0)	0.0 (0.0, 0.0)	0.173	**0.043**
HRCT Fibrosis median (IQR) N=206	7.0 (4.0, 12.0)	5.0 (3.0, 9.0)	**0.001**	**0.002**	HRCT Fibrosis median (IQR) N=113	6.0 (3.0, 11.0)	4.0 (2.0, 7.0)	**0.031**	**0.028**

Table 1. Lung function z-scores and High-Resolution CT (HRCT) scores at baseline (within 2 weeks of TB treatment) and 6 months after TB treatment. P-values show statistical significance using the Wilcoxon rank-sum test. If not already accounted for in the z-score (which adjusts for age, sex, and height, and is race-neutral), adjustments were made for HIV, antiretroviral therapy, smoking, and alcohol with linear regression.

Conclusions: The baseline top neutrophil tertile cohort had significantly worse baseline lung obstruction, impaired gas exchange, and greater consolidation and fibrosis. At month 12, significant differences in consolidation and fibrosis persisted, while lung function differences were attenuated. Baseline neutrophils can be an important marker for persistent lung damage.

TBS-EP92 Features of lesions on PET-CT predict progression from subclinical TB to symptomatic TB disease, but interferon gamma release assays do not

S.T. Malherbe,[1] J. Shaw,[1] K. Urdahl,[2] D. Lewinsohn,[3] N. Du Plessis,[1] G. Walzl,[1] [1]South African Medical Research Council Centre for Tuberculosis Research and Division of Immunology, Stellenbosch University, Cape Town, South Africa, [2]Seattle Children's Research Institute and Departments of Paediatrics and Immunology, University of Washington, Seattle, United States of America, [3]Division of Pulmonary and Critical Care Medicine, Oregon Health and Science University and Portland Veterans Administration Medical Center, Portland, United States of America
e-mail: malherbe@sun.ac.za

Background: Understanding the progression or resolution of early and subclinical TB lesions are challenging due to lack of reference tests. Interferon gamma release assays (IGRAs) are considered the investigation of choice for latent tuberculosis (TB) infection. However, little is known about IGRA in subclinical TB, and there is no validated classification system for subclinical TB lesions.
We investigated the association between IGRA status after TB exposure, characteristics of subclinical TB lesions on FDG PET-CT, and progression to clinical TB disease, in South Africa, one of the WHO high TB burden countries.
Methods: A prospective cohort study was conducted from July 2020 - July 2024. We recruited adult household contacts of people recently diagnosed with pulmonary TB, and people from the same community with no known exposure (controls). Those with HIV or prior TB were excluded. Active TB was excluded with symptom screen, sputum MGIT culture, Xpert Ultra, and Chest X-ray. All participants had IGRA, and a subset had FDG PET-CT. Participants were followed up for a minimum of 12 months.
Results: Most participants were IGRA positive irrespective of TB exposure: 249/308 (80.8%) contacts; 103/143 (72.0%) controls. 64/282 (22.7%) were PET-CT positive for subclinical TB: 52 (27.2%) contacts ($p=0.003$); 12 (13.2%) controls. Nine (3.2%) participants progressed to symptomatic pulmonary TB over a median of 12 months (range 3-38); 8 were originally PET-CT positive

(p<0.001). IGRA status did not predict subclinical TB on PET-CT or progression to symptomatic pulmonary TB; nor did the unstimulated (nil) or the TB-antigen stimulated interferon gamma levels. Multiple-nodular patterns on CT and high FDG avidity on PET were most strongly associated with progression to clinical TB.
Conclusion: The prevalence of PET-CT-defined subclinical TB was high in community members and TB contacts and predicted progression to active TB disease, but IGRAs failed at both outcomes.

TBS-EP95 The expansion of an immune-evasive Mycobacterium tuberculosis subclade of lineage 2 in Lima, Peru

C. Huang,[1] L. Leonid,[2] X. Tovar,[3] C. Contreras,[2] J. Jimenez,[2] R. Yataco,[2] K. Tintaya,[2] R. Calderon,[4] N. Howard,[5] M. Mendoza,[2] Q. Liao,[6] M. Murray,[3] [1]Brigham and Women's Hospital, Division of Global Health Equity, Boston, United States of America, [2]Socios En Salud, Socios En Salud, Lima, Peru, [3]Harvard Medical School, Department of Global Health and Social Medicine, Boston, United States of America, [4]Universidad de San Martin de Porres, Lima, Peru, [5]Harvard T.H. Chan School of Public Health, Boston, United States of America, [6]University of North Carolina at Chapel Hill, Chapel Hill, United States of America
e-mail: chuang17@bwh.harvard.edu

Household-based studies of tuberculosis transmission often use tuberculin skin test (TST) conversion among contacts to infer transmissibility. However, whether these household-level metrics truly reflect broader population dynamics remains unclear.
To investigate this, we conducted two prospective cohort studies in Lima, Peru with 10 years apart (2009–2012 and 2020–2022). In the earlier cohort, we enrolled 4,044 individuals with pulmonary TB and 14,044 of their household contacts (HHCs), following the latter for one year to assess incident TB infection via TST conversion. The later cohort enrolled 2,000 TB patients.
Whole-genome sequencing was performed on 3,567 isolates from the first cohort and 1,765 from the second. We focused on a specific subclade of Mycobacterium tuberculosis Lineage2 (exp-L2), assessing its transmissibility relative to other L2 strains (non-exp-L2) using two indicators:
1. The risk of TST conversion among exposed HHCs in the first cohort;
2. Changes in its population prevalence in over 10 years.
Among 222 initially TST-negative HHCs exposed to L2 strains, those exposed to exp-L2 (n=112) had a significantly lower risk of TST conversion (P=0.016) compared to those exposed to non-exp-L2 strains (N=110). Paradoxically, the prevalence of exp-L2 nearly doubled—from 6.6% to 12.6%—during the ten years. Immunological studies suggest that exp-L2 infection induces hypo-inflammatory transcriptional responses in macrophages. In an aerosol infection model using C3HeB/FeJ mice, exp-L2-elicited T cells produced lower levels of protective Th1 cytokines IFN-γ and TNF-α in response to Mtb-specific antigens, compared to non-exp-L2 infection. These features may facilitate immune evasion and lead to under-detection by both household-based and routine TB control programs.
Individuals infected with exp-L2 may be less likely to receive TB preventive therapy due to false-negative TST results. These findings suggest that the exp-L2 may gain a selective advantage via immune evasion, allowing it to escape TST-based detection and intervention under current TB control strategies.

TBS-EP98 Molecular profiles and functional dynamics of monocyte mRNAs across TB infection spectrum

R. Bethunaickan,[1] P. Sampath,[2] M. Moorthy,[3] B. Syed,[2] M. Dhanapal,[2] N. Alangudi Palaniappan,[1] S. Hissar,[1] G. Ramaswamy,[4] U.D. Ranganathan,[2] [1]ICMR-National Institute for Research in Tuberculosis, Chennai, India, [2]ICMR-National Institute for Research in Tuberculosis, Immunology, Chennai, India, [3]Theracues Innovations Pvt. Ltd, Bangalore, India, [4]Theracues innovations Pvt. Ltd, bioinformatics, Bangalore, India
e-mail: bramalingam@gmail.com

Background: Monocyte expansion and altered subset frequencies in TB, as observed through phenotypic and transcriptomic studies, are closely associated with disease severity, heightened inflammation, and immune dysregulation. Building on these findings, we hypothesize that monocyte-driven molecular signatures could provide valuable insights into the underlying pathophysiology, regulatory mechanisms across the TB spectrum, towards identifying the biomarkers and monocyte directed therapeutics.
Methods: We sorted total monocytes including all three subsets (HLA-DR+CD14+, HLA-DR+CD14+CD16+, and HLA-DR+CD16+cells) from peripheral blood mononuclear cells of healthy and TB-infected and diseased (latent TB [LTB], pulmonary drug-sensitive TB [DS-TB] and pulmonary drug-resistant TB [DR-TB]) individuals through flow cytometry and subjected to Illumina-based mRNA sequencing. Gene co-expression modules were constructed using Weighted Gene Co-Expression Network Analysis and organized into functional clusters using k-means clustering. Module clusters were annotated for functional enrichment using large language models.
Results: The analysis identified 7,749 differentially expressed genes across all group comparisons, with 5,729 upregulated and 2,020 downregulated. The transcriptomic landscape of active TB revealed marked hyperactivation of multifunctional pathways, contrasting with their

suppression in LTB. Enrichment analyses highlighted significant upregulation of immune-related pathways, cell migration dynamics, secretory functions, cell death signalling, ER stress, and oxidative responses in active pulmonary TB, underscoring critical shifts in monocyte gene functionality.
Notably, DR-TB showed a distinct inflammatory secretory signature, with a parallel reduction in classical monocyte gene expression, suggesting a coordinated shift in monocyte functional programming. WGCNA identified 33 co-expression modules organized into 5 functionally distinct clusters. Trajectory analysis revealed disease-specific expression patterns. Our biomarker analysis identified several genes with potential diagnostic value, of which 35 (32 for DS-TB and 3 for DR-TB) were bioinformatically validated as treatment-responsive biomarkers through comparison with public datasets.
Conclusion: These findings highlight how monocyte functional states are systematically altered and provide insights into host-pathogen interactions across the TB disease spectrum.

TBS-EP101 Improving the efficiency of drug resistant tuberculosis treatment trials: A time-to-event alternative marker for bacteriological response and adaptive minimization for randomization

A. Van Rie,[1] E. De Vos,[1] S. Abrams,[1] [1]Global Health Insitute, Faculty of Medicine, University of Antwerp, Antwerp, Belgium
e-mail: annelies.vanrie@uantwerpen.be

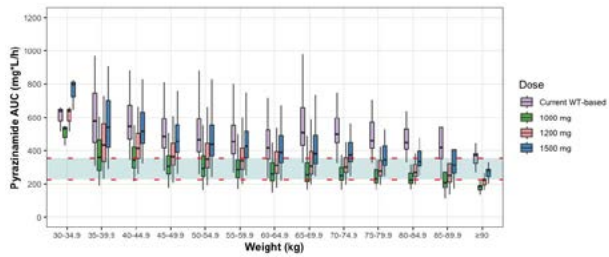
Background: Establishing the efficacy of new rifampicin-resistant tuberculosis (RR-TB) treatments is challenging due to the long-term clinical endpoint of relapse-free survival. We aimed to evaluate the effect of an alternative indicator of treatment response on sample size requirements and the use of a minimization strategy for randomization.
Methods: Sample size estimates were compared between a commonly used endpoint of proportion of patients achieving stable culture conversion at 12 weeks (SCC_{12}) and a novel indicator of treatment response based on a model of changes in mycobacterial load (MBL) over time. The non-linear mixed effects model, calibrated using data from an RR-TB cohort, included a longitudinal MBL decline, a probabilistic component for mycobacteria presence in sputum, and a time-to-event model for culture positivity. Data were simulated for a prespecified treatment effect to compare the power of detecting the treatment effect for various sample sizes when using either the SCC_{12} endpoint or the novel alternative change in MBL indicator of treatment response. Additionally, the impact of random patient allocation versus a minimization strategy for randomization on covariate imbalance was assessed.
Results: To achieve 80% power, 410 individuals were needed using the commonly used SCC_{12} endpoint versus 110 participants when using the non-linear mixed effects MBL model, corresponding to a 73% reduction in sample size. A small sample size results in high baseline covariate imbalance with random treatment group allocation, with a median relative imbalance of 0.104 for 110 participants versus 0.053 for 410 participants. This imbalance was reduced to 0.036 for 110 participants when an adaptive minimization procedure was implemented.
Conclusion: Using a model of MBL changes over time as an alternative indicator of treatment response, combined with a minimization procedure during the randomization process, significantly reduced the sample size. This approach could, if validated, enhance the efficiency of RR-TB clinical trials design.

TBS-EP104 Assessment of effect of weight on pyrazinamide pharmacokinetics in support of flat dosing in adults with TB

S. Hwang,[1] Q. Wang,[1] P. Van Brantegem,[1] R. Savic,[1,2] [1]Department of Bioengineering and Therapeutics, Schools of Pharmacy and Medicine, University of California, San Francisco, San Francisco, United States of America, [2]UCSF Center for Tuberculosis, University of California, San Francisco, San Francisco, United States of America
e-mail: sejung.hwang@ucsf.edu

Background: The current dosing regimen of pyrazinamide for tuberculosis is based on body weight derived from concerns at higher doses. The largest pyrazinamide exposure-response and safety analysis was performed and showed that weight was not a clinically significant predictor of clearance, suggesting the validity of a 1,000 mg flat dose. However, according to the analysis, the bioavailability of pyrazinamide was affected by dose levels preventing a clear evaluation of the weight effect on clearance which is influenced by bioavailability.
Therefore, we aimed to demonstrate the effect of weight on pyrazinamide pharmacokinetics (PK) using flat dosing data excluding the dose effect and to strengthen the dosing strategy for adults with tuberculosis.
Methods: Data from three phase 2 clinical trials (NC-002, NC-005, and SimpliciTB) and one phase 3 clinical trial (STAND) were used to develop the population PK modeling. Population PK modeling was performed using NONMEM and linear, power, and piecewise linear relationship were explored to explain the weight effect on PK parameters. We compared the proportion of participants within therapeutic window across the current weight-based and flat dosing strategies.
Results: A total of 820 participants with 1500 mg flat dose were included. The PK of pyrazinamide was appropriately explained by a one-compartment model, first-order absorption with lag time, and first-order elimination. The

effect of weight on clearance and volume of distribution was best described by a linear relationship, indicating that the clearance increases by approximately 11% for every 10 kg increase in body weight. The flat dosing of pyrazinamide with 1,000 mg achieved 55% of participants within the therapeutic window while current weight-based dosing achieved 12%.



Conclusions: This analysis indicated that the effect of weight on pyrazinamide PK was not significant factor to justify weight-based dosing and a flat dosing of pyrazinamide with 1,000 mg once-daily would be appropriate.

TBS-EP107 Impact of nutritional support on transcriptomics of persons with latent tuberculosis infection: Why does nutritional support prevent TB?

E. Johnson,[1] A. VanValkenburg,[1] P. Sinha,[2] P.B.N. Prakash Babu Narasimhan,[3] M. Dauphinais,[2] K. Jain,[3] S. Lakshminarayanan,[3] L. Locks,[2] [1]Rutgers University, Newark, United States of America, [2]Boston University, Boston, United States of America, [3]Jawaharlal Institute of Postgraduate Medical Education and Research, Pondicherry, India
e-mail: wj183@njms.rutgers.edu

Background: Nutritionally acquired immunodeficiency is a recognized risk factor for progression from latent tuberculosis infection (LTBI) to active TB disease. Emerging evidence indicates nutritional support can reduce incident TB in household contacts, though the underlying mechanisms remain unclear.
Methods: The TB LION study prospectively followed a cohort of household contacts with LTBI in southern India. Undernourished participants (BMI <18.5 kg/m²) received nutritional supplementation consisting of a food basket (2600 kcal/day and 80g protein/day for adults; half for children under 13 years) and multivitamins. Enough food was provided for the entire household for a duration of 6 months. Helminth-infected participants received antihelminthic treatment. Bulk RNA-seq was performed on blood samples from 98 participants at baseline and after 6 months. Data analyses included dimensionality reduction, differential expression via limma, Ingenuity Pathway Analysis (IPA), and assessment of TB progression risk signatures (RISK4 and PREDICT29) using TBSignatureProfiler.
Results: Undernourished participants exhibited distinct baseline transcriptomic profiles compared to well-nourished controls, characterized by elevated proinflammatory gene expression, particularly in the interferon-gamma signaling pathway. Post-intervention analyses showed downregulation of TB progression-associated genes (C1QA, SERPING1, SIGLEC1) and reduced expression of the inflammation-centric RISK4 signature, though the PREDICT29 signature remained unchanged. Pathway analysis indicated decreased interferon-alpha signaling and attenuated TLR7 and TLR9 signaling, suggesting enhanced antigen presentation and autophagy following nutritional supplementation.

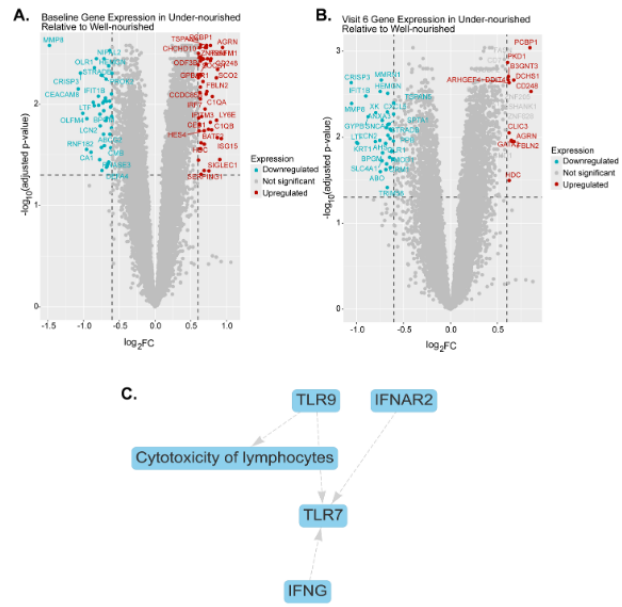


Figure overview: Differentially expressed genes (DEGs) from undernourished individuals (BMI < 18.5) relative to well-nourished individuals at baseline (A) and after nutritional intervention (B). DEGs between baseline and post-nutritional intervention were analyzed with Qiagen's IPA and decreased interferon alpha and gamma signaling was associated with nutritional intervention (C).

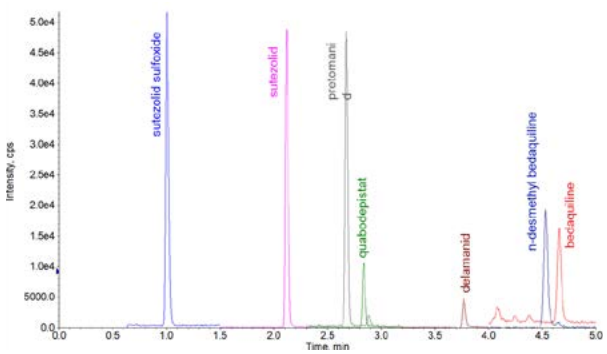
Conclusion: Malnourished individuals with LTBI demonstrate proinflammatory transcriptomic profiles distinct from their well-nourished counterparts. Nutritional support modulates these profiles, promoting changes associated with improved innate and adaptive immune responses that may reduce TB progression risk.

TBS-EP110 Bioanalytical strategies to support the development of novel anti-TB drug regimens

E. Wickremsinhe,[1] D. Holtzman,[1] J. Plomley,[2] D. Qasrawi,[2]
[1]Gates Medical Research Institute, Cambridge, United States of America, [2]Altascience, Quebec, Canada
e-mail: enaksha.wickremsinhe@gatesmri.org

Background: Generating pharmacokinetic data for clinical trials and regulatory submissions often involves multiple validated analytical methods. In the recent multi-drug multi-regimen PAN-TB trial, three distinct LC-MS/MS assays were required, complicating scheduling and logistics, and significantly increasing analytical costs and timelines. Developing a single, multi-analyte assay presents analytical challenges but offers substantial benefits, including reduced operational complexity, lowers analytical costs, expedites analyses, and reduces blood volume requirements for participants.
Design/Methods: A single LC-MS/MS method was developed and validated to simultaneously quantify key drugs in novel regimens: pretomanid, delamanid, quabodepistat, sutezolid, sutezolid sulfoxide, bedaquiline, and n-desmethyl bedaquiline. Sample preparation involved protein precipitation, followed by chromatographic separation on a Synergi Polar RP column. Detection was performed using a SCIEX API 6500+ with positive ion MRM scans across five scanning periods to optimize peak resolution and achieve the required LLOQ. Stable isotope-labeled internal standards were used except for quabodepistat. All compounds were sourced from commercial suppliers.
Results: Simultaneous chromatographic separation of seven analytes with a wide range of physicochemical properties (cLogP from -0.1 to 7.2) was achieved within an 8-minute run time. The validated assay range for all analytes was 10–10,000 ng/mL. Between-run accuracy ranged from 95.8% to 106.6%, and precision from 1.3% to 9.8%. Stability was confirmed for all analytes in whole blood (2 hours on wet ice), plasma (12 hours at 4°C), through three freeze-thaw cycles, and for 84 hours post-extraction at 4°C. The efficiencies of this assay will be highlighted and compared with the execution of multiple assays.



Conclusions: This work demonstrates the successful development and validation of a robust multi-analyte LC-MS/MS assay capable of supporting the pharmacokinetic evaluation of novel TB regimens. The method accommodates a broad range of analyte properties and offers significant advantages in terms of efficiency, cost, and minimizing blood volumes.

TBS-EP113 Genotypic-phenotypic discordance and emerging drug resistance in rifampicin-resistant extrapulmonary tuberculosis

M. Singh,[1] P. Jain,[2] R. Garg,[1] U. Singh,[2] R. Ratnam,[2] S. Yadav,[1]
[1]Department of Respiratory Medicine King George's Medical University, Lucknow, India, [2]Department of Microbiology, King George's Medical University, Lucknow, India
e-mail: rathorems0501@gmail.com

Background: Rifampicin-resistant extrapulmonary tuberculosis (RR-EPTB) presents diagnostic and therapeutic challenges due to its paucibacillary nature and limited availability of extended drug susceptibility testing (DST). This study aimed to characterize resistance profiles in culture-confirmed RR-EPTB cases using phenotypic and genotypic
Methods: This prospective study included 31 culture-positive RR-EPTB isolates from the Intermediate Reference Laboratory, King George's Medical University, Lucknow. Phenotypic DST was performed using the BACTEC MGIT 960 system for isoniazid (INH), pyrazinamide (PZA), moxifloxacin (MOX), bedaquiline (BDQ), delamanid (DLM), pretomanid (PTM), and linezolid (LZD). Genotypic resistance was determined using MTBDRplus and MTBDRsl line probe assays (Hain Lifescience), targeting mutations in *katG*, *inhA*, *gyrA*, *gyrB*, *rrs*, and *eis* genes.
Results: All 31 isolates were resistant to rifampicin and isoniazid, confirming MDR-TB. Phenotypic resistance was observed for PZA in 13 (41.9%), MOX in 11 (35.4%), BDQ in 2 (6.5%), and PTM in 2 (6.5%) isolates; all were susceptible to LZD and DLM.
Among INH-resistant isolates, *katG* mutations were seen in 21 (67.7%), *inhA* in 4 (12.9%), and both in 6 (19.3%). LPA detected fluoroquinolone resistance-associated mutations in 16 (51.6%) isolates, while phenotypic MOX resistance was found in 11 (35.4%). One isolate showed second-line injectable resistance. Based on combined findings, 16 (51.6%) were pre-XDR and 2 (6.5%) XDR-TB.
Conclusion: A significant proportion of RR-EPTB isolates showed additional resistance to fluoroquinolones and newer agents such as BDQ and PTM. Discordance between genotypic and phenotypic resistance to fluoroquinolones highlights the need for both methods. Routine second-line DST, including newer drugs, is essential for personalized RR-EPTB management.

Keywords: RR-EPTB, MDR-TB, Pre-XDR-TB, XDR-TB, Line Probe Assay, DST, Fluoroquinolone, Bedaquiline

TBS-EP116 Urine LAM quantification using ultrasensitive single-molecule counting technology: A novel approach for improved tuberculosis diagnosis and treatment monitoring

C. Le,[1] J. Nguyen,[1] E. Zheng,[1] H. Ramachandraiah,[2] N. Nolan,[1] R. Tobias,[1] F. Zaugg,[1] P. Wagner,[1] V. Brachet,[1] J. Sandlund,[1] [1]Fluxus, Inc., Sunnyvale, United States of America, [2]FIND, Geneva, Switzerland
e-mail: jsandlund@fluxus.bio

Background: There is a need for rapid and sensitive non-sputum diagnostic tools for pulmonary and extrapulmonary tuberculosis (TB) in all patient populations. Lipoarabinomannan (LAM), a mycobacterial glycolipid, is a validated TB biomarker in urine, particularly in people living with HIV.
However, LAM concentrations in patient samples are typically very low and existing assays have limited sensitivity. Quantitative, ultrasensitive detection of LAM may enable a novel approach for diagnosis and treatment monitoring.
Methods: An ultrasensitive LAM assay was developed using Fluxus' single-molecule counting platform, which integrates optics and microfluidics for biomarker detection. Limits of detection (LoD) and quantification (LoQ), dilution linearity, intra- and interassay precision, spike recovery, and matrix compatibility were determined.
Clinical sample testing was performed using biobanked specimens from ten adults with suspected TB; patient sputum samples had been tested for presence of *M. tuberculosis* using smear microscopy, culture, and nucleic acid amplification test, and urine LAM concentration had been quantified using electrochemiluminescence assay. Testing in larger cohorts is ongoing.
Results: LoD and LoQ were 0.068 and ~2 pg/mL, respectively, with a >5-log dynamic range. Mean spike recovery across 0.01–100 ng/mL was 106%, and dilution linearity was 102%. Intraassay and interassay CVs averaged 7.4% and <15%, respectively. No crossreactivity was observed with *Mycobacterium smegmatis* LAM.
LAM was detected in urine from all patients with microbiologically confirmed TB (n=4) and not detected in non-TB patients (n=6), and concentrations were comparable to those observed using electrochemiluminescence.
Conclusions: Fluxus' ultrasensitive LAM assay demonstrates strong analytical performance and sub-pg/mL sensitivity. The assay detected LAM in urine from all patients with TB and was negative in all non-TB patients, and concentrations were comparable to those observed with a quantitative method. Fluxus' platform supports the development of a non-sputum tool for TB diagnosis and treatment monitoring, addressing a critical gap in high-burden, resource-limited settings.

TBS-EP119 Development of a CRISPR-Cas13a based SNP assay for detection of bedaquiline resistance in *Mycobacterium tuberculosis*

M.K.J.R. Mendoza,[1] C. Pangilinan,[1] S.M. Geganzo,[2] J.M. Cuales,[1] J.M. Bislumbre,[1] J.M.L. Majaducon,[1] M. Kato Maeda,[3] R.V. Destura,[1,2] [1]University of the Philippines-National Training Center for Biosafety and Biosecurity, Manila, Philippines, [2]University of the Philippines-National Institutes of Molecular Biology and Biotechnology, Manila, Philippines, [3]University of California San Francisco, San Francisco, California, United States of America
e-mail: mbmendoza7@up.edu.ph

Bedaquiline (BDQ) treatment for multidrug-resistant (MDR) and extensively drug-resistant (XDR) tuberculosis began in the Philippines in June 2016. Single nucleotide polymorphisms (SNPs) in the *atpE* gene, particularly Ala63Pro (A63P; GCA→CCA), are linked to BDQ drug resistance. Development of detection tools for SNP based drug resistance still posed challenges in molecular diagnostics. To address this, Specific High Sensitivity Enzymatic Reporter UnLOCKing (SHERLOCK) was utilized to enable SNP detection dependent on CRISPR-Cas13a system and programmable rational crRNA design. This study aimed to develop CRISPR-Cas13a-based SHERLOCK fluorescence assay for rapid and specific detection of A63P mutation.
Three rational crRNA designs were generated through optimized in-house overlap extension PCR and invitro transcription protocol. Their discriminatory ability was evaluated using synthetic wild-type (WT) and mutant (MT) RNA, with SHERLOCK fluorescence monitored over 2 hours at 5-minute intervals. The mutant-to-wild-type signal ratio (MT/WT) was calculated to determine crRNA performance across time points. All endpoint SHERLOCK reactions were confirmed via electrophoresis to visualize cleaved RNA.
crRNA2 exhibited the highest discriminatory power, achieving a signal ratio of 14.88 at 30 minutes(N=3), compared to 3.90 for crRNA1(N=3) and 2.20 for crRNA3(N=3). Although the other two designs can effectively discriminate, crRNA2 was chosen for assay simplification integrating T7 transcription and SHERLOCK-Cas13a detection in one reaction allowing DNA as starting input. Optimization of SHERLOCK components enabled this conversion to one-step detection, yielding a signal ratio of 4.34 at 30 minutes (N=3). Notably, higher DNA input allowed fluorescence-based differentiation between WT and MT as early as 5 minutes offering flexibility in reducing detection time dependent on the assay sensitivity requirements.

These findings demonstrate the potential of a CRISPR-Cas13a SHERLOCK assay via a programmable crRNA rational design for SNP-based BDQ resistance testing. Furthermore, the platform shows potential for application for the detection of other *Mtb* genes harboring SNPs linked to drug resistance.

TBS-EP122 Breaking the TB Cycle: AI-driven mobile X-ray screening with CAD4TB enhances early detection in high-risk coal mining communities of Punjab, Pakistan

Q. Mehmood,[1] I. Ahmed,[1] M. Sohail,[1] B. Ahmed,[1] N. Munir,[1] F. Fayyaz,[1] [1]Provincial TB Control Program Punjab, Lahore, Pakistan
e-mail: sppo@ptp.gop.pk

Summary: A 2024 study in Punjab, Pakistan, used AI-powered mobile X-ray screening (CAD4TB) to detect TB among 34,500 coal miners, revealing a prevalence of 522 per 100,000—nearly double the national incidence. This underscores AI's role in early TB detection and supports targeted interventions.

Background: Tuberculosis (TB) poses a significant occupational health risk for coal miners in Pakistan, with Punjab accounting for 55–60% of the national TB burden (277 per 100,000) [1]. Punjab province accounts for approximately 55-60% of this burden, with 290,000 cases reported in 2024 (Provincial TB Control Program, Punjab, 2024). Miners face heightened risks from silica dust exposure and limited healthcare access. Globally, TB prevalence in mining communities ranges from 1,200–2,500 per 100,000 [2]. This study evaluates AI-assisted active case finding (ACF) using mobile X-ray screening with CAD4TB to enhance early TB detection in this high-risk group.

Design/Methods: In 2024, a cross-sectional study screened 34,500 coal miners across Punjab using mobile X-ray units with CAD4TB, a deep-learning tool for TB detection. X-rays scoring ≥60 were flagged for GeneXpert MTB/RIF testing. Risk factors, including silica exposure and healthcare access, were documented, aligning with WHO screening guidelines [3].

Results: Of 7,260 X-rays analyzed, 1,704 (23.5%) were flagged, leading to 180 confirmed TB cases (prevalence: 522 per 100,000), nearly double the national incidence (277 per 100,000). The case detection rate was 10.6%, with silica exposure and poor healthcare access as key risk factors, consistent with global mining trends [2,4].

Conclusions: The high TB prevalence among coal miners supports their classification as a high-risk group under WHO guidelines. AI-driven mobile screening offers a scalable, high-impact approach for early detection. Policy recommendations include silica dust mitigation and nationwide AI-assisted ACF, aligning with WHO's End TB Strategy to enhance Pakistan's TB control [5].

Parameter	Value / Finding
Study Population	Coal Miners, Punjab
Total Individuals Screened	34,500
Individuals with CXR suggestive of TB (CAD4TB Score ≥60)	1,704 (4.94% of screened)
Bacteriologically Confirmed TB Cases (via Xpert MTB/RIF)	180
Yield among Presumptive Cases (Confirmed TB / CAD4TB ≥60)	10.6%
Prevalence of Confirmed TB among Screened Coal Miners	522 per 100,000
National TB Incidence (Pakistan, WHO 2024)	277 per 100,000
Relative Burden in Coal Miners vs. General Population	1.89 times higher
Key Technology Utilized	Mobile Digital X-ray, CAD4TB (AI), GeneXpert MTB/RIF

TBS-EP125 Treatment of chronic pulmonary cavitary aspergillosis using an endobronchial valve and local antifungal therapy

O. Lovacheva,[1] I. Vasilyeva,[1,2] E. Veselova,[3] T. Naumova,[3] A. Gracheva,[3] A. Samoylova,[1] A. Gaida,[4] [1]Federal State Budgetary Institution „National Medical Research Center for Phthisiopulmonology and Infectious Diseases" of the Ministry of Health of the Russian Federation, Scientific Department of Diagnostics and Differential diagnosis of Tuberculosis and combined infections, Moscow, Russian Federation, [2]Pirogov Russian National Research Medical University, Department of Phthisiology, Moscow, Russian Federation, [3]Federal State Budgetary Institution „National Medical Research Center for Phthisiopulmonology and Infectious Diseases" of the Ministry of Health of the Russian Federation, Москва, Russian Federation, [4]Federal State Budgetary Institution „National Medical Research Center for Phthisiopulmonology and Infectious Diseases" of the Ministry of Health of the Russian Federation, Moscow, Russian Federation
e-mail: nsovca@yandex.ru

Introduction: Aspergillosis can affect cavitary lung lesions that develop after infectious diseases, often tuberculosis. Sometimes, fungal growth within the cavity progresses to form a mycetoma, which is clearly visible on computed tomography (CT) scans of the lungs. Aspergillosis impedes the healing of cavitary lesions, even if the preceding infection has resolved favorably. Patients with chronic pulmonary cavitary aspergillosis (CPCA) may experience various respiratory and constitutional symptoms, including dyspnea, persistent cough, hemoptysis, sputum production, chest discomfort, weight loss, fatigue, and general malaise.

Treatment for CPCA involves long-term (4–12 months) antifungal therapy with a high risk of adverse effects or surgical intervention.

Objectives: This study explored the possibility of treating CPCA using local antifungal drug administration combined with endobronchial valve (EBV) placement.

Materials and Methods: Six patients with CPCA in post-tuberculosis lung cavities were treated. The diagnosis was confirmed by laboratory testing (Aspergillus was detected in lavage fluid from the cavity). Drug susceptibility of the pathogen was determined.
Treatment involved EBV (MedLung, Russia) placement via fiberoptic bronchoscopy into the lobar, zonal, or segmental bronchus draining the CPCA cavity. After 3–6 days, a single daily intravenous dose of antifungal medication (10 mL) was administered once through a plastic catheter into the space distal to the EBV during repeat bronchoscopy.
Results: In five patients, the cavity healed within three months. One patient retained a thin-walled cavity. CPCA was successfully treated in all six patients, as confirmed by CT and laboratory tests.
Conclusions: Successful CPCA treatment is facilitated by high local antifungal drug concentrations and prolonged direct exposure to Aspergillus, achieved through combined EBV placement and localized antifungal administration.

TBS-EP128 Diagnostic accuracy of a novel high-sensitivity urine LAM assay

A. Andama,[1] W. Worodria,[1] R. Crowder,[2] S. Yerlikaya,[3] P. Nahid,[2] C. Denkinger,[3] A. Cattamanchi,[2,4] G. Theron,[5]
[1]Makerere University College of Health Sciences, Kampala, Uganda, [2]University of California San Francisco, San Francisco, United States of America, [3]Heidelberg University Hospital, German Center of Infection Research, Heidelberg, Germany, [4]University of California Irvine, Irvine, United States of America, [5]DSI-NRF Centre of Excellence for Biomedical Tuberculosis Research, South African Medical Research Council Centre for Tuberculosis Research, Division of Molecular Biology and Human Genetics, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa
e-mail: andamaalf@gmail.com

Lipoarabinomannan (LAM) is a tuberculosis (TB) biomarker detected in urine, but the current commercially available urine LAM test has low sensitivity and is recommended only for TB diagnosis in people living with HIV (PLHIV). A next generation LAM prototype leverages a novel sample pre-treatment, sample concentration and advanced lateral flow assay to increase sensitivity.
Between October 2024 and February 2025, we enrolled consecutive people ≥12 years old with presumptive TB (based on having cough ≥2 weeks or being HIV-positive with C-reactive protein >5 mg/L) at outpatient health centers in Kampala, Uganda and Cape Town, South Africa.
Participants provided urine for next generation LAM prototype (Ref. 08FK60) and Determine TB LAM Ag (Determine LAM; Abbott, USA) testing and sputum for Xpert MTB/RIF Ultra and two MGIT cultures. Diagnostic accuracy of the LAM prototype was assessed against sputum-based reference standards and compared it with Determine LAM.
Among 192 participants (median age 36, 52% female, 36% PLHIV, 14% living with diabetes), 3 (1.6%) test results were invalid on the first LAM prototype test, but all returned valid test results after repeat testing. Prototype LAM sensitivity was 53.5% (23/43, 95% confidence interval [CI] 37.7-68.8) against culture and 63.2% (24/38, 95% CI 46.0-78.2) against Xpert Ultra. Specificity exceeded 98% against both reference standards. The LAM prototype had higher sensitivity (53.5% vs. 11.6%, difference +41.9%, 95% CI 24.8-58.9) and specificity (99.2% vs. 94.0%, difference +5.0%, 95% CI 0.2–10.3) than Determine LAM. It performed better in PLHIV compared to in HIV-negative participants (sensitivity against culture 72.7% vs. 46.9%). However, accuracy of the LAM prototype exceeded Determine LAM in both subgroups.
This next generation LAM prototype demonstrated improved sensitivity and specificity over the current LAM test and has potential for broader use in TB diagnosis. Further evaluation of its usability and performance in diverse settings is warranted.

	Next generation LAM prototype		Determine TB LAM		Difference in sensitivity	Difference in specificity
	Sensitivity	Specificity	Sensitivity	Specificity		
Reference standard: MGIT culture						
Overall	23/43 (53.5%, 37.7-68.8)	132/133 (99.2%, 95.9-100)	5/43 (11.6%, 3.9-25.1)	125/133 (94.0%, 88.5-97.4)	+41.9% (24.8-58.9)	+5.3% (0.2, 10.3)
HIV-positive	8/11 (72.7%, 39.0-94.0)	50/51 (98%, 89.6-100)	2/11 (18.2%, 2.3-51.8)	47/51 (92.2%, 81.1-97.8)	+54.5% (16.0-93.1)	+5.9% (-4.5, 16.3)
HIV-negative	15/32 (46.9%, 29.1-65.3)	82/82 (100%, 95.6-100)	3/32 (9.4%, 2.0-25.0)	78/82 (95.1%, 2.0-25.0)	+37.5% (17.6-57.4)	+4.9% (-1.0, 10.8)
Reference standard: Sputum Xpert Ultra						
Overall	24/38 (63.2%, 46.0-78.2)	145/147 (98.6%, 95.2-99.8)	5/38 (13.2%, 4.4-28.1)	139/147 (94.6%, 89.6-97.6)	+50.0% (31.5, 68.5)	+4.1% (-0.8, 8.9%)
HIV-positive	8/8 (100%, 63.1-100)	57/59 (96.6%, 88.3-99.6)	2/8 (25.0%, 3.2-65.1)	55/59 (93.2%, 83.5-98.1)	+75.0% (32.5-117.5)	+3.4% (-6.4, 13.2)
HIV-negative	16/30 (53.3%, 34.3-71.7)	88/88 (100%, 95.9-100)	3/30 (10.0%, 2.1-26.5)	84/88 (95.5%, 88.8-98.7)	+43.4% (22.3-64.4)	+4.5% (-0.9, 10.0)

TBS-EP131 Host and pathogen diversity influence the efficacy of tyrosine kinase inhibitor–based host-directed therapies in tuberculosis

L.D. Tientcheu,[1,2] N. Top,[1] D. Grint,[2] A. Coussens,[3] R.J. Wilkinson,[4] A. Rachow,[5] J. Sutherland,[1] B. Kapmann,[1,6] R. Wallis,[7] D. Kalman,[8] [1]MRC Unit The Gambia at LSHTM, Banjul, Gambia (Republic of The), [2]London School of Hygiene & Tropical Medicine, London, United Kingdom of Great Britain and Northern Ireland, [3]Infectious Diseases and Immune Defence Division, The Walter & Eliza Hall Institute of Medical Research, Melboune, Australia, [4]The Francis Crick Institute, London, United Kingdom of Great Britain and Northern Ireland, [5]Division of Infectious Diseases and Tropical Medicine, University of Munich, Munich, Germany, [6]Centre for Global Health, Charité Universitatsmedizin, Berlin, Germany, [7]Aurum Institute, South Africa, Johannesburg, South Africa, [8]Emory University, Atlanta, United States of America
e-mail: leopold.tientcheu@lshtm.ac.uk

Host-directed therapies (HDTs) offer a promising adjunctive strategy for tuberculosis (TB) treatment by enhancing host immunity and mitigating post-treatment pathology. However, the lack of a universally effective HDT reflects underlying variability in host immune responses and *the diversity of the Mycobacterium tuberculosis complex (MTBC) lineages*, factors often overlooked in translational research.

We evaluated the efficacy of tyrosine kinase inhibitors (TKIs), including Imatinib, Gefitinib, and Erlotinib, using an ex vivo monocyte infection model with clinical MTBC strains. Monocytes from 111 Gambian TB patients (3 months post-treatment) were infected (MOI = 1) with fluorescently labelled isolates representing Mtb-lineage2, Mtb-lineage4, *Mycobacterium bovis*, and West African *Mycobacterium africanum* lineages 5 and 6. Infected monocytes were treated or left untreated, and the intracellular bacterial burden was quantified by fluorescence over 7 days. Supernatants were assayed for 48 cytokines. Responders were defined as patients whose monocytes exhibited reduced bacterial fluorescence with TKI treatment compared to controls by day 7. Multivariable linear models with Bayesian information criterion (BIC)–based variable selection were used to identify clinical and immune correlates of TKI response.

Erlotinib achieved the highest proportion of responders (59%), followed by Gefitinib (36%) and Imatinib (27%). Erlotinib-mediated bacterial control was consistent across MTBC lineages, while response to Gefitinib and Imatinib varied markedly by lineage.

Distinct cytokine signatures were associated with TKI responsiveness: doubling of IL-12p70 and IL-13 levels predicted reduced response to Erlotinib and Gefitinib in Mtb-lineage 2 and Maf-lineage 6 infections, respectively. In contrast, male sex and elevated IL-7 were associated with enhanced response.

TKIs, particularly Erlotinib, show promise as HDT candidates across diverse MTBC lineages. However, their efficacy is modulated by both the host immune profile and the infecting MTBC strain. These findings underscore the need for precision-based HDT strategies that integrate host immune profiling and pathogen diversity to optimise TB treatment outcomes.

TBS-EP134 Nitroimidazole resistance amongst people with tuberculosis: A meta-analysis of prevalence and genotypic-phenotypic concordance

C. Nimmo,[1] R. Perumal,[2] J. Tulsi,[2] D. Chetty,[2] S.-h. Seo,[3] A. Wolf,[3] M. Larsen,[4] K. Naidoo,[2] M. O'Donnell,[3] [1]University College London, UCL Respiratory, London, United Kingdom of Great Britain and Northern Ireland, [2]Centre for AIDS Programme of Research in South Africa, Treatment Research, Durban, South Africa, [3]Columbia University Irving Medical Center, Division of Pulmonary, Allergy, and Critical Care Medicine, New York, United States of America, [4]Albert Einstein College of Medicine, Department of Microbiology & Immunology, New York, United States of America
e-mail: camus.nimmo@gmail.com

Background: Delamanid and pretomanid are nitroimadazoles licensed for the treatment of RR-TB, and their usage has increased rapidly over the last 5 years. Global rates of baseline and emergent resistance have not been evaluated. Targeted/whole genome sequencing is a potentially cost effective and scalable diagnostic for these drugs, but WHO mutation catalogue sensitivity for resistance is only 14.7%.

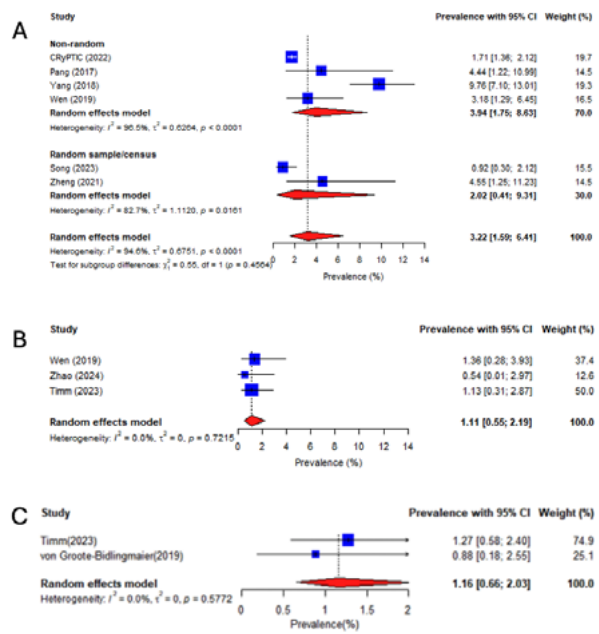
We report a meta-analysis of studies evaluating nitroimidazole resistance in patients and determine theoretical performance of a genomic resistance test utilising all mutations in candidate resistance genes (*fbiA/B/C/D*, *ddn*, *fgd1*).

Methods: The study protocol was registered in PROSPERO (CRD42023469823). We screened public databases for articles published up to April 2025. We included studies which reported nitroimidazole resistance by phenotyping and genome sequencing of *Mtb* isolates obtained from patients with RR-TB.

Results: The systematic search identified 914 abstracts, 866 of which were eligible for further screening. We reviewed 803 full texts and 30 studies met all inclusion criteria.

Amongst patients with RR-TB, pooled prevalence of baseline phenotypic delamanid resistance was 3.22% (95% CI 1.59%-6.41%) (**FigA**) and pretomanid resistance was 1.11% (0.55%-2.19%) (**FigB**). The pooled prevalence of treatment-emergent phenotypic nitroimidazole resistance amongst people with TB receiving a nitroimidazole-containing regimen was 1.16% (0.66%-2.03%) (**FigC**).

From the clinical isolates analysed, 3383 had ³1 mutation in a candidate gene, of which 255 were phenotypically resistant to delamanid. Sensitivity of candidate gene variants for delamanid resistance was 62.7% (255/407), specificity was 74.2% (9118/12491) and positive predictive value (PPV) was 7.5% (255/3383). *ddn* variants were more predictive of resistance (PPV 46.3%) than those in other genes, but occurred less frequently.



Conclusions: Nitroimidazole resistance prevalence in patients with RR-TB is 1-3%, and emergent resistance occurs in 1%. These rates originate from isolates collected before widespread nitroimidazole use for TB. Resistance-associated gene mutations do not explain >30% of clinical delamanid resistance.

TBS-EP137 Diagnostic performance of a new near-point-of-care assay to detect TB from tongue and sputum swabs

C. Mbuli,[1] J.B. Taya Fokou,[1] N.N. Mbuh,[1] N. Nyah Ndi,[2] I.A. Goupeyou Wandji,[3] T. Garg,[4] J. Creswell,[4] M. Sander,[1]
[1]Center for Health Promotion and Research, Research, Bamenda, Cameroon, [2]Cameroon Baptist Convention Health Services, Bamenda, Cameroon, [3]National Tuberculosis Program, Regional Technical Group, Cameroon, [4]Stop TB Partnership, Geneva, Switzerland
e-mail: cyrillembuli@gmail.com

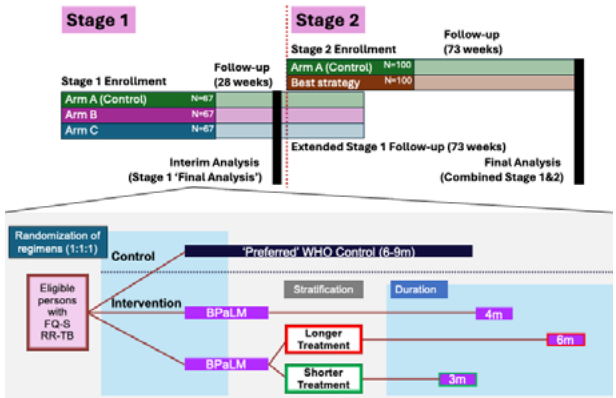
Background: New near point-of-care assays, including the MTB Nucleic Acid Test Card (Pluslife, China), have the potential to replace or complement existing rapid molecular diagnostics for TB in different settings and populations. Compared to existing rapid diagnostics, these new assays are less expensive, more portable, and designed to test tongue and sputum swab specimens. Evaluations of the diagnostic performance of these assays are needed.M
Methods: We conducted a prospective diagnostic accuracy study at five health facilities and in active case-finding (ACF) in two regions of Cameroon. Consecutive people ≥15 years with presumptive TB were recruited; each participant was asked to provide at least two tongue swabs (self or provider collected) and two sputum specimens.
We evaluated the diagnostic accuracy of the PlusLife tongue and sputum swabs against a sputum culture microbiological reference standard, as well as to comparators of sputum Xpert MTB/RIF Ultra and smear microscopy.
Results: From February to May 2025, 984 participants were recruited at health facilities (634) and community screening events (350), including 163 (17%) people living with HIV. Among participants, 818 (83%) chose supervised self-collection of tongue swabs. Among 138 people (14%) with TB detected on sputum Ultra, TB was detected on PlusLife from sputum swabs in 87% (77/89; 95%CI: 78-92%) at health facilities and 57% (28/49; 43-70%) in ACF; TB was detected in tongue swabs from 79% (70/89; 69-86%) at health facilities and 44% (22/50; 31-58%) in ACF. Performance evaluation compared to TB culture is ongoing.
Conclusion: As an inexpensive, highly portable assay, the PlusLife MiniDock MTB assay may facilitate increased access to molecular testing for TB with acceptable accuracy, especially among people seeking care at health facilities.

TBS-EP140 A multi-arm multi-stage trial design using desirability of outcome ranking and stratified medicine for MDR-TB

V. Hsu,[1] B. Aldana,[1] L. Chaisson,[1] J.-M. Do,[1] A. Austin,[1] K. Yang,[1] G.E. Velásquez,[1] P.P.J. Phillips,[1] [1]University of California, San Francisco, San Francisco, United States of America
e-mail: vera.hsu@ucsf.edu

Background: The 2025 WHO guidelines for treatment of multidrug-resistant tuberculosis (MDR-TB) include six 6-9 month regimens, yet all are cited as conditional recommendations with very low certainty of evidence. Drug toxicities remain an important concern and meta-analyses suggest that shorter treatment durations can be effective. Novel trial designs are needed to evaluate new regimens that can yield strong recommendations.
Methods: The PRISM-TB (NCT06441006) trial aims to identify, among participants with fluoroquinolone-susceptible-MDR-TB, the preferred BPaLM strategy for participants stratified to receive shorter (13 or 17 weeks) or longer treatment (17 or 24 weeks) based on risk criteria, and to evaluate whether this BPaLM strategy has noninferior 73-week efficacy to the control. PRISM has

a novel, seamless Phase 2/3 design that combines three innovative elements. First, four stratified treatment strategies are evaluated, testing two durations in each of two subgroups.
Second, a multi-arm multi-stage design is employed to select the preferred strategy, leading to faster results with fewer participants.
Third, a novel person-centered ordinal endpoint combining efficacy, safety, and tolerability is used in Phase 2 to guide progression to Phase 3, which uses a traditional 73-week endpoint.
Results: In Stage 1, 200 participants will be randomized to a standard-of-care control or one of two experimental arms, representing four possible treatment strategies. The primary endpoint uses desirability of outcome ranking (DOOR), combining efficacy at end of follow-up and safety at 28-weeks post-randomization. After DSMB review of the results, acceptability, and feasibility, one experimental strategy will advance to Stage 2, where 200 additional participants will be randomized between this strategy and the control. We expect 90% power to demonstrate noninferiority of the preferred strategy with a 12% noninferiority margin.

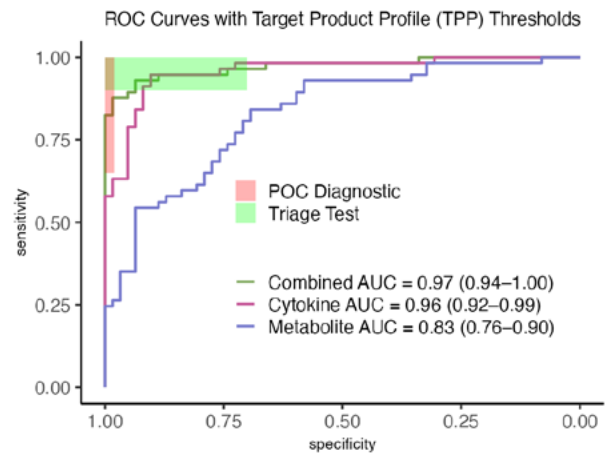


Conclusions: By implementing a staged and stratified design, PRISM-TB offers a novel approach that can efficiently identify and evaluate the optimal treatment duration for MDR-TB.

TBS-EP143 Machine learning of plasma multi-omics data distinguishes pulmonary tuberculosis from other respiratory infections

Z. Mousavian,[1] F. Nabeemeeah,[2] N.R. Gandhi,[1] R.R. Kempker,[1] M.J. Magee,[1] N. Martinson,[2] A.A. Sharma,[1] J.M. Collins,[1]
[1]Emory University, Atlanta, GA, United States of America, [2]University of the Witwatersrand, Johannesburg, South Africa
e-mail: zeinabosadat.mousavianhor@emory.edu

Novel blood-based biomarkers for tuberculosis (TB) are needed to develop rapid, point-of-care diagnostics. We applied an artificial intelligence (AI) approach using random forest feature selection on multi-omics data to identify a biomarker signature that differentiates pulmonary TB (PTB) from other respiratory infections in hospitalized and ambulatory persons with presumed TB.
We analyzed plasma samples from 391 adults (≥18 years) presenting with respiratory symptoms suggestive of TB, including 187 with PTB confirmed by Xpert MTB/RIF Ultra and/or *M. tuberculosis* sputum culture and 204 in whom PTB was excluded. The latter included 165 hospitalized participants and 39 people who had contact with someone with pulmonary TB. Plasma concentrations of 28 cytokines and 118 metabolites were integrated for biomarker discovery. Random forest models were trained on 70% of the dataset and evaluated on the remaining 30%.
Among participants with PTB, 41% were female, mean age was 35 years, and 21% were people living with HIV (PLWH). The control group was 50% female, mean age was 51 years, and 20% were PLWH. The random forest feature selection identified five cytokines (IFN-γ, IL-1β, IL-22, IL-10, and IFN-β) and two metabolites (methionine and oxoproline). The combined cytokine-metabolite model achieved an AUC of 0.97 (95% CI: 0.94–1.00) in the test set. Both the cytokine-only and combined model had 95% sensitivity (95% CI: 89%–100%) at 80% specificity. However, at 98% specificity, sensitivity was higher in the combined model at 88% (95%CI: 75%–96%) versus the cytokine-only model [63% sensitivity (95% CI: 47%–93%)]. The combined model showed consistent performance (AUC=0.97, 95% CI: 0.90-1.00) regardless of HIV status and across both hospitalized and ambulatory participants.



This plasma biomarker signature meets the optimal WHO target product profile for both non-sputum triage and diagnostic TB tests, highlighting the value of AI-driven biomarker discovery approaches to improve TB diagnosis.

TBS-EP146 Field Deployment of a TB-Mobile Diagnostic System (TB-MDS) for Latent Tuberculosis Infection (LTBI) detection in Resource-limited Setting

G. Xie,[1] L. Liu,[1] J. Lou,[1] X. Yang,[1]
[1]Leide Biosciences Co., LDT, Guangzhou, China
e-mail: yangx@leidebio.com

With an estimated 2 billion individuals affected by LTBI worldwide, majority of the LTBI population is within resource-limiting regions and 5%-10% are at risk of progressing to active TB. Addressing LTBI is critical to achieving the WHO's END-TB strategy. IGRA (Interferon-Gamma Release Assay) is only the effective diagnostic method of LTBI detection due to the high specificity and sensitivity, but the adaption of IGRA in the TB high-burden countries is largely limited due to its high cost and lab instrument requirements. We reported here a TB-Mobile Diagnostic System (TB-MDS) which is designed to be implemented in community health centers in Resource-limited countries.

TB-MDS is a completed system which includes all lyophilized IGRA reagents (AIMTB), auto incubator (AIM 37), fluorescence chromatographic Analyzer, and standardized consumable suite (endotoxin-free blood collection tubes, pre-loaded pipettes, and consumables). The whole system is room temperature stable for 18 months, easy to transportation (22 kg in weight), and simple to operation. In field validation studies, TB-MDS can be reliably run over 24 hours of continuous operation without grid power, novice operators achieved proficiency within 30 minutes of training, and its assay performance achieved 98.2% agreement with laboratory-based IGRA reference assay.

Fig 1: TB- Mobile Diagnostic System (TB-MDS) components and Operational Workflow
1)TB-MDS; 2) Blood Collection, Collect blood into the three-chamber stimulation tubes (Negative, T, Positive) and label accordingly; 3) Gently invert to mix; 4) Incubate in the portable incubator (AIM37) at 37°C for 20 hours; 5) Centrifuge the tubes at 1000 g for 5 minutes; 6) Sample Loading into the lateral flow card. Incubate for 15 minutes; 7) Detection by the fluorescence detector.

TB-MDS provides one viable for decentralized LTBI detection in remote, disaster-affected, and other primary care settings. Its mobility, simplicity, and reliability support the global drive toward TB eradication.

TBS-EP149 Comparing early outcomes of BPaL-L and 9-month regimens for drug-resistant tuberculosis in South Africa

Y. Kock,[1] M. Enwerem,[1] Q. Mahlulo,[1] F. Conradie,[1]
D. Goldberg,[2] W. Jassat,[1] N. Ndjeka,[1]
[1]National Department of Health, Pretoria, South Africa,
[2]Clinton Health Access Initiative SA, Pretoria, South Africa
e-mail: yulene.kock@health.gov.za

Background: South Africa bears a high burden of drug-resistant tuberculosis (DR-TB), historically associated with poor outcomes due to lengthy, toxic regimens. Following WHO recommendation of BPaLM (bedaquiline, pretomanid, linezolid, moxifloxacin), South Africa introduced BPaL-L (bedaquiline, pretomanid, linezolid, levofloxacin), a 6-month all-oral regimen replacing moxifloxacin with levofloxacin, aiming for improved efficacy, safety, and shorter treatment duration.

Methods: We conducted a retrospective review of routinely collected data from the national DR-TB database (EDRWeb), describing patient characteristics, outcomes and adverse events for those initiated on BPaL-L between 1st September 2023 and 30th June 2024. Multivariate logistic regression identified factors associated with unfavourable outcomes.

Results: During the study period, 4,718 patients were initiated on BPaL-L across 445 facilities in 49/52 districts. The median age was 38 years; 62% being male and 62% HIV-positive. Treatment outcomes for BPaL-L showed 75% treatment success rate, with 9% LTFU and 7% mortality.

In comparison, among 1,285 patients initiated on the 9-month regimen during the same period, the treatment success rate was 62%, LTFU rate14% and mortality rate 13%.

Of 744 reported adverse events during this period for BPaL-L, anaemia was the commonest with 221/744 (30%) followed by peripheral neuropathy 93/744 (13%).

Unfavourable outcomes were associated with previous DR-TB (OR 1.9, 95% CI 1.5–2.5), undernutrition (OR 1.3, 95% CI 1.1–1.6), HIV-positive status without antiretroviral therapy (ART) (OR 4.2, 95% CI 1.8–9.9), and unknown ART status (OR 5.1, 95% CI 2.1–12.4). Nurse-initiated treatment was protective (OR 0.7, 95% CI 0.6–0.9).

Discussion: Early implementation and robust real-time monitoring of the BPaL-L regimen in South Africa demonstrated an improved treatment success rate and acceptable safety in routine settings. These findings are showing that the introduction of BPaL-L was a very good decision that has potential to enhance DR-TB care in South Africa.

TBS-EP152 *M. tuberculosis* exosome detection in peripheral blood for pediatric TB

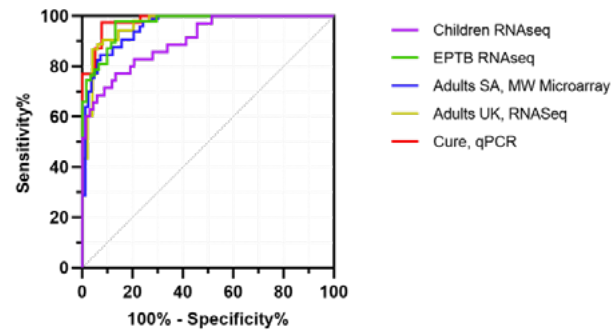
S. LaCourse,[1] W. Zheng,[2] S. Das,[2] J. Escudero,[1] J. Githua,[3] J. Mecha,[4] G. John-Stewart,[1] M. Ndunge,[4] E. Maleche-Obimbo,[5] T. Hu,[2] V. Nduba,[4] C. Lyon,[2] PDTBDx Study Group [1]University of Washington, Seattle, United States of America, [2]Tulane University, New Orleans, United States of America, [3]Centre for Respiratory Diseases Research, Nairobi, Kenya, [4]Centre for Respiratory Diseases Research, Kenya Medical Research Institute, Nairobi, Kenya, [5]University of Nairobi, Nairobi, Kenya
e-mail: sylvial2@uw.edu

Background: Non-sputum-based diagnostics for pediatric tuberculosis (TB) are urgently needed, as children are often missed by conventional respiratory sampling. We developed a nanoplasmon-enhanced scattering (nPES) assay to detect *Mycobacterium tuberculosis*-specific lipoarabinomannan (LAM) and its carrier protein LprG within extracellular vesicles (EVs) derived from endosomal compartments and circulating in peripheral blood.
Methods: We tested cryopreserved plasma from two Kenyan cohorts: children with suspected TB (PDTBDx) and healthy infants without known TB exposure (MITIPS). PDTBDx participants underwent sputum or gastric aspirate testing via Xpert and culture, with plasma collected at baseline. MITIPS infants had plasma collected at 6 weeks of age and were followed for 2 years, remaining tuberculin skin test (TST) negative at both 1 and 2 years, with no hospitalizations beyond birth and no known TB exposure.
Results: Among 47 symptomatic PDTBDx participants (53% female, median age 4 years [IQR 1.5–7.6]), 25% (12/47) had microbiologically confirmed TB, and 70% (33/47) initiated TB treatment. Among 20 healthy MITIPS infants, 65% were female and all received BCG vaccination at birth. In symptomatic PDTBDx participants, median nPES-detected LAM and LprG levels were 39.4 AU (IQR 30.7–45.4) and 50.3 AU (IQR 43.6–55.2), respectively, with similar values in children with confirmed and clinically diagnosed TB. Sensitivity was 100% (12/12) among children with confirmed TB (LAM 100%, LprG 75.0%) with LAM identifying 95.2% and LprG identifying 85.7% additional children with clinical TB diagnosis. In healthy infants, median LAM and LprG levels were 23.5 AU (IQR 20.4–25.4) and 29.0 AU (IQR 27.6–31.2), respectively. Specificity was 90% (18/20), with LAM and LprG specificities of 90% and 100%, respectively.
Conclusion: The nPES assay demonstrated high sensitivity for detecting LAM and LprG in symptomatic children with confirmed TB. Detection in children without microbiologic confirmation may reflect TB missed by respiratory sampling.

TBS-EP155 MAMS_6 – A novel transcriptome-informed quantitative real-time PCR-based signature for monitoring tuberculosis treatment success

M.I.M. Ahmed,[1,2] L. Rogers,[1,2] O. Baranov,[1,3,2] M. McLean,[1,4] N. Heinrich,[1,2,3] C. Geldmacher,[1,3,2] U. von Both,[5,2] K. Held,[1,3,2] PanACEA consortium [1]Institute of Infectious Diseases and Tropical Medicine, LMU University Hospital, LMU Munich, Munich, Germany, [2]German Centre for Infection Research (DZIF), Munich, Germany, [3]Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Immunology, Infection and Pandemic Research, Munich, Germany, [4]Institute of AI for Health, Helmholtz Munich, Munich, Germany, [5]Dr. von Hauner Children's Hospital, LMU University Hospital, LMU Munich, Muncih, Germany
e-mail: Kathrin.Held@med.uni-muenchen.de

Background: Timely diagnosis and effective treatment monitoring remain key challenges in tuberculosis (TB) care. There is an urgent need for reliable, sputum-independent biomarkers to support rapid diagnosis and assess treatment response.
Methods: Through a multi-step process, we developed a parsimonious real-time quantitative PCR (RT-qPCR) signature for TB cure. Whole blood transcriptomes from participants in the Phase IIB PanACEA MAMS-TB-01 trial (n=21) conducted in South Africa and Tanzania were profiled using RNA sequencing at baseline and at weeks 2, 12, and 26 of treatment. We prioritised genes highly differentially expressed in this study and appearing in published signatures to develop an RT-qPCR-based assay. Gene expression was quantified using microfluidic RT-qPCR in a training (n=21) and validation cohort (n=39), followed by ROC curve analysis to identify genes discriminating between active and cured TB. The resulting six-gene signature, MAMS_6, was further validated using both in-house and public transcriptomic datasets.



ROC curves showing MAMS_6 signature performance across in-house and public datasets.
Red: TB at treatment start vs. end (MAMS validation cohort RT-qPCR). Yellow: TBI vs. TB (UK RNA-seq; Singhania, 2018). Blue: TBI vs. TB (African microarray; Kaforou, 2013). Green: Controls vs. extrapulmonary TB (RNA-seq; Blankley, 2016). Purple: TB vs. TBI (paediatric RNA-seq; Tornheim, 2020).

Results: TB treatment induced rapid and dynamic transcriptomic shifts, particularly in genes related to leukocyte activation and inflammatory signalling. The MAMS_6 signature demonstrated 97% sensitivity and 82% specificity for predicting treatment completion. Its performance was consistent across clinical subgroups and correlated with stable culture conversion. Additionally, MAMS_6 showed diagnostic utility in external datasets, highlighting its broader relevance.
Conclusion: The MAMS_6 RT-qPCR signature holds promise as a dual-purpose tool for TB diagnosis and treatment monitoring. It may be particularly valuable for individuals unable to reliably produce sputum, supporting more inclusive and effective TB care.

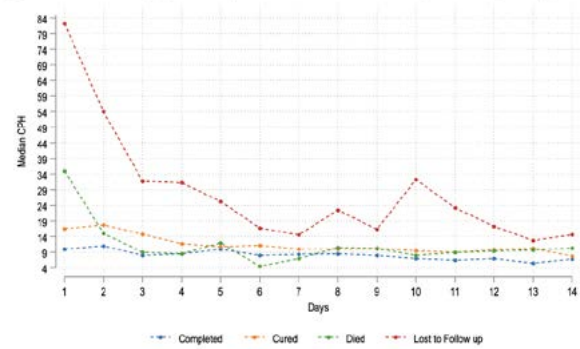
TBS-EP158 Automated cough frequency monitoring as a predictor of unfavorable TB outcomes

C. Aviles-Guaman,[1] A. Kityamuwesi,[2] J. Kakeeto,[2] R. Madaya,[2] R. Nerurkar,[3] L. Asege,[4] A. Andama,[2,4] E. Mwebaze,[2,5] A. Cattamanchi,[1,6] S. Huddart,[7] C. Sekaggya-Wiltshire,[5] D. Jaganath,[1] [1]University of California San Francisco, Division of Pulmonary and Critical Care Medicine, San Francisco, United States of America, [2]Walimu, Uganda Tuberculosis Implementation Research Consortium, Kampala, Uganda, [3]University of California San Francisco, Division of Pediatric Infectious Diseases, San Francisco, United States of America, [4]Makerere University College of Health Sciences, Department of Medicine, Kampala, Uganda, [5]Makerere University, Infectious Diseases Institute, Kampala, Uganda, [6]University of California Irvine, Division of Pulmonary Diseases and Critical Care Medicine, Irvine, United States of America, [7]University of California San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States of America
e-mail: devan.jaganath@ucsf.edu

Background: AI-enabled mobile phone applications can support continuous and automated cough monitoring while on tuberculosis (TB) treatment. This has potential to serve as an early warning system to identify individuals at risk of unfavorable treatment outcomes.
Methods: We enrolled adults ≥18 years in Kampala, Uganda who were initiated on treatment for drug-sensitive pulmonary TB based on a microbiological (sputum Xpert MTB/RIF) or clinical diagnosis. We collected clinical and sociodemographic data, and participants wore smartphones for 14 days with the Hyfe application for automated cough detection. We calculated the daily median coughs per hour and applied an anomaly detection model to identify individuals with an extreme cough frequency. TB registry data were used to identify unfavorable outcomes (Death or loss to follow up). We developed a 10-fold cross validated LASSO regression model to predict unfavorable outcomes and calculated the accuracy.

Results: Among 152 participants, median age was 32 years (IQR 40-26), 66 (43.42%) were living with HIV, 94 (61.84%) had bacteriologically confirmed TB, and 6 (3.9%) had an unfavorable outcome (3 deaths and 3 lost to follow up). Participants with unfavorable outcomes had a higher median cough per hour on Day 1 than those who were cured or completed treatment, but levels were similar by Day 14 (Figure 1). A Day 1 cough frequency anomaly classified an unfavorable outcome with 83% sensitivity (95% CI 45-100) and 78% specificity (95% CI 25-85). When combined with presence of hemoptysis, microbiological TB status, and history of HIV, diabetes or allergies, sensitivity remained 83% and specificity improved to 94%.

Figure 1: Median Cough per hour by Treatment Outcome During the 14-days study period



Conclusions: Continuous automated cough monitoring in the first 24 hours identified individuals with unfavorable outcomes with high accuracy when combined with routine baseline clinical data and should be further evaluated as a TB treatment monitoring tool in larger validation studies.

TBS-EP161 Optimizing approaches to recover high quality *M. tuberculosis* genome-wide and within-host variation

K. Walter,[1] T. Cohen,[2] B. Mathema,[3] C. Colijn,[4] A. Carey,[1] S. Shakir,[1] J. Croda,[5] J. Andrews,[6] [1]University of Utah, Salt Lake City, United States of America, [2]Yale University School of Public Health, Epidemiology of Microbial Disease, New Haven, United States of America, [3]Columbia University Mailman School of Public Health, Epidemiology, New York City, United States of America, [4]Simon Fraser University, Mathematics, Burnaby, Canada, [5]Federal University of Mato Grosso do Sul, Medicine, Campo Grande, Brazil, [6]Stanford University, Infectious Diseases and Geographic Medicine, Stanford, United States of America
e-mail: katharine.walter@hsc.utah.edu

Mycobacterium tuberculosis (*Mtb*) genomic epidemiology studies often require culturing patient sputa, a time and labor-intensive process that can also impose a bottleneck on *Mtb* variation. Hybrid capture approaches have been successfully used to enrich *Mtb* DNA from complex clinical samples. However, the accuracy of both consensus and minority variants identified by hybrid capture approaches has not yet been evaluated, making it difficult to evaluate its more widespread utility.

We conducted a serial dilution experiment in which we mixed two *Mtb* DNA standards representing lineages 2 and 4, such that the minority strain represented 0-100% of the total DNA and then diluted *Mtb* DNA in human DNA, to simulate clinical samples which are overwhelmingly human DNA. We enriched for *Mtb* DNA with hybrid capture, conducted whole genome sequencing, and measured the performance of variant identification for both consensus and minority variants.

Additionally, we prospectively sampled matched *Mtb* diagnostic cultures and sputum and performed hybrid capture and Illumina whole genome sequencing on matched samples. In our serial dilution experiment, hybrid capture enabled efficient sequencing of *Mtb*, even when *Mtb* DNA comprised a small proportion of input DNA (97.3% efficiency when *Mtb* DNA comprised 0.01% of input DNA). Consensus SNP variants identified through hybrid capture were accurate, with a sensitivity of 97.1% and precision of 97.1% in a lineage 4 DNA standard, outside of PE/PPE genes. Observed minor allele frequencies were closely correlated ($r = 0.97$, $p < 0.001$) with input minor allele frequences. In our prospectively collected sputa samples, hybrid capture efficiency was high, >93%. Hybrid capture of clinical sputa samples can generate accurate *Mtb* whole genome sequences and minority variant calls, without the need for culture. Further optimization could make hybrid capture more practical for large-scale genomic epidemiology studies.

TBS-EP164 Benchmarking surrogate endpoints for relapse in TB trials: A statistical framework for assessing new biomarkers

M. Warden,[1] N. Walter,[2,3,4] C. Underkofler,[2,4] A. Purvis,[5] P. Phillips,[1] [1]University of California, San Francisco, United States of America, [2]University of Colorado Anschutz Medical Campus, Aurora, United States of America, [3]Rocky Mountain Regional VA Medical Center, Aurora, United States of America, [4]Consortium for Applied Microbial Metrics, Aurora, United States of America, [5]Angie Purvis, LLC, Aurora, United States of America
e-mail: mark.warden@ucsf.edu

Background: Treatment monitoring in tuberculosis (TB) clinical trials still relies heavily on culture-based endpoints, despite well-known limitations in predicting relapse. A comprehensive statistical framework for evaluating TB surrogate endpoint biomarkers is lacking yet is essential to accelerate drug development.

Objective: We applied individual- and trial-level surrogate endpoint evaluation methods to culture-based data from recent late-phase TB clinical trials to quantify how well culture-based biomarkers predict relapse-free cure. Using state-of-the-art surrogate endpoint methodology, the objective of this work is to establish a statistical benchmark against which novel molecular biomarkers, such as the RS ratio, can be compared.

Methods: Using harmonized data from 7 trials (19 treatment arms, 4,614 participants), we applied the proportion of treatment effect explained (PTE) and meta-analytic surrogacy models to time to culture conversion in relation to relapse as the primary endpoint. We assessed individual-level and trial-level predictions of relapse across regimens.

Results: Our analyses show negligible trial-level relapse surrogacy for time to culture conversion ($R^2 \approx 0.1$) in a meta-regression. The trial-level effect was small with a wide confidence interval that contained zero, precluding estimation of a surrogate threshold effect (STE). The STE likely lies outside the range of observable values. PTE estimates were low, with an upper bound of ~10% for time to culture conversion. These findings affirm limitations of culture-based markers and demonstrate a generalizable evaluation framework that we will be applying to other molecular biomarkers.

Conclusion: Culture-based biomarkers describe treatment response but have only limited value as surrogate endpoints for relapse. Better biomarkers are needed to more efficiently guide TB regimen development. Our relapse surrogacy framework supports evaluation of emerging biomarkers. Future work will expand its application to culture time to positivity and to the RS ratio.

TBS-EP167 Pharmacogenomic prediction of adverse drug reactions to tuberculosis preventive therapy: Role of CYP2C19 and CYP2E1 polymorphisms in household contacts of TB patients

U. Kumar R,[1] A. Kunoor,[2] F. Francis,[1] L. Biswas,[3] S. David,[2] M. Kumar Jeengar,[1] [1]Amrita School of Pharmacy, Amrita Institute of Medical Sciences, Amrita Vishwa Vidyapeetham, Kochi, Kerala, India, [2]Amrita Institute of Medical Sciences, Kochi, Kerala, India, [3]Amrita Centre for Nanosciences and Molecular Medicine, Kochi, Kerala, India
e-mail: udaykumarr@pharmacy.aims.amrita.edu

Tuberculosis (TB) remains a global public health challenge, with preventive therapy (TPT) being a key strategy in reducing latent TB infection (LTBI) progression. However, adverse drug reactions (ADRs) associated with TPT regimens, particularly those containing rifapentine and isoniazid, impact adherence and treatment outcomes. This study investigates the role of genetic polymorphisms in drug-metabolizing enzymes, CYP2C19 and CYP2E1, in predicting ADRs among individuals receiving TPT.

Conducted in Kerala, India, this interventional study included 43 household contacts of TB patients. DNA extraction and genotyping for CYP2C19 (rs4986893) and CYP2E1 (rs2515641, rs2070676) were performed using TaqMan assays and T-ARMS PCR. Statistical analysis assessed the association between genetic variants and ADR occurrence.

Results indicate a significant correlation between CYP2C19 polymorphism and ADRs, with individuals carrying the CC genotype experiencing a higher incidence of ADRs (61.29%) compared to those with CT (20%). The TT genotype also showed an increased risk, though with a smaller sample size.

Notably, no genetic variation in CYP2E1 was observed, suggesting its limited role in ADR predisposition. The most common ADRs included sleepiness and lethargy (63.63%), hypersensitivity (27.27%), and gastrointestinal discomfort (18.18%).

The findings highlight the potential of pharmacogenomics in optimizing TPT regimens to enhance patient safety and adherence. Implementing genetic screening before initiating TPT may aid in personalized treatment approaches, reducing ADR incidence and improving therapeutic outcomes. Further studies with larger populations are required to validate these associations and facilitate precision medicine in TB management.

TBS-EP170 *CYP3A5* polymorphisms influence bedaquiline and clofazimine pharmacokinetics in clinical trial participants with MDR/RR-TB across six countries

K.E. da Silva,[1] B. Ngara,[2] P.V. Brantegem,[2] E. Yang,[2] B.P. Solans,[2] H. McIlleron,[3] G.E. Velásquez,[4,5] J.R. Andrews,[1] [1]Stanford University, Department of Medicine, Division of Infectious Diseases and Geographic Medicine, Stanford, United States of America, [2]Department of Bioengineering and Therapeutic Sciences, University of California, San Francisco, San Francisco, United States of America, [3]Department of Medicine, University of Cape Town, Cape Town, South Africa, [4]UCSF Center for Tuberculosis, University of California San Francisco, San Francisco, United States of America, [5]Division of HIV, Infectious Diseases, and Global Medicine, University of California, San Francisco, San Francisco, United States of America
e-mail: kesiaeds@stanford.edu

Background: The endTB (NCT02754765) and endTB-Q (NCT03896685) clinical trials evaluated the efficacy and safety of six experimental, all-oral regimens for fluoroquinolone-susceptible and fluoroquinolone-resistant multidrug/rifampicin-resistant tuberculosis (MDR/RR-TB). These regimens included new and repurposed drugs such as bedaquiline (BDQ), clofazimine (CFZ), and linezolid (LZD). As a sub-study of these trials, we investigated the pharmacogenetics of these drugs in trial participants.

Methods: We examined the association between *CYP3A5* rs776746 polymorphisms and the pharmacokinetics of BDQ, CFZ, and LZD in 143 participants from Kazakhstan, Lesotho, Pakistan, Peru, South Africa, and Vietnam. Genotyping was conducted using the Infinium Global Diversity Array with Enhanced PGx and TaqMan SNP assays. Genotypes were classified as AA (*1/*1, functional), AG (*1/*3, intermediate), and GG (*3/*3, nonfunctional). Individual clearance (CL) estimates for BDQ, CFZ, and LZD were derived from established population pharmacokinetics models. The Kruskal-Wallis test was used to compare CL across genotype groups.

Results: Among the 143 participants, the nonfunctional GG genotype was the most prevalent (51.7%, 74/143), followed by AG at 26.6% (38/143), and AA at 22.4% (32/143), with considerable variation by region. The nonfunctional GG genotype was absent in Lesotho and South Africa, followed by Pakistan (57.7%; 15/26), Kazakhstan (64.7%; 22/34), Vietnam (66.7%; 6/9) and Peru (72.1%; 31/43). Model-derived individual CL values were obtained for 94 CFZ-treated and 96 BDQ-treated participants using established pharmacokinetics models.

Significant differences in clearance were observed across *CYP3A5* genotypes for both CFZ ($p = 0.0118$) and BDQ ($p = 0.0189$), with lower mean clearance among individuals with the GG genotype consistent with reduced metabolic activity (Figure 1). No significant association was found between *CYP3A5* genotype and LZD clearance ($p= 0.9577$).

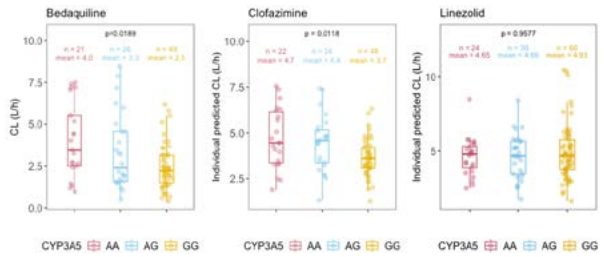


Figure 1.

Conclusion: *CYP3A5* genotype significantly affects BDQ and CFZ CL. Incorporating pharmacogenetic profiling into TB treatment strategies may support personalized dosing, especially in populations with a high prevalence of the nonfunctional GG variant.

TBS-EP176 Urinary extracellular vesicle-linked lipoarabinomannan for precise diagnosis of active tuberculosis

A. Byne,[1] [1]George Mason University, Manassas, United States of America
e-mail: byneahana26@gmail.com

Lipoarabinomannan, a glycolipid component of the *Mycobacterium tuberculosis* (Mtb) cell wall, is an important determinant of immunogenicity, and it has been recently validated in clinical studies as a marker of active tuberculosis infection. LAM (Lipoarabinomannan) is known to be present on culture Mtb infected eukaryotic cell extracellular vesicles, and LAM presence was confirmed in EVs of serum from tuberculosis patients.

We have found that urinary EVs are a new source of LAM as a diagnostic biomarker. Urine is a convenient non-invasive biofluid that collects and integrates molecular information over many hours yielding a higher abundance of diagnostic molecules than blood.

We conducted a clinical study showing that urine measurement of Mtb LAM achieved high sensitivity and specificity (0.90; 95% CI: 0.87-0.93, 90% sensitivity, 73.5% specificity, at a cut off of 80 pg/mL) in patients with active pulmonary and extrapulmonary (pleural, meningeal, laryngeal, bone, and ganglionic tuberculosis) tuberculosis (N=430), in absence or presence of co-morbidities (HIV and diabetes).

Patients and controls were accrued from five different countries: Peru, Guinea Bissau, Venezuela, Uganda and the United States. Structural variations of LAM influenced its diagnostic performance. Epitope 5-methylthio-D-xylofuranose (MTX)-mannose (Man) was less influenced by glycosuria and identified culture positive pediatric (N=19) and extrapulmonary (N=24) patients with high accuracy (ROAUC 0.87, 95% CI:0.77-0.98, 0.90 sensitivity 0.80 specificity at 80 pg/mL; ROAUC = 0.96, 95% CI:0.92-0.99, 96% sensitivity, 80% specificity at 82 pg/mL, respectively).

We are in the process of characterizing what class of urinary EVs contains LAM in patients with culture positive tuberculosis, and to evaluate what other Mtb molecules are associated with LAM-EVs.

Of particular interest are differences in LAM carbohydrate structure and, in particular, in the nonreducing terminal arabinan of LAM, that have important implications in prognosis, disease stage, immunogenicity, and diagnosis.

TBS-EP179 Sputum MGIT culture versus lipoarabinomannan (LAM) assay for evaluating regimen activity in phase 2B trials

A. Geronimo,[1] N.K. Ng,[2] E.M. Dela Cruz,[1] R.G.M.S. Veto,[1] V. Dalay,[3] V. Balanag,[4] J. Benedicto,[5] N. Paton,[2] TRUNCATE-TB Trial Team [1]Tropical Disease Foundation, Makati City, Philippines, [2]National University of Singapore, Singapore, Singapore, Singapore, [3]De La Salle Medical and Health Sciences Institute, Dasmariñas, Cavite, Philippines, [4]Lung Center of the Philippines, Manilla, Philippines, [5]Philippine Tuberculosis Society Inc. Quezon Institute, Manilla, Philippines
e-mail: aageronimo@tdf.org.ph

Background: Time to sputum culture conversion (TT**C**C) in mycobacterial growth indicator tube (MGIT) is a standard phase 2b trial outcome. Sputum lipoarabinomannan (LAM) has potential advantages over MGIT (unaffected by contamination; faster result; cheaper) but has not previously been evaluated in a 2b trial.

Methods: TRUNCATE-TB was a phase 2/3 adaptive trial using novel 8-week, 5-drug regimens within a treatment strategy. We analysed participants enrolled at 4sites in the Philippines; assigned to standard treatment or two fully-enrolled, novel 5-drug regimen groups (high-dose rifampicin and linezolid [RIF-LZD], or bedaquiline and linezolid [BDQ-LZD]; each given with isoniazid, pyrazinamide and ethambutol); and with positive baseline MGIT and LAM. MGIT time to positivity (TTP) was analysed in real-time. LAM concentration was measured in stored decontaminated sputum samples at trial end using PATHFAST TB LAM Ag test. Baseline TTP and LAM were compared by Spearman's test; TT**C**C (time to first of two negative MGIT cultures to week 8) and time to LAM conversion (TT**L**C; time to first of two consecutive LAM results below 10pg/ml) by Kaplan-Meier methods; and hazard ratio (HR-**C**C and HR-**L**C) by Cox model.

Results: Correlation (negative) between TTP and LAM at baseline was good (> 0.85, all 3 groups). TT**C**C was similar to standard regimen and HR-**C**C compared to standard regimen was increased to a similar extent in both novel treatment regimens (Table).

TT**L**C was slower in RIF-LZD than in the standard or BDQ-LZD regimen, and the HR-**L**C compared to standard treatment was lower in RIF-LZD (1.17) than in BDQ-LZD regimen (1.41).

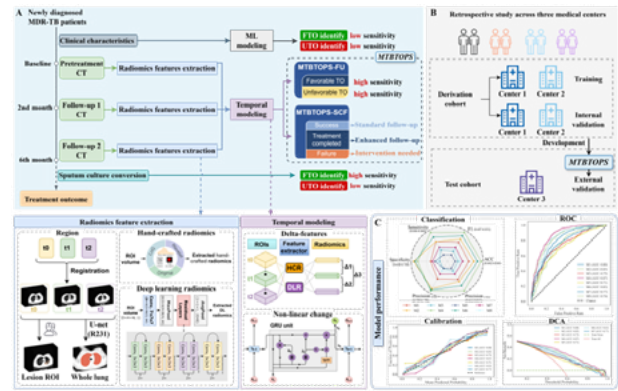
	r (TTP vs LAM)	TTCC median (95%CI), days	TTLC median (95%CI), days	HR-CC (95%CI) vs standard	HR-LC (95%CI) vs standard
Standard regimen (n=37)	-0.90	41 (30-52)	30 (29-56)	(reference)	(reference)
RIF-LZD regimen (n=39)	-0.85	40 (29-43)	40 (29-43)	1.43 (0.87–2.37)	1.17 (0.69-1.99)
BDQ-LZD regimen (n=41)	-0.85	41 (39-43)	30 (29-43)	1.54 (0.95-2.52)	1.41 (0.85-2.34)

Conclusion: TTP and LAM showed reasonable agreement. LAM identified RIF-LZD as potentially the less efficacious of the two novel regimens (consistent with later performance on phase 3 relapse outcome).
Initial findings support inclusion of LAM in phase 2b trials to gain further experience on utility for predicting regimen efficacy.

TBS-EP182 Deep learning on longitudinal chest CT predicts treatment outcomes in multidrug-resistant tuberculosis: A multicentre retrospective study

L. Jie,[1] Z. Qilong,[1] X. Tongshun,[2] Q. Huifang,[3] W. Maoshui,[3] W. Xianghua,[1] l. honglian,[1,1] [1]Nanchang Medical College, Nanchang, China, [2]The Fifth People's Hospital of Jingdezhen city, Jingdezhen, China, [3]Shandong Public Health Clinical Center, Jinan, China
e-mail: lijie_3608@126.com

Background: Multidrug-resistant tuberculosis (MDR-TB) poses a significant global health threat, with persistently low treatment success rates despite prolonged, individualized therapies. Traditional clinical and microbiological predictors show limited performance in forecasting treatment outcomes.
This study aimed to develop a deep learning-based system that integrates longitudinal chest CT imaging to predict MDR-TB treatment outcomes.
Methods: We conducted a retrospective multicenter cohort study involving 265 patients with multidrug-resistant tuberculosis from three hospitals in China. Each patient underwent chest CT imaging at baseline, at two months, and at six months after the initiation of treatment. Radiomics features, including both handcrafted features and features derived from deep learning methods, were extracted from manually segmented lesions and the entire lung regions.
A total of 64 predictive models were developed by combining different radiomics strategies with various temporal modeling approaches. The optimal model, named MTBTOPS, was selected based on its performance in both internal and external validation cohorts. Model performance was assessed using classification metrics, receiver operating characteristic curves, calibration curves, and decision curve analysis.
Findings: MTBTOPS achieved superior predictive accuracy in both binary (favorable vs. unfavorable outcome) and multiclass (success, completion, failure) tasks.
In the test cohort, the best-performing model yielded an AUC of 0.838 (MTBTOPS-FC) and 0.849 (MTBTOPS-SCF), significantly outperforming clinical and microbiological indicators, such as 6-month sputum culture conversion.
The integration of three-timepoint CT data and GRU-based temporal modeling significantly enhanced predictive performance over static imaging or clinical variables alone.



Interpretation: This study demonstrates the potential of longitudinal CT-based deep learning to improve early, non-invasive prediction of MDR-TB treatment outcomes. By enabling individualized risk stratification and timely intervention, the MTBTOPS framework may inform precision treatment strategies and resource allocation in high-burden settings.

TBS-EP185 Development of a biomarker to monitor children treated for non-severe tuberculosis

C. Dunican,[1] V. Muwanga,[2] S. Mendelsohn,[2] O. Vito,[3] S. Mbandi,[2] M. Erasmus,[2] R. Raphela,[2] M. van der Zalm,[4] M. Palmer,[4] M. Kaforou,[1] T. Scriba,[2] J. Seddon,[1]
On behalf of the SHINE trial team [1]Imperial College London, London, United Kingdom of Great Britain and Northern Ireland, [2]University of Cape Town, Cape Town, South Africa, [3]AstraZeneca, Cambridge, United Kingdom of Great Britain and Northern Ireland, [4]Stellenbosch University, Stellenbosch, South Africa
e-mail: james.seddon@.imperial.ac.uk

Background: SHINE was a randomised phase 3 multi-country trial which found that 4-months of standard treatment was non-inferior to 6-months for non-severe tuberculosis (TB) drug-susceptible in children, allowing for global treatment shortening recommends. There are however no biomarkers of treatment response that allow for tailoring treatment in individual children.

We aimed to identify a transcriptomic signature of treatment response in children and assess its viability as a biomarker of treatment response.
Methods: Of children enrolled into SHINE, 198 children enrolled in Cape Town were retrospectively classified into having confirmed, unconfirmed, and unlikely TB by an independent endpoint committee (n=771 samples). PAXgene whole blood RNA samples were collected at enrolment, 2, 8 weeks, and at the end of treatment (week 16 or 24), and expression of 85 TB-associated genes measured by qPCR, compared across treatment timepoints.
Results: Using the enrolment and end -of-treatment samples in the confirmed TB group (n=37), we identified a new 4-gene monitoring biomarker-based disease risk score (area under the receiver operating characteristic curve, AUROC: 0.89, 95% CI: 0.81-0.97). Performance did not significantly differ between the 4- and 6-month arms. This signature was also validated in an independent, publicly available RNA-Seq dataset of children from India with TB (n=16, PMID: 31796955, AUROC: 0.81, 95% CI: 0.64-0.98).
We adapted this 4-gene signature into a monitoring score, with equal weighting assigned per gene. A score of 1 was assigned per gene if its expression value was within 1.5 standard deviations of each groups averaged end of treatment value, subsequently summed (Figure 1).

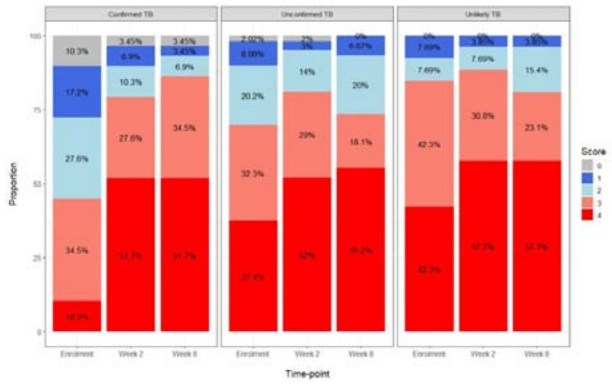


Figure.1 Monitoring score proof of concept – higher scores associated with a return to "baseline" expression levels.

Conclusions: We have demonstrated proof of principle that a novel transcriptomic treatment monitoring biomarker could be used to measure antituberculosis treatment responses in children allowing for future tailored of treatment in children.

TBS-EP188 Novel nanoparticle respiratory tract mucosal tuberculosis vaccine

F. Quinn,[1] [1]University of Georgia, Infectious Diseases, Athens, United States of America
e-mail: fquinn@uga.edu

Background: We developed/tested a BCG intranasal mucosal booster vaccine comprised of three *Mycobacterium tuberculosis* (*Mtb*) surface or secreted antigens. Importantly, there is increasing evidence that mucosal immune responses are important for protection against diseases that initially interact with mucosal cells. Epithelial cells, including the respiratory epithelium and particularly alveolar epithelial cells (AECs), are primary targets for mucosal vaccines.
Design/Methods: The three *Mtb* proteins chosen for this study include HBHA, an epithelial cell heparin-binding hemagglutinin adhesin, Rv3351c, which induces host cell lipid rafts, and ESAT6 (early secretory antigenic target 6) which forms pores in host cell membranes. We showed that *Mtb* native HBHA and recombinant Rv3351c and ESAT6 administered subcutaneously or intranasally induced such immune responses in mice.
Thus, we hypothesized that combining these three epithelial cell-targeting *Mtb* proteins as an intranasal booster vaccine with BCG prime will drive robust protective mucosal, cellular, and humoral responses in the lungs compared to subcutaneous vaccination with BCG alone.
Results: As hypothesized, intranasal delivery of the booster preparations composed of PLGA nanoparticles with VacSIM matrix were the most protective in mice as demonstrated by lung (and spleen) CFU numbers being less by greater than 1.0 log , showed less lung necrosis and granuloma formations, and overall affected lung areas also were less than mice only BCG vaccinated.
Although all cytokine levels were relatively higher than BCG alone, generally lower levels of pro-inflammatory cytokine TNF-a and increased production of IL-17 and IFN-g were observed in mice booster vaccinated.
Conclusions: Our nanoparticle intranasal mucosal booster vaccine generated greater protection than BCG alone through lower lung (and spleen) CFU numbers, less lung necrosis and granuloma formations, and less overall affected lung areas, and with the accelerated recruitment of protective Th1 cells by the enhanced production of IFNg and IL-17 and reduction proinflammatory cytokines.

TBS-EP191 Adaptation of MBLA for quantification of bacterial load in the clinical routine laboratory

B. Andersson,[1] M. Jonsson Nordvall,[1,2] C. Braian,[1] K. Niward,[1,3] T. Schön,[1,3,4] [1]Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection, Linköping University, Linköping, Sweden, [2]Department of Clinical Microbiology, University Hospital, Linköping, Sweden, [3]Department of Infectious Diseases, Linköping University Hospital, Linköping, Sweden, [4]Department of Clinical Microbiology, Kalmar County Hospital, Linköping University, Kalmar, Linköping, Sweden
e-mail: katarina.niward@liu.se

Background: Rapid quantification of *M. tuberculosis* (Mtb) is important for monitoring bacterial load during treatment and in clinical studies but time to positive culture (TTP) is a slow method unsuitable for clinical practice. The molecular bacterial load assay (MBLA) by detection of 16S rRNA is a much faster method, quantifying the bacterial load within hours. However, the sample preparation of MBLA involves toxic chemicals and manual RNA-extraction, making it less feasible for the routine clinical laboratories or large sample sizes. Thus, our aim was to optimize MBLA to facilitate implementation in clinical settings and trials.
Method: First, several strategies to inactivate sputum samples containing Mtb or *M. avium* were compared including GTC-DTT recommended by the current MBLA kit as well as 8% acetic acid, 1M NaOH and heating for 20 minutes at 80°C. The kit-recommended phenol-chloroform RNA-extraction was compared to automated extraction with Qiagen (RNA Tissue Mini kit) and Maelstrom (TANBead Nucleic Acid Extraction Kit Tissue RNA) using Mtb-spiked sputum samples from 10^6 to 10^1 CFU/ml.
Results: The most efficient inactivation procedure was heating at 80°C whereas GTC-DTT did not inactivate Mtb. Also, sample homogenization by bead beating (MP FastPrep) and DNAse (Turbo DNAse kit) treatment following RNA-extraction were found to be essential steps. Automated RNA-extraction by Maelstrom had a lower detection limit (10^3/ml) than Qiagen (10^4/ml) and performed similarly to phenol-chloroform extraction with a detection limit of 10-100 CFU (median Ct levels: 35 (33.4-36.4) and 34.2 (33.6-35.6), n=6).

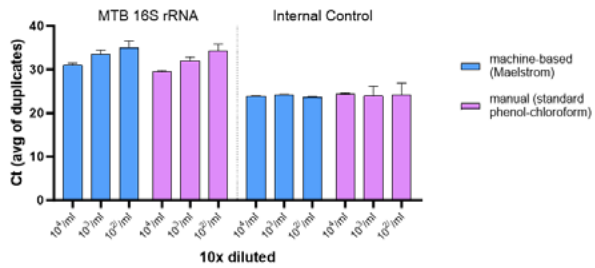

Fig.1. Spiked-sputum samples were heat-inactivated at 80° for 20 min and an extraction control (100µl/sample) was added to all samples. RNA samples were diluted 10x and Mtb was quantified by qPCR following standard phenol-chloroform manual RNA extraction protocol or machine-based RNA extraction protocol. Data are presented as median Ct-values (n=6).

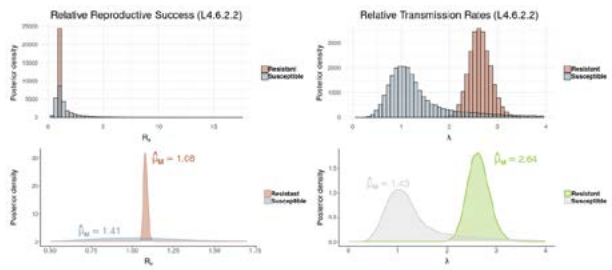
Discussion: We adapted the MBLA method for rapid throughput by using heating at 80°C for 20 minutes followed by automated RNA-extraction achieving equal sensitivity compared to the original MBLA method with more time-consuming phenol-chloroform based extraction. The updated MBLA method will now replace TTP for determination of clinical load in routine as well as in future clinical trials.

TBS-EP197 Strain-specific host-pathogen sympatry drives tuberculosis spread and drug resistance dissemination in Nigeria

O. Alayande,[1,2] S. Cadmus,[1,3,4,5] [1]University of Ibadan, Damien Foundation Genomics and Mycobacteria Research and Training Centre, Ibadan, Nigeria, [2]Department of Biochemistry, Faculty of Basic Medical Science, University of Ibadan, Ibadan, Nigeria, [3]Nigerian Institute of Medical Research, Yaba, Microbiology, Lagos, Nigeria, [4]University of Ibadan, Department of Veterinary Public Health and Preventive Medicine, Ibadan, Nigeria, [5]Centre for Control and Prevention of Zoonoses, University of Ibadan, Ibadan, Nigeria
e-mail: opealayandea@gmail.com

Background: Global tuberculosis (TB) research and scientific efforts have often focused on a few globally disseminated *Mycobacterium tuberculosis* (*Mtb*) lineages. However, in many high-burden settings, transmission is predominantly driven by geographically restricted strains characterized by long-term co-localization with host populations. These "specialist" lineages remain underrepresented in research guiding vaccine and therapeutic development.
Therefore, to inform more context-sensitive interventions, it is essential to quantify the epidemiological contributions of sympatric and allopatric *Mtb* subgroups in settings where multiple lineages coexist.
Methods: We analyzed whole-genome sequences (WGS) and associated metadata of *Mtb* isolates collected across Nigeria over a 15-year period. Isolates were stratified by sub-lineage, drug resistance (DR), and host-pathogen sympatry status. Using Bayesian phylodynamic modeling and ancestral sequence reconstruction, we estimated changes in population composition over time for parameters including transmission rates, effective population size, reproductive success, and resistance acquisition or dissemination timelines. We used these parameters to infer the relative transmission fitness of circulating subgroups in Nigeria.
Results: Analysis of 400 WGS samples revealed that Lineage 4.6.2.2, compared to other circulating strains in Nigeria, has expanded more than 2-fold in effective population size and prevalence over the past 20 years. DR-conferring mutations did not attenuate L4.6.2.2 dominance and relative fitness. Notably, DR L4.6.2.2 strains harbor-

ing *rpoB* S450L mutations were significantly ($p < 0.001$) more associated with higher "transmitter status," reproductive success, and elevated transmission rates relative to other (sub)lineages regardless of their "specialists" or "generalists" status.



Discussion: This study demonstrates the role of strain-specific adaptation and host-pathogen co-localization in driving DR-TB transmission in Nigeria. The epidemiological success of L4.6.2.2 with its sympatric hosts supports a reframing of the global TB burden estimates "more" as the cumulative outcome of diverse, localized epidemics fueled by highly-adapted, regionally restricted lineages. Integrating this perspective will be crucial to refining and achieving global TB prevention targets.

TBS-EP200 Prominent *M. tuberculosis* biomarkers among sputum culture-negative patients

Y. Xie,[1] N. Modi,[1] K. Lopez,[1] R. Reiss,[1] C. Eichberg,[2] C. Centner,[3] K. McCarthy,[4] L. Nakiyingi,[5] J. Ellner,[1] D. Alland,[1] S. Dorman,[2] [1]Rutgers New Jersey Medical School, Newark, NJ, United States of America, [2]Medical University of South Carolina, Charleston, SC, United States of America, [3]University of Cape Town, Cape Town, South Africa, [4]CDC/KEMRI, Kisumu, Kenya, [5]Makerere University, Kampala, Uganda
e-mail: ylx1@njms.rutgers.edu

Background: Highly-sensitive molecular tests like GeneXpert MTB/RIF Ultra improve detection of paucibacillary pulmonary tuberculosis (TB) but occasionally detect *Mycobacterium tuberculosis* (Mtb) DNA in sputum from culture-negative individuals, with unclear significance. We hypothesized that Ultra may be detecting culture-negative TB, and manifest in a higher prevalence of TB biomarkers compared to Ultra-negative/culture-negative ('sputum-negative') individuals.
Methods: From 1200 symptomatic African adults undergoing evaluation for TB, we identified 66 with sputum-discordant results (Ultra-positive, culture-negative), and matched 52 sputum-negative (Ultra-negative, culture-negative) and 30 sputum-positive (Ultra-positive, culture-positive) participants. Over 12 months, participants were assessed for Mtb biomarkers (Mtb growth in augmented or follow-up sputum cultures, Mtb mRNA in baseline sputum, and symptomatic Ultra-positive after baseline) and TB-associated host transcriptional signatures.
Results: At baseline, Mtb bacterial biomarker(s) were detected in 16.7 % of sputum-discordant and 26.9% of sputum-negative patients ($p = 0.26$). Longitudinally, 26.5 % of untreated sputum-discordant versus 41.7 % of untreated sputum-negative participants had Mtb bacterial biomarkers ($p = 0.17$) despite most reporting symptom improvement. Notably, 30% of untreated sputum-negative participants converted to Ultra-positive at month 2. One sputum-discordant and one sputum-negative participant developed culture-confirmed TB at follow-up.
Conclusion: TB bacterial and host biomarkers were prevalent and no different between sputum-discordant and sputum-negative participants, raising concern for a considerable population of undiagnosed culture-negative TB. These findings parallel new evidence of Mtb aerosolization from sputum-negative individuals and highlight a need for more comprehensive diagnostics that detect sputum culture-negative TB with respect to infectiousness, pathology, and risk of progression.

	Sputum-DISC (n = 66)	Sputum-NEG (n = 52)	p-value Sp-Neg-Disc	Sputum-POS (n = 30)
Any Mtb bacterial biomarker -% (n/ N_{all})	16.7% (11/66)	26.9% (14/52)	0.26	N/A
Mtb growth in extended incubation MGIT cultures[1] - % (n/N_{all})	1.7% (1/58)	0.0% (0/51)	1.00	N/A
Mtb mRNA detected in baseline sputum[2] - % (n/ N_{all})	15.2% (10/66)	26.9% (14/52)	0.17	93.1% (27/29)
Any longitudinal Mtb bacterial biomarker - % (n/$N_{untreated}$)	26.5% (9/34)	41.7% (20/48)	0.17	N/A
Mtb growth in month 2 supplemented cultures[4] - % (n/$N_{untreated}$)	10.3% (3/29)	9.8% (4/41)	1.00	N/A
Progression to culture-positive TB (longitudinal) - % (n/$N_{untreated}$)	2.9% (1/34)	2.1% (1/48)	1.00	N/A

[1]Extended MGIT culture results missing for eight discordants and one sputum-negative.
[2]Sputum samples for mRNA analysis not collected from one sputum-positive.
[3]Nine discordants lost to follow-up prior to month 2 and two discordants LTFU after month 2 phone visit excluded from "untreated".
[4]Supplemented month 2 MGIT results are missing for five untreated discordants and seven untreated sputum-negatives.

Table. Frequencies of baseline and longitudinal TB disease biomarkers among sputum-discordant, sputum-negative, and sputum-positive cohorts.

TBS-EP203 Performance of the *DREstimator* tool to predict the phenotypic effect of genomic variants in *Mycobacterium tuberculosis* – A validation study

M. de Diego Fuertes,[1] T. Maseko,[1] V. Rennie,[1] W. Quispe Rojas,[1] A. Van Rie,[1] [1]University of Antwerp, Antwerp, Belgium
e-mail: miguel.dediegofuertes@uantwerpen.be

Background: The WHO catalogue greatly advanced knowledge on phenotypic resistance associated with genomic variants, but 70% of variants are classified as of 'uncertain significance' due to lack of statistical associations. This complicates the use of next generation sequencing (NGS) results for clinical care.
Methods: We developed the *DREstimator* tool to integrate results of AI models predicting the impact of mutations on protein structure and function, expanded expert grading rules, and paired genotype-phenotype data. A Bayesian probabilistic framework then assigns a probability of drug resistance for each variant in tier 1/2 candidate drug resistance genes.
Performance was assessed for 14 drugs currently used for TB treatment using the Seq&Treat data as an independent validation dataset, the *MAGMA* pipeline for analysis of WGS data and MGIT phenotypic drug susceptability test (DST) results as the reference.
Results: Drug resistance predictions were computed for 51,355 variants detected in 723 Mtb isolates. Of the 19,047 (37%) variants classified in the WHO catalogue as of uncertain significance, the DRestimator classified 293 (1.5%) variants as having a high probability, 18,173 (95.4%) as low, and 581 (3.1%) as moderate probability of conferring phenotypic drug resistance.
The *DREstimator* achieved an overall 95.1% sensitivity and 90.5% specificity (Table). Sensitivity exceeded the WHO Target product profile threshold for next-generation drug-susceptibility testing for all drugs except linezolid (63%). Specificity was ≥90% except for rifampicin (80%), ethambutol (80%), amikacin (87%) and streptomycin (88%).

Drug	Variants assoc. with R (+interim)	Variants not assoc. with R (+interim)	Variants of uncertain significance	DREstimator Sensitivity	DREstimator Specificity
AMK	142 (4%)	1488 (41%)	2004 (55%)	97%	87%
BDQ	93 (2%)	2454 (57%)	1778 (41%)	84%	97%
CFZ	89 (1%)	3115 (47%)	3475 (52%)	92%	97%
EMB	409 (10%)	2579 (62%)	1166 (28%)	95%	80%
INH	672 (18%)	1913 (53%)	1062 (29%)	97%	95%
FQ	348 (9%)	2989 (79%)	455 (12%)	96%	96%
LIN	15 (1%)	790 (72%)	296 (27%)	63%	90%
PZA	376 (12%)	1880 (59%)	925 (29%)	92%	95%
RIF	586 (13%)	2969 (66%)	944 (21%)	99%	80%

Conclusion: The *DREstimator* can extend the predictive capability of sequencing data by employing state-of-the-art methods that go beyond statistical association. Our validation study suggests that WGS-based DST can exceed the requirements of the WHO target product profile for NGS DSTs for all drugs except linezolid. Paired genotype-phenotype data for pretomanid/delamanid should be generated and shared to further improve evaluation of the performance of genomic DST interpretation frameworks.

TBS-EP206 Revisiting the mouse model for tuberculosis-malaria co-infections through the natural routes to measure immunopathology and pathogen fitness

T. Gupta,[1] D. Sarr,[1] R. Sharma,[1] K. Rzepka,[1] M. Menos,[1] B. Rada,[1] D. Kyle,[1] F. Quinn,[1] A. Pathak,[1]
[1]University of Georgia, Athens, United States of America
e-mail: tgupta@uga.edu

Human tuberculosis (TB), caused primarily by *Mycobacterium tuberculosis* (*Mtb*), and malaria, transmitted by mosquitoes infected with *Plasmodium falciparum)*, together accounted for 273.8 million cases and 3 million deaths in 2023. While these diseases overlap geographically, the contribution of co-infection has received little attention. The role of host sex in immunomodulation is critical, as the number of TB cases in men is higher than in women, similarly, men carry malaria parasites longer than women.
We developed a mouse model to study TB-malaria co-infections, mimicking natural infection routes. In this study, we exposed mice to aerosolized *Mtb* followed by mosquito-mediated *P. berghei ANKA* (*Pb*); *Pb* induces cerebral human malaria-like pathology in mice. We hypothesized that *Mtb*-infected mice exposed to *Pb*-infected mosquitoes would show increased pathogen burden and immune pathology, with males experiencing exacerbated inflammation and reduced survival.
Male and female C57BL/6 mice were divided into four groups:
1. Mosquito bites only,
2. Only *Mtb* infected,
3. Only exposed to *Pb*-infected mosquitoes, and;
4. *Mtb* infected followed by exposure to *Pb*-infected mosquitoes at day 28.

Mice were euthanized at days 3–6 post-exposure, and blood, bronchoalveolar lavage (BAL), lung, spleen, liver, and brain were collected for pathogen burden, histopathology, immune cell infiltration, and cytokine/chemokine analysis.
We observed that the mouse model demonstrates higher bacterial and disease burdens (pathology) in males infected with *Mtb* bacilli alone. Second, bacterial and disease burdens were reduced in co-infected male mice than females. Third, these differences correlate with elevated Pb parasitemia and changes in percent immune effector

cells (CD4+ and CD8+) infiltrating the lungs. Finally, compared to mice infected with Pb alone, parasitemia was reduced in co-infected mice of both sexes. Systemic and localized cytokine and chemokine measurement and humoral response to individual infectious agents are ongoing.

TBS-EP209 Can emergence of canonical mechanisms of isoniazid resistance in tuberculosis be predicted?

A. Valafar,[1] S. Valafar,[2] F. Valafar,[3] [1]San Diego State University / University of California San Diego, San Diego, United States of America, [2]Loyola Medical Center, Chicago, United States of America, [3]San Diego State University, San Diego, United States of America
e-mail: faramarz@sdsu.edu

Resistance in *Mycobacterium tuberculosis*, the obligate pathogen of tuberculosis, typically follows a stepwise trajectory: isoniazid (INH) resistance often arises first, followed by resistance to rifampicin, pyrazinamide, ethambutol, and eventually second-line drugs. Preventing INH resistance may therefore delay or reduce broader drug resistance. This study investigates the prognostic value of specific mutations in predicting the emergence of canonical INH resistance mutations—*katG* S315T, *inhA*-15C>T, and *inhA*-8T>C.

We analyzed genomic and phenotypic data from over 16,000 isolates sourced from the TB Portals and the CRyPTIC consortium. Using logistic regression and deep neural networks, we trained predictive models on TB Portals data and validated them on CRyPTIC data. The top-performing model was a deep neural model, which identified promising prognostic mutations. We evaluated the predictive power of individual mutations and all two-mutation combinations using metrics including accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV).

The most effective model employed a combination of two prognostic genomic markers, achieving 73% accuracy, 55% sensitivity, 84% specificity, 69% PPV, and 75% NPV in predicting the emergence of the three canonical INH resistance mutations. While the sensitivity is moderate, it reflects the diversity of evolutionary pathways leading to INH resistance; our model captures only those involving the selected prognostic markers.

Our findings support the hypothesis that INH resistance in *M. tuberculosis* evolves in a stepwise manner, with identifiable genomic precursors. These results suggest that resistance prediction—and potentially prevention—may be possible through early genomic surveillance. Future studies with time-resolved datasets will be critical to uncover additional prognostic markers and map alternate evolutionary trajectories toward drug resistance.

TBS-EP212 Assessing the translational value of *in vitro* time-kill assays in TB drug regimens development

M.S. Rabodoarivelo,[1] S. D'Agate,[2,3] R. Bailo,[1] P. Laddomada,[2,3] J. Calvet,[4] D. Ndjogou,[5] O. Della Pasqua,[2,3] S. Ramón- García,[1,6,7] ERA4TB, grant No 853989

e-mail: mrabodoarivelo@unizar.es

To accelerate the timely introduction of novel tuberculosis (TB) treatments, innovative translational *in vitro* biomarkers and modeling approaches can be used. *In vitro* evaluations often test bacteria in exponential-phase in synthetic 7H9 glycerol medium and rely only on colony-forming units (CFU) as biomarker readout, which overlooks non-culturable bacteria, a limitation partially addressed in clinical trials by incorporating time to positivity (TTP).

Additionally, focusing only on exponential-phase bacteria may fail to capture drug efficacy against slower-growing populations.

Using BPaL - bedaquiline (BDQ, B), pretomanid (PTD, Pa), and linezolid (LZD, L)- as a model combination with *in vivo* and clinical available data, we generated predictive *in vitro* data and develop a translational modeling framework using *in vitro* time-kill assays (TKA) with novel biomarkers to interrogate different bacterial states.

We integrated additional biomarkers such as Most Probable Number (MPN) in TKA, which correlates with TTP, as well as RNA synthesis (RS) ratio and Molecular Bacterial Load Assay (MBLA) readouts, along with stationary-phase bacteria and the more physiologically relevant cholesterol medium.

First, we characterized natural bacterial growth over 110 days to establish baseline behavior, followed by 14-day TKA monotherapy to characterize the individual drug effect in both exponential and stationary conditions.

Then, conducted a 50-day combinatorial TKA, evaluating PTD and LZD´s effect on BDQ potency. Compound stability was measured by LC/MS-MS in the same TKA samples.

BDQ monotherapy showed delayed bactericidal activity. BPa demonstrated stronger interaction than BL. Overall potency was enhanced in the 3-drug combination with increasing PTD concentrations, while changes in LZD concentration had minimal impact. BDQ and Pa were the

key drivers of BPaL potency. Our *in vitro* data suggest that linezolid may be dispensable, leaving room for other improved drugs in development.
Future work will assess this *in vitro* translational framework to predict the activity of novel TB regimens.

TBS-EP215 Integrating Spatial Modelling and Contextual Data to Optimize the Identification of People Living with TB in Uganda

M. Potgieter,[1,2] C. Van Cauwelaert,[1] M. Mudiope,[3] J. Stow,[1] A.-L. Budts,[1] A. Zitho,[1] [1]EPCON, Cape Town, South Africa, [2]Computational Biology Division, Department of Integrative Biomedical Sciences, University of Cape Town, Cape Town, South Africa, [3]Infectious Diseases Institute, College of Health Sciences, Makerere University, Kampala, Uganda
e-mail: anne-laure@epcon.ai

Tuberculosis (TB) continues to affect many communities in Uganda. To enhance the efficiency of Active Case Finding (ACF), we developed a spatially resolved predictive model combining retrospective ACF data (2024–2025) with contextual vulnerability indicators. Our dataset included ACF screening volumes, bacteriologically confirmed TB (B+) identification rates, and geolocated demographic and environmental factors.
We applied a weighted k-means clustering algorithm to create approximately 10,000-sized Thiessen clusters across Uganda, aggregating all predictor variables and TB identification rates at the cluster level. Predictor features included population density, motorized travel time to health services, relative deprivation index, vaccination coverage, literacy levels, HIV prevalence, and malnutrition prevalence.
To evaluate model performance, we used district-level cross-validation by holding out all clusters within specific districts during training and using them solely for testing. We compared three machine learning algorithms—Naive Bayes (NB), Random Forest (RF), and XGBoost—using Relative Risk Increase (RRI) as the primary metric. We used RRI to quantify the relative identification yield of people living with TB in the top 30% predicted high-risk areas compared to the remaining 70%.
XGBoost showed the strongest performance, with an RRI of 0.74, indicating a 74% higher rate of diagnosing people living with TB in prioritized hotspots. NB and RF performed less effectively, demonstrating that XGBoost more reliably identified high-risk locations in unseen districts.
The final XGBoost model, retrained on all available cluster data, is deployed on the Epi-Control geoportal, enabling health teams to visualize and prioritize areas for targeted ACF activities.
This approach represents the first application of 10,000 weighted Thiessen clusters combined with district-level validation for TB risk modeling in Uganda. Ongoing updates will improve hotspot precision, supporting Uganda's National TB Program to optimize resource allocation and accelerate TB detection.

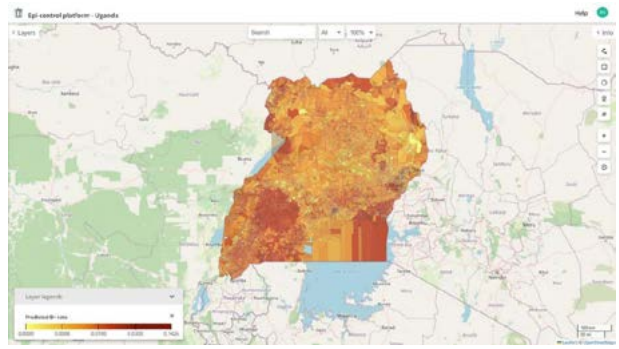

Fig. 1 - Visualisation of the TB Predictive Model: B+ rate

TBS-EP218 Spread and drug resistance of a lineage-2 *Mycobacterium tuberculosis* subgroup in Hanoi, Vietnam

H.T.-L. Nguyen,[1] M. Hijikata,[2] S. Maeda,[3] T.H. Pham,[4] H.V. Hoang,[5] H.P. Nguyen,[5] S. Seto,[2] N. Keicho,[2,6] [1]Japan Institute for Health Security-Bach Mai Hospital Medical Collaboration Center, Hanoi, Viet Nam, [2]The Research Institute of Tuberculosis, Japan Anti-Tuberculosis Association, Tokyo, Japan, [3]Hokkaido University of Science, Hokkaido, Japan, [4]My Duc District General Hospital, Hanoi, Viet Nam, [5]Hanoi Lung Hospital, Hanoi, Viet Nam, [6]Japan Institute for Health Security, Tokyo, Japan
e-mail: lehang0310@gmail.com

Background: Ongoing transmission combined with drug resistance makes tuberculosis difficult to control. We investigated the characteristics of *Mycobacterium tuberculosis* (Mtb) strains that have been more prevalent in Hanoi, Vietnam, over the past decade.
Methods: Patients newly diagnosed with smear-positive pulmonary tuberculosis were recruited into cohorts in 2007 and 2017. Mtb DNA was extracted from clinical isolates collected prior to treatment, and genome sequencing data, including drug resistance-conferring mutations, were obtained using a short-read (Illumina) sequencer with TB-Profiler version 4.3.
Results: Whole-genome sequencing was performed on 332 Mtb strains in 2007 and 320 in 2017. The proportion of predominant lineage-2 ancient Beijing strains rose from 36.8% (2007) to 48.1% (2017), largely driven by a phylogenetically defined subgroup designated as G strains, which increased from 14.8% to 27.5%. In the 2017 cohort, this G subgroup was more predominant among patients living in urban than sub-urban areas (31.5% vs. 18.4%, P = 0.028), a trend not observed in 2007. While drug resistance–conferring mutations were significantly more frequent in G strains in both cohorts, the higher

frequency of rifampicin resistance in these strains was significant only in the 2017 cohort (20.5% vs. 7.8%, P = 0.001).
In multivariate analyses, multidrug resistance was associated with G strains in the 2017 cohort (adjusted odds ratio = 3.90, 95% confident interval: 1.81–8.43), but not in 2007, after adjusting for patients' age, gender, and living area. Shorter phylogenetic terminal branch lengths of G strains (P < 0.0001 vs. other strains; P = 0.027 vs. other ancient Beijing strains) suggested recent transmission.
Conclusions: In Hanoi, a subgroup of ancient Beijing Mtb strains (G strains) expanded over ten years, becoming more drug-resistant and showing evidence of recent transmission. Further analyses are needed to elucidate contributing factors, and thus improve tuberculosis control, especially in urban areas of large cities.

TBS-EP221 Biomarker combinations of TB-MBLA with CFU and TTP give greater biological insight in EBA studies

M. McClean,[1,2] S. Koele,[3] J. Dreisbach,[2,4] P. Phillips,[5] K. Narunsky,[6] E. Svensson,[3,7] F.P. Casale,[1] M. Hoelscher,[2,4,8]
[1]Helmholtz Zentrum München, German Research Center for Environmental Health, Neuherberg, Munich, Germany, [2]Division of Infectious Diseases and Tropical Medicine, University Hospital Ludwig Maximilian University (LMU), LMU Munich, Munich, Germany, [3]Department of Pharmacy, Pharmacology, and Toxicology, Radboud Institute for Medical Innovation, Radboud university medical center, Nijmegen, Netherlands, [4]German Center for Infection Research (DIZF), Partner Site Munich, Munich, Germany, [5]UCSF Center for Tuberculosis, University of California San Francisco, San Franscisco, United States of America, [6]University of Cape Town Lung Institute, Cape Town, South Africa, [7]Department of Pharmacy, Uppsala, Sweden, [8]Fraunhofer Institute for Translational Medicine and Pharmacology ITMP, Immunology, Infection and Pandemic Research, Munich, Germany
e-mail: mairi.mcclean@helmholtz-munich.de

Introduction: Culture-based monitoring of bacterial load is slow and susceptible to missing data, contributing to the length and cost of TB clinical trials. Non-culture-based alternatives, like the Tuberculosis Molecular Load Bacterial Assay (TB-MBLA), could represent a solution. Our objectives were to evaluate TB-MBLA as a biomarker in early bactericidal activity (EBA) studies and explore whether combining biomarkers with joint modelling could provide insight into underlying biological processes and reduce data loss.
Methods: We performed TB-MBLA (LifeArc) on sputum samples from all 78 patients from the BTZ-043 Phase Ib/IIa trial. We developed a probabilistic principal component analysis (pPCA)-based joint model of paired TB-MBLA, colony forming units (CFU) and time-to-positivity (TTP) data, and extracted the first principal component (PC1). With TB-MBLA alone and the PC1 marker we recapitulated the original stage IIa dose-response and stages Ib/IIa pharmacokinetics - pharmacodynamics (PK-PD) exposure-response models, applying linear and non-linear mixed models, respectively.
Results: In the stage IIa dose-response model, TB-MBLA alone indicated 500mg as the best performing arm, similar to TTP. In the stage Ib/IIa PK-PD analysis we could not detect an exposure-response effect, in contrast with CFU and TTP. When combining biomarkers, the stage IIa dose-response model of the PC1 marker identified 1000mg as the best arm - similar to CFU. In the stage Ib/IIa PK-PD analysis, we did observe evidence for an Emax exposure-response between days 0-3, and the model of the PC1 marker described the data well (Figure 1).

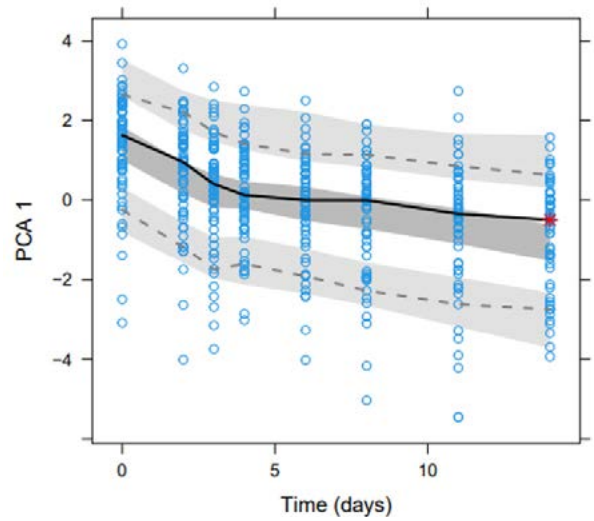

Figure 1. Visual predictive plot for PC1 PK-PD model using the $AUC_{0\text{-}24}$ $BTZ\text{-}043_{total}$.

Conclusions: Our PK-PD results in TB-MBLA offer new insights into the early temporal dynamics of BTZ-043 and its interaction with 16S ribosomal activity. We also successfully applied pPCA as a modelling framework, and showed that combined biomarkers may detect effects otherwise missed by single markers.

TBS-EP224 Optimizing the thresholds of the computer-aided detection for tuberculosis (CAD4TB) algorithms for tuberculosis screening in Mozambique

I. Manhica,[1] D. Macheque,[1] B. Macuacua,[2] E. Klinkenberg,[3] E. Klinkenberg,[4] M. van Erp,[5] J. Pedro,[6] [1]Ministry of Health, Maputo, Mozambique, [2]USAID, Maputo, Mozambique, [3]DELFT Imaging Systems, s-Hertogenbosch, Netherlands, [4]Independent Consultant, the Hague, Netherlands, [5]Delft Imaging Solutions, s-Hertogenbosch, Netherlands, [6]DELFT Imaging, 's-Hertogenbosch, Netherlands
e-mail: evelineklinkenberg@gmail.com

Background: In Mozambique, despite rising incidence, TB screening and diagnosis remain challenging due to limited access to chest X-rays (CXR) and skilled radiologists. Computer-Aided Detection for Tuberculosis (CAD4TB), recommended by the WHO, offers a potential solution by automating CXR analysis.
However, the frequent software updates require constant evaluation. This study was conducted to assess the accuracy and optimal threshold of CAD4TB version 8, compared to earlier versions.
Design/Methods: We conducted a secondary data analysis of the National TB Prevalence Survey conducted in 2017. Participants ≥15 years, screened for TB symptoms, with CXR images and TB microbiological reference (Xpert MTB/RIF/culture) were included. CXRs were analysed using CAD4TB versions 5, 6, and 8.
Thresholds corresponding to 90% sensitivity were identified and compared. Receiver operating characteristic (ROC) curves were plotted to compare the accuracy of newer versus older versions and tested for significance. A subgroup analysis was conducted for people living with HIV.
Results: A total of 23.776 individuals were included in the analysis, of which 60 tested positive for TB. The 90% sensitivity threshold differed between versions: v5 and v6, v8. All versions did not show a significant difference between the algorithms in terms of AUC-ROC: CAD4TB v5 (0.96), v6 (0.96), and v8 (0.94) in the general population, as detailed in Figure 1.
Although CAD4TB v8 showed a higher AUC-ROC among individuals living with HIV (AUC v8: 0.98; v6: 0.96; v5: 0.90), the difference observed was not statistically significant (v5 vs. v8; *p-value* = 0.052).

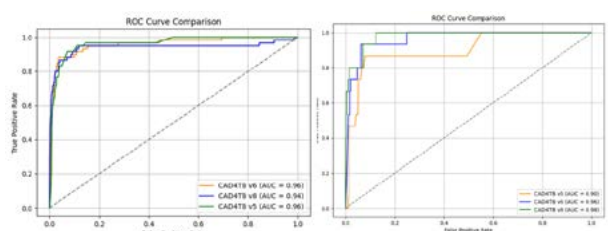

Figure 1: AUC-ROC for several CAD4TB versions in the general population (Left), people living with HIV (Right).

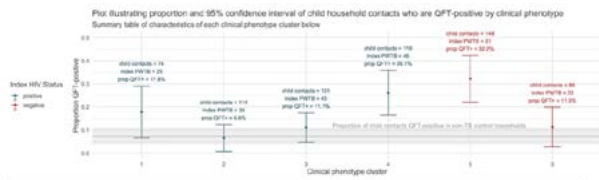
Conclusions: The updated versions of CAD4TB (v8) had comparable performance with their predecessors. This data also suggests that the new version can be used as a screening tool in high-risk populations where there is a lack of radiography experts.

TBS-EP227 Machine learning approach identifies distinct clinical phenotypes of HIV-associated pulmonary tuberculosis associated with differences in household transmission risk

P.Y Khan,[1] I. Govender,[1] T. Smit,[2] M. Sithole,[3] N. McCreesh,[4] K. Fielding,[5] A. Grant,[1,6] [1]London School of Hygiene & Tropical Medicine, Clinical Research Department, London, United Kingdom of Great Britain and Northern Ireland, [2]Africa Health Research Institute, Diagnostic Research Division, Durban, South Africa, [3]Africa Health Research Institute, Data Science Unit, Durban, South Africa, [4]London School of Hygiene & Tropical Medicine, Department of Infectious Disease Epidemiology and Dynamics, London, United Kingdom of Great Britain and Northern Ireland, [5]London School of Hygiene & Tropical Medicine, Department of Infectious Disease Epidemiology and International Health, London, United Kingdom of Great Britain and Northern Ireland, [6]Africa Health Research Institute, Durban, South Africa
e-mail: palwasha.khan@lshtm.ac.uk

Background: Traditional classifications of pulmonary tuberculosis stratified by HIV status may over-generalise and miss heterogeneity in clinical phenotypes, which may be associated with differences in household transmission risk. This study investigates the association between machine learning-derived clinical phenotypes of pulmonary TB and household transmission risk in a high-HIV/TB burden context.
Methods: We recruited sputum-positive index PWTB (≥15 years) starting treatment at 12 health facilities in KwaZulu-Natal and measured QuantiFERON-TB Gold Plus (QFT) positivity among their child household contacts (2-14 years) as a proxy measure of household transmission risk. An unsupervised machine learning (ML) algorithm was used to decompose clinical, microbiological and radiological features of index PWTB into distinct phenotypes stratified by HIV status. The numbers of clusters for each HIV stratum was determined *a priori* (minimum cluster size ≥ 30).
We assessed the association between ML-derived clinical phenotypes and QFT-positivity in child contacts using a GEE logistic regression model.
Results: 291 index PWTB were included in the ML analysis, of whom 62% were people living with HIV (PLHIV). 4 distinct ML-derived phenotypes in PLHIV (clinical phenotype 1 – 4) and 2 distinct ML-derived phenotypes in HIV-negative PWTB (clinical phenotype 5 – 6)

were identified. Figure below includes a plot illustrating the proportion of child contacts QFT-positive by clinical phenotype and a summary table of characteristics of each clinical phenotype cluster. Note not all index PWTB contributing to ML analysis had a household visit to assess child contact QFT-status. Child contacts of clinical phenotypes 4 and 5 had a 5.0 and 6.7-fold higher odds of being QFT-positive compared to clinical phenotype 2 (p-value 0.003 and <0.001 respectively).



Cluster characteristics	Clinical phenotype 1	Clinical phenotype 2	Clinical phenotype 3	Clinical phenotype 4	Clinical phenotype 5	Clinical phenotype 6
HIV status	HIV+	HIV+	HIV+	HIV+	HIV-	HIV-
No. index PWTB per cluster	31	40	33	31	71	40
Percentage male	77%	29%	42%	47%	66%	52%
Median age (years)	32	39	51	35	38	47.50
Median BMI	20.10	26.10	24.60	20.20	20.10	23.65
Percentage with previous history of TB	16%	25%	51%	42%	3%	20%
Percentage reporting cough	90%	16%	79%	86%	63%	50%
Percentage reporting weight loss	90%	13%	63%	73%	57%	40%
Percentage reporting nights sweats/fever	94%	13%	69%	84%	63%	55%
Median CADHTB score	65	47	52	92	97	62.50
Percentage with cavitation on CXR	13%	2%	0	27%	48%	8%
Median Ultra Ct value (4 rpoB probes)	24.20	40	40	20.90	16.50	40
Percentage rpoBres confirmed	100%	23%	3%	100%	99%	17%
Percentage AKT client in last 3 months	94%	2%	9%	0	-	-
Median HIV VL log10copies/ml	4.43	0	0	0	-	-
Median CD4 count	137	508	620	201	-	-

Conclusion: A ML approach identified distinct TB phenotypes based on clinical, bacteriological and radiological data. Phenotypes with more radiological cavitation and higher bacillary burden were associated with a higher household transmission risk irrespective of HIV status.

TBS-EP230 A dual-CRISPRi system to probe gene-gene interactions in *M. tuberculosis*

V. Faulkner,[1] J.C. Evans,[1] E.O. Johnson,[1]
[1]The Francis Crick Institute, London, United Kingdom of Great Britain and Northern Ireland
e-mail: valwynne.faulkner@crick.ac.uk

Mycobacterium tuberculosis, which causes human tuberculosis, remains one of the world's deadliest pathogens. The continual rise in drug resistant strains poses significant challenges for treatment and control, emphasising the urgent need for new drugs with novel targets, ideally with a high bar for evolution of resistance.
Paths to resistance against target-specific inhibitors could be revealed by gene-gene interactions, which constrain evolution at some genomic loci by requiring, for example, complementary mutations on a protein-protein interface. On the other hand, the extended network of genetic interactions can buffer the effects of loss-of-function, which may fuel evolution at other genomic loci. To better understand the target vulnerability spectrum in *M. tuberculosis*, anticipate resistance, reveal synthetic lethal gene pairs, and annotate new gene functions as pioneered in *Saccharomyces cerevisiae*, we aim to map genetic interdependencies and identify gene-gene interactions essential for mycobacterial survival.
To systematically probe gene-gene interactions in *M. tuberculosis*, we built on previous work by others, to develop a dual-CRISPRi/dCas9 system employing synthetic guide RNA scaffolds and synthetic promoters driving guide RNA expression to enable programmable titration of transcription of gene pairs independently in *M. tuberculosis*. Alongside, we optimised *M. tuberculosis* transformation efficiencies to enable dual-CRISPRi libraries of 10^6 clones per electroporation, whose multiplexed fitness can be determined using next-generation sequencing.
Having recapitulated known synthetic rescue pairs implicated in drug resistance, we are aiming to understand (i) the concordance between metabolic pathway topology and gene-gene interactions and (ii) the collateral sensitivity of evolved resistance emerging from loss-of-function of specific genes.
The resulting gene-gene interaction networks will also comprise a reference dataset to assist interpretation of data from PROSPECT a large-scale chemical-genetic interaction screening platform, to prioritise small molecules with new targets towards developing therapies with reduced selective pressures.

TBS-EP233 Differential responses of *Mycobacterium tuberculosis* complex lineages to tuberculosis treatment regimens

F. Faal,[1] N. Top,[1] M. Duran-Frigola,[2] O. Jobe,[1]
S.M. Colley,[1] A.P. Pandurangan,[3] J.E. Phelan,[4]
L.D. Tientcheu,[1,4] [1]Medical Reserach Council Unit The Gambia at London School of Hygiene and Tropical Medicine, Banjul, Gambia (Republic of The), [2]Ersilia Open-Source Initiative, Spain, Spain, [3]VPD Heart and Lung Research Institute, University of Cambridge, Cambridge, United Kingdom of Great Britain and Northern Ireland, [4]Department of Infection Biology, Faculty of Infectious and Tropical Diseases, London School of Hygiene and Tropical Medicine, London, United Kingdom of Great Britain and Northern Ireland
e-mail: fatou.faal@lshtm.ac.uk

Background: Tuberculosis (TB), caused by the *Mycobacterium tuberculosis* complex (MTBC), comprises ten lineages globally, all present in Africa. While some lineages, like Mtb lineages 2 and 4, are widespread, others, such as *M. africanum* (Maf lineages 5 and 6), are restricted to West Africa. Despite this diversity, drug-susceptible TB is treated uniformly with a six-month antibiotic regimen, ignoring lineage-specific variations that may affect outcomes. Addressing these differences is crucial for improving TB control.
Methods: We transformed drug-susceptible clinical isolates representing Africa's MTBC diversity with luminescence and green fluorescent protein reporter plasmids. These isolates were tested in a 20-day drug susceptibility assay to evaluate lineage-specific responses. Inhibitory

concentrations (ICs) for first-line, second line, and new anti-TB drugs were determined using the Collaborative Drug Discovery (CDD) Vault. Custom Python scripts identified optimal IC values and time points per lineage. These findings guided the evaluation of nine novel treatment regimens in clinical trials using checkerboard assays.

Results: IC measurements were most consistent between days 10 and 15 post-treatment across all lineages, with earlier or later time points showing variability. Notably, the IC50 of first-line drugs like rifampicin varied up to 4-fold between Mtb-lineage 4 and Maf-lineage 6.

Combination testing revealed significant differences in regimen efficacy from day 10, with day 20 as a robust benchmark. Trial1 (bedaquiline, linezolid and rifapentine), and Trial2 (bedaquiline, clofazimine and moxifloxacin) were less effective against Mtb-lineage 2, while SimpliciTB (bedaquiline, preteonamid, moxifloxacin and pyrazinamide) and Trial1 showed reduced activity against Mtb-lineage 4. For Maf-lineage 6, only End-TB (bedaquiline, moxifloxacin and pyrazinamide) and Trial1 outperformed the standard regimen, with all differences statistically significant.

Conclusion: MTBC lineage diversity significantly impacts anti-TB regimen efficacy. Some regimens showed enhanced efficacy against specific lineages, underscoring the potential of lineage-tailored treatments to shorten therapy and improve TB control outcomes.

TBS-EP239 The impact of phylogenetic lineages on the drug susceptibility of *Mycobacterium tuberculosis*

L. Muñoz-Muñoz,[1] D.A. Aguilar-Ayala,[1] R. Bailo-Vergara,[1] A. Picó Marco,[1] B.L. Gracia Díaz,[1] C. Villellas-Arilla,[1] A. Lucía-Quintana,[1,2] S. Ramón-García,[1,2,3] (ERA4TB Consortium. Grant No 853989) [1]Department of Microbiology. University of Zaragoza, Zaragoza, Spain, [2]Spanish Network for Research on Respiratory Diseases (CIBERES), Carlos III Health Institute, Madrid, Spain, [3]Research & Development Agency of Aragón (ARAID) Foundation, Zaragoza, Spain
e-mail: laramm@unizar.es

Background: *Mycobacterium tuberculosis* complex can be classified into seven major phylogenetic lineages (L1-L7). Despite this diversity, most *M. tuberculosis* research has traditionally focused on H37Rv strain, and to a lesser extent Erdman strain, both belonging to L4. To reset this gap, Borrell *et al.* recently published a set of 20 genetically well-characterized clinical strains that represent all seven lineages (PMID:30908506).

Here, we aim to explore the impact of phylogenetic lineages on *M. tuberculosis* drug development by evaluating the susceptibility of classical anti-tuberculous drugs against the lineage reference set.

Results: Minimum inhibitory concentrations (MIC) of classical anti-tuberculous drugs were performed using a standardised protocol. Following EUCAST guidelines, only final bacterial inocula between 10^4 and 10^6 CFU/mL were accepted as valid.

Clinical strains exhibited a wide range of susceptibility profiles to the drugs tested. Moxifloxacin showed the most consistent MIC values (0.25mg/L) for all strains. In contrast, considerable variability was observed for most anti-tuberculous compounds, even within the same lineages.

L1 and L3 were associated with a tendency toward higher MIC for certain antibiotics, such as bedaquiline, pretomanid, isoniazid and ethambutol. General trends showed that the clinical strain set displayed MIC values equal or higher than those of H37Rv strain.

Furthermore, the use of different carbon sources influenced antimicrobial activity. Delamanid showed lower MIC values in cholesterol media, while ethambutol and rifampicin in fatty acid broth.

Conclusion: This work highlights that the use of the laboratory *M. tuberculosis* H37Rv strain and synthetic regular 7H9 media may not fully represent the clinical landscape, emphasizing the need for research with a wider range of strains from different lineages and carbon sources.

The lineage reference set could serve as a valuable tool for the initial screening of drug activity. However, establishing susceptibility trends associated with specific lineages would require a larger set of clinical strains.

TBS-EP242 The clinical potential of targeting the free fatty acid receptor 4 in COPD and asthma

B. Strellis,[1] S. Polcownuk,[1] G. Milligan,[1] A. Tobin,[1]
[1]University of Glasgow, School of Molecular Biosciences, Glasgow, United Kingdom of Great Britain and Northern Ireland
e-mail: beth.strellis@glasgow.ac.uk

The free fatty acid receptor 4 (FFA4) has been implicated in the regulation of inflammation and FFA4 agonists have shown promise as therapeutic agents in reducing inflammation in preclinical studies. Asthma and COPD involve chronic inflammation, however the precise physiological role of FFA4 in the lung remain underexplored. Our aim is to profile the expression of the FFA4 receptor within the airway and explore the functional role of this receptor in a model of lung disease.

To profile the transcriptional landscape of the FFA4 receptor in the lung, hybridisation chain reaction followed by smFISH was performed on 10 μm FFPE lung sections from FFA4-HA and FFA4-KO mice. To analyse FFA4 protein expression, lungs from FFA4-HA and FFA4-KO mice underwent Western blot analysis performed utilising an antibody against the HA-epitope tag. To examine

the functional role of FFA4 in the lung, 100 μM carbachol was administered onto precision cut lung slices (PCLS) from wildtype, FFA4-HA, and FFA4-KO mice to cause bronchoconstriction, then 100 μM of the FFA4 agonist TUG-891 was added to the lung slices. The resulting changes in airway diameter were imaged using the eVOS microscope.

Our findings demonstrate that FFA4 is expressed in the lung and plays a role in airway relaxation. Spatial transcriptomic analysis revealed that FFA4 is transcribed throughout the airway and also detected at the protein level in the lung. The PCLS model demonstrated significant contraction of the airway lumen following carbachol treatment in all three mouse lines ($P<0.0001$, two-way ANOVA; n=6), however only the wildtype and FFA4-HA mouse lines gave significant airway relaxation following treatment with TUG-891 ($P<0.05$, two-way ANOVA; n=6), indicating an FFA4-specific effect.

These data reveal the expression of the FFA4 receptor in the airway and provide evidence of its function in airway relaxation, providing a therapeutic target for lung diseases involving bronchoconstriction.

TBS-EP245 Evaluation of locally synthesized silica-coated magnetic nanoparticles for development of a *Mycobacterium tuberculosis* DNA concentration assay

J.M. Cuales,[1] B. Alcantara,[2] C. Pangilinan,[1] M.F.J. Ordoñez,[3] R.J. Guerrero,[3] M. Vasquez Jr.,[2] M. Kato-Maeda,[4] R. Destura,[1]
[1]National Training Center for Biosafety and Biosecurity, National Institutes of Health, University of the Philippines Manila, Manila, Philippines, [2]Department of Mining, Metallurgical, and Materials Engineering, University of the Philippines, Diliman, Quezon City, Philippines, [3]Ateneo Research Institute of Science and Engineering, Ateneo De Manila University, Quezon City, Philippines, [4]University of California, San Francisco, San Francisco, California, United States of America
e-mail: jdcuales@up.edu.ph

Tuberculosis (TB), especially with the rise of multidrug resistant TB (MDR-TB), has prompted intensified efforts to develop point-of-care testing (POCT). While most molecular diagnostics tools focus on simplifying gene amplification and detection of MDR-TB specific mutations, the limit of detection of these assays depends on efficiency and portability of the DNA concentration method. In this context, magnetic nanoparticles (MNPs) offer advantages for rapid and efficient DNA extraction in limited resource settings.

Our goal was to develop a Magnetic Nanoparticle-based DNA concentration workflow capable of yielding sufficient TB DNA from sputum samples that can be used for subsequent downstream applications. For this, iron oxide MNPs modified with silica coating (Si-MNPs) were locally synthesized. Using *Mycobacterium smegmatis* with known concentration as test samples, the DNA extraction performance of Si-MNPs (50, 100, 150, 200, and 250 mg/mL) and one commercial magnet-based kit was compared.

Three extraction runs using 10^5 CFU/mL of *M. smegmatis* and one extraction run with lower bacterial concentrations (10^4-10^1 CFU/mL) were conducted. Then, the concentration of DNA extracts was measured using a Qubit fluorometer and relative quantities were assessed by quantitative PCR targeting the 465 bp 16S rRNA of *M. smegmatis*.

TABLE 1. Qubit measurements of DNA extracts (Average DNA concentration in ng/mL) obtained from different concentrations (CFU/mL) of *M. smegmatis*.

Magnetic Nanoparticle	10^5 CFU/mL	10^4 CFU/mL	10^3 CFU/mL	10^2 CFU/mL	10^1 CFU/mL
Commercial MNPs	2.44 ± 0.54	2.7 ± 1.17	2.85 ± 0.8	2.77 ± 0.8	1.99 ± 0.27
50 mg/mL Si-MNPs	2.26 ± 0.54	1.83 ± 0.79	0.99 ± 0.33	1.28 ± 0.4	1.72 ± 0.97

150 mg/mL Si-MNPs	2.64 ± 0.47	1.28 ± 0.66	0.65 ± 0.05**	0.71 ± 0.21*	0.57 ± 0.01**
200 mg/mL Si-MNPs	2.97 ± 0.41	0.88 ± 0.02**	< 0.50 ± 0***	0.69 ± 0.15*	0.60 ± 0.01**
250 mg/mL Si-MNPs	4.91 ± 1.31	1.34 ± 0.03	1.73 ± 0.83	1.59 ± 0.68	1.27 ± 0.5

NOTE: Three extraction runs using 10^5 CFU/mL of *M. smegmatis* and one extraction run of lower bacterial concentrations (10^4-10^1 CFU/mL) were conducted. For each extraction run, the six extraction protocols with varying MNPs (5 concentration of Si-MNPs and 1 commercial kit) were tested in triplicates. Asterisks (*, **, ***) denote the number of replicates that yielded a Qubit reading of "too low" (< 0.50 ng/mL).

For runs utilizing 10^5 CFU/mL, the 250 mg/mL Si-MNPs obtained the lowest average Cq value from qPCR (18.40). As shown in Table 1, Qubit measurements also revealed that there was a significant difference (p value < 0.001) across the protocols tested wherein the average DNA yield of 250 mg/mL Si-MNPs was significantly higher than that of 50-200 mg/mL Si-MNPs and the commercial kit.

Moreover, consistent and successful DNA extraction was observed using 250 mg/mL Si-MNPs even at 10^1 CFU/mL. With the potential for portability of MNPs, these results serve as a foundation towards development of DNA concentration method that can be coupled with POCT of MDR-TB.

TBS-EP248 A multiplex Mtb-specific FluoroSpot assay measuring IFNγ, TNF, and IL2-secreting cells can improve accuracy and differentiation across the tuberculosis spectrum

E. Folkesson,[1,2] F. Foroogh,[1,2,3] L. Kleberg,[1,2,3] M.S. Gower,[1,2,3] C. Sousa Silva,[1,2,3] H. Grönlund,[3,4] M. Correia-Neves,[1,5,6] B. Makower,[7] G. Källenius,[1,2,3] J. Bruchfeld,[1,2] C. Sundling,[1,2,3]
[1]Division of Infectious Diseases, Department of Medicine Solna,Karolinska Institute, Stockholm, Sweden, [2]Department of Infectious Diseases, Karolinska University Hospital, Stockholm, Sweden, [3]Center for Molecular Medicine, Karolinska University Hospital, Stockholm, Sweden, Stockholm, Sweden, [4]Therapeutic Immune Design, Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden, [5]Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga, Portugal, [6]ICVS/3B's-PT Government Associate Laboratory, Braga, Portugal, [7]Mabtech AB, Nacka Strand, Sweden
e-mail: elin.folkesson@ki.se

Introduction: Diagnostic tests to differentiate within the TB infection (TBI) spectrum are needed to improve diagnostic precision and to identify individuals with an increased risk of TB disease (TBD) progression.
Methods: FluoroSpot (Mabtech™) uses fluorescence-labeled antibodies detecting up to four cytokines from individual cells, i.e. "spots".
We evaluated a multiplex IFNγ,TNF,IL2 FluoroSpot assay and compared it to a standard IFNγ ELISpot following overnight incubation with *Mtb* antigens ESAT-6, CFP-10, and EspC.
Results: In a cohort of 114 individuals (TBD=24, TBI=63, IGRA- controls=27) FluoroSpot and ELISpot showed a good agreement for IFNγ detection, with spot forming units (SFUs) highly correlated (r^2=0.72, p<0.001).
Triple IFNγ/IL2/TNF+ cells (i.e. all three cytokines detected in one SFU), total IFNγ, and total IL2 had the highest positivity rate in both TBD (88%) and TBI (81-84%). Higher specificity for IFNγ/IL2/TNF resulted in higher Area-under-the-curve (AUC) than for IFNγ in both TBD (0.91 vs 0.87) and TBI (0.90 vs 0.87) compared to controls.

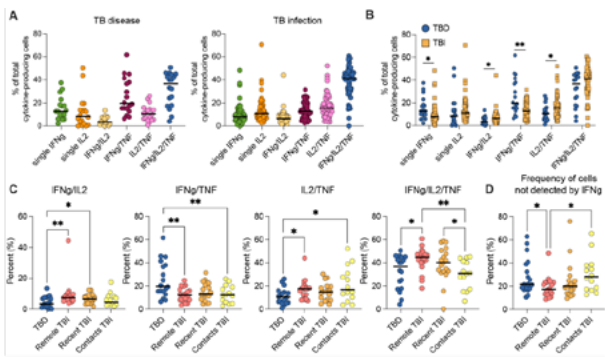

*Figure 1. Frequency of single, double and triple cytokine-producing cells after stimulation with Mtb antigens ESAT-6, CFP-10 and EspC. **A and B)** TB Disease (TBD) (n=18) and TB infection (TBI) (n=53). Comparisons using Mann-Whitney test. **C and D)** TBD (n=18) and TBI grouped by time since exposure: remote TBI; >2 years (n=20), recent TBI; 6 months to 2 years (n=19) and TB contacts; <6 months (n=14). Comparisons using a Kruskal-Wallis test followed by uncorrected Dunn's test. *p<0.05, **p<0.01*

Across the TB spectrum, non IFNγ+ cells constituted 17-28% of *Mtb* specific cells. Triple IFNγ/IL2/TNF+ cells were the most common celltype in individuals with TBD and TBI alike. The proportions of double IFNγ/IL2+ and IL2/TNF+ cells were higher in TBI (both p<0.05), with more single IFNγ+ (p<0.05) and double IFNγ/TNF+ (p<0.01) cells in TBD.
Furthermore, we detected differences within the TBI group; TB contacts with a recently aquired TBI (<6 months) had lower proportion of IFNγ/IL2/TNF+ cells compared to those with a long-standing TBI. By contrast, IFNγ/IL2+ cells were more abundant in TBI (>6 months) when compared to TBD.
Conclusion: Adding IL2 and TNF improved detection of TB specific immune responses compared to IFNγ alone. Distinct cytokine profiles associated with different stages of the TB spectrum merit further exploration and could be used for risk stratification in TBI, while providing clues to T-cell differentiation.

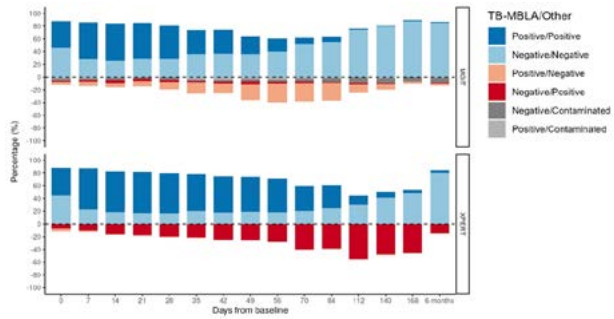
TBS-EP251 Clinical evaluation of the LifeArc Tuberculosis Molecular Bacterial Load Assay (TB-MBLA) for the diagnosis and monitoring of pulmonary tuberculosis

T. Martin,[1] R. Gray,[1] N. Elias Ntinginya,[2] A. Sessolo,[3] F. Lyamuya,[4] P. Mbelele,[5] P. Smith,[1] [1]LifeArc, Edinburgh, United Kingdom of Great Britain and Northern Ireland, [2]National Institute for Medical Research (NIMR)- Mbeya Medical Research Centre (MMRC), Mbeya, United Republic of Tanzania, [3]Infectious Diseases Research Collaboration (IDRC), Kampala, Uganda, [4]Kilimanjaro Clinical Research Institute (KCRI), Moshi, United Republic of Tanzania, [5]Kibongo'to Infectious disease Hospital (KIDH), Moshi, United Republic of Tanzania
e-mail: tamara.martin@lifearc.org

Drug-resistant TB is a major contributor to antimicrobial resistance and antimicrobial stewardship is hindered by the lack of reliable TB treatment monitoring tools. Limitations of culture include long time-to-result (>6 weeks), low sensitivity, and contamination risks. The LifeArc TB-MBLA offers several advantages by quantifying *Mycobacterium tuberculosis* (MTB) in <24h with improved sensitivity and specificity. TIME (**T**B D**i**agnosis and **M**onitoring **E**valuation)-a multi-centred, longitudinal, prospective study- evaluated the performance of LifeArc TB-MBLA for the detection and monitoring of pulmonary tuberculosis in the sputum of symptomatic adults. Participants were evaluated in comparison with MGIT (Mycobacteria Growth Indicator Tube) culture and Xpert MTB/RIF Ultra (molecular DNA test). Performance was evaluated against a compositive reference standard of 'MGIT plus clinical diagnosis'. Bacteriologically positive participants with a positive clinical diagnosis attended 13 monitoring visits during standard anti-TB treatment, followed by one visit 6-months later.

Of 514 participants, 255 were TB-positive, 180 TB-negative, and 107 unconfirmed TB (but prescribed treatment). TB-MBLA demonstrated high specificity (≥98%) for ruling out TB and strong sensitivity (≥80%) for detecting TB. Participants with unconfirmed TB had TB-MBLA readings comparable to TB-negative participants, suggesting inappropriate stewardship of antibiotics. TB-MBLA demonstrated strong concordance with culture in detecting viable bacilli, though concordance reduced slightly during treatment as bacterial load decreased and the limits of culture sensitivity are realised. Before treatment, TB-MBLA showed strong/moderate concordance with Xpert, but this declined during treatment in part due to persisting DNA from non-viable bacilli.

The stronger concordance of TB-MBLA with culture, compared to Xpert, supports its utility as a surrogate biomarker of viable bacilli by quantifying MTB 16S rRNA (Figure).



TB-MBLA is uniquely positioned to meet the unmet need for real-time TB treatment monitoring. TIME study validated its utility as a monitoring tool and highlighted its potential to replace culture in both clinical trials and routine care.

TBS-EP254 The diagnostic value of interferon-γ and IP-10 in latent and active tuberculosis: A comparative analysis

N. Sudharshan,[1] G. Jella,[1] S. Majeti,[1] T. Syed,[1] M. Patil,[1] S. Mudigonda,[1] [1]Nizams Institute of Medical Sciences, Hyderabad, India
e-mail: neelimasudharshan@gmail.com

Introduction: Tuberculosis (TB) remains a major global health challenge, with difficulties in diagnosing latent TB infection (LTBI). The Interferon-Gamma Release Assay (IGRA) is widely used but has limitations, particularly in immunocompromised patients and in distinguishing TB stages. Interferon gamma induced protein (IP-10), an immunomodulatory cytokine, may influence TB diagnosis by affecting immune responses. This study investigates whether IP-10 can serve as a complementary biomarker alongside interferon gamma.

Methodology: Between January 1 and March 31, 2025, blood samples from 198 patients (mean age 41.66, male-predominant) with either LTBI or active TB were collected. IP-10 levels were measured via ELISA (RIDASCREEN®TB), and Interferon-γ responses were assessed using QuantiFERON®-TB Gold Plus. Patients were categorized into immunocompromised and active TB groups. Statistical analysis included McNemar's test to compare test performance.

Results:

- IGRA was positive in 20.48% overall, 53.12% of active TB cases.
- IP-10 was positive in 28.9% overall, 71.87% of active TB cases.
- Concordant positivity (both tests) was seen in 28 immunocompromised cases (9%).
- Discordance: 4 IGRA+/IP-10– and 5 IGRA–/IP-10+ cases.
- Indeterminate IGRA results were higher (29.2%) than IP-10 (18%).
- McNemar's test showed no significant difference in positivity rates between the assays in either group ($p > 0.05$), though IP-10 trended higher in active TB.

Conclusion: Interferon-γ and IP-10 demonstrated comparable diagnostic performance. IP-10 showed a non-significant trend toward higher sensitivity in active TB and yielded fewer indeterminate results, suggesting it may be a useful adjunct in TB diagnosis, especially in immunocompromised patients or when IGRA results are inconclusive.

TBS-EP257 Estimating the national transmission impact of household contact management and tuberculosis preventive treatment for drug-susceptible and multidrug-resistant tuberculosis in South Africa

M.J. Harker,[1] J.A. Seddon,[2,3] S.E. Purchase,[2] A.J. Garcia-Prats,[4] H.S. Schaaf,[2] A.C. Hesseling,[2] M. Quaife,[1] C.F. McQuaid,[1] [1]TB Modelling Group, London School of Hygiene and Tropical Medicine, London, United Kingdom of Great Britain and Northern Ireland, [2]Desmond Tutu TB Centre, Department of Paediatrics and Child Health, Stellenbosch University, Cape Town, South Africa, [3]Department of Infectious Disease, Imperial College London, London, United Kingdom of Great Britain and Northern Ireland, [4]Department of Pediatrics, University of Wisconsin-Madison, Madison, United States of America
e-mail: martin.harker@lshtm.ac.uk

Background: Multidrug-resistant (MDR) tuberculosis (TB) presents a major threat to the End TB Strategy, with 150,000 people dying of MDR-TB in 2023 alone. The household remains an important source of transmission, which can be addressed through household contact management (HHCM) and providing TB preventive

treatment (TPT) to individuals at high risk. Recent trials have shown the effectiveness of providing levofloxacin as TPT to prevent MDR-TB disease in high-risk household contacts, leading to WHO guideline recommendations in 2024 for TPT for those exposed to MDR-TB. However, HHCM and TPT coverage remains low, and the wider impact on transmission beyond the household is unknown.

Methods: We developed a novel transmission model of the South African TB epidemic, that represents household TB status, to estimate the impact of implementing HHCM and TPT for drug-susceptible (DS) TB and MDR-TB between 2025 and 2030. We compared the impact of 1) providing HHCM to household contacts of 50% of people with diagnosed infectious pulmonary TB, 2) providing both HHCM and TPT (for individuals at risk of either DS-TB or MDR-TB) to 50% of household contacts, 3) implementation of both HHCM and TPT to 100% of household contacts, against a baseline scenario with no HHCM or TPT.

Results: Compared to the baseline scenario, 50% coverage of HHCM could prevent 48,200 (7.7%) people from developing TB and 2,600 (1.3%) TB deaths over the first five years. Addition of TPT would modestly increase these benefits, whilst widening both HHCM and TPT to all contacts could prevent a total of 102,800 (16.4%) of disease episodes and 6,800 (3.5%) deaths. There were only small differences in the impact on DS-TB compared to MDR-TB.

Scenario	TB deaths	TB deaths prevented	Incident TB	Incident TB prevented	Incident DS-TB prevented	Incident MDR-TB prevented
Baseline	192,300	-	626,400	-	-	-
50% HHCM	189,700	2,600 (1.3%)	578,200	48,200 (7.7%)	7.8%	7.3%
50% HHCM & TPT	189,000	3,300 (1.7%)	577,500	48,900 (7.8%)	7.9%	7.5%
100% HHCM & TPT	185,500	6,800 (3.5%)	523,600	102,800 (16.4%)	16.6%	15.2%

DS-TB: drug-susceptible TB; MDR: multidrug-resistant TB; HHCM: household contact management; TB: tuberculosis; TPT: TB preventive treatment

Table 1: Impact of household contact management and TB preventive treatment on TB deaths and incident TB in South Africa between 2025 and 2030.

Conclusion: Widespread implementation in South Africa of HHCM and TPT for DS-TB and MDR-TB amongst household contacts could prevent a substantial proportion of incident TB and TB deaths.

TBS-EP260 Comparative transcriptomics uncover the mechanisms of transcripts regulation by coding and non-coding RNAs within the *Mycobacterium tuberculosis* complex strains

A. Nyide,[1] T. de Oliveira,[2,3,4] N.E. Mvubu,[1] [1]University of KwaZulu-Natal, Medical Micobiology, Durban, South Africa, [2]Stellenbosch University, Centre for Epidemic Response and Innovation, Cape Town, South Africa, [3]Wellcome Sanger Institute, Genomics Surveillance Unit, Hinxton, Cambridgeshire, United Kingdom of Great Britain and Northern Ireland, [4]University of KwaZulu-Natal, KwaZulu-Natal Research Innovation and Sequencing Platform, Durban, South Africa
e-mail: 214513230@stu.ukzn.ac.za

Tuberculosis is caused by the *Mycobacterium tuberculosis* complex (MTBC), a group of closely related pathogens infecting humans and animals globally. Although molecular mechanisms of pathogenesis remain unclear across diverse strains, next-generation sequencing offers powerful means to explore MTBC regulatory networks and their disease roles.

Drug-susceptible clinical MTBC strains from lineages 1 through 8, isolated from geographically diverse regions, were selected alongside virulent and avirulent laboratory controls (H37Rv and H37Ra).

These strains were cultured in Middlebrook 7H9 broth and minimal media supplemented with cholesterol to simulate a host-like cholesterol-rich environment. Total RNA was extracted and subjected to deep RNA-sequencing, generating approximately 100 million reads per sample using the Illumina NovaSeq 6000 platform.

Differential gene expression was assessed by comparing transcriptomic profiles of strains grown in 7H9 versus cholesterol media using the *Hisat2*, *Stringtie,* and *DESeq2* bioinformatics tools.

Functional annotation and biological pathway analysis were conducted using Gene Ontology (GO) terms and KEGG pathway enrichment to determine the molecular functions, cellular components, and biological processes associated with differentially expressed transcripts across MTBC lineages. Our findings revealed differential regulation of coding (~1500) and non-coding RNA transcripts (~400) among the MTBC strains.

Comparative analysis identified distinct transcriptional profiles among the 8 lineages compared to the H37Rv and H37Ra controls. Several antisense RNAs overlapping virulence genes were differentially expressed, suggesting a potential role in fine-tuning virulence factors.

Functional enrichment analysis revealed significant representation of GO terms related to lipid metabolic process, response to stress, and regulation of transcription. Notably, both coding and ncRNA were implicated in cholesterol metabolism, a critical pathway for intracellular survival of the MTBC. Although ncRNAs have been identified in *M. tuberculosis*, their regulatory roles across

MTBC lineages remain unclear. Our study reveals lineage-specific RNA regulation in cholesterol, uncovering key pathways in pathogenesis that offer promising targets for novel TB therapeutics.

TBS-EP263 Tongue and rectal swab samples processed by manual qPCR enhance clinical decision-making in paediatric patients with presumptive tuberculosis

M.K.H. Nasr,[1] M.J. Christie,[2] S.L. Olifant,[1,3] M.M. Teffu,[2] N.M. du Plessis,[2] M. Said,[1,4] T.J Avenant,[2] P.B. Fourie,[1,3]
[1]Department of Medical Microbiology, University of Pretoria, Pretoria, South Africa, [2]Department of Paediatrics and Child Health, Kalafong Provincial Tertiary Hospital, University of Pretoria, Pretoria, South Africa, [3]Tuberculosis Research Centre, University of Pretoria, Pretoria, South Africa, [4]National Health Laboratory Services, Tshwane Academic Division, Pretoria, South Africa
e-mail: sharon.l.olifant@gmail.com

Background: Initiation of chemotherapy in young children with presumptive tuberculosis (TB) is commonly preceded by standard of care (SOC) procedures that include clinical and radiological assessments supplemented by laboratory tests for detection of Mycobacterium tuberculosis. In this study, tongue and rectal swab sample types for manual qPCR processing were investigated as potential additional options to inform clinical decision for initiating treatment in paediatric TB.
Design/Methods: Forty-five children (<5 years old) with signs/symptoms of TB (cough, fever, failure to thrive, lethargy) were admitted to a tertiary care facility (Kalafong Hospital) in Pretoria, South Africa. SOC assessments over 3 days included clinical evaluation, determining HIV status, chest x-ray and gastric aspirate/sputum collections for smear microscopy and molecular diagnostic assay (GeneXpert/Cobas). In patients with HIV, urine LAM testing was also performed. For study purposes, tongue and rectal flocked swab samples were collected daily into PrimeStore Molecular Transport Medium (PS-MTM) for batched manual qPCR processing (Quantstudio 5). PS-MTM samples remain stable without refrigeration and are rapidly rendered noninfectious. The decision to initiate TB treatment was based on SOC assessments, clinicians were blinded to the swab results.
Results: SOC procedures led to 10 of the 45 patients being initiated on anti-TB chemotherapy, predominantly based on clinical presentation, chest x-ray and HIV status. In all cases, gastric aspirates/sputum returned negative laboratory results. A combined total of 16 qPCR positive results from oral swabs (11/45) and rectal swabs (5/43) were obtained. Only 2 of the 16 patients with positive qPCR were initiated on anti-TB treatment on the basis of the SOC assessment.

Patient information	
Age (months) (n=45) / Gender distribution (n=42)	Mean: 21,5; SD: 12,8; Range: 02-58 / M: 18/42 (42,9%); F: 24/42 (57,1%)
Clinical and diagnostic	
TB treatment initiated (SOC)	10/45 (22,2%)
Patients with lower respiratory tract infections or pneumonia	14/42 (33,3%); 9/14 presented with abnormal chest x-ray, of whom 3 were initiated on TB treatment
Patients with HIV	7/39 (17,9%)
Gastric aspirate (smear microscopy, GeneXpert, Cobas)	All negative
Swab PCR results	
Tongue or rectal swab qPCR positive	16/45 (35,6%); 13/16 had CXR results of which 7 (53,8%) showed abnormalities

Table 1. Patient population and TB diagnostic yield from qPCR tongue/rectal swab processing by qPCR.

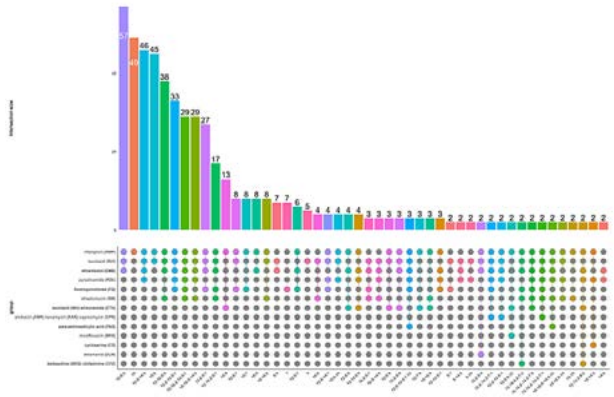
Conclusions: Tongue and rectal swab samples collected serially from infants and young children with presumptive TB and batch processed by manual qPCR enable the detection of TB in a significant proportion of paediatric patients regarded as not eligible for anti-TB treatment by SOC protocols.

TBS-EP266 Mutational profiling and phylogenetic analysis of *Mycobacterium tuberculosis* strains from Pakistan

N. Khursheed,[1] J. Aijaz,[1] V. Dreyer,[2] Z. Rehman,[1] S. Niemann,[2] [1]Clinical Laboratory, Indus Hospital and Health Network, Karachi, Pakistan, [2]Molecular and Experimental Mycobacteriology Group, Research Center Borstel, Borstel, Germany
e-mail: nazia.khursheed@tih.org.pk

Pakistan ranks 5th among the high tuberculosis (TB) burden nations.Only limited information is available on mutation profiles, and population structure of *M. tuberculosis* complex (Mtbc) strains based on high resolution whole genome sequencing (WGS) data. To address this knowledge gap, we performed a retrospective WGS study across Sindh province of Pakistan using 600 primarily drug resistant Mtbc strains collected in years 2015-2023 at Indus Hospital & Health Network, Karachi. Briefly, DNA was extracted from MTB strains followed by WGS using illumine NextSeq 2000. Mtbc lineages and genotypic resistance profiles were determined via MTBseq.
Of the 600 MTB isolates, 46.5% were MDR, while 24% were pre-XDR, and 0.7% XDR. Overall, rifampicin (RIF) resistance was most frequent (85% isolates), followed by resistance to isoniazid (INH) (79%) and ethambutol (EMB) (61%). Among the 512 RIF resistant Mtbc strains, 35% (n=177) were pre-XDR and 1.5% (n=8) were resistant to either delamanid and/or bedaquiline. When resistance combinations are considered, combined RIF, INH, and EMB was found to be most common followed by

mono resistance to RIF, and combined resistance to the four first line drugs. The most frequently mutated genes included *rpoB* (S450L) for RIF, and *katG* (S315T) and *inhA* (I194T and I21V) for INH, *gyrA* (D94G and A90V) and *gyrB* (A504V) for FQ. Lineage 3 was most common (66%), followed by lineage 1(12%) and 4(12%), and few cases of lineage 2 (4.7%). Interestingly there was one strains classified as *M. bovis*.



In conclusion, our data show a high rate of FQ resistance among RR Mtbc strains of the study population. Still, resistance to other group A drugs such as bedaquiline, is infrequent.The future development needs to be thoroughly monitored as the high rate of FQ resistance may path the way for rapid development of bedaquiline resistance as observed in other regions of the world.

TBS-EP269 Using affinity proteomics to understand the host response and identify diagnostic signatures of TB infection and disease

C. Sundling,[1] Z. Mousavian,[1] H. Aso,[1] E. Folkesson,[1] M. Correia-Neves,[2] D. Goletti,[3] J. Bruchfeld,[1] G. Källenius,[1] [1]Karolinska Institutet, Stockholm, Sweden, [2]University of Minho, Braga, Portugal, [3]National Institute for Infectious Diseases L. Spallanzani-IRCCS, Rome, Italy e-mail: christopher.sundling@ki.se

Non-sputum-based biomarkers for early diagnosis of TB disease are urgently needed to control transmission and achieve the World Health Organizations goals of ending TB. Host derived proteins, such as cytokines and acute-phase proteins are important mediators in controlling pathogen-specific responses. The pattern of these proteins can be informative in understanding the underlying disease biology and biomarkers can be identified that correlate with infection or disease status.
In this study, we have used the Olink proximity extension assay (PEA) to assess 5400 protein in 92 human donors. These donors included individuals with different types and severity of TB disease (n=27) and individuals with Recent (< 2 years, n=22) or Remote (> 2 years, n=25) TB infection and IGRA– controls (n=18). Using network-based analysis we could identify modules specific for the different groups which upon Gene Ontology analysis indicated activation of different biological pathways.
In addition to this exploratory study, we previously identified a 12-marker plasma protein signature associated with TB disease severity when measuring 92 inflammation-associated proteins with the Olink PEA. We have now validated the signature's performance in identifying TB disease in independent Swedish and Italian cohorts, including individuals with TB infection and other respiratory diseases (total n=317 samples from 273 donors).
We condensed the 12 proteins to smaller 6 (CDCP1, VEGFA, IFN-g, CXCL9, IL6 and MCP-3) and 4 (CDCP1, VEGFA, IFN-g, CXCL9)-protein signatures which remained highly enriched and even improved accuracy when compared with ten other published protein signatures for TB disease. Sensitivity in TB disease compared with TB-infection was 89% in the entire cohort and 97% in the Italian cohort, with specificity fixed at 70%.
We further confirmed that the signatures perform well in both heparin and EDTA plasma. These studies highlight the value of investigating host protein responses for biological and diagnostic insights in TB research.

TBS-EP272 Evaluation of the WHO Mutation Catalogue (second edition) for genomic characterization of bedaquiline-, pretomanid- and linezolid-resistant *M. tuberculosis* isolates in South Africa

L. Joseph,[1] M. Motsei,[1] P. Malope,[1] A. Bulane,[1] F. Ismail,[1,2] M. Mmatli,[1] L. Shrestha,[3] F. Willis,[3] R. Khouri,[4] N. Gandhi,[3] B. Mathema,[4] S.V. Omar,[1,2,5] [1]National Institute for Communicable Diseases, Centre for Tuberculosis, Johannesburg, South Africa, [2]University of Pretoria, Department of Medical Microbiology, Pretoria, South Africa, [3]Emory University Rollins School of Public Health, Department of Epidemiology, Atlanta, United States of America, [4]Columbia University Mailman School of Public Health, Department of Epidemiology, New York, United States of America, [5]University of the Witwatersrand, Department of Haematology and Molecular Medicine, Johannesburg, South Africa e-mail: lavaniaj@nicd.ac.za

Background: The second edition of the WHO Mutation Catalogue, published in 2023, serves as the global reference for interpreting mutations associated with resistance to TB drugs. A key feature of this edition is the inclusion of mutations associated with bedaquiline (BDQ), pretomanid (Pa) and linezolid (LZD) resistance. Given its integration with WHO-endorsed next generation sequencing assays, we sought to evaluate the catalogue in characterising isolates resistant to BDQ, Pa and LZD.

Methods: A total of 339 *M. tuberculosis* isolates, collected from four referral laboratories across South Africa and displaying phenotypic resistance to BDQ, Pa or LZD, were included. Minimum inhibitory concentration (MIC) testing using MGIT 960 was performed for each drug at four concentrations above, below and at the WHO recommended critical concentration (CC).
Whole genome sequencing (WGS) was performed using the Illumina NextSeq 1000 platform and variant analysis performed on CLC Genomics Workbench. The WHO Mutation Catalogue was applied to assign mutation gradings for all associated genetic targets.
Results: The agreement between MICs and mutations graded as either associated or not associated with resistance was 94.2% for BDQ, 95.3% for Pa and 99.2% for LZD. False BDQ resistance was observed in isolates harbouring resistance mutations and displayed MICs bordering the CC; and false Pa susceptibility observed in wild-type isolates displaying MICs above the CC excluding lineage 1.
Overlap between MICs was observed for uncertain significance mutations associated with BDQ and Pa. Uncertain significance and ungraded mutations for LZD were associated exclusively with low-level LZD MICs. Two BDQ ungraded isolates harboured the *Rv0678* Leu154Pro mutation and displayed BDQ MICs of 8.0µg/mL.

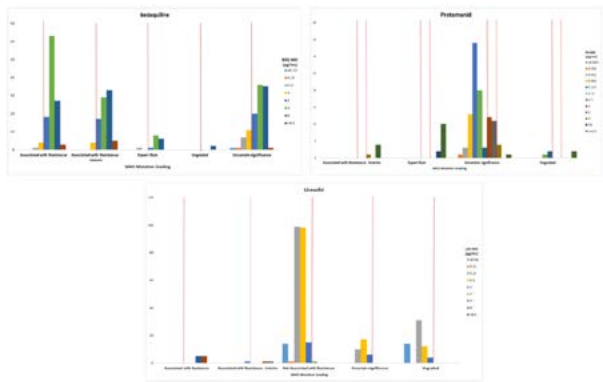


Figure: Distribution of MICs and associated WHO mutation gradings. The red line represents the WHO-recommended critical concentration for each drug.

Conclusions: The WHO Mutation Catalogue (second edition) shows good performance in classifying graded mutations. Our findings underscore the importance of continuous global contribution to updates of the catalogue, ensuring resistance conferring mutations are represented and improving overall susceptibility calls.

TBS-EP275 Assessing diagnostic delays in tuberculosis testing: Turnaround time from computer-aided diagnostic X-ray to GeneXpert in selected Ugandan health facilities

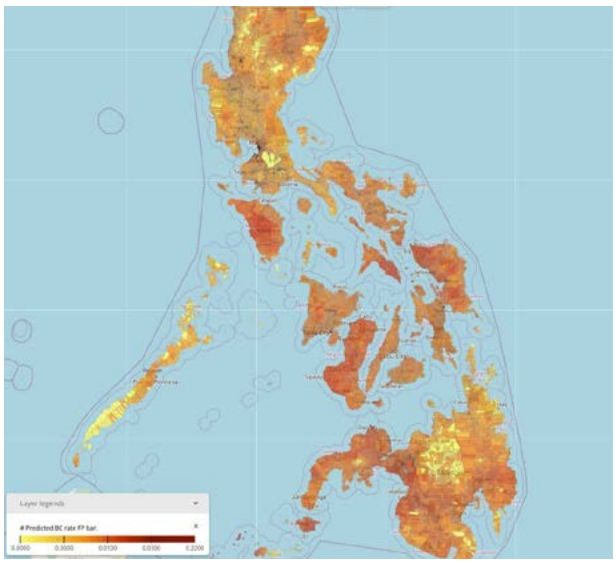
D. Mujuni,[1,2] L. Ocen,[3] [1]Makerere University, Kampala, Uganda, [2]Alpha Biomedical Research and Innovation Network, Kampala, Uganda, [3]Uganda Catholic Medical Bureau, Kampala, Uganda
e-mail: dennismujuni.n@gmail.com

Background: Getting a quick diagnosis for tuberculosis (TB), including drug-resistant TB (DR-TB), is vital in places like Uganda where TB is widespread. We used digital chest X-rays with computer-aided diagnostic (CAD) systems as the first step, followed directly by GeneXpert to confirm TB and check for rifampicin resistance. Delays in this process could slow down treatment initiation and affect patients.
Our study looked at how long it took to go from CAD X-ray to GeneXpert results, focusing on DR-TB cases and school-going children.
Methods: We ran a retrospective study with data from 13,823 digital chest X-ray images, including 1,934 from school-going children, collected at UCMB-affiliated health facilities in Uganda from January 2024 to June 2025. We focused on patients with positive GeneXpert results (confirmed TB) and calculated the turnaround time (TAT) as the days between CAD X-ray analysis and GeneXpert result.
We used basic stats like mean, median, and range, and broke down TAT by rifampicin resistance (DR-TB vs. drug-susceptible TB), age (children vs. adults), and facility type. We secured ethical approval and anonymized all data to protect patient privacy.
Results: From the 13,823 cases, including 1,934 kids, we estimated an average TAT of about 2–5 days. School-going children often had faster results, likely around 1–3 days, thanks to prioritized CAD screening in school programs and quick GeneXpert follow-up. DR-TB cases, where rifampicin resistance was detected, took slightly longer, around 3–5 days, likely due to extra steps in confirming resistance. TAT varied by facility, reflecting differences in CAD integration and lab capacity.
Conclusion: Our study showed that the CAD X-ray-to-GeneXpert pathway for TB and DR-TB diagnosis is efficient, especially for kids in school programs. These findings will help guide efforts to make TB diagnosis even faster and improve care in Uganda.

TBS-EP278 Real-time predictive modelling for TB hotspots at the barangay level in the Philippines

A.-L. Budts,[1] S. Hashmi,[1] M. Calnan,[2] N. Nabong,[3] L. Teodosio,[3] M. Kelly Mijares,[3] M. Potgieter,[1] V. Meurrens,[4]
[1]EPCON, Cape Town, South Africa, [2]University Research Co., Wisconsin, United States of America, [3]International Care Ministries, Pasig City, Philippines, [4]EPCON, Antwerp, Belgium
e-mail: anne-laure@epcon.ai

Background: Despite ongoing control efforts, tuberculosis (TB) remains unevenly distributed across Philippine communities. To enable precise, data-driven targeting, we built a real-time predictive model that combines geospatial context with Active Case Finding (ACF) data to forecast TB risk at barangay level - the smallest admin unit in the Philippines.
Feature Development: We incorporated retrospective ACF outcomes with geospatial datasets, including: population density; access to clean water; open defecation; childhood vaccination; female literacy; satellite-derived nightlights; travel times to the nearest health facility; relative wealth index; child stunting and under-five mortality; road networks; and leveraging self-organizing map (SOM) encodings for population distribution, proximity to health services, land type, and indigenous status.



Model Training: We aggregated all data at the barangay level (n ≈ 42 000) and evaluated three classifiers—Naive Bayes (NB), Random Forest (RF), and XGBoost—using province-level cross-validation. In each fold, entire provinces were held out from training. We used Relative Risk Increase (RRI)—the ratio of TB yield in the top 30 % predicted hotspots versus the bottom 70 %—to compare models. Under these conditions, NB achieved RRI = 0.4785, indicating a 48 % higher TB yield in predicted hotspots. XGBoost and RF underperformed, with RRI = 0.0775 and RRI = 0.0085, respectively. When predicting the rates of people living with all-forms TB, Naive Bayes achieved RRI = 1.0101, XGBoost RRI = 0.4911, and Random Forest RRI = 0.7317.
Deployment and Impact: The NB models were retrained on the full dataset and embedded into the Epi-Control geoportal. Health workers can now access risk maps, filter by key covariates, and rank Barangays for targeted ACF campaigns. By directly predicting at the barangay scale this framework transforms ACF data into actionable insights, enabling stakeholders to concentrate resources on the most vulnerable communities to accelerate finding people living with TB.

TBS-EP281 *Mycobacterium tuberculosis* curli pili (MTP) and heparin-binding haemagglutinin adhesin (HBHA) in combination modulate central carbon metabolism of the pathogen *in vitro*

T.J. Naidoo,[1,2] S. Ashokcoomar,[1] B. Truebody,[3] J.S. Mackenzie,[3] A.J.C. Steyn,[3,4] M. Pillay,[1] [1]University of KwaZulu-Natal, Durban, South Africa, [2]University of Cape Town, Cape Town, South Africa, [3]Africa Health Research Institute (AHRI), Durban, South Africa, [4]University of Alabama at Birmingham, Birmingham, United States of America
e-mail: tarienjael@gmail.com

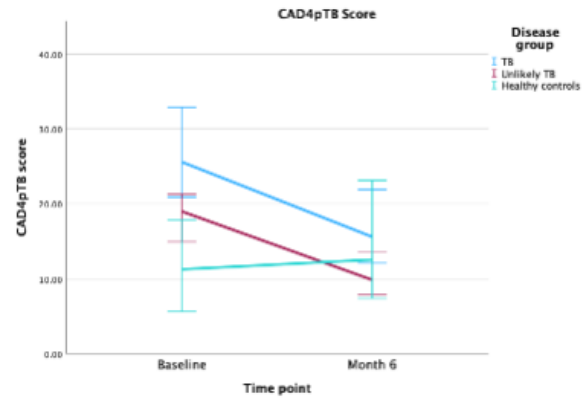
Tuberculosis (TB) remains the global leading infectious cause of death. A deeper understanding of *Mycobacterium tuberculosis* (*Mtb*) virulence factors associated with pathogenesis is crucial for the improvement of current TB control strategies. *Mtb* encodes a plethora of surface adhesins which aid in its pathogenicity.
Of these, the *Mtb* curli pili (MTP) and heparin-binding haemagglutinin adhesin (HBHA) have been reported as suitable targets for TB diagnostics/intervention strategies. Although regarded as adhesins, previous "omics" studies highlighted the role of HBHA and MTP-HBHA in modulation of *Mtb* central carbon metabolism (CCM).
However, their precise contribution to *Mtb* metabolism remain unknown. Therefore, this study examined the impact of these adhesins on the bioenergetic profile and metabolic flux of *Mtb* using extracellular flux analysis, ^{13}C-isotopomer analysis, and *Mtb hbhA* and *mtp-hbhA* proficient and deficient strains.
The findings demonstrated that HBHA and MTP-HBHA decreases bacterial respiration and CCM, potentially aiding in *Mtb's* survival. The presence of HBHA resulted in increased glycolytic flux and decreased flux through the pentose phosphate pathway (PPP), glycerolipid metabolism, and tricarboxylic acid cycle (TCA).
The absence of MTP-HBHA resulted in the rerouting of carbons from PPP and glycerolipid metabolism toward glycolysis and the TCA cycle. Thereafter, RNA was extracted from the bacterial broth cultures of the adhesin/s-

proficient and deficient strains to determine the expression levels of genes associated with CCM and dormancy. The *hbhA* and *mtp-hbhA* induced increased expression of dormancy-linked genes (*devR*, *devS*, *dosT*, *moaA1*, and *moeX*) and amino acids linked to the TCA cycle (*serA2*, *icd1*, *ilvC*, and *trpD*), thereby potentially aiding in the survival, replication, and virulence of *Mtb*.
These findings support the growing evidence that HBHA and MTP significantly contribute to the pathogenicity of *Mtb,* and emphasizes the combined use of both MTP and HBHA, as a prominent dual-adhesin biomarker for TB diagnostics, vaccine development, and therapeutics.

TBS-EP284 The use of chest X-ray computer-aided detection scores in assessing post-TB lung disease in children

C. Hulsman,[1] H. van Deventer,[1] M. van Niekerk,[1] P. Goussard,[2] H.S. Schaaf,[2] E. Klinkenberg,[3] M. Palmer,[1] M. van der Zalm,[1] [1]University of Stellenbosch, Desmond Tutu TB Centre, Cape Town, South Africa, [2]University of Stellenbosch, Paediatrics and Child Health, Cape Town, South Africa, [3]Delft Imaging, Delft Imaging, Delft, Netherlands
e-mail: chulsman@sun.ac.za

Background: Computer-aided detection (CAD) software is being refined to support the diagnosis of pulmonary tuberculosis (PTB) in children. We aimed to investigate an association between CAD scores at diagnosis and changes after 6-months in children with presumptive PTB using adapted paediatric TB CAD software.
Methods: We analysed chest x-rays (CXRs) from children aged 0-13 years who were enrolled in the Umoya TB diagnostic study in Cape Town, South Africa. CXRs at baseline and after 6-months of treatment were read by a blinded TB expert and classified as typical or not-typical for TB. CXR images were processed by the CAD4TBpTBv7 (CAD4TBv7 software retrained with paediatric images). CAD scores were compared between children with TB, non-TB respiratory illnesses (non-TB RI) and healthy controls. CXR features were assessed for any association with reduction (≥20 points) in CAD scores using binary logistic regression.
Results: There were 233 children with TB, 267 with non-TB RI and 34 healthy controls, with a median age 25.4 months (IQR 11.5; 53.5), 255 (50%) female and 46 (9%) living with HIV. At baseline, children with TB had significantly higher CAD scores compared to children with non-TB RI (p<0.00;1 Figure 1).
Children with TB who had volume loss noted on baseline CXRs were 11.63 (95% CI 1.35; 100; p=0.01) times less likely to have a ≥20 point CAD4pTB score reduction, whereas the presence of enlarged lymph nodes, pleural effusions and opacifications had no effect on the likelihood of a CAD score reduction.



Conclusion: Our findings show that CAD scores from children with TB and non-TB RIs decrease over time, suggesting good radiological improvement in most children. A poor radiological response may assist in identifying children at risk for post-TB lung disease. These results highlight the need for further development of CAD tools for paediatric TB and post-TB lung disease assessment.

TBS-EP287 The accuracy of an infrasound vibroacoustic signature to screen for tuberculosis disease

D. Marcelo,[1] H. Poore,[2] D.J. Christopher,[3] H. Phan,[4,5] G. Theron,[6] A. Cattamanchi,[2,7] W. Worodria,[8] D. Jaganath,[9,7] [1]De La Salle Medical and Health Sciences Institute, Dasmariñas, Philippines, [2]Division of Pulmonary Diseases & Critical Care Medicine, University of California, Irvine, Irvine, United States of America, [3]Department of of Pulmonary Medicine, Christian Medical College, Vellore, India, [4]Center for Promotion of Advancement of Society, Hanoi, Viet Nam, [5]UCSF–VNTP Research Collaboration Unit, Hanoi, Viet Nam, [6]DSI-NRF Centre of Excellence for Biomedical Tuberculosis Research, South African Medical Research Council Centre for Tuberculosis Research, Division of Molecular Biology and Human Genetics, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa, [7]Center for Tuberculosis, Institute for Global Health Sciences, University of California, San Francisco, San Francisco, United States of America, [8]Makerere University, Kampala, Uganda, [9]Division of Pediatric Infectious Diseases, University of California, San Francisco, San Francisco, United States of America
e-mail: pooreh@hs.uci.edu

Background: Accurate, easy-to-use tuberculosis (TB) screening tests are needed to aid case finding in high TB burden areas. We assessed the accuracy of a "vibroacoustic" signature, collected using a point-of-care electronic stethoscope, to detect TB disease.
Methods: From March 2022 through February 2024, people ≥12 years with presumptive TB were consecutively enrolled at outpatient health centers in India, the Philip-

pines, South Africa, Uganda, and Vietnam. Participants provided sputum for TB testing (Xpert MTB/RIF Ultra x1 and liquid culture x2). We used the imPulse® UNA full spectrum electronic stethoscope to record subaudible vibrations at six different chest sites for 30 seconds each (3 minutes total). We trained, validated, and blind-tested an autoencoder-transformer hybrid AI model to determine the accuracy of a vibroacoustic signature to detect microbiologically confirmed TB.

Results: Vibroacoustic data was collected from 2,642 participants, among whom median age was 41 years (IQR 29-55), 48.5% were female, 12.9% were living with HIV, 21.2% had prior TB, 13.1% had diabetes, and 20.7% had microbiologically confirmed TB. In a blinded out-of-sample test dataset (N=709 participants), the AI model achieved a sensitivity of 80.8% (95% CI 73.7- 86.6) and a specificity of 63.3% (95% CI 59.1- 67.3) for microbiologically confirmed TB, approaching the minimum accuracy targets for a high sensitivity TB screening test (≥90% sensitivity and ≥60% specificity). Accuracy was similar among participants living with HIV (sensitivity: 80.0%, 95% CI 56.3-94.3 and specificity: 64.8%, 95% CI 52.5-75.8).

	Sensitivity n/N, % (95% CI)	Specificity n/N, % (95% CI)
Overall (n=709)	126/156, 80.8% (73.7-86.6)	350/553, 63.3% (59.1-67.3)
PLHIV (n=91)	16/20, 80.0% (56.3-94.3)	46/71, 64.8% (52.5-75.8)
Country		
India (n=79)	7/10, 70.0% (34.8-93.3)	44/69, 63.8% (51.3-75.0)
Philippines (n=166)	23/29, 79.3% (60.3-92.0)	99/137, 72.3% (64.0-79.6)
South Africa (n=80)	11/13, 84.6% (54.6-98.1)	51/67, 76.1% (64.1-85.7)
Uganda (n=249)	63/70, 90.0% (80.5-95.9)	92/179, 51.4% (43.8-58.9)
Vietnam (n=135)	22/34, 64.7% (46.5-80.3)	64/101, 63.4% (53.2-72.7)

Table 1. Accuracy of a vibroacoustic signature for classifying tuberculosis disease

Conclusion: Vibroacoustic data collected with a point-of-care full spectrum electronic stethoscope demonstrated promise as a screening tool for pulmonary TB, including among people living with HIV. Ongoing data collection and algorithm refinement across the full infrasonic-to-ultrasonic range aim to enhance model accuracy and the potential of vibroacoustic diagnostics.

TBS-EP290 Possible role of amino acid synthesis suggested in contributing to tolerance under BDQ pressure in *Mycobacterium tuberculosis* (Mtb) clinical isolates

D. Saeed,[1] S. Shakoor,[1] J. Ashraf,[1] Z. Hasan,[1] R. Hasan,[1,2] [1]Aga Khan University, Pathology and Lab Medicine, Karachi, Pakistan, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom of Great Britain and Northern Ireland
e-mail: dania.khalid@scholar.aku.edu

Background: Metabolic changes occurring in bedaquiline (BDQ) exposed H37Rv have been reported to contribute to a temporary persistence period (24-96 hours). While a similar persistence period is reported for BDQ-resistant clinical isolates, differences in transcriptome of H37Rv and clinical isolates have been observed. This period thus presents a window to study mechanisms supporting BDQ resistance unique to clinical isolates.

Therefore, we aimed to explore the transcriptomic profile of BDQ-resistant clinical isolates to identify pathways that may be critical in establishing drug tolerance during this period.

Design/Methods: We performed whole transcriptome RNA-seq analysis of clinical Mtb isolates (n=6, BDQ minimum inhibitory concentration (MIC) ≥ 0.5 µg/ml) and H37Rv (MIC = 0.03 µg/ml) after 72 hours of exposure to 3.75µg/ml of BDQ (7.5x MIC of BDQ-R isolates). Differential gene analysis was carried out comparing transcriptome of BDQ-exposed isolates with unexposed controls using DESeq in R studio vr. 4.3.0.

Results: After 72 hours of BDQ exposure, 1123 and 585 genes were significantly differentially expressed (DE) in H37Rv and BDQ-resistant clinical isolates, respectively. For both H37Rv and clinical isolates 22% and 21% of DE genes belonged to intermediate metabolism and respiration. While genes involved in fatty acid and cholesterol degradation were upregulated in both H37Rv and clinical isolates, genes in biosynthesis of amino acids including L-arginine and L-cysteine were upregulated in BDQ-resistant isolates only.

Conclusions: Our findings suggest amino acid metabolism as having an important role in establishing BDQ tolerance by possibly serving as an alternate energy generating pathway. These pathways need to be studied further to understand their role in establishing extensive drug tolerance and resistance and as potential drug targets and prognostic markers of TB therapy.

TBS-EP293 Host driven evolution of antimicrobial resistance in mycobacteria

C. Rush,[1] L. Woodbury,[1] A. Kupz,[2] C. Coulter,[3,4] J. Warner,[1]
[1]College of Medicine and Dentistry and Australian Institute of Tropical Health and Medicine, James Cook University, Townsville, Australia, [2]Australian Institute of Tropical Health and Medicine, James Cook University, Cairns, Australia, [3]Queensland Mycobacterium Reference Laboratory (QMRL) and Pathology Queensland Central laboratory at Royal Brisbane Hospital, Brisbane, Australia, [4]WHO Collaborating Centre for Tuberculosis Bacteriology, Brisbane, Australia
e-mail: catherine.rush@jcu.edu.au

Background: Acquired antimicrobial resistance (AMR) rates are higher in TB patients with comorbid conditions such as chronic obstructive pulmonary disease and type 2 diabetes. Oxidative stress in the lung environment and within the macrophage niche of *Mycobacterium tuberculosis* (Mtb), is a feature of these conditions.
We hypothesised that the selective pressures in these host-derived oxidant-rich conditions contribute to the acquisition of Mtb drug tolerance and resistance.
Aims and Methods: The aims of the current study were to establish and evaluate an *in vitro* macrophage model to:
1. Test the effects of intracellular and extracellular oxidants on macrophage phenotypes, and oxidative stress responses;
2. Determine if oxidant-stimulated macrophages were impaired in their abilities to take up and kill mycobacteria;
3. Assess the frequency and spectrum of mutations emerging in conditions of macrophage oxidative stress and;
4. Identify the mechanisms of mutagenesis linked to host OS.
Results: Dysfunction in macrophage uptake and killing of mycobacteria was seen when macrophages were exposed to oxidants at higher concentrations for longer periods compared to short periods. A higher frequency of phenotypic rifampicin resistance was found in macrophages under oxidative stress compared to unstressed macrophages. We used whole genome and shotgun metagenomic analyses to examine the frequency of mutations and mutational signatures related to increased host oxidative stress. Transcriptomic analyses of mycobacterial DNA damage and repair pathways was used to identify mycobacterial gene functions compromised by host oxidative stress.
Conclusions: This study developed a tractable model of macrophage oxidative stress to facilitate future investigations of Mtb DNA damage and mutagenesis mediated by host immune responses. Understanding mycobacterial oxidative DNA repair pathways compromised by the host may inform strategies to minimise mutations emerging when TB antibiotic treatment is commenced.

TBS-EP296 Polymer microparticles surface functionalized with phages to improve intracellular efficacy of phage therapy

D. Smalchuk,[1,2] A. Virgós,[1,3] D. Vulcano,[1] G. Landa,[4,5] M. Arruebo,[4,5] A. Lacoma,[1,2,6] J. Domínguez,[1,2,6] [1]Germans Trias i Pujol Research Institute, Badalona, Spain, [2]Departament de Genètica i Microbiologia, Universitat Autònoma de Barcelona, Barcelona, Spain, [3]Departament de Bioquímica i Biomedicina Molecular, Universitat de Barcelona, Barcelona, Spain, [4]Instituto de Nanociencia y Materiales de Aragón (INMA), CSIC-Universidad de Zaragoza, Zaragoza, Spain, [5]Department of Chemical and Environmental Engineering, Universidad de Zaragoza, Zaragoza, Spain, [6]CIBER Enfermedades Respiratorias (CIBERES), Instituto de Salud Carlos III, Badalona, Spain
e-mail: smalchukdaria@gmail.com

Background: The growing prevalence of drug-resistant tuberculosis highlights the need for alternative antimicrobial strategies. Phage therapy is a promising approach, but its efficacy against intracellular pathogens is limited. Phage delivery using polymer microparticles may enhance phage stability and intracellular uptake.
This study aimed to evaluate and compare the activity of free and PLGA-adsorbed mycobacteriophage D29 against *Mycobacterium smegmatis* in infected human macrophages.
Materials and Methods: Human monocytic cells were differentiated into macrophages and infected with *M. smegmatis* at a multiplicity of infection of 10 (MOI 10). Mycobacteriophage D29 was adsorbed onto porous PLGA microparticles via passive nonspecific adsorption by hydrophobic interactions. Infected macrophages were treated with equivalent doses of free phages or PLGA-adsorbed phages (MOI 10). Over a 72-hour period, extracellular and intracellular bacterial and phage titers were measured using colony counting and plaque assays, respectively.
Results: Bacteria were detected in the supernatant throughout the experiment, with a notable decline after 60 hours, likely due to macrophage lysis and release of intracellular bacteria into the extracellular space, where phage replication was more efficient. Intracellular bacterial levels remained stable for the first 24 hours, followed by a decline after 36 hours, coinciding with increasing free phage concentrations.
In untreated controls, bacterial counts continued to rise. Phages adsorbed on the surface of polymeric microparticles achieved faster intracellular delivery and higher titers after 24 hours (7.6×10^6 PFU/ml vs. 2×10^4 PFU/ml for free phages), resulting in earlier and more pronounced bacterial reduction.
Conclusions: Mycobacteriophage D29 effectively reduced *M. smegmatis* populations both extracellularly and intracellularly, although the intracellular effect was delayed. Polymer microparticle adsorption improved phage delivery to macrophages, leading to earlier onset of an-

tibacterial activity. Complete elimination of bacteria was not achieved within the experimental timeframe. Future strategies may involve combining phages with antibiotics to enhance efficacy and reduce treatment duration.

TBS-EP299 Identification of bacterial cell envelope factors that influence tuberculosis treatment outcome

J. Nigou,[1] K. Fonseca,[2] C. Sopegno,[2] S. Nicolas,[1] S. Vashakidze,[3] N. Martinson,[4] J. Farrés,[2] C. Vilaplana,[2] SMA-TB RCT team [1]Institute of Pharmacology and Structural Biology, CNRS / Université de Toulouse, Toulouse, France, [2]Germans Trias i Pujol Research Institute & Hospital, Badalona, Spain, [3]National Center for TB and Lung Diseases Georgia, University of Georgia, Tbilisi, Georgia, [4]Perinatal HIV Research Unit (PHRU), University of the Witwatersrand, Johannesburg, South Africa
e-mail: jerome.nigou@ipbs.fr

Bacterial factors are assumed to influence tuberculosis disease and treatment outcome. Yet, this remains poorly investigated in the context of human infection.
In the frame of the SMA-TB EU-funded project (GA847762) Phase II clinical trial (NCT04575519), conducted to evaluate ibuprofen and acetylsalicylic acid as anti-inflammatory adjunctive to anti-tuberculosis treatment, we analyzed a set of 155 *Mycobacterium tuberculosis* clinical isolates collected at baseline to explore the relationship between the abundance of certain compounds in the bacterial envelope and the clinical data of patients.
M. tuberculosis cell envelope is typified by its extraordinarily high and diverse lipid content, most of these lipids exhibiting immunomodulatory properties in vitro or in animal models of infection.
We quantified the lipoglycan lipoarabinomannan (LAM), the lipoprotein 19 kDa, and a series of lipids and glycolipids, including mycolic acids, phtiocerol dimycocerosate (DIM), triacylglycerols (TAG), sulfoglycolipids (SGL), diacyltrehaloses (DAT), phosphatidylinositol mannosides (PIM), and tuberculosinyladenosine (TbAd) in bacterial strains grown on solid medium, using dot-blot and targeted lipidomic analyses.
We also investigated the capacity of the *M. tuberculosis* strains to activate NF-kB, a key transcription factor in the secretion of pro-inflammatory molecules, in THP-1 macrophages.
We found that the production of some of the bacterial compounds analyzed was statistically different between the strains isolated from either good or bad responder patients in term of time to stable sputum culture conversion, and evolution of TB score during treatment. We also observed that patients who had a bad evolution of X-Ray score were associated with the *M. tuberculosis* strains that induced NF-kB the most.
Altogether, our data strongly suggest that bacterial factors, as well as the intrinsic inflammatory potential of *M. tuberculosis* strains, influence human tuberculosis disease and treatment outcome.

TBS-EP305 Long-acting bedaquiline: A novel preventive strategy against tuberculosis in a murine model

V. Fontaine,[1] A. Chauffour,[1] M. Rima,[1] A. Aubry,[1] C. Aguilar Pérez,[2] L. Ballell Pages,[2] N. Veziris,[1] [1]Sorbonne Université / Centre d'Immunologie et des Maladies Infectieuses, Paris, France, [2]Janssen Global Public Health, LLC, Janssen Pharmaceutica NV,, Beerse, Belgium
e-mail: nicolas.veziris@sorbonne-universite.fr

Background: Although isoniazid preventive therapy (IPT) for tuberculosis (TB) is recommended by the WHO for people living with HIV, its use remains limited. Bedaquiline long-acting (BDQ-LAI), an injectable antitubercular drug with a long terminal half-life (23 weeks), may simplify TB prevention, akin to long-acting antivirals. This study evaluated BDQ-LAI as a preventive therapy using a novel murine model.
Methods: Seventy-two female Balb/c mice (6 weeks old) were assigned to three treatment groups receiving BDQ-LAI intramuscularly at low, middle or high dosing (N=24/group), and one untreated control group (N=30). Ten days post-treatment, all mice were infected intranasally with 32 CFU/mouse of M. tuberculosis H37Rv. On day 1 post-infection, six untreated mice were sacrificed to assess baseline lung CFU and plasma exposure. Lung CFU counts and drug levels in plasma and lungs were assessed on days 14, 21, 28, and 100 in six mice per group.
Results: in the untreated control group, CFU increased up to 5.7+/-0.6 log10 CFU at D100.The low dose of BDQ-LAI, did not prevent bacillary growth (5.4+/-0.7 log10 CFU at D100) and had a minimal impact on bacterial replication. The high BDQ-LAI dose completely prevented bacillary growth at all time-points evaluated. The middle BDQ-LAI dose displayed intermediate activity with 2/6 mice culture positive at D14, D21 and D28 (with 0.6 to 1.2 average log10 CFU count) and no positive mouse at D100.
Conclusions: BDQ-LAI demonstrated dose-dependent protection against TB in mice, with complete prevention at the highest dose. These findings support further investigation of BDQ-LAI as a simplified, long-acting TB preventive therapy, particularly beneficial for high-burden regions and global TB control efforts.

TBS-EP308 Shifts in Mycobacterium tuberculosis complex lineages and drug resistance patterns in Georgia: A whole genome sequencing-based cohort study (2014–2020)

D. Butov,[1,2] N. Shubladze,[3] A. Rosenthal,[4] A. Grinev,[4] V. Dreyer,[2,5] Z. Avaliani,[3,6] S. Niemann,[2,5] S. Vashakidze,[3,7]
[1]Kharkiv National Medical University, Kharkiv, Ukraine, [2]Research Center Borstel, Borstel, Germany, [3]National Center of Tuberculosis and Lung Diseases, Tbilisi, Georgia, [4]U.S. National Institute of Allergy and Infectious Diseases, Rockville, MD, United States of America, [5]German Center for Infection Research (DZIF), Partner Site Hamburg-Lübeck-Borstel-Riems, Borstel, Germany, [6]European University, Tbilisi, Georgia, [7]The University of Georgia, Tbilisi, Georgia
e-mail: do.butov@knmu.edu.ua

Background: Understanding the lineage distribution of *Mycobacterium tuberculosis* complex (MTBC) strains and their association with drug resistance is essential for informing public health strategies and tuberculosis (TB) control efforts in country.
Methods: We conducted a prospective cohort study of patients with culture-confirmed pulmonary tuberculosis treated at the National Center for Tuberculosis and Lung Diseases in Tbilisi, Georgia, from 2014 to 2020. Clinical and genomic data were stored in the NIAID TB Portals database. Whole genome sequencing was performed on DNA extracted from 1,516 MTBC isolates using Illumina platforms. Lineages (L) and genotypic resistance profiles were determined using the MTBseq bioinformatics pipeline.
Results: Among 1,516 patients, 705 (46.5%) had drug-susceptible TB (DS-TB), 210 (13.9%) had non-multidrug-resistant (MDR) TB, 510 (33.6%) had MDR-TB, and 91 (6%) had pre-extensively drug-resistant (XDR) or XDR-TB. Strains belonging to L2 were identified in 729 (48.1%) patients, while strains of L4 were found in 753(49.7%); 34(2.2%) isolates belonged to other or mixed lineages. L4 strains were predominant among patients with DS-TB (492/705,69.7%; $p \leq 0.001$), whereas L2 strains were significantly associated with MDR, pre-XDR, and XDR-TB (481/599,80.3%;$p \leq 0.001$).
While in 2014, 76.8% (103 out of 134) of patients were infected with a L2 strains, this proportion decreased to 36.1% (126 out of 349)in 2020, coinciding with an increase in DS-TB cases and a decline in the prevalence of MDR, pre-XDR and XDR-TB cases.
Conclusion: Our findings demonstrate a strong association between MTBC Lineage 2 and drug-resistant tuberculosis, including MDR, pre-XDR, and XDR-TB, in Georgia. The predominance of Lineage 4 among drug-susceptible TB cases suggests differential transmission dynamics and pathogenicity between major MTBC lineages. Notably, the substantial decline in the proportion of L2 strains from 2014 to 2020 coincided with a marked reduction in drug-resistant TB burden, underscoring the potential impact of public health interventions targeting L2-driven transmission.

TBS-EP311 Sputum microbiome among newly admitted patients with HIV in a high TB prevalence setting: A study from a teaching hospital in Ghana

P. Asare,[1] T. Afum,[1] E. Obike,[1] S. Osei-Wusu,[1] J.A. Opintan,[2] E. Sampane-Donkor,[2] M. Lartey,[3] S. Bjerrum,[4] D. Yeboah-Manu,[1] I. Somuncu Johansen,[4] J. Åhsberg,[4]
[1]Noguchi Memorial Institute for Medical Research, College of Health Sciences, University of Ghana, Legon, Ghana, [2]Department of Medical Microbiology, University of Ghana Medical School, Korle-Bu, Ghana, [3]Department of Medicine & Therapeutics, Medical school, College of Health sciences, University of Ghana, Accra, Ghana, [4]Research Center of Infectious Diseases, Department of Clinical Research, University of Southern Denmark, Odense, Denmark
e-mail: pasare@noguchi.ug.edu.gh

Background: Emerging evidence links the respiratory microbiome to tuberculosis (TB) susceptibility and progression, but its role in severely ill patients with HIV is unclear.
This study investigated whether the sputum microbiome at hospital admission differed by (i) TB status at 8 weeks and (ii) 8-week survival.
Furthermore, we investigated whether the sputum microbiome collected at 8-week follow-up differed by (iii) TB treatment status.
Methods: Adults with HIV admitted to Korle-Bu Teaching Hospital (Oct 2019–Nov 2021) with severe illness, advanced HIV, or TB symptoms were prospectively enrolled. Admission and 8-week follow-up sputum were cryopreserved and analyzed by 16S rRNA microbiome analysis (Illumina) at Noguchi Memorial Institute for Medical Research. QIIME 2 was used for bioinformatics. TB definition was based on any specimen GeneXpert, sputum culture, urine Determine LF-LAM, or sputum 16S.
Results: Seventy-one patients provided admission sputum; 23 provided 8-week follow-up sputum. Patients with TB (n=39) vs. without TB (n=32) were similar in age (median 42 years), CD4 count (median 74 cells/mm^3), and ART coverage (32%). More patients with TB were female (72% vs. 53%) and fewer were newly diagnosed with HIV (44% vs. 69%). Two and 5 patients were excluded from diversity respective taxonomy analyses due to poor sequence quality.
No significant differences in alpha diversity (Shannon Index) or beta diversity (Bray-Curtis & PERMANOVA) were observed when stratified by TB status or 8-week survival (**Figure 1A-B**). However, significant differences in alpha (p=0.03) and beta diversity (p=0.016) were ob-

served in follow-up sputum stratified by TB treatment status (**Figure 1C**). Taxonomic analysis showed reduced prevalence of *Mogibacterium* and *Lancefieldla* among participants on anti-TB treatment. Among patients starting TB treatment during follow-up, we observed a shift from *GWA2-37-10* to *Actinomyces*.

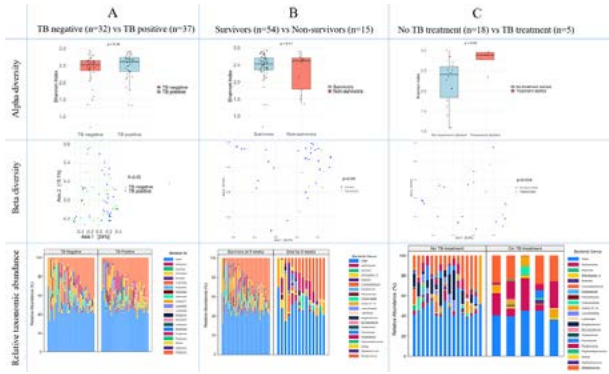


Figure 1.

Conclusion: Sputum microbiome diversity and taxonomy differed by TB treatment status but not by TB diagnosis or survival among inpatients with HIV.

TBS-EP314 Plasma metabolites of tryptophan catabolism and reduced lung function during and after TB treatment

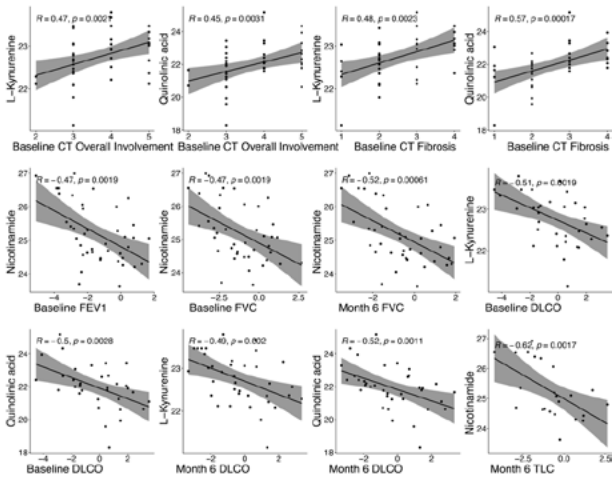
J. Chandler,[1] J. Lyles,[1] G. Collins,[1] M. Aldeca,[1] A. Queiroz,[2] P. Maenetje,[3] J. Benyera,[3] N. Baloyi,[3] L. Nkangane,[3] J. Pilusa,[3] G. Bisson,[4] S. Auld,[1] [1]Emory University, Atlanta, United States of America, [2]FIOTEC, Salvador, Brazil, [3]The Aurum Institute, Johannesburg, South Africa, [4]University of Pennsylvania, Philadelphia, United States of America
e-mail: joshua.chandler@emory.edu

Introduction: Despite the global burden of post-TB lung disease (PTLD), metabolic pathways driving pathologic tissue damage are poorly understood. We evaluated the association between plasma metabolites and lung health during and after TB treatment.

Methods: We collected blood plasma from adults with and without HIV who were newly diagnosed with drug-susceptible pulmonary TB in Johannesburg, South Africa and enrolled in a longitudinal cohort study within 2 weeks of TB treatment initiation. Metabolomics was performed on plasma using hydrophilic interaction liquid chromatography coupled to an Orbitrap mass spectrometer.

Pulmonary function testing was performed at baseline, 6 months (end of TB treatment), and 12 months, and high-resolution chest CT was performed at baseline and 12 months and semi-quantitatively scored by a radiologist. Spearman's correlation was calculated between metabolites and pulmonary variables (p-value < 0.05, FDR < 0.05).

Results: Among 40 participants, 7 (18%) were female, the median age was 37 (IQR 32-49), and 12 (30%) had HIV coinfection. At baseline, 22 (55%) had a reduced forced expiratory volume in 1 second (FEV1) (z-score ≤ 1.65) and 39 (98%) had radiographic abnormalities encompassing > 25% of the lungs. Among 177 known metabolites, 76 were correlated with lung function or radiographic involvement, including several linked to tryptophan catabolism and NAD+ biosynthesis/catabolism, namely kynurenine, quinolinic acid, and nicotinamide (Figure). Kynurenine and quinolinic acid correlated inversely with baseline and 6-month DLCO, and positively with overall CT involvement and fibrosis, while nicotinamide correlated with baseline FEV1 and forced vital capacity (FVC) and 6-month FVC and total lung capacity (TLC).



Conclusion: Among individuals with pulmonary TB, metabolites reflecting tryptophan catabolism and NAD+ biosynthesis correlated with impaired lung function and greater radiographic involvement, both at the time of diagnosis and after TB treatment completion. Future analyses can explore whether these metabolites function as biomarkers of PTLD risk.

TBS-EP317 Collagen-targeted PET/CT for evaluation of post-TB lung disease in adults with TB

A.A. Ordonez,[1] M.D.T.W Vangu,[2] S.B. Montesi,[3] P. Caravan,[4] L. Gabuza,[2] T. Ngwanto,[5] N. Glover,[5] R. Nkanyane,[5] A. Queiroz,[6] M. Marll,[7] S.C Auld,[7] G.P Bisson,[8]
[1]Department of Radiology, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, United States of America, [2]Department of Radiation Sciences, University of the Witwatersrand, Johannesburg, South Africa, [3]Division of Pulmonary and Critical Care Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, United States of America, [4]Institute for Innovation in Imaging, Department of Radiology, Massachusetts General Hospital and Harvard Medical School, Boston, United States of America, [5]The Aurum Institute, Pretoria, South Africa, [6]Fundação Oswaldo Cruz, FIOCRUZ, Salvador, Brazil, [7]Departments of Medicine and Epidemiology, Emory University School of Medicine, Atlanta, United States of America, [8]Department of Medicine, Division of Infectious Diseases, Perelman School of Medicine at the University of Pennsylvania, Philadelphia, United States of America
e-mail: alvaro.ordonez@pennmedicine.upenn.edu

Post-TB lung disease (PTLD) is characterized by fibrosis after TB treatment, but novel tools to assess pulmonary profibrotic activity are needed. We used a type I collagen-specific positron emission tomography (PET) probe, ^{68}Ga-CBP8, to test whether increased PET signal correlates with worse lung function and radiographic abnormalities in adults with pulmonary TB in Johannesburg, South Africa.

We enrolled 55 adults (14 females, 20 with HIV) with first-time, microbiologically confirmed, rifampin-susceptible pulmonary TB within two weeks of starting four-drug therapy. At baseline, patients received ~151 MBq of ^{68}Ga-CBP8 intravenously, followed by PET/CT imaging.

High-resolution CT (HRCT) was performed at baseline and scored by a radiologist using standardized systems for overall lung involvement, fibrosis, and consolidation. Lung segmentation was performed using MIM 7.2.2 to determine the percentage of lung volume with PET signal above mean standardized uptake value (SUV) ≥1, adjusted to blood SUV. Pulmonary function tests, including spirometry normalized as z-scores, were performed at baseline and treatment completion.

Multivariable linear regression adjusted for age, sex, and HIV status. ^{68}Ga-CBP8 uptake localized to TB-affected lung regions on CT, including cavity walls. Higher PET signal at diagnosis was significantly and independently associated with lower forced expiratory volume in one second (FEV_1), lower forced vital capacity (FVC), and greater radiographic involvement, consolidation, and fibrosis at baseline (Table).

Baseline PET signal also correlated with lower lung function at treatment completion. Increased ^{68}Ga-CBP8 PET signal at TB diagnosis is associated with worse lung function and radiographic involvement early during treatment and at treatment completion in adults with pulmonary TB. PET imaging of fibrosis offers a promising clinically translatable approach for early detection of fibrotic changes in PTLD, potentially informing prognosis and guiding antifibrotic interventions. Follow-up HRCTs at month 12 are being performed to assess relationships between baseline PET signal detection and lesion persistence.

Time point	Baseline		At treatment completion	
	Adjusted β (95% CI)	P-value	Adjusted β (95% CI)	P-value
FEV_1 z-score	-0.29 (95% CI -0.54 to -0.04)	0.023	-0.38 (95% CI -0.64 to -0.13)	0.007
FVC z-score	-0.36 (95% CI -0.61 to -0.10)	0.007	-0.44 (95% CI -0.68 to -0.19)	0.001
DLCO z-score	-0.32 (95% CI -0.68 to 0.05)	0.086	-0.35 (95% CI -0.61 to -0.08)	0.013
HRCT overall involvement score	1.78 (95% CI 0.83 to 2.73)	<0.001		
HRCT consolidation score	1.33 (95% CI 0.73 to 1.94)	<0.001		
HRCT fibrosis score	1.04 (95% CI 0.24 to 1.84)	0.012		

Table. β coefficients, adjusted for age, sex and HIV, relating lung PET signal to lung function and radiology scoring.

TBS-EP320 Long-term morbidity after tuberculosis treatment in a high-burden country

R. Miyahara,[1] A. Kasamatsu,[2] W. Sawaengdee,[3] H. Yanai,[4] S. Mahasirimongkol,[5] [1]National Institute of Infectious Diseases, Japan Institute of Health Security, Department of Epidemiology and Global Health, Tokyo, Japan, [2]National Institute of Infectious Diseases, Japan Institute for Health Security, Department of Epidemiology and Global Health, Tokyo, Japan, [3]Department of Medical Sciences, Ministry of Public Health Thailand, Department of Thai Traditional and Alternative Medicine, Bangkok, Thailand, [4]Research Institute of Tuberculosis, Japan Anti-Tuberculosis Association, Tokyo, Japan, [5]Department of Thai Traditional and Alternative Medicine, Ministry of Public Health Thailand, Department of Thai Traditional and Alternative Medicine, Bangkok, Thailand
e-mail: rmiyahara@niid.go.jp

Background: Survivors of tuberculosis (TB) may face increased risks of acute and chronic health conditions after completing anti-TB therapy. However, few cohort studies in high-TB burden countries have systematically examined changes in morbidity patterns before and after treatment.

Current criteria for determining treatment completion rely on standard treatment duration, sputum culture, or acid-fast bacilli (AFB) smear conversion. However, these indicators may not fully capture long-term clinical outcomes.

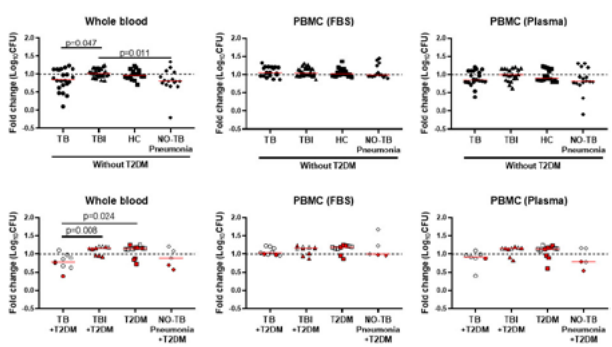
Objective: To assess changes in the monthly number of diagnosed cases and hospital admission rates for lower respiratory tract infections (LRTIs), chronic respiratory diseases (CRDs), and diabetes mellitus (DM) before and after TB treatment.
Methods: A retrospective cohort of patients who survived during TB treatment was linked to the Health Data Center (HDC), managed by the Ministry of Public Health, Thailand. Diagnoses recorded during the "pre-TB" period (–30 to –6 months before treatment) and the "post-TB" period (+6 to +30months after treatment) were identified using ICD-10 codes and categorized as LRTIs (J12–J18), CRDs (J40–J47), or DM (E10–E14). Monthly diagnosis rate ratios (IRRs) and hospital admission IRRs (post- vs. pre-TB) were calculated with 95% confidence intervals (CIs) using a Poisson Regression model.
Results: A total of 757 patients were analyzed. The monthly number of LRTIs diagnosis increased non-significantly after TB treatment (IRR 1.38; p = 0.091), while hospital admissions rose markedly (IRR 15.20; p = 0.008). CRD diagnosis nearly doubled post-TB compared to pre-TB (IRR 2.42; p < 0.001), with a fivefold increase in admission risk (IRR 4.90; p < 0.001). DM diagnosis increased by 36% post-TB (IRR 1.36; p < 0.001) and remained elevated throughout follow-up.

Conclusions: These findings highlight the importance of incorporating long-term clinical indicators into TB care. Such indicators may support more individualized treatment durations and improved patient outcomes.

TBS-EP326 The ability of patients with TB disease to control mycobacterial replication in vitro is not impaired by diabetes

A. Aiello,[1] S. Sbarra,[1] A. Salmi,[1] G. Cuzzi,[1] I. Palucci,[2,3] G. Delogu,[4] G. Gualano,[1] D. Goletti,[1] [1]National Institute for Infectious Diseases Lazzaro Spallanzani-IRCCS, Rome, Italy, [2]Università Cattolica del Sacro Cuore, Rome, Italy, [3]Fondazione Policlinico Universitario A. Gemelli-IRCCS, Rome, Italy, [4]University of Parma, Parma, Italy
e-mail: alessandra.aiello@inmi.it

Background: This study investigated the ability of immune cells from different cohorts to control the mycobacterial outgrowth to identify possible correlates of protection and evaluate the impact of type 2 diabetes mellitus (T2DM), a known risk factor for tuberculosis (TB), on mycobacterial growth.
Methods: We enrolled 120 subjects, including patients with TB disease (n=22), TB and type 2 diabetes (TB-T2DM) (n=9), TB infection (TBI, n=29), TBI-T2DM (n=10), healthy controls (n=16), T2DM (n=12), subjects with pulmonary disease other than TB (NO-TB pneumonia, n=16) and NO-TB pneumonia with T2DM (n=6). The mycobacterial growth inhibition assay (MGIA) was performed for each sample. Both whole blood (WB) and fresh peripheral mononuclear cells (PBMCs), supplemented with fetal bovine serum (FBS) or autologous plasma, were infected with about 150 CFU of BCG Pasteur for 4 days, then lysed and incubated in the BACTEC MGIT instrument until positivity.
Results: Preliminary results show a significantly higher ability of TB patients to control BCG replication compared to TBI patients (p=0.047), as detected by MGIA performed on whole blood. Similarly, whole blood of TB patients with T2DM (TB-T2DM) significantly controls BCG growth compared to both TBI (p=0.008) and T2DM subjects (p=0.024). In contrast, PBMCs supplemented with FBS or autologous plasma do not show significant differences in their ability to control BCG outgrowth between TB patients and TBI. Moreover, no significant differences were found between diabetic and non-diabetic subjects within each group in any of the cell systems evaluated, whether whole blood or PBMC supplemented with FBS or autologous plasma.



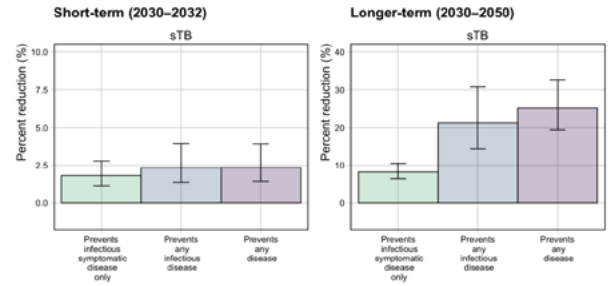
Conclusions: These findings indicate that factors in the blood of individuals with TB disease modulate BCG outgrowth. Ongoing research is assessing whether secreted immune factors or antibodies are expressed differently across various groups. Identifying immune factors involved in mycobacterial control may help define new biomarkers of protection in TB.

TBS-EP329 Population impact of new TB vaccines may depend on efficacy against infectious asymptomatic TB: A modelling study

H. Tanvir,[1] R.A. Clark,[1] T. Sumner,[1] K.C. Horton,[1] T.O. Prŷs-Jones,[1] R. Bakker,[1] K. Rade,[2] V. Mave,[3] M. Hatherill,[4] G. Churchyard,[5] R.M.G.J. Houben,[1] R.G. White,[1] [1]LSHTM, Department of Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [2]Stop TB Partnership, International Technical Consultant, New Delhi, India, [3]JHU, Byramjee Jeejeebhoy Government Medical College (BJGMC)-JHU Clinical Trials Unit (CTU), Pune, India, [4]University of Cape Town, South African Tuberculosis Vaccine Initiative, Institute of Infectious Disease and Molecular Medicine and Department of Pathology, Cape Town, South Africa, [5]Aurum Institute, School of Public Health, University of Witwatersrand, Johannesburg, South Africa
e-mail: rebecca.clark@lshtm.ac.uk

Background: Tuberculosis (TB) remains a leading cause of infectious disease death. Modelling predicts new TB vaccines may reduce global burden but rely on assumptions about vaccine efficacy by TB disease stage and TB natural history, which may be incorrect. We explored the sensitivity of estimates of the impact of new TB vaccines to uncertainties in efficacy by disease stage and natural history.
Methods: We developed a dynamic compartmental TB model for India, including early TB disease stages. Scenarios assumed 50% vaccine efficacy for 10 years and prevented progression to a) only infectious symptomatic disease, or b) any infectious disease, or c) any disease.
We estimated impact on averting disease episodes over 2030–2050, compared to no-new-vaccine introduction.
Results: Results suggest, over three years, there was little difference in the proportion of cumulative symptomatic disease episodes averted by vaccines preventing only infectious symptomatic disease, any infectious disease, or any disease (1.8%, 2.3%, and 2.4%, respectively).
However, over 20 years, compared to vaccines preventing only infectious symptomatic disease, vaccines preventing any infectious disease, or any disease, averted a markedly higher proportion of symptomatic disease episodes (8.2%, 21.0%, and 25.1%, respectively), due to preventing continued transmission from infectious asymptomatic disease.

Figure Percent reduction in symptomatic TB episodes for each vaccine scenario compared to no-new-vaccine introduction over the short- and longer-term



Abbreviations: sTB = symptomatic tuberculosis

Conclusions: The population impact of new TB vaccines may depend on efficacy against infectious asymptomatic disease. TB vaccine trials should measure impact on infectious asymptomatic disease to enable better estimates of the potential value of new TB vaccines. Further data collection is required to better understand the transmissibility, morbidity, and dynamics of asymptomatic disease.

TBS-EP332 Comparison of phylogenetic metrics of transmission in symptomatic and asymptomatic tuberculosis

K.E. da Silva,[1] P.C. Pereira dos Santos,[2] K.S. Walter,[3] E.A. Totumi Cunha,[4] C. Colijn,[5] T. Cohen,[6] J. Croda,[2,6,7] J.R. Andrews,[1] [1]Stanford University, Department of Medicine, Division of Infectious Diseases and Geographic Medicine, Stanford, United States of America, [2]School of Medicine, Federal University of Mato Grosso do Sul, Campo Grande, Brazil, [3]Division of Epidemiology, University of Utah, Salt Lake City, United States of America, [4]Laboratory of Bacteriology, Central Laboratory of Mato Grosso do Sul, Campo Grande, Brazil, [5]Department of Mathematics, Simon Fraser University, Burnaby, Canada, [6]Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, United States of America, [7]Fiocruz Mato Grosso do Sul, Fundação Oswaldo Cruz, Campo Grande, Brazil
e-mail: kesiaeds@stanford.edu

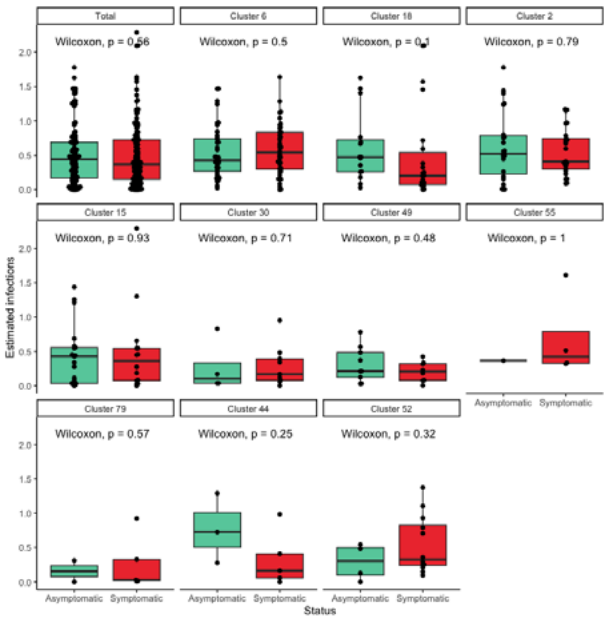
Background: *Mycobacterium tuberculosis* (*Mtb*) transmission remains a critical challenge in high-burden settings. While tuberculosis control efforts traditionally target symptomatic individuals, the contribution of asymptomatic cases to ongoing transmission remains poorly understood.
Methods: We conducted a genomic and epidemiological analysis of *Mtb* strains collected in Mato Grosso do Sul, Brazil, between 2008 and 2024. From 2017 to 2022, tuberculosis (TB) active case finding was performed in three of the largest prisons in the state, whereby sputum was collected from individuals irrespective of symptoms and tested by GeneXpert and culture. We evaluated phylogenetic clustering, Time-scaled Haplotype Density (THD), Local Branching Index (LBI), and Bayesian Reconstruc-

tion and Evolutionary Analysis of Transmission Histories (BREATH) to compare metrics of transmission between symptomatic and asymptomatic individuals.

Results: We sequenced 2,794 *Mtb* strains, yielding 2,362 high-quality lineage 4 sequences. Among 2,362 individuals with TB, 1,137 were incarcerated at the time of diagnosis, of which 505 were identified through active case finding: 277 had symptomatic disease and 228 had asymptomatic TB.

While incarceration status was strongly associated with higher transmission metrics (THD estimate = 0.60, $p < 0.001$; LBI estimate = 0.00071, $p < 0.001$), there was no significant difference in phylogenetic clustering proportion (77% vs. 85%; p= 0.816), THD (median 0.50 vs. 0.39; p = 0.120), or LBI (median 0.00863 vs. 0.00871; p = 0.086) between symptomatic and asymptomatic individuals.

Bayesian transmission trees revealed no significant difference in the number of secondary infections inferred from symptomatic compared with asymptomatic individuals (p = 0.56) (*Figure 1*). These findings were consistent across genomic clusters and robust to model assumptions.



Conclusions: Evidence from multiple genomic metrics of transmission identified no differences in isolates from symptomatic compared with asymptomatic individuals, underscoring the substantial contribution that asymptomatic TB makes to transmission at the population level.

TBS-EP335 A new blood-based RNA signature (R7), effectively identifies TB disease and predicts response to therapy

H.-C. Lai,[1] T.A. Nguyen,[2] B.H. Nguyen,[3] G. Fox,[4] G. Mark,[5] W. Britton,[1] B. Saunders,[6] [1]Centenary Institute, Sydney, Australia, [2]Woolcock Institute of Medical Research, Sydney, Australia, [3]National Lung Hospital, Hanoi, Vietnam, Hanoi, Viet Nam, [4]The University of Sydney Faculty of Medicine and Health, Sydney, Australia, [5]Burnet Institute, Melbourne, Australia, [6]University of Technology, Sydney, School of Life Sciences, Sydney, Australia
e-mail: Bernadette.Saunders@uts.edu.au

Tuberculosis (TB) treatment requires a six-month drug regimen with effectiveness often unclear until months into therapy. Delays in TB diagnosis and difficulty identifying treatment non-responders increases the risk of developing drug resistance, further lung damage and continued transmission. There is an urgent need for new non-sputum-based tools to aid early TB diagnosis and monitor treatment response.

Through transcriptomes analysis of 45 candidate genes in blood, we identified a 7-gene signature (R7) that distinguishes individuals with active multi-drug resistant (MDR) TB from controls (AUC 0.838 95% CI: 0.919-0.682). In a Vietnam cohort study this signature-accurately identified successful treatment responders after 4- and 6-months treatment AUC 0.817 95% CI: 0.936-0.549 and AUC 0.762 95% CI: 0.918-0.395, respectively.

The R7-score also differentiated active TB from Healthy controls across other published cohorts in South Africa and Gambia (GSE 79362) and South India (GSE 193777) with AUC between 0.777-0.928 95% CI 0.72-1.

Further, the R7 signature also successfully predicted response to therapy in a South African cohort (GSE89403) at 7 days, week 4 and week 24 with AUCs between 0.800-0.920. This novel R7-score signature could also distinguish TB from other lung diseases including Pneumonia and Lung Cancer (GSE 42834): AUC 0.841-0.908. The R7-gene signature performed well in all age groups, and was more enriched with female patients, at the diagnostic point.

These findings support the R7-score as a promising biomarker to aid, both TB diagnosis and predict the response to therapy in patients.

TBS-EP338 Granulysin antimicrobial activity promotes dormancy in *Mycobacterium tuberculosis*

S. Schmidiger,[1] E.F. McCaffrey,[2] J.M. Schmidt,[3] O. Abdul Hameed,[4] K. Reither,[1] J.M. Carballido,[3] A. Arbués,[1] D. Portevin,[1] [1]Swiss Tropical and Public Health Institute & University of Basel, Allschwil, Switzerland, [2]Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Disease, National Institutes of Health, Bethesda, United States of America, [3]Translational Medicine-Preclinical Safety, Novartis Biomedical Research, Basel, Switzerland, [4]Anatomy Unit, Department of Oncology, Microbiology and Immunology, Faculty of Science and Medicine, University of Fribourg, Fribourg, Switzerland
e-mail: sarah.schmidiger@swisstph.ch

Human tuberculosis (TB) caused by *Mycobacterium tuberculosis* (*Mtb*) remains a global public health threat. Granulomas constitute a hallmark of TB pathogenesis that can clear, contain or exacerbate an infection. Containment is exploited by *Mtb* as a hideout to persist in a dormant, antibiotic-tolerant state only to resuscitate upon immunosuppression. The immune determinants of a granulomatous response driving *Mtb* persistence remain elusive.

We here generated *ex vivo* granulomas from peripheral blood mononuclear cell specimens of TB patients and applied high-dimensional mass cytometry to elucidate immune factors prompting *Mtb* dormancy.

Compared to healthy controls, patient-derived *ex vivo* granulomas rapidly forced *Mtb* to become dormant-like. This observation correlated with an enrichment in activated, innate (-like) cytotoxic lymphocytes and required the presence of $CD56^+$ lymphocytes or more specifically, the content of their granules.

Finally, we demonstrated that direct exposure to granulysin induces *Mtb* dormancy, thereby unravelling an immune escape mechanism to cytotoxic lymphocyte activity. Our findings may inspire clinical TB research, for tailored boosting of granulysin activity could prevent proliferation and favor *Mtb* clearance from the lung of infected individuals. Reciprocally, neutralization of granulysin activity could promote *Mtb* resuscitation and susceptibility to antibiotics to shorten treatment.

In addition, cytotoxic functions and granulysin production in particular may be considered as relevant correlates of protection urgently needed for TB vaccine development.

TBS-EP341 Peripheral CD34+ cells as a potential niche for *Mycobacterium tuberculosis*

T. Alonzi,[1] D. Peruzzu,[1] F. Repele,[1] A. Aiello,[1] G. Bontempi,[1,2] G. Gualano,[1] G. Delogu,[3] D. Goletti,[1] [1]National Institute for Infectious Diseases L. Spallanzani IRCCS, Rome, Italy, [2]Sapienza University of Rome, Rome, Italy, [3]University of Parma, Parma, Italy
e-mail: tonino.alonzi@inmi.it

Background: Effective tuberculosis (TB) control and reduction of Mycobacterium tuberculosis (Mtb) transmission necessitate accurate diagnosis of TB infection (TBI), as well as the identification of TB progressors, TBI individuals at higher risk of developing the disease.

Since no gold standard exists for TBI diagnosis, and the Mtb immune-response based methods have a low positive predictive value for disease progression, new methodologies are necessary. Recent studies, including ours, have shown the presence of Mtb-DNA in peripheral CD34+ cells of TBI or TB individuals.

However, it remains unclear whether:

i. Mtb can infect CD34+ cells, and;

ii. Mtb-DNA detection correlates with the host immunological state.

Objectives:

1. Evaluate whether Mtb can infect CD34+ cells;

2. Evaluate whether Mtb-DNA presence differs between immunocompromised and immunocompetent TBI subjects.

Methods:

Objective 1: CD34+ cells isolated immunomagnetically from peripheral blood mononuclear cells (PBMC) of healthy donors (95% purity) were in vitro infected with constitutively fluorescent laboratory Mtb strains (H37Rv) and analysed by confocal microscopy.

Objective 2: We enrolled a cohort of immunosuppressed TBI with concomitant rheumatological diseases or multiple sclerosis (n=86), immunocompetent TBI (n=52), immunocompetent TB (n=60), and Mtb-uninfected (n=52) individuals. CD34+ cells were isolated from PBMC, DNA extracted, and Mtb genome level measured by digital-PCR (dPCR) detecting IS6110 and rpoB sequences.

Results:

Objective 1: We observed intracellular localization of Mtb in CD34+ cells at a low frequency (<3%), using a three-dimensional reconstruction of images by confocal microscopy.

Objective 2: Mtb-DNA was detected in less than 10% of CD34+ cells in immunosuppressed TBI, similarly to immunocompetent TBI individuals.

Conclusions: Our research indicates that CD34+ cells can be infected by Mtb and may serve as a potential reservoir for this bacterium. These findings propose a novel method for diagnosing TBI, which involves directly identifying Mtb rather than relying solely on measuring the host's immune response.

TBS-EP344 Mycobacterium tuberculosis complex lineage 1: A frequent but neglected cause of tuberculosis with implications for vaccine design

V.M. Rojas,[1] S. Gagneux,[1] S. Borrell,[1] [1]University of Basel / Swiss Tropical and Public Health Institute, Allschwil, Switzerland
e-mail: venus.rojas@swisstph.ch

The genetic diversity of MTBC, although smaller when compared to other bacteria, is not to be ignored. This diversity is due to SNPs, indels, repeats, duplications, and homologous recombination within the MTBC genome. MTBC genetic diversity has implications on regulation of gene translation and in epigenetic mechanisms, which allow for phenotypic variation. Because of phenotypic variation, we observe between- and within-lineage differences in MTBC clinical phenotypes.
Unfortunately, most TB vaccines in the clinical pipeline fail to consider MTBC genetic diversity. Many of these vaccines are based on BCG or on L4 strains. However, most high burden TB countries are actually L1-endemic countries. L1 also infects more TB patients than any other MTBC lineage. The objective of our research hence, is to understand the understudied MTBC L1, in terms of its genetic diversity, distribution and clinical phenotypes.
We studied around 4000 representative L1 genomes from all over the world using short- and long-read sequencing. With long-read sequencing, we are comparing the genes implicated in host-pathogen interaction and virulence. With short-reads, we examined the distribution and genetic distance of different L1 strains.
Moreover, we looked at genomes covering 27 years in the Philippines – a L1-endemic country that has the highest population of L1 cases globally and is also a high burden country for TB, TB-HIV, and RR/MDR-TB.
Preliminary results of our research suggest that the genetic diversity within L1 alone is significantly high. The distribution of different L1 strains indicate possible local adaptation to certain populations.
Lastly, the contribution of L1 in drug resistance epidemics is currently underestimated. Our research suggests that TB vaccine development will benefit greatly from being informed of L1 diversity

TBS-EP347 Targeted sequencing directly on sputum samples for optimizing detection of *M.tuberculosis*

M. Jonsson Nordvall,[1,2] J. Welander,[1,3] M. Bergman-Jungeström,[1,3] L. Serrander,[1,2,4] J. Paues,[1] M. Lerm,[1] T. Schön,[1,4,5] [1]Department of Biomedical and Clinical Sciences, Division of Inflammation and Infection, Linköping University, Linköping, Sweden, [2]Department of clinical microbiology, University hospital, Linköping, Sweden, [3]Precision medicine laboratory, University hospital, Linköping, Sweden, [4]Department of Infectious Diseases, University Hospital, Linköping, Sweden, [5]Department of Infectious Diseases, Kalmar County Hospital, Kalmar, Sweden
e-mail: michaela.nordvall@gmail.com

Background: Targeted next-generation sequencing (tNGS) enables early, comprehensive detection of genotypic drug susceptibility testing (gDST). Current methods have a long turnaround time (TAT) and are also validated for decontaminated samples which may decrease sensitivity. Our aim was to investigate whether tNGS with Nanopore directly on sputum samples would reduce TAT and enable detection on paucibacillary samples.
Method: Pooled Mycobacterium tuberculosis complex-negative sputum samples were spiked in triplicates with 10^4 and 500 CFU/ml of *M. tuberculosis* ATCC 27294 (Mtb) and analysed with Abbot real time PCR with and without decontamination. Samples were then concentrated and heat inactivated in 80°C for 20 minutes. After DNA extraction using the EZ1 Tissue Kit (Qiagen), target enrichment was performed with Deeplex Myc-TB (GenoScreen), followed by library preparation (Rapid Sequencing Kit V14) and sequencing with Flongle flow cell on MinION MkC1b (Oxford Nanopore). Data was analysed with an in-house pipeline in CLC (Qiagen).
Finally, tNGS was performed on clinical samples comparing the standard protocol using decontaminated samples and Illumina sequencing and direct Nanopore sequencing.
Results: By Abbot PCR-analysis, decontaminated samples had a significantly higher cycle threshold (Ct) than direct analysis (mean±SD: 31.0±3.3), at 10^4 CFU/ml compared to direct sputum samples (24.7±2.2, n=18). In spiked sputum samples, comparing Deeplex standard protocol using decontaminated samples and Illumina sequencing, direct analysis of sputum samples with Nanopore sequencing showed similar performance for gDST (97-100% coverage) down to 10^3 CFU/ml. Smear positive clinical samples (n=3) showed a 100% resistance gene coverage in both methods. TAT for the standard protocol and optimized protocol was 144-168 h and 10-21h respectively.
Conclusion: Nanopore tNGS analysis directly on sputum with Deeplex kit is efficient and at least as sensitive as analysis from decontaminated samples. Further investigation of the sensitivity of nanopore tNGS directly on sputum in clinical samples is warranted.

TBS-EP350 Distinct macrophage subsets associate with varying roles that contribute to human lung tissue damage during TB disease

T. Mpotje,[1] T. Lawrence,[1,2] D. Moodley,[1] K. Rajkumar-Bhugeloo,[1,2] T. Naidoo,[1] F. Martinez,[3] S. Gordon,[4] A. Steyn,[1,2,5] A. Leslie,[1,2,6] M. Marakalala,[7,8]
[1]Africa Health Research Institute, Durban, South Africa, [2]University of KwaZulu Natal, Durban, South Africa, [3]University of Surrey, Guildford, United Kingdom of Great Britain and Northern Ireland, [4]University of Oxford, Oxford, United Kingdom of Great Britain and Northern Ireland, [5]University of Alabama at Birmingham, Birmingham, United States of America, [6]University College London, London, United Kingdom of Great Britain and Northern Ireland, [7]SAMRC Centre for TB Research, Cape Town, South Africa, [8]Biomedical Research Institute, Cape Town, South Africa
e-mail: thabo.mpotje@ahri.org

Tuberculosis (TB) remains a significant global health challenge, with many previously exposed individuals suffering from persistent pulmonary dysfunction due to lung complications. A hallmark of TB progression is granuloma formation, which results from a complex interplay of immune cells mediating regulatory, inflammatory, and fibrotic responses. When these immune responses become dysregulated, pulmonary caseation and fibrosis can occur, even after Mycobacterium tuberculosis has been cleared. Macrophages are central to this process, playing a major role in the formation and maintenance of TB-induced granulomas.

Therefore, we sought to characterize and demonstrate the presence of distinct macrophage subsets associated with TB-induced lung pathology. Through immunofluorescent assay, we identified macrophage subsets with unique protein signatures (CD68+ ACE, CD68+ SPP1+, CD68+ CD206+, CD68+ MARCO+, CD68+ CD163+) that are potentially involved in various roles during disease progression. These subsets were spatially localized across different regions of granulomatous lung pathology during TB.

Furthermore, our *in vitro* and *in vivo* assays revealed the presence of inflammatory macrophage subsets driven by ALOX5 signaling, which contributed to lung pathology development.

Notably, the CD68+ MARCO+ macrophage subset was highly expressed in the inflammatory layer of caseous granulomas, exhibiting fibroblast-like characteristics, suggesting a role in fibrosis during TB. This role was further supported by the subset's expression of TGF-beta, a known driver of fibrosis.

The study provides compelling evidence of the diverse macrophage subsets present in patients with TB-related complications.

Therefore, our findings reveal the presence of heterogeneous macrophages, which mediate a complex interplay of the host's immune responses, contributing to regulation, inflammation, and fibrosis during TB progression. As such, the varying macrophage subsets could serve as critical targets for the development of improved therapeutics and novel vaccine candidates to better manage TB.

TBS-EP491 Lineage identification and mutation profile of *Mycobacterium tuberculosis*: A study from National Reference Laboratory, India

R.N. Yadav,[1] R. Singhal,[1] M. Bhalla,[1] U. Agarwal,[1]
[1]National Institute of Tuberculosis and Respiratory Diseases, New Delhi, India
e-mail: raj6apr@gmail.com

Purpose: The present study aimed to find out the most prevalent lineage of *Mycobacterium tuberculosis* (MTB) and analysis of their mutation profile conferring to drug resistance at National Reference Laboratory (NRL) in New Delhi.

Methods: A total 212 liquid culture MTB isolates of presumptive multidrug resistance tuberculosis (MDR-TB) patients were selected at NRL and subjected to whole genome sequencing (Illumina Miseq, USA). The genome sequencing data of 194 samples was successfully obtained in fastq files from instrument and analysed by Mykrobe predictor for lineage and mutation identification conferring drug resistance.

Results: In a total 194 isolates, the number of isolates belonging to lineage and sub-lineage of lineage 1, 2, 3 and 4 were 13 (6.7%), 63 (32.4%), 82 (42.2%) and 28 (14.4%) respectively. Out of total 194 culture isolates analysed, 179 harbor at least one or more mutations. Among these 179 mutated isolates, following gene mutations were found in either single or in combinations: *rpoB* (146, 81.5%), *katG* (138, 77%), *pncA* (62, 34.6), *gyrA* (121, 67.5%), *embB* (106, 59.2%), *rpsL* (86,48%) followed by *fabG1* (31, 17.3%), *embA* (18,10%), *gid* (6,3.3%), *inhA* (4), *eis* (4,2.2%), *rrs* (17, 9.4%).

Lineage 2 was found to be most mutated MTB strains having atleast one or more mutations. In lineage 2, the frequency of *rpoB, katG, gyrA, embB*, and *pncA* gene mutations was 92%, 82.5%, 93.6%, 68.2%, and 61.9%, respectively. This was higher than in lineage 1 (30.7%, 53.8%, 15.2%, 38.4%, 0% respectively), lineage 3 (69.5%, 68.2%, 46.3%, 46.3%, 24.3% respectively), and Euro-American lineage 4 (74%, 62.9%, 48.1%, 40.7%, 26.9% respectively).

Conclusions: Based on this study, lineage 3 may the most prevalent strain of MTB in north India. More attention required to take care patients having Lineage 2 infection to break chain of transmission as it was found to be most mutated/resistant strains.

TBS-EP493 Oral rinse outperforms facemask capture for non-sputum diagnosis of pulmonary TB

S.C Mendelsohn,[1] G.T Jackson,[1] E. Wessels,[2] E. Beyers,[1] S. Visagie,[1] K. Hadley,[1] M. Steyn,[1] N. Bilek,[1] S. Sivarasu,[2] B.D Kana,[3] T.J Scriba,[1] M. Hatherill,[1] Facemask Study Team
[1]South African Tuberculosis Vaccine Initiative, Institute of Infectious Disease and Molecular Medicine, University of Cape Town, Cape Town, South Africa, [2]Biomedical Engineering Research Centre, Department of Human Biology, University of Cape Town, Cape Town, South Africa, [3]School of Pathology, University of Witwatersrand, Johannesburg, South Africa
e-mail: simon.mendelsohn@uct.ac.za

Background: Non-sputum-based rapid diagnostics are urgently needed to test both symptomatic and asymptomatic people with tuberculosis (TB) who are missed by current sputum-based tools. We performed head-to-head comparison of two non-sputum sampling approaches, oral rinse and facemask capture, for diagnosis of pulmonary TB.
Methods: We recruited HIV-negative adults (≥18 years) with newly-diagnosed, bacteriologically-confirmed pulmonary TB and healthy controls in Worcester, South Africa (October 2024-May 2025). TB participants were excluded if treated for >1 day or previously diagnosed within 2 years. Facemasks fitted with polyvinyl alcohol (PVA) patches were worn for ≥1 hour. Thereafter, a patch was dissolved in 2mL sterile water. Oral rinse samples were obtained using a 1-minute rinse with 5mL sterile water. Both sample types were mixed with Xpert SR buffer (0.75mL:1.5mL ratio) and tested at the clinical field site laboratory with Xpert Ultra. Thereafter, sputum samples were collected. TB cases were both sputum MGIT culture and Ultra (excluding trace) positive.
Results: Among symptomatic clinic attendees with TB (n=25), oral rinse sensitivity was 64.0% (95%CI: 44.5-80.0) vs. 32.0% (95%CI: 17.2-52.0) for facemask capture (McNemar p=0.0047). Specificity among 86 healthy controls was 100% (95%CI: 95.7-100) for both methods. In 6 asymptomatic TB cases identified through community screening, oral rinse sensitivity was 33.3% (95%CI: 9.7-70.0) vs. 16.7% (95%CI: 3.0-56.0) for facemask capture. Sensitivity of oral rinse and facemask capture among participants with sputum semi-quantitative Xpert Ultra graded medium/high (n=20) was 85.0% (95%CI: 64.0-95.0) and 45.0% (95%CI: 25.8-66.0), respectively; and for those graded very-low/low (n=11), 18.2% (95%CI: 5.1-48.0) and 0.0% (95%CI: 0.0-26.0), respectively.
Conclusions: Oral rinse sampling was more sensitive than facemask capture for pulmonary TB diagnosis by Xpert Ultra. Sensitivity appears higher among symptomatic individuals and those with higher sputum bacillary burden. These findings support further optimisation of oral rinse as a promising non-sputum diagnostic alternative for pulmonary TB.

TBS-EP638 Comparison of different chemicals as an alternative sputum liquefaction reagent to N-acetyl-L-cysteine with Sodium Hydroxide (NALC-NaOH)

J.M.L. Majaducon,[1] J.M. Bislumbre,[1] J.M. Cuales,[1] M.K.J. Mendoza,[1] C. Pangilinan,[1] R. Basilio,[2] M. Kato-Maeda,[3] R. Destura,[1] [1]National Training Center for Biosafety and Biosecurity, National Institutes of Health, University of the Philippines Manila, Manila, Philippines, [2]National Tuberculosis Reference Laboratory, Research Institute for Tropical Medicine, Muntinlupa City, Philippines, [3]University of California San Francisco, San Francisco, California, United States of America
e-mail: jcmajaducon@up.edu.ph

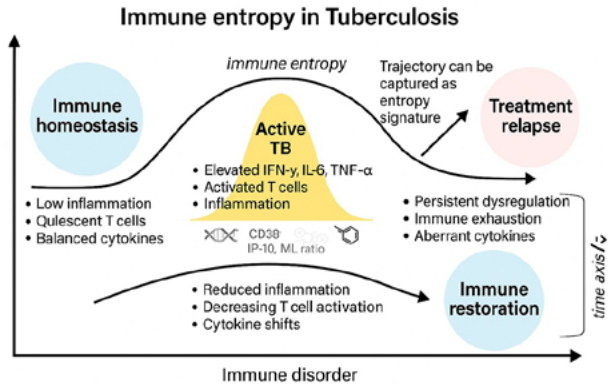
Mycobacterium tuberculosis (*Mtb*) infection continues to be a threat to millions of Filipinos, as one of the leading causes of death in the country. Sputum analysis, a valuable tool in diagnosing tuberculosis, continues to hinder molecular analysis due to its high viscosity and lumpy nature. N-acetyl-L-cysteine with Sodium Hydroxide (NALC-NaOH) is often used; however, it must be freshly prepared as it loses its activity rapidly in a solution.
We aim to find an alternative sputum liquefaction reagent that is cost-effective, has fewer preparation requirements, and eliminates the need to be freshly prepared. This study tested seven chemicals, namely hydrogen peroxide (H2O2), trisodium phosphate (TSP), guanidine thiocyanate (GuScn), dithiothreitol (DTT), sodium hydroxide with sodium dodecyl sulfate (NaOH-SDS), water (dH2O) and NALC-NaOH as negative and positive controls.
We prepared a 15 mL artificial synthetic sputum from porcine mucin spiked with *Mycobacterium smegmatis* to avoid the risks of handling *Mtb*-positive samples. Each chemical was added to create a 1:1 ratio setup and performed in triplicate.
The tubes were observed at 0, 10, 20, and 30 minutes before and after adding chemical treatments. The viscosity of the solutions was rated with '++++', '+++', '++', and '+' for most viscous to least viscous. Viscosity was also measured with a rotational viscometer.
A statistical analysis of the comparison of chemicals at time 30 was performed. Against the Control (no added liquefaction reagent), only NALC-NaOH and GuSCN were significantly less viscous ($p < 0.05$).
Comparison of timepoints, not accounting for the chemicals, was also performed. Viscosity readings of times 20 and 30 were found to be highly significant from Time 0 ($p < 0.001$) and significantly different from Time 10 ($p < 0.05$). NALC-NaOH yielded the lowest viscosity value. GuScn presents promising results as a substitute for NALC-NaOH in the molecular analysis of sputum.

TBSCIENCE UNMODERATED E-POSTERS

TBS-EP362 Toward entropy-based precision monitoring of tuberculosis: A systematic review of immune dysregulation as a predictive framework for treatment innovation

S.P. Purwanto,[1,2] [1]Prince of Songkla University, Epidemiology, Hat Yai, Thailand, [2]East Java Provincial Health Office, Communicable Disease, Surabaya, Indonesia
e-mail: satiti.palupi@yahoo.co.id

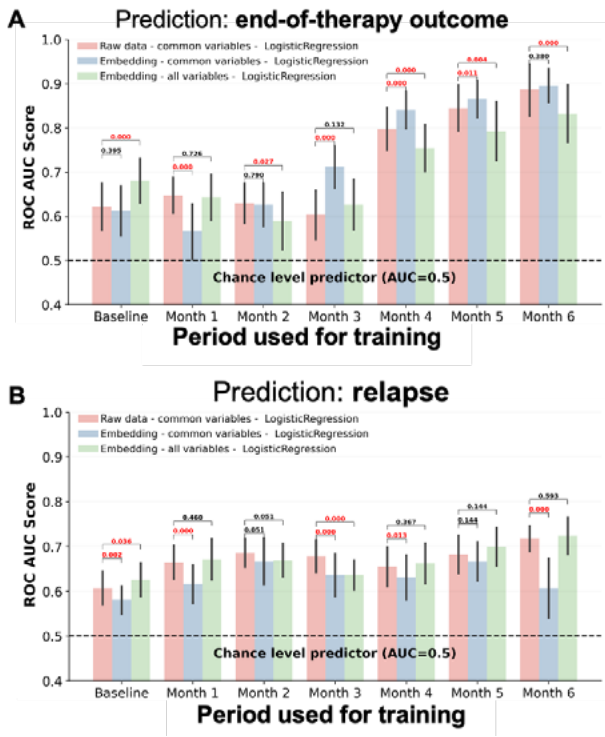
Background: Tuberculosis (TB) progression reflects not just bacterial persistence but a dynamic collapse of immune system order — a phenomenon conceptualized as rising biological entropy. Current treatment monitoring, reliant on sputum culture conversion, poorly captures the host immune state and overlooks the systemic destabilization underpinning poor outcomes.
This systematic review integrates evidence from immunology, systems biology, and complexity theory to propose immune entropy as a unifying predictive framework for TB treatment monitoring and precision intervention.
Methods: We systematically reviewed studies from 2000 until 2025 measuring immunologic, transcriptomic, and metabolomic biomarkers across TB infection states and treatment courses, via searches of PubMed, Embase, and Web of Science. Eligibility required linkage of immune markers to clinical trajectories: progression, treatment response, relapse, or mortality. Data were synthesized to map trajectories of immune order versus disorder.
Results: Progression from latent TB to active disease consistently aligned with surges in inflammatory signals (IP-10, IL-6), elevated T-cell activation (CD38+, HLA-DR+, Ki-67+), dysregulated monocyte/lymphocyte ratios, and IFN-driven transcriptomic shifts.
Successful treatment reversed these signatures, restoring immune equilibrium. Persisting dysregulation despite therapy predicted relapse and death. Integrating multiscale biomarkers suggests the feasibility of constructing "entropy signatures" — composite immune state maps that anticipate individual treatment trajectories earlier and more precisely than sputum-based measures.
Conclusions: Reframing TB treatment response through an entropy lens reveals actionable opportunities: to design dynamic, individualized treatment strategies based on immune system stability, not bacterial detection alone. Developing and validating entropy-driven models — potentially enhanced by AI and systems immunology — could revolutionize TB therapeutic monitoring, shortening trials, accelerating cure prediction, and preventing drug resistance emergence. This visionary paradigm urges a shift from static microbiological endpoints toward dynamic, host-centric monitoring frameworks.



TBS-EP365 Machine learning models reveal predictive signatures of therapy outcome in Phase 3 TB trials

D. Garger,[1] F.P. Casale,[1] D. Sloan,[2] G. Maher-Edwards,[3] M. Menden,[1] [1]Helmholtz Munich, Munich, Germany, [2]Radboud UMC, Nijmegen, Netherlands, [3]GSK, Walton-On-Thames, United Kingdom of Great Britain and Northern Ireland
e-mail: daniel.garger@helmholtz-munich.de

Early identification of tuberculosis (TB) patients at risk of unfavorable end-of-therapy (EOT) outcomes or relapse remains a major clinical challenge. To address this, we analyzed data from the REMoxTB and OFLOTUB Phase 3 trials to predict both EOT outcomes and post-treatment relapse, restricting the relapse analysis to patients with a favorable EOT response. We also aimed to identify the key clinical features driving predictive performance.
First, we trained machine learning models routinely utilised in clinical predictions (logistic regression and XGBoost) on our clinical and treatment-related variables, employing a sliding-window prediction strategy of progressively incorporating data from baseline to each month of the six-month therapy period.
For EOT outcome prediction (Panel A), model performance (ROC-AUC) remained stable between baseline and Month 3 (0.60–0.65), then improved from Month 4 onward (0.80–0.90).
In contrast, relapse prediction showed fluctuating performance (Panel B), peaking at Month 2 (0.69) and Month 6 (0.72). Model performances were compared using 25x5 cross-validation, with paired t-tests and Benjamini-Hochberg correction. SHAP value analysis identified male sex, older age, drug adherence, and sputum test results (particularly LJ culture) as top predictors of EOT outcome. For relapse, male sex, older age, Ziehl–Neelsen staining, and symptoms such as cough and chest pain were most informative.



In addition, we leveraged a large language model (LLM)-based approach using two configurations: one embedding data from the latest visit, and one embedding all visits up to each cutoff. For EOT prediction, the last-visit LLM matched or outperformed models trained on raw variables (Panel A, blue bars); for relapse, the all-visits LLM setup performed comparably but not better (Panel B, green bars). These findings suggest that LLMs can effectively leverage sparse, sequential inputs for complex outcomes like relapse, while simpler, static representations suffice for more immediate outcomes such as EOT.

TBS-EP368 The use of unmanned aerial vehicles (UAV) on delivering biological samples for tuberculosis and COVID-19 diagnosis: A scoping review

O.M. Machado Rodrigues,[1,2] I. Gimenes Lopes,[2,3] M.E. Ferreira de Oliveira,[2,4] M.A. Carreira Fragoso,[2,5] M.R. Fernandes de Oliveira,[1,6] G.R. de Castro e Caldo Lima,[7] A. Sabino Damazo,[1] W. de Jesus Martins,[2] [1]University of Brasilia (UnB) / Tropical Medicine Center, Brasilia, Brazil, [2]Fiocruz Brasilia / ColLaboratory of Science, Technology, Innovation and Society (CTIS), Brasilia, Brazil, [3]Escola Nacional de Saúde Pública Sérgio Arouca / Public Management Innovation Laboratory (Polen/ENSP/Fiocruz), Rio de Janeiro, Brazil, [4]University of Brasilia (UnB) / Institute of Biological Sciences, Brasilia, Brazil, [5]University Center of Planalto Central Aparecido dos Santos (UNICEPLAC), Brasilia, Brazil, [6]Federal University of Rio Grande do Sul (UFRGS) / Institute for Health Technology Assessment (IATS), National Council for Scientific and Technological Development (CNPq), Porto Alegre, Brazil, [7]Laboratório Central de Saúde Pública do Distrito Federal / Secretaria de Estado da Saúde do Distrito Federal, Brasilia, Brazil
e-mail: olga.rodrigues@fiocruz.br

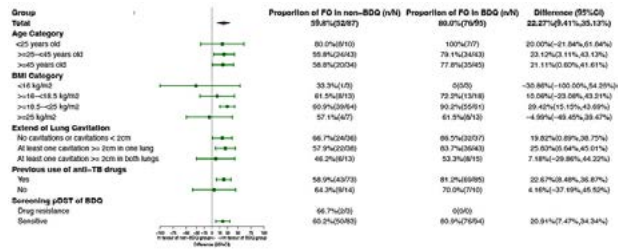
Background: Although the evolution of laboratory techniques for diagnosing tuberculosis (TB) and other transmissible lung diseases, such as COVID-19, is accelerating, populations in remote and hard-to-reach areas often face delays in diagnosis due to logistical challenges in delivering samples to laboratories. Among the potential solutions for this reality, using unmanned aerial vehicles (UAVs), commonly known as drones, for transporting laboratory samples has been evaluated in various scenarios worldwide.
Purpose: To identify and review scientific evidence from experimental studies utilizing UAVs to transport samples for the diagnosis of TB and COVID-19. This exploratory study aims to support the future development of UAVs for transporting biological samples within the Brazilian Unified Health System (SUS).
Methods: This scoping review defined its eligibility criteria using the PECO acronym, focusing on: **P**opulation: biological samples for diagnosing COVID-19 or TB; **E**xposure: UAV transportation; **C**omparator: land transportation; **O**utcomes: Cost, effectiveness, methods for sample preservation, flight parameters (time, altitude, speed, distance), and quality of transported samples. Eligible studies were identified through searches in Medline via PubMed, Scopus, Embase, and Web of Science. Grey literature was explored via Google Scholar.
Results: Of the 2,052 articles initially found, 797 were duplicates. From the 1,255 remaining, 1,247 were excluded after title and abstract screening. Eight articles were retrieved for full-text review, of which five met the eligibility criteria and were included in the review. These studies provided diverse evidence regarding cost, operational performance, safety, and sample integrity.

Conclusion: The review demonstrated promising applications of UAVs in healthcare logistics. However, regulatory and legal frameworks require adaptation to ensure operational safety. Further experimental studies are necessary, particularly involving beyond visual line of sight (BVLOS) operations, to evaluate scalability and potential cost reductions.

TBS-EP371 Evaluation of an oral bedaquiline regimen for treating multidrug-resistant TB in China: A randomized trial

J. Gao,[1] M. Gao,[1] L. Li,[1] Y. Jiang,[2] R. Zhang,[2]
PROSPECT Study Team [1]Beijing Chest Hospital, Capital Medical University, Beijing, China, [2]Johnson & Johnson Innovative Medicine, Research & Development, Shanghai, China
e-mail: jingtaogao88@126.com

Background: The efficacy and safety of a bedaquiline (BDQ)-containing oral short-course regimen (SCR) in Chinese population remains unvalidated in large-scale clinical trials. Therefore, the Pragmatic Randomized Controlled Trial to Evaluate the Efficacy and Safety of an Oral SCR Including BDQ for the Treatment of Patients with Multidrug-resistant Tuberculosis (MDR-TB) in China(PROSPECT study) was conducted.
Design: We conducted a randomized, non-inferiority, open-label trial at 17 hospitals, targeting adult pulmonary MDR-TB patients. Participants were assigned in a 1:1 ratio to receive either a 40-week oral BDQ-containing SCR or a non-BDQ-containing SCR. The primary endpoint was the proportion of favorable outcome(three consecutive negative cultures for *Mycobacterium tuberculosis* without prior unfavorable outcomes) at Week 40.
Unfavorable outcomes included treatment discontinuation, death, lost follow-up, major treatment change, treatment extension, and bacteriological failure. The non-inferiority of the difference in proportion between the BDQ-group and control group in the modified intent-to-treat population (mITT) was set at -15%.
Rates of modified favorable outcome (two consecutive negative cultures without prior unfavorable outcomes) and cured status(WHO criteria) in both groups were also evaluated.
Results: A total of 217 participants were randomized and took at least one dose of study drug, with 182 included in the mITT population. By Week 40, 76(80.0%) of 95 participants in the BDQ group, and 52(59.8%) of 87 participants in the control group achieved favorable outcomes, with an adjusted (site, lung cavitation) difference of 22.27% (95%CI, 9.41% to 35.13%), indicating the non-inferiority of BDQ-containing SCR.
The main reason for unfavorable outcomes was treatment discontinuation (16.8% in BDQ vs. 32.2% in control). Higher rates of modified favorable outcomes (80.0% vs. 59.8%) and cured status (80.0% vs. 58.6%) were also observed in the BDQ group. No new safety signal was identified during the allocated treatment phase.



Conclusion: The 40-week BDQ-containing SCR demonstrated efficacy and tolerability, presenting a viable treatment option for MDR-TB patients in China.

TBS-EP374 Treatment outcomes and risk factors among tuberculosis patients infected with *Mycobacterium tuberculosis* Beijing lineage in Ukraine (2020–2023)

D. Butov,[1,2] T. Butova,[3] A. Rosenthal,[4] C. Gerlach,[2] A. Grinev,[4] J. Kilmnick,[4] S. Niemann,[2] V. Dreyer,[2]
Ukrainian team of TB-portal [1]Kharkiv National Medical University, Kharkiv, Ukraine, [2]Research Center Borstel, Borstel, Germany, [3]Merefa Central District Hospital, Merefa, Ukraine, [4]U.S. National Institute of Allergy and Infectious Diseases, Rockville, MD, United States of America
e-mail: do.butov@knmu.edu.ua

Objective: To evaluate the association between infection with *Mycobacterium tuberculosis* (MTBC) strains of the Beijing lineage (L2) and clinical outcomes, comorbidities, and risk factors among tuberculosis (TB) patients in Ukraine.
Methods: We conducted a nationwide study of patients with culture-confirmed pulmonary TB across 18 of Ukraine‘s 24 regions between 2020 and 2023.
Whole-genome sequencing was performed on DNA extracted from 4,332 MTBC strains using Illumina paired-end platforms. MTBC lineages (L) and genotypic resistance profiles were determined via the bioinformatic pipeline MTBseq. Data were stored in the NIAID Ukraine TB-Portals database.
Results: Infection with a L2 strain was identified in 3,028 (69.9%) patients, while L4 strains where found in 1,302 (30.0%) cases. Single strains belonged to Lineage 3 and *M. bovis* (0.1%).
Lineage 2 was disproportionately represented among multidrug-resistant tuberculosis (MDR) / pre-extensively drug-resistant / extensively drug-resistant (XDR-TB) cases (2,649/3,028;87.5%), whereas Lineage 4 predominated in drug-susceptible or non-MDR\ (rifampicin-resistant) RRTB cases (781/1,302;59.9%)(p≤0.001).

Unfavorable treatment outcomes (treatment failure, death) were significantly more frequent among patients with L2 (713/3,028;23.5%) compared to L4 (231/1,302;17.7%) (OR=1.4; 95% CI:1.2–1.7;p≤0.001).
Independent predictors of poor treatment outcomes among patients infected with L2 included:
Tobacco use (OR=1.6;95% CI:1.3–1.8;p≤0.001),
Homelessness (OR=1.6;95% CI:1.1-2.3; p≤0.001),
Injection drug use (OR=2.2;95% CI:1.6-2.9;p≤0.001),
Previous incarceration (OR=1.8;95% CI:1.3-2.4;p≤0.001),
HIV co-infection (OR=1.8;95% CI:1.5-2.2;p≤0.001),
Hepatitis B (OR=2.4;95% CI:1.1-4.8;p=0.005),
Hepatitis C (OR=1.7;95% CI:1.3-2.3;p≤0.001),
Anemia (OR=1.5;95% CI:1.3-1.8;p≤0.001).
Conclusion: Our findings highlight the widespread dominance of the Lineage 2 in Ukraine and its strong association with drug resistance and adverse clinical outcomes. The presence of comorbid conditions such as HIV, viral hepatitis, substance use, and social vulnerabilities further compounds the risk of unsuccessful treatment.
These results underscore the urgent need for a better understanding of MTBC lineage effects on TB treatment efficacy and intensified care models targeting high-risk populations in Eastern Europe.

TBS-EP377 Addressing tobacco industry tactics in university campuses and its impact on tobacco cases in Iraq

T. Alhilfi,[1] [1]Madenat Alelem University College, Baghdad, Iraq
e-mail: thamerls.yousif804@gmail.com

Addressing tobacco industry tactics on university campuses in Iraq is a crucial step toward reducing tobacco use among youth and young adults—a population particularly vulnerable to industry marketing and misinformation. University students represent a significant portion of future healthcare professionals, educators, and policymakers, making them key agents of change.
By implementing strict anti-tobacco policies and countering industry influence within academic institutions, Iraq can reduce smoking prevalence, thereby decreasing TB incidence and improving overall public health outcomes. This research adopted a mixed-methods approach, combining qualitative and quantitative techniques to comprehensively examine tobacco industry interference in public universities across Iraq.
The study was conducted across seven major public universities strategically selected to reflect geographic, demographic, and institutional diversity. This ensured the findings captured variations in tobacco control enforcement and exposure to industry tactics. The document analysis showed that four out of seven institutions had active or passive partnerships with the tobacco industry, often disguised as cultural or student events.
Stakeholder interviews confirmed these findings, highlighting limited awareness among faculty and student leaders about tobacco industry tactics. Institutions with higher levels of interference showed weaker policy enforcement and higher student smoking rates. This pattern correlates with an increased risk of TB transmission, as tobacco use is a well-documented risk factor for both TB infection and disease progression, especially in dense, poorly ventilated university environments.
The study concludes that tobacco industry interference remains a pervasive issue in Iraqi public universities, with significant gaps in the enforcement of WHO FCTC Articles 5.3 and 8. This interference not only promotes tobacco use among students but also indirectly contributes to the increased risk and burden of tuberculosis (TB), especially in densely populated academic settings.
Universities with weaker tobacco control measures exhibited higher exposure to industry-sponsored events and student smoking prevalence. To address these challenges.

TBS-EP380 Breath-based pathogen detection technologies for diagnosing respiratory infections: A scoping review

S. Jain,[1] M.M. Baarends,[1] M. Grilli,[2] M. Gaeddert,[1]
E.L. MacLean,[3] C. Denkinger,[1] A.G. Wright,[1,4] S. Yerlikaya,[1]
[1]Department of Infectious Diseases and Tropical Medicine, Heidelberg University Hospital, Heidelberg, Germany, [2]Medical Faculty Mannheim, Library, Heidelberg University, Heidelberg, Germany, [3]NHMRC Clinical Trials Centre, Faculty of Medicine and Health, The University of Sydney, Sydney, Australia, [4]Department of Infectious Disease, Imperial College London, London, United Kingdom of Great Britain and Northern Ireland
e-mail: sonal.jain@uni-heidelberg.de

Background: Accurate and rapid diagnostics could reduce the burden of respiratory infections and antimicrobial resistance. However, conventional respiratory sampling has limitations. Sputum is difficult to collect and variable in availability and sample quality. Upper respiratory tract swabbing has lower sensitivity for lower respiratory tract pathogens. Exhaled breath is a promising sample that enables direct pathogen detection, while potentially providing insights into infectiousness.
This review maps the rapidly evolving landscape of technologies for breath sampling and direct pathogen capture and/or detection, detailing their underlying methodologies, use cases, technological gaps, and diagnostic accuracy.
Methods: We searched MEDLINE, Embase, and Web of Science for pre-clinical and clinical studies utilizing exhaled breath aerosol or condensate for pathogen capture and/or detection. We excluded studies without data from contrived and/or clinical samples and studies reporting solely on volatile organic compounds (VOC)-based

detection. Two reviewers are performing title/abstract screening followed by full-text screening, discrepancies will be resolved through consensus or consultation with an additional reviewer. Data extraction will be conducted by a single reviewer, followed by verification by a second reviewer. Missing data will be addressed by searching grey literature sources.

Results: 5600 titles were identified for screening based on our search strategy. A pilot screening of ten studies reveals diversity in sample collection devices (for e.g. face masks, mouthpieces, and straws) and collection methodology (breathing technique and duration). Findings will be categorized by device characteristics, collection and detection methodology, diagnostic performance, use case, and operational considerations. A narrative summary will be included to highlight trends, strengths and weaknesses, and areas for further research.

Conclusion: Exhaled breath sampling holds promise as an accessible and accurate detection of respiratory infections. This review will offer an overview of breath-based pathogen detection technologies, highlighting their diagnostic potential and readiness for clinical adoption.

TBS-EP383 Leveraging artificial intelligence driven mobile X-ray screening on TB detection in high-risk brick Kiln communities of Punjab, Pakistan

Q. Mehmood,[1] M. Sohail,[1] B. Ahmed,[1] N. Munir,[1] I. Kamal,[1] U. Awan,[1] M.R. Naeem,[1] [1]Provincial TB Control Program Punjab, Lahore, Pakistan
e-mail: sppo@ptp.gop.pk

Summary: A 2024 study in Punjab, Pakistan, utilized AI-enhanced mobile X-ray screening to detect tuberculosis (TB) among brick kiln workers, revealing a prevalence of 1.17%, significantly higher than national averages. This research highlights the critical need for targeted TB interventions in high-risk occupational groups and demonstrates the potential of AI in advancing TB diagnostics and treatment strategies.

Background: Tuberculosis (TB) remains a major public health challenge in Pakistan, with an incidence of 277 per 100,000 population in 2023 [1]. Brick kiln workers, exposed to silica dust and poor ventilation, face amplified TB risks but are not classified as high-risk under current policies. In diagnostics, AI-powered tools like Computer-Aided Detection for TB (CAD4TB) have shown high accuracy in identifying TB from chest X-rays, making them valuable for active case finding in resource-limited settings [2].

Design/Methods: In 2024, a mobile X-ray screening initiative was conducted in Punjab, Pakistan, targeting brick kiln workers. Using mobile X-ray vans equipped with CAD4TB, 53,188 brick kiln workers were screened. Individuals with abnormal radiographs underwent GeneXpert MTB/RIF testing. Comparative data were collected from 78,560 individuals screened in general community hotspots using similar methods.

Results: The study found a TB prevalence of 1.17% (624/53,188) among brick kiln workers, which is 4.2 times higher than the national incidence (0.28%) and 4.5 times higher than the provincial average (0.27%).

In comparison, community hotspots showed a prevalence of 1.40% (1,100/78,560). Brick kiln workers had a higher diagnostic yield, with 18.7% GeneXpert positivity compared to 22.0% in hotspots.

Metric	Brick Kiln Workers	Community Hotspots	National Incidence (Pakistan)	Provincial Incidence (Punjab)
Sample Size	53,188	78,560		
TB Prevalence	1.17% (624 cases)	1.40% (1,100 cases)	0.28%	0.27%
Gene Xpert Positivity Rate	18.7%	22.0%		
Prevalence vs National Incidence	4.2x higher	5.0x higher		

Conclusions: This study underscores the effectiveness of AI in TB diagnostics for high-risk populations and advocates for the reclassification of brick kiln workers as a high-risk group. Moreover, it illustrates the broader potential of AI in TB research, from optimizing treatment regimens to accelerating the discovery of new drugs and vaccines.

TBS-EP386 Drug resistance detection from swab samples - A proof of principle pilot study using Molbio Truenat MTB-RIF-Dx and MTB-INH assays

M.M. Golla,[1] T. Pfurtscheller,[2] S. Jain,[2] V. Dalay,[1] S. Yerlikaya,[2,3] R. Basilio,[4] C. Yu,[5,6] A. Gupta-Wright,[7,2] [1]De La Salle Medical and Health Sciences Institute, Infectious Disease and Tropical Medicine, Manila, Philippines, [2]University Hospital Heidelberg, Infectious Disease and Tropical Medicine, Heidelberg, Germany, [3]German Center for Infection Research DZIF, Partner Site Heidelberg, Heidelberg, Germany, [4]National Tuberculosis Reference Laboratory - Research Institute for Tropical Medicine (NTRL- RITM), Infectious Disease and Tropical Medicine, Manila, Philippines, [5]De La Salle Medical and Health Sciences Institute (DLSMHSI), Manila, Philippines, [6]Asian Hospital and Medical Center Manila, Manila, Philippines, [7]Imperial College, London, United Kingdom of Great Britain and Northern Ireland
e-mail: seda.yerlikaya@uni-heidelberg.de

Background: Many patients at high risk for tuberculosis (TB) and drug resistance cannot produce sputum, thus alternative sample types are a World Health Organization research priority. While new, near point-of-care swab-based tests for Mycobacterium tuberculosis (MTB) detection are emerging, approaches for drug susceptibility testing (DST) on these samples remain unexplored. This pilot study aimed to establish proof-of-principle for detecting drug resistance from swabs using the Truenat MTB-RIF-Dx and MTB-INH prototype assays (Molbio Diagnostics, India), designed for sputum-based rapid diagnosis of resistance to rifampicin and isoniazid.
Methods: The study was conducted in the Philippines and included 50 paired swab samples from 25 patients with drug-resistant TB, one frozen tongue swab and one sputum swab prepared from frozen raw sputum per participant. Presence of MTB and resistance to rifampicin and isoniazid were confirmed with culture and phenotypic DST from sputum using the BACTEC MGIT 960 system (Becton Dickinson, USA). All participants had rifampicin-resistant TB, 15/25 had isoniazid-resistant TB. All samples were tested with Truenat MTB Ultima for MTB detection. MTB-positive samples were subsequently tested with MTB-RIF-Dx and MTB-INH. Indeterminate results were repeated once.
Results: Truenat MTB Ultima detected MTB in 20/25 (80.0%) tongue swabs and 25/25 (100.0%) sputum swabs. Sensitivity for rifampicin resistance detection was 91.7% (11/12, 95% CI 61.5-99.8) for tongue swab and sputum swab samples. Sensitivity for isoniazid resistance detection was 100.0% (6/6 95%CI 54.1-100.0) for tongue swabs and 90.9% (10/11, 95%CI 58.7-99.8) for sputum swabs. Proportions of indeterminate test results ranged from 40.0%-45.0% in tongue swab testing and 36.0%-52.0% in sputum swab testing. 29/39 (74.36%) indeterminate results occurred in samples with low bacillary load (see table).

	TP	TN	FP	FN	Indeterminate Low bacterial Load[a]	Indeterminate High bacterial Load[b]	Total (N)
Tongue swab - MTB-RIF-Dx	11	0	0	1	7	1	20
Tongue swab - MTB-INH	6	4	1	0	9	0	20
Sputum swab - MTB-RIF-Dx	11	0	0	1	7	6	25
Sputum swab - MTB-INH	10	5	0	1	6	3	25

[a] cycle threshold values ≥25 on MTBUltima [b] cycle threshold values <25 on MTBUltima
TP true positive TN true negative FP false positive FN false negative

Conclusion: Our findings support the feasibility of detecting drug-resistance from swab samples. Further research on reducing indeterminate results by optimizing assay design for swab samples should be pursued, given the need for non-sputum-based diagnostics.

TBS-EP389 AI-powered TB screening revolution: Impact of CAD4TB and DELFT portable X-ray machines in Punjab, Pakistan

Q. Mehmood,[1] M. Sohail,[1] B. Ahmed,[1] N. Munir,[1]
[1]Provincial TB Control Program Punjab, Lahore, Pakistan
e-mail: projectmanager@ptp.gop.pk

Introduction: Tuberculosis (TB) remains a global health challenge, necessitating innovative diagnostic solutions. Under the theme Artificial Intelligence Advancing the TB Field, Punjab, Pakistan, implemented a pioneering AI-driven TB screening program in 2024, leveraging 37 DELFT Imaging Portable X-Ray Machines integrated with CAD4TB software.
This initiative aimed to enhance early case detection and Tuberculosis Preventive Treatment (TPT) uptake in resource-limited settings.
Methods: In 2024, Punjab deployed 37 DELFT Portable X-Ray Machines across urban and rural communities, conducting 80,000 chest X-rays. The CAD4TB software, utilizing deep learning algorithms, analyzed X-ray images for TB-specific abnormalities, enabling rapid and accurate diagnosis. Screening targeted the general population, a first in Punjab, with data compared to 2023 (256,000 TB cases, no AI screening) and 2024 (290,000 cases). TPT enrollment was tracked, rising from 27,433 (9% of cases) in 2023 to 36,610 (11%) in 2024. Data were analyzed for case detection rates, TPT uptake, and diagnostic accuracy.
Results: The program achieved a 13.3% increase in TB case detection (290,000 vs. 256,000) and a 33.3% rise in TPT enrollment, driven by CAD4TB's high sensitivity (AUC > 0.90). The table below summarizes outcomes. Community-based screening overcame logistical barriers, enhancing access and reducing diagnostic delays.

YEAR	TB CASES REPORTED	CAD 4 TB X-RAYS CONDUCTED	TPT ENROLLMENT (RATE)
2023	256,000	Nil	27,433 (9%)
2024	290,000	80,000	36,610 (11%)

Table: TB Screening and TPT Outcomes in Punjab (2023–2024)

Conclusion: This AI-driven initiative demonstrates scalability and precision, offering a replicable model for global TB control. The accompanying image illustrates a DELFT X-Ray Machine in a Punjab health camp, highlighting AI's transformative impact.

TBS-EP392 Validation of a rapid point-of-care chromatographic test for screening TB cases in immunocompetent patients – Pilot study

J.F.C.L.S. Monteiro,[1] R.M. Costa Souza,[1] J.N.d.S. Nascimento,[1] R.M. Araújo,[1] L.M. Lapa Montenegro,[1] R.A. Montenegro,[1] K.K. Batista da Silva,[1] R.I.d.S. Tejo,[1] V. Saini,[2] H.C. Schindler,[1]
[1]Aggeu Magalhães Institute-FIOCRUZ-PE, Recife, Brazil, [2]OSTIC Pharma - Envision Healthy World, Mumbai, India
e-mail: jujufig@hotmail.com

Tuberculosis is a public health problem, with high morbidity and mortality rates worldwide. Improving access to early and rapid TB diagnosis is one of the main factors against active TB, since conventional diagnosis has several limitations. The Lateral Flow Assay for detection of LAM (lipoarabinomannan) represents a promising tool to fill the gap on TB diagnosis. It is rapid, point-of-care and cost-effective test available to screening TB in urine. Commercial LAM tests are indicated for use in immunocompromised patients (Alere LAM-TB test, Abbott).
This study evaluated the accuracy of rapid lateral flow immunochromatographic test as a point-of-care screening strategy in immunocompetent patients.
The „One-Step Tuberculosis-LAM-Antigen-Detection Test" (LAM-TB Test), from India, was used in adults with suspicion of pulmonary-TB. Patients from both sexes, coming from outpatient clinics or wards of Public Reference Health Services for TB of Brazil, Pernambuco, followed prospectively and double-blinding manner. Tests were performed at FIOCRUZ-Pernambuco, between January and June 2024. The statistical analysis were done on SPSS 20.0 and OpenEpi: accuracy, sensitivity (Se), specificity (Sp), predictive values (PV).
A total of 191 patients, whose 70.2% were male, with age ranged from <18 to >70 years old were tested by LAM-TB Test, on urine. Compared to Gene-Xpert, considering only negative-HIV patients (*n*=162), the accuracy of LAM-TB test was 65.4% (CI=57.8-72.3), Se=53% (CI=42.5-63.4); Sp=78.5% (CI=68.2-86.1); PPV=72.1% (CI=59.8-81.8) and NPV=61.4% (CI=51.4-70.3). Including all patients (with and without HIV), positivity of LAM-TB was 38.2% (n=74). WHO recommends the Alere LAM-TB test for HIV positive patients, whith Se=42% (95%CI=31–55), however, it's not recomend for HIV-negative patients due to its low sensitivity (Se=17.5%).
One-Step-LAM-TB is a screening poin-of-care test with accuracy over 65% on immunocompetent patients, is an advantage over recommended test by WHO, which has a poor Se on this group of patients using a non-invasive sample, adding comfort and practicality.

TBS-EP395 Preventive practices of pulmonary tuberculosis in Chitwan districts

K. Kalakheti,[1] A. Adhikari,[2] [1]Bagmati Welfare's Society Nepal, Ilam, Nepal, [2]Aasmaan Nepal, Janakpur, Nepal
e-mail: kkalakheti@gmail.com

Background: Tuberculosis (TB) is one of the world's most serious infectious diseases caused by Mycobacterium tuberculosis. Tuberculosis typically attacks the lungs, but can also affect other parts of the body. The disease has become rare in high income countries, but is still a major public health problem in low- and middle-income countries. According to the World Health Organization (WHO), one-third of the world's populations are infected with TB. Each year, there are over nine million cases of TB and almost 1.8 million TB-related deaths worldwide. Furthermore, TB is one of the leading causes of death in HIV-infected people.
Methods: Analytical cross- sectional study design was using to preventive practices of tuberculosis patient in Chitwan districts, This study was Quantitative method. Study population of this study was suffering from tuberculosis and taking Anti-TB medicine from different DOTS center of Chitwan. Patents who were taking anti-TB drugs from different DOTS centers were the study population.
Results: In this study showed that the practice of the 36.4% respondents had poor practice and 63.6% had good practice.

Variables	Frequency(%)
practice for sputum disposal before**	
Indiscriminate spitting	222(78.4)
Using paper/handkerchief	57(20.1)
Disposing in dustbin/waste	32(11.3)
practice for the disposal of sputum now	
Indiscriminate spitting	73(25.61)
Using paper/handkerchief	90(31.5)
Disposing in dustbin	79(27.7)
Burning	54(18.94)

Conclusions: This study concludes that the majority of the respondents who are male by gender, low economic class (janajati), and whose religion is Hindu, had a high prevalence of tuberculosis. The burden of tuberculosis is

high among labour and joint types of families. The majority of respondents had pulmonary tuberculosis. A tuberculosis cause was found by examination. The majority of the respondents have heard about tuberculosis and the majority of the respondents asked about pathogenic organisms which cause tuberculosis.

TBS-EP398 Genetic pattern of the ST 61 cluster of the Cameroon family among *Mycobacterium tuberculosis* complex strains collected during the CANTAM I project in Cameroon

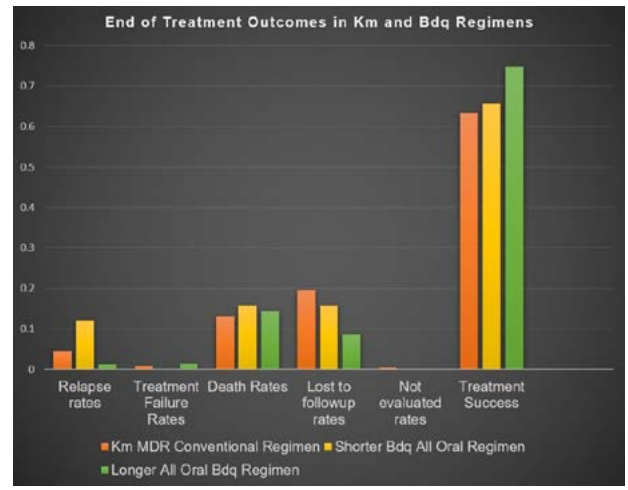
A.K. G. T. Tchoupe,[1] [1]Laboratory of Research on Tuberculosis and Pharmacology (LRTP), Yaoundé, Cameroon
e-mail: didytchoupe@yahoo.com

Background: Tuberculosis (TB) remains an outstanding diseases in global health concern. Caused by Mycobacterium Tuberculosis Complex (MTBC) strains. ST 61, a cluster of the LAM10_CAM family has been shown to be the most prevalent cluster implicated in TB transmission in Cameroon.
Objectives: We aimed at revealing the most discriminative loci applied to this cluster and investigating the genetic pattern in the ST 61 cluster samples.
Methods: A cross sectional study of 12 months (between October 2019 and January 2020) that included 45 randomly selected clinical specimens previously collected during the CANTAM 1 project. DNA extraction, amplification of 12-locus Mycobacterial Interspersed Repetitive Unit-Variable Tandem Repeat (MIRU-VNTR) analysis of each locus (MIRU 40, ETR A, QUB 26, Mtub 39, QUB 4156, MIRU 26, MIRU 31, MIRU 16, MIRU 02, MIRU 04, MIRU 23, and MIRU 27), PCR assay and gel electrophoresis performed. The amplicon sizes, the allele assignations, the allelic pattern and the technic discriminative potential were determined using MIRU-VNTR plus web application and a dendogram was generated.
Results: All the 45 isolates of clade ST61 where analyzed with MIRU/VNTR typing and detected 26 different patterns (Haplotypes). Comprising 11 sub clusters formed by 30 isolates and 15 unique patterns formed by 15 isolates (Orphans).
Reported 45% genetic pattern, and 66,6% clustering rate. Loci MIRU 4, 16, 23, 27 and ETRA were highly discriminative.Loci MIRU 40 and QUB 4156 were moderately discriminative and loci MIRU 2, 26, 31, Mtub 39 and Qub 26 were poorly discriminative. ETR A, MIRU 4, MIRU 16, MIRU 23, MIRU 27 revealed as the most discriminating loci applied to the cluster ST 61.
Conclusion: The most discriminative locus ETRA, MIRU 4, MIRU 16, MIRU 23, and MIRU 27 applied to a precise cluster is a safe economic and time gain option to enhance the difference between strains at the cluster level.

TBS-EP401 SHIFTING paradigms in DR-TB management: Real-world outcomes of injectable Kanamycin vs. Bedaquiline all-oral regimens using Ni-Kshay surveillance data

Z.J. Shaikh,[1] P. Meshram,[1] G. Kalbande,[1] H.K. Shaikh,[1]
[1]Grant Government Medical College, Mumbai, India
e-mail: zuha.jabeen1823@gmail.com

Background: This study extends our work presented at the Union World Conference on Lung Health 2024, with a revised methodology and reanalysis yielding distinct findings.
This study evaluates and compares the effectiveness of Kanamycin (Km) -based and Bedaquiline (Bdq) -based regimens while analyzing relapse timing and the influence of Gender, Diabetes and HIV.
Methods: Data from Ni-Kshay Version 2 (Byculla Region) was extracted. Of 13,407 patients screened (2018–2021), 1,672 rifampicin-resistant cases were identified and categorized into freshly diagnosed MDR and Pre-XDR/XDR groups. Data included demographics, treatment regimens, outcomes, comorbidities, and Binary Coded DST profiles. Statistical analysis was performed to compare relapse, treatment failure, death, lost to follow-up, and treatment success across regimens.



Results: ***Shorter Bdq vs. Km Conventional (MDR patients)****:*
Insignificant increase in relapse and death, no significant difference in treatment failure with Bdq
Slightly improved treatment success with Bdq (ARR = –0.0253; p = 0.7272)
Longer Bdq vs. Km Conventional (MDR patients)*:*
Significantly higher treatment failure (ARR = – 0.00534 ; $p = 3.13*10^{-135}$) with Bdq;
Diabetes (n = 26) and HIV (n = 49) both associated with higher deaths in Longer Bdq regimen.
Better outcomes with Bdq in MDR EPTB, but higher treatment failures than Km.

Males show similar treatment failure rates as females with Km, but higher failure with the Longer Bdq regimen. In contrast, females have higher relapse with Km and lower relapse with the Longer Bdq regimen compared to males.

Longer Bdq vs. Shorter Bdq:

Increased treatment success in Longer regimen (Not significant)

Pre-XDR/XDR vs. MDR on Longer Regimens:

Higher relapse and treatment failure with Pre – XDR/ XDR

All Bdq-based regimens showed earlier relapse trends vs. Km regimens with 50 % having relapse- timing of less than 6 months. (n = 15)

Conclusion: Effectiveness studies show mixed outcomes.

TBS-EP404 Analysis of the incidence of tuberculosis lung injury and related factors of lung function after cure of pulmonary tuberculosis: A prospective observational study

W. Cao,[1] [1]Beijing Geriatric Hospital, Beijing, China
e-mail: yangqiang@tsinghua.org.cn

Introduction: Post-tuberculosis lung damage (PTLD) refers to the residual pulmonary impairment following the completion of antituberculosis (TB) therapy, characterised by persistent respiratory symptoms and abnormal pulmonary function. The risk factors and biomarkers for PTLD have been scarcely investigated. More importantly, whether and to what extent cigarette smoking is involved in PTLD remain to be known.

Methods and analysis: This prospective observational study will enrol 400 male smoking or non-smoking patients aged 25–65 years, with newly confirmed active TB between 2022 and 2024, from the Department of Respiratory and Critical Care Medicine at Peking University Third Hospital and the Tuberculosis Department at Beijing Geriatric Hospital. Because females rarely smoke in China, we will enrol only males in this study.

Demographic data, smoking history and amount, clinical symptoms, lung function, and chest CT findings will be prospectively collected. Respiratory questionnaires, lung function measurements and chest CT examinations will be performed immediately after, and 1 year, 2 years and 3 years after the completion of TB treatment.

Peripheral blood samples will be obtained at baseline and at the end of anti-TB therapy, and a Luminex xMAP-based multiplex immunoassay will be used to measure inflammatory mediators and cytokines in serum.

The collected data will be analysed to determine the incidence and factors/ biomarkers of PTLD according to smoking status.

Ethics and dissemination: The study was approved by the Ethics Committee of Peking University Third Hospital (approval number: (2022)271-03; approval date: 8 June 2022). The research results will be disseminated through scientific and medical conferences and will be published in an academic journal.

TBS-EP407 Stool as an alternative diagnostic sample for TB in children under 14 years: Roll out study in Uganda

J. Kabugo,[1] A. Nyombi,[1] M. Sekadde,[2] [1]NTRL-Uganda, NHLDS, Kampala, Uganda, [2]NTLP-Uganda, NHLDS, Kampala, Uganda
e-mail: abdunoorn@gmail.com

Each year, 1.1 million children globally fall ill with tuberculosis (TB), of whom only 400,000 are notified with the case detection gap being highest in children aged under 5 years. Obtaining bacteriological confirmation of TB is challenging in children because of the frequent paucibacillary presentation of the disease. In children, it is complicated by difficulty in obtaining a quality specimen due to the hardship in sputum expectoration and the invasiveness of other procedures such as gastric aspiration. In 2021, the World Health Organization (WHO) recommended using stool as an alternative specimen type for TB diagnosis due to its user-friendliness combined with a sensitivity of 53% (95% CI: 35–70) and a specificity of 98% (95% CI: 93–99). This showed potential to close the pediatric TB diagnostic gap.

To introduce stool testing in Uganda, a phased early implementation approach was adopted from August 2023 to May 2024. These efforts saw 56 sites trained as trainers for the simple one-step (SOS) method. By the ninth month of implementation, 64 additional GeneXpert testing sites and 113 non-GeneXpert testing sites that routinely refer samples were further trained. Stool testing led to bacteriological confirmation of 124 patients in this period, giving a yield of 2.9%. A grand increase in the number of pediatric pulmonary bacteriologically confirmed (PBC) patients among all implementing sites increased by 6%. All SOS-negative patients were further screened clinically, leading to 22.1% (971/4397) getting started on childhood-friendly formulations.

The introduction of stool testing increased the number of confirmed TB cases among children and demonstrated its effectiveness in providing a definitive diagnosis. Scale-up and integration of the SOS technique within the routine diagnostic program of TB among children across the country is required to sustain and ensure universal access among all children in Uganda.

TBS-EP410 Human reader vs CAD4TB: Enhancing TB case detection through AI-supported mobile screening in Cambodia

M. Chry,[1] C. Leng,[2] K. Mom,[3] T.E. Mao,[4] S. Soung,[5] S.T. Kheang,[6] S. Sam,[7] [1]Cambodia Anti-Tuberculosis Association, Programme, Phnom Penh, Cambodia, [2]National Center for Tuberculosis and Leprosy Control (CENAT), Sub-Implementer of the GFATM, Phnom Penh, Cambodia, [3]Cambodia Anti-Tuberculosis Association, Management, Phnom Penh, Cambodia, [4]Ministry of Health - Cambodia, Public Health, Phnom Penh, Cambodia, [5]Cambodia Anti-Tuberculosis Association, TB program, Phnom Penh, Cambodia, [6]Health and Social Development, Management, Phnom Penh, Cambodia, [7]Cambodian Health Committee, Management, Phnom Penh, Cambodia
e-mail: rath@thecata.org.kh

Background: Although Cambodia was recently removed from the WHO's list of top 30 high TB burden countries, tuberculosis (TB) remains a significant public health concern. In 2024, an estimated 54,000 TB cases occurred nationwide, yet only 33,769were officially notified—indicating a 37% detection gap. Addressing this gap remains critical to national TB control efforts.
Intervention: A mobile active case-finding (ACF) initiative was implemented across five operational districts in Cambodia. Village Health Support Groups (VHSGs) were trained to conduct community screening and refer presumptive TB cases to mobile diagnostic sites established at nearby health centers.
Participants underwent chest X-rays (CXRs), interpreted by both human readers (HRs) and computer-aided detection software (CAD4TB). Individuals with abnormal findings were subsequently tested using GeneXpert.
Results: Among 4,225 individuals screened with CXR, 773 were tested with GeneXpert based on HR assessments. Of these, 59% had CAD4TB scores ≥60 (173/294). The distribution of GeneXpert-confirmed TB cases by CAD4TB score bands was: 10–19.99 (1.9%), 20–29.99 (1.3%), 30–39.99 (7%), 40–49.99 (7%), 50–59.99 (5.7%), and ≥60 (77.2%).
CAD4TB identified 31 GeneXpert-positive cases that had been missed by HRs, spanning various CAD score ranges. This highlights CAD4TB's ability to recover missed cases and enhance diagnostic sensitivity. The GeneXpert positivity rate of 20% (158/773) also reflects efficient cartridge utilization when guided by CAD scoring.
Conclusion: CAD4TB demonstrated strong potential to complement human interpretation in TB screening, identifying cases that might otherwise be overlooked. Its integration into mobile ACF efforts can strengthen early detection, improve diagnostic efficiency, and contribute to narrowing the TB detection gap in high-burden and resource-limited settings such as Cambodia.

TBS-EP413 Tuberculosis recurrence prediction: A machine learning approach

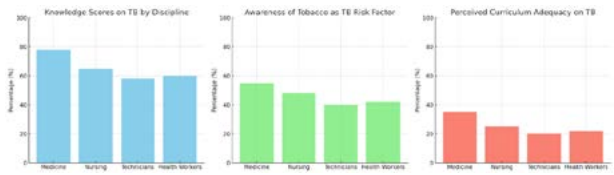
O.Z. Wieromiejczyk,[1,2] [1]University of Copenhagen, Copenhagen, Denmark, [2]Statens Serum Institut, Copenhagen, Denmark
e-mail: olga.wiero@gmail.com

Tuberculosis (TB) continues to be one of the world's deadliest infectious diseases. Even after treatment, many patients face the risk of recurrence, which complicates recovery and puts additional burden on healthcare systems—especially in low-resource settings. The biological and clinical factors driving TB recurrence remain poorly understood, making early identification of high-risk individuals particularly challenging.
In this study, we used clinical data from the H56:IC31 vaccine Phase 2b clinical trial to explore whether machine learning can predict which patients are most likely to recur. The dataset comprised over 700 previously treated, TB-negative patients, with extensive demographic, clinical, and laboratory collected over one year.
One of the key challenges was the relatively low proportion of recurrence cases in the dataset (around 6% of all cases) —a common challenge in medical datasets where the outcomes of interest are rare but clinically significant. To address this, we applied machine learning techniques specifically designed for imbalanced data, including sampling strategies and evaluation metrics that prioritize sensitivity to rare events.
These approaches allowed to uncover subtle patterns across more than 200 clinical variables, which could be missed by the traditional statistical methods. By doing so, we explored the potential for predictive models to identify individuals at elevated risk of recurrence. The models achieved a mean AUC of 0.65 and PR AUC of 0.24, with a recall of 56% for identifying recurrence cases.
Moreover, the analysis points to specific clinical variables that may be most informative and deserve closer examination in future studies.
Our findings demonstrate that integrating clinical trial data with machine learning can guide long-term patient monitoring and inform next-generation TB vaccine design—unlocking value from clinical datasets that are often overlooked after primary trial analyses.

TBS-EP416 Bridging the knowledge gap: KAP assessment on tuberculosis among undergraduate health professional students in Baghdad with a focus on tobacco smoke and curriculum adequacy

T. Alhilfi,[1] [1]Madenat Alelem University College, Baghdad, Iraq
e-mail: thamerls.yousif804@gmail.com

Background: Tuberculosis (TB) remains a persistent public health threat in Iraq, exacerbated by preventable risk factors such as tobacco smoke. Despite its national burden, limited data exist on future healthcare providers' knowledge, attitudes, and practices (KAP) toward TB and how adequately their undergraduate training prepares them to address it.
Objective: This study aims to evaluate the KAP regarding TB epidemiology, transmission, risk factors, especially tobacco smoke, and student perceptions of the sufficiency of TB content within the curricula of selected health professional colleges in Baghdad.
Methods: A cross-sectional study was conducted from October 2024 to July 2025 across four undergraduate health disciplines—Medicine, Nursing, Health Technicians, and Allied Health Workers—at Madenat Alelem University College. A validated structured questionnaire was administered to final-year students (n = 400).
The tool assessed core domains: (1) knowledge of TB epidemiology and risk factors, (2) attitudes toward TB patients and prevention, (3) clinical and public health practices, and (4) perceptions on curriculum adequacy.
Descriptive and inferential statistics were used to analyze findings, with subgroup comparisons by specialty and exposure to clinical TB training.
Results: Preliminary results indicate variable knowledge levels, with significant gaps in understanding tobacco smoke as a risk factor for TB. While most students recognized TB as a national concern, only 37% reported confidence in managing suspected cases.



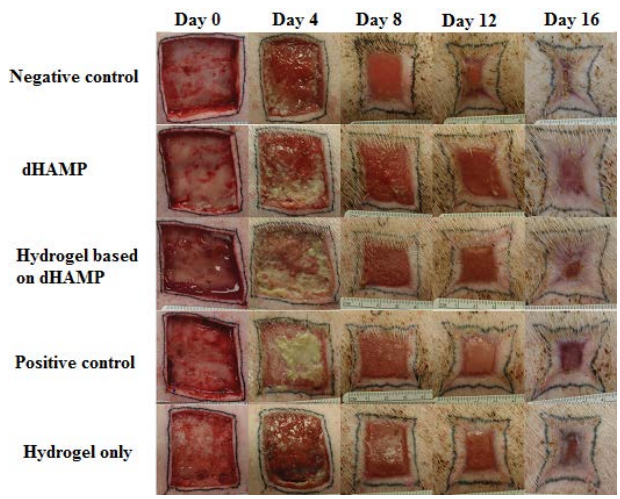
Conclusion: The study highlights critical gaps in TB-related education among future healthcare providers in Iraq, particularly regarding tobacco-related risk and community prevention.
These findings suggest the urgent need for curriculum enhancement and interprofessional TB training tailored to national epidemiological priorities. Integrating tobacco control and community-based TB care into undergraduate education may strengthen Iraq's health system response to TB.

Keywords: *Tuberculosis, Iraq, KAP Study, Tobacco Smoke, Undergraduate Curriculum, Health Professional Education, Madenat Alelem University College*

TBS-EP419 Development and evaluation of hydrogel loaded with human amniotic membrane in wound healing

F. Jan,[1] N. Waheed,[1] A. Jan,[1] [1]Common Management Unit (AIDS, TB & Malaria), Islamabad, Pakistan
e-mail: drfaheem82@gmail.com

Introduction: The purpose of this study was the preparation and evaluation of the potential use of thermoresponsive hydrogels formulation for topical delivery using human amniotic membrane as a model drug substance.
Methodology: Cold method was used for the preparation of these temperature triggered thermoresponsive hydrogels formulations by varying the concentrations of the poloxamer 338 (P 338), poloxamer 188 (P 188) and pectin. In each formulation decellularized human amniotic membrane (dHAMP) concentration was 1% (w/v).
Each of these formulations were evaluated for sol-gel temperature and release of dHAMP. Sol-gel transition temperatures were within the range of 31-37°C for all the final formulations. Sol-gel transition temperature of F30 was altered by increasing the concentration of P 188 and brings it close to physiological temperature (37°C) by comparing the formulation with those formulations containing minimum concentration of P 188. Tube inversion method was used to analyze the effect of polymer concentration on the gelation behavior. Moreover wound healing activity and drug release behavior of these formulations were also evaluated.



Results: dHAMP release study of the formulations showed sustained release properties. Wound healing study showed significant results in group treated with hydrogels based on dHAMP when compared with other treated groups.

Group treated with hydrogels based on dHAMP showed complete healing and average re-epithelialization in 16 day with 73.5% healing. Fourier Transform Infrared Spectroscopy (FT-IR) and Differential Scanning Calorimetry (DSC) were performed to analyze dHAMP and polymer interactions. FT-IR spectra of the physical mixture showed the same bands as that of poloxamers and pectin indicating no interaction between poloxamers and pectin. However, FT-IR spectra of the formulations showed significant changes in bands which suggest the successful synthesis of hydrogels. DSC curve of physical mixture showed the same peak at 60°C for physical mixtures before and after addition of dHAMP.

TBS-EP422 Integrated surveillance of polio-negative AFP cases for childhood tuberculosis: A novel approach in Rivers State, Nigeria

V. Oris-Onyiri,[1] I. Nwadiuto,[2] [1]Rivers State Tuberculosis Control Program, Port Harcourt, Nigeria, [2]Rivers State University, Port Harcourt, Nigeria
e-mail: mastervictor@hotmail.co.uk

Background: Nigeria, certified free of wild poliovirus in 2020, continues nationwide acute flaccid paralysis (AFP) surveillance to detect potential polio-virus re-emergence. With tuberculosis (TB) remaining a leading cause of childhood mortality and under-diagnosis persistent in Nigeria, integrating childhood TB testing into AFP case investigations offers a novel strategy for pediatric TB detection. This study evaluates the yield of TB testing among polio-negative AFP cases under 15 years in Rivers State, Nigeria.
Methods: A retrospective analysis was conducted using AFP surveillance line-list data from January 2022 to March 2025. All children under 15 years with polio-negative AFP who were tested for TB using GeneXpert MTB RIF assay were included. Demographic and clinical variables were analyzed using descriptive statistics. Associations between TB positivity and sociodemographic factors were assessed using chi-square tests and logistic regression.
Results: A total of 118 AFP cases were tested for TB. The mean age was 3.6 years (SD ±3.25), with 76.3% under five years and 52.5% male. Five cases (4.2%) tested positive for TB, with no significant differences in TB positivity by sex (p=0.923) or age group (p=1.000). Logistic regression revealed no significant predictors of TB positivity, though most TB cases were under five years and presented with limb weakness, suggesting possible extra-pulmonary TB.
Conclusion: The integration of TB testing into AFP surveillance yielded a 4.2% TB detection rate among children under 15 with non-polio AFP, highlighting the potential of surveillance synergy. This innovative approach may help bridge the pediatric TB detection gap. Policymakers should consider adopting integrated protocols to maximize surveillance platforms and strengthen early case detection in high-burden settings.
Keywords: AFP, tuberculosis, polio surveillance, pediatric TB, integrated disease surveillance, Nigeria, Rivers State, case finding

TBS-EP425 Impact of discordant isoniazid and rifampicin susceptibility results between the Anyplex™ II MTB/MDR assay and the BACTEC MGIT 960 system on treatment decisions

K. Wongjarit,[1,2] P. Torvorapanit,[2,3] S. Petsong,[1] A. Sawatpanich,[1] W. Sawaengdee,[4] P. Dhepakson,[4] S. Rotcheewaphan,[1,5] G. Suwanpimolkul,[2,3,5] [1]Department of Microbiology, Chulalongkorn University, Bangkok, Thailand, [2]Division of Infectious Diseases, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [3]Thai Red Cross Emerging Infectious Diseases Clinical Center, King Chulalongkorn Memorial Hospital, Bangkok, Thailand, [4]Genomics Medicine Center, Medical Life Sciences Institute, Department of Medical Sciences, Ministry of Public Health, Nonthaburi, Thailand, [5]Center of Excellence in Tuberculosis, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand
e-mail: kanphai.w@gmail.com

Background: Anyplex™ II MTB/MDR is a rapid diagnostic test used to detect Mycobacterium tuberculosis (MTB) and mutations associated with isoniazid (INH) and rifampicin (RIF) resistance. However, discordance with phenotypic drug susceptibility testing (DST) can complicate treatment decisions.
Materials and Methods: A retrospective review was conducted on patients with drug-susceptible TB (DS-TB), isoniazid mono-resistant TB (Hr-TB), rifampicin mono-resistant TB (RR-TB), and multidrug-resistant TB (MDR-TB) at King Chulalongkorn Memorial Hospital (KCMH), a tuberculosis referral center in Thailand, from 2018 to 2023.
The correlation between genotypic and phenotypic DST using the Anyplex™ II MTB/MDR and BACTEC MGIT 960 assays, respectively, was investigated from clinical specimens and MTB clinical isolates recovered from clinical specimens collected in the same period.
Results: Among 836 MTB isolates from 796 patients, 44 (5.2%) showed statistically significant discordant susceptibility to INH (p<0.001) or RIF (p=0.022). The majority of INH discordances (29 of 32, 90.6%) exhibited genotypic susceptibility but phenotypic resistance, while most RIF discordances (11 of 13, 84.6%) exhibited genotypic resistance but phenotypic susceptibility. The impact of these discordant results on clinical decision-making is summarized in Figure 1.

Among patients with discordant DST results, 52.2% were potentially undertreated, 2.3% were overtreated, and 40.9% had no change in treatment. Moreover, 6 of 11 genotypic-resistant/phenotypic-susceptible (G^R/P^S) RIF-discordant isolates harbored one of the following *rpoB* mutations: Leu430Pro, Asp435Tyr, or Leu452Pro, which are associated with low-level resistance. The susceptibility profiles and whole-genome sequencing results of these isolates are summarized in Table 1.

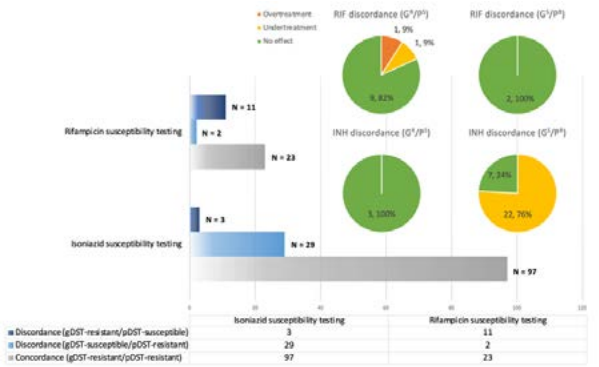


Figure 1. Isoniazid and rifampicin discordant results and their effect on physicians' treatment decisions.
Abbreviations: genotypic-resistant (G^R), genotypic-susceptible (G^S), phenotypic-resistant (P^R), phenotypic-susceptible (P^S).

Table 1. The susceptibility profile and WGS results of G^R/P^S rifampicin-discordant isolates

Isolate No.	TB treatment history	BACTEC MGIT 960 results	Anyplex™ II MTB/MDR results	WGS results using TB-Profiler v6.6.0	Strain lineage	RIF SNP using TB-Profiler v6.6.0	INH SNP using TB-Profiler v6.6.0	RIF MIC (mg/mL), susceptible (S) and resistant (R) classified according to the CRyPTIC consortium	INH MIC (mg/mL), susceptible (S) and resistant (R) classified according to the CRyPTIC consortium
MTBD13	Previously treated	Hr-TB	MDR-TB	MDR-TB	2.2.1	rpoB p.Leu430Pro	katG p.Ser315Thr	0.25, S	2, R
MTBD15	Previously treated	DS-TB	RR-TB	RR-TB	2.2.1	rpoB p.Asp435Tyr	None	2, R	1, R
MTBD22	Previously treated	DS-TB	RR-TB	RR-TB	2.2.1	rpoB p.Leu452Pro	None	1, R	<=0.03, S
MTBD26	Previously treated	DS-TB	RR-TB	DS-TB	2.2.1	None	None	0.12, S	<=0.03, S
MTBD28	Previously treated	DS-TB	RR-TB	DS-TB	2.2.1	None	None	0.12, S	0.06, S
MTBD31	New	Hr-TB	MDR-TB	MDR-TB	2.1	rpoB p.Leu430Pro	katG p.Ser315Thr	0.25, S	2, R
MTBD33	New	DS-TB	RR-TB	RR-TB	2.2.1	rpoB p.Leu430Pro	None	0.5, R	<=0.03, S
MTBD34	New	Hr-TB	MDR-TB	MDR-TB	2.2.1	rpoB p.Leu452Pro	katG p.Ser315Thr	1, R	2, R
MTBD40	Previously treated	Hr-TB	MDR-TB	Hr-TB	2.2.1	None	katG p.Ser315Thr	0.25, S	4, R

Conclusion: The Anyplex™ II MTB/MDR assay exhibited a substantial number of discordant results compared to the BACTEC MGIT 960 assay. These discordances may impact treatment decisions. Furthermore, certain cases of G^R/P^S RIF-discordant isolates were associated with borderline *rpoB* mutations, highlighting the need for careful interpretation of discordant results, as has also been reported for the Xpert MTB/RIF Ultra assay.

TBS-EP428 The role of physiotherapy in demystifying pulmonary tuberculosis in Uganda

S.T. Nakisanze,[1] D. Mujuni,[2] [1]Masaka Regional Referral Hospital, Masaka, Uganda, [2]Alpha Biomedical Research and Innovation Network, Kampala, Uganda
e-mail: tabithanakisanze99@gmail.com

Background: In Uganda, profound cultural misconceptions have long linked Pulmonary tuberculosis to witchcraft resulting in delayed diagnosis, maltreatment stigma and isolation hence hindering effective management. Physiotherapy plays a dual role in this context through providing essential rehabilitative services to improve lung capacities and quality of life while serving as a critical platform for public education on the pathological origin of this condition.
Methods: With ethical approval and informed consent, a cohort study involving twenty-five persons (25) affected by pulmonary tuberculosis and their caregivers was conducted. Participants received three structured physiotherapy sessions per week for three months and a daily home exercise program. Data on lung function, quality of life, and stigma-related stress were collected at baseline and post-intervention. Perceived Stress Scale (PSS) were used for assessment of stigma related stress. Qualitative data on drug dosage adherence and well-being were analyzed thematically.
Results: The patient-caregiver support group that comprised of 25 patients and a sole care-giver for each had a retention rate of 75% over the 3 months of study which improved overall drug adherence. ($p < 0.5$).
Additionally self-reported reduction in isolation and stigma related stress calculated using the Perceived Stress Scale (PSS), decreased from 60% to 35% post intervention indicating psycho-social improvement. ($p < 0.5$).
Pulmonary function was measured using parameters such as Tidal Volume, Forced Expiratory Volume in one second (FEV_1) and exercise endurance. Quality of life improved by 30% using the SF-36 scale from 42 to 54.6 ($p < 0.5$).
Conclusion: These results highlight the potential of targeted rehabilitation and psychosocial support in addressing social challenges and demonstrate the effectiveness of physiotherapy interventions in improving clinical outcomes and emphasizing the pathological basis of pulmonary tuberculosis rather than moral failings and witchcraft which minimizes societal stigma thus increasing willingness of patients to seek and adhere to treatment.

TBS-EP431 Clinical performance of the CAD4TB AI system for pulmonary tuberculosis detection among young adults in Mongolia: A diagnostic screening study

N. Batbayar,[1] N. Purev,[1] U.-U. Atarsaikhan,[2] E. Choijil,[3] P. Batsuren,[4] U. Boldbaatar,[1] C. Lkhagvajav,[1] S. Bazarragchaa,[1] G. Ganbaatar,[1] Y. Purevsuren,[1]
[1]National Center for Communicable Diseases, Ulaanbaatar, Mongolia, [2]Songino-Khairkhan District Health Center, Ulaanbaatar, Mongolia, [3]Mongolian Association of Family Medicine Specialists, Ulaanbaatar, Mongolia, [4]Bayanzurkh District Health Center, Ulaanbaatar, Mongolia
e-mail: yanja2332@gmail.com

Background: Artificial intelligence (AI)-based diagnostic tools are increasingly integrated into tuberculosis (TB) screening workflows to improve early case detection, especially in underserved populations. In 2024–2025, Mongolia utilized the CAD4TB system—an AI-powered chest X-ray interpretation software—during military pre-enlistment health screenings for the first time.
This study evaluates the diagnostic yield and clinical relevance of CAD4TB in identifying pulmonary TB in young adults outside routine healthcare coverage.
Methods: Between September 2024 and May 2025, 6,231 individuals aged 18–25 years who were deemed medically unfit for military enlistment were screened using mobile CAD4TB units across two screening phases. Standardized chest X-rays were interpreted using the CAD4TB algorithm and individuals with high CAD scores were referred for confirmatory testing via molecular diagnostics (GeneXpert MTB/RIF). Clinical data, radiological scores, and test outcomes were analyzed to evaluate the diagnostic yield and profile of detected TB cases.
Results: During the pilot phase (Fall 2024), 2,086 individuals were screened, resulting in 7 bacteriologically confirmed pulmonary TB cases. In the national rollout (May 2025), 4,145 additional individuals were screened; CAD4TB flagged 169 (4.1%) for further testing, of whom 11 TB cases were confirmed (8 bacteriologically, 2 clinically, and 1 multidrug-resistant). Among all confirmed cases, 82% had infectious pulmonary TB. TB case detection was highest in 25-year-olds (36.4% of cases).
Overall, the study yielded 1.5 TB cases per 10,000 individuals screened. The CAD4TB system demonstrated efficient clinical identification of TB cases in an asymptomatic cohort with otherwise limited healthcare interaction.
Conclusion: This is the first clinical dataset from Mongolia evaluating the diagnostic performance of the CAD4TB system among young adults. The results support its clinical utility in early identification of both drug-sensitive and drug-resistant TB, highlighting its potential role in targeted TB screening strategies in low-prevalence, under-screened populations.

TBS-EP434 Addressing access to treatment and diagnostic barriers in TB treatment through the Market and Patent Intelligence Study: A focus on intellectual property barrier

D. Otieno,[1] [1]KELIN, Nairobi, Kenya
e-mail: dukeotieno@kelinkenya.org

Background: Tuberculosis remains a major public health issue in Kenya with diagnostic and testing barriers contributing to delayed or missed treatments. Access to appropriate diagnostic tools is hampered by market inefficiencies, regulatory challenges and patent constraints.
Objective:
1. To identify the patent status of WHO-recommended TB treatment drugs.
2. To identify availability and barriers related to WHO-recommended TB diagnostics.
3. To evaluate the general market and patent landscapes affecting access to drugs.
4. To inform policy and procurement decisions.
Methods:
• Market Intelligence- Reviewed of Kenya's Procurement data for TB commodities and diagnostics.
• Patent Status- Assessed patent status of key TB drugs and diagnostic technologies through publicly available databases (Medspal, Espacenet, WIPO).
• Stakeholder interviews with Government procurement agency (KEMSA).
Findings:
1. High dependency on imports for TB drugs and diagnostics.
2. Patents currently are not an access barrier but supply chain, registration delays and procurement inefficiencies are.
3. Most adult anti-TB drugs in Kenya don't have patent barriers in Kenya due to bilateral agreements but other countries have Intellectual Property as barrier.
4. Regulatory bottlenecks delay the registration and roll out of newer TB diagnostic technologies.
5. Limited availability of WHO recommended diagnostics like Urine LAM and GeneXpert cartridges.
Recommendations:
1.Accelerate registration and policy adoption of new TB diagnostics.
2. Improved forecasting and procurement planning for consistent supply- use of AI.
3. Leverage TRIPS flexibilities when patents become a barrier especially because Kenya has been elevated to a Middle-Income Country where they may be left out of bilateral licences
4. Strengthen local manufacturing and regional collaboration.
Conclusion: Market and patent intelligence study is a tool to identify and address barriers in TB Drugs and diagnostics access. Collaboration among policymakers,

regulators and procurement agencies is essential to ensure timely availability of TB commodities and diagnostic technologies in Kenya.

TBS-EP437 Tuberculosis Big Model (TBM): An integrated simulation framework

H. Cui,[1] Z. Wang,[1] Y. Xing,[1] L. Qin,[1] K. Ouyang,[1] T. Li,[2] Y. Zhao,[2] Z. Jia,[2] [1]Department of Global Health, School of Public Health, Peking University, Beijing, China, [2]Chinese Center for Disease Control and Prevention, Beijing, China
e-mail: pkubruce@bjmu.edu.cn

Tuberculosis (TB) led global infectious-disease mortality in 2023, overtaking COVID-19 and underscoring gaps in the End-TB Strategy. Although ultraportable molecular diagnostics, sequencing-based resistance testing, novel drugs, shorter regimens, and nineteen vaccine candidates have emerged, no integrated tool yet projects the epidemiologic, economic, and life-course impact of implementation at scale. Existing models dissect single steps of the care cascade, ignore resistance dynamics, overlook post-TB morbidity, and assume fixed diagnostic performance.

To address these limitations, we are developing the Tuberculosis Big Model (TBM) - an open-source, modular, and extensible simulation platform that unifies four previously siloed domains into a single analytic engine:

1. Core model (natural TB history)
2. Drug-resistance model
3. Diagnostic model
4. Life-long post-TB sequelae model

Core Model: Seven compartments represent the spectrum from uninfected to active disease. Flexible parameterization allows alternative assumptions regarding (1) progression or clearance of latent infection, (2) transmission within and between populations, and (3) recurrence after treatment, calibrated to epidemiologic data.

Drug-Resistance Model: Resistance emergence and transmission are captured through seven pathways across three stages representing both primary infection with drug-resistant strains and acquisition during treatment: (1) latent infection via mutation or sub-optimal chemoprophylaxis, (2) active treatment under inadequate regimens, and (3) post-treatment reinfection or reactivation of dormant resistant clones.

Diagnostic Model: Stratified into symptom screening, laboratory testing and chest radiography, the module (1) quantifies context-dependent sensitivity and specificity, (2) evaluates novel molecular platforms and AI-assisted image interpretation and (3) supports cost-effectiveness analyses of alternative algorithms.

Post-TB Sequelae Model: Post-TB morbidity is modelled separately from active or recurrent TB to reflect its distinct, long-term health burden. The framework incorporates excess risks for: (1) chronic pulmonary disease; (2) cardiovascular disease; (3) neurological disorders. Recurrent TB remains an explicitly modelled state within the core module, ensuring consistent linkage between active disease and subsequent sequelae.

TBS-EP440 Shortened treatment regimens for drug resistant (DR)-TB patients in Azerbaijan: First results

I. Akhundova,[1] G. Aliyeva,[1] K. Karimova,[1] A. Aslanova,[1] H. Hajmammadli,[1] A. Huseynova,[1] [1]Scientific-Research Institute of Lung Diseases, Baku, Azerbaijan
e-mail: gulzarino@yahoo.com

Background: Tuberculosis remains a serious problem in many countries. The fight against resistant forms of the disease is particularly difficult. Many patients, for various reasons, interrupt long and tedious treatment. Short therapy regimens help prevent such cases.

Objective: to analyze the first results of BPaL (Bedaquiline400/200, Pretomanid 200, Linezolid 600) and BPaL/M(Bedaquiline400/200, Pretomanid200, Linezolid 600/Moxifloxacin400) short treatment regimens for DR-TB patients in Azerbaijan.

Materials and methods: Since March 2024, the 346 DR-TB patients (aged from 15 to 55 y.o., 241 men, 105 women, and 13 adolescents (ads) <18y.o. among them) have been involved in new short treatment regimens.

BPaL 9-month treatment regimen implemented in 96 (8ads) preXDR-TB patients (1group), BPaL/M 6-month treatment regimen implemented in 250 (5ads) MDR-TB patients (2group).

Results: Currently, 185 patients continue to receive treatment. The treatment results of 161 patients were evaluated. Fully recovered 5 patients in 1 group and 25 patients in 2 group. Treatment was completed with residual elements in the lungs of 87 people (19 in 1, 68 in 2 groups). In these patients, bacterial shedding stopped in a shorter period of time (2-4 weeks), and the closure of the cavities in the lungs was observed. 5 and 13 people refused treatment, mortality was observed in 2 and 12 cases, unsuccessful treatment results without microbiological conversion and radiological dynamics were observed in 3 and 9 patients in groups 1 and 2, respectively.
The treatment caused temporary side effects, including peripheral neuropathy in 15(9.4%), myelosuppression in 102(63.4%), and QT interval prolongation in 9(5.6%) cases, but these were eliminated on time through careful monitoring
Conclusion: It is too early to properly compare BPaL and BPaL/M results, but the effectiveness of these shortened treatment regimens in the treatment of DR-TB patients was quite high at 72.7%(62% previous regimens). Also, shorter regimens increase patient adherence to treatment.

TBS-EP443 Concomitant subclinical pulmonary tuberculosis in patients with extra-pulmonary tuberculosis

T. Gude,[1] R. Jhamb,[1] [1]UCMS & GTBH, New Delhi, India
e-mail: gudetejaswini@gmail.com

A cross-sectional study was conducted from May 2023 to October 2024 at the University College of Medical Sciences and Guru Teg Bahadur Hospital, Delhi. Sixty-two newly diagnosed EPTB patients above 12 years of age, without pulmonary symptoms, were enrolled. Each patient underwent chest X-ray (CXR), sputum testing (AFB smear, culture on LJ medium, Gene-Xpert MTB via CBNAAT), and contrast-enhanced CT (CECT) chest. Routine haematological, renal, liver, and inflammatory markers were analysed. Sociodemographic data and co-morbidities were recorded.
All 62 patients underwent CXR, sputum analysis, and CECT chest. Abnormalities on CXR were found in 59.7% of cases, with 17.7% suggestive of PTB. Sputum AFB smear was positive in 4.8% (3/62), Gene-Xpert in 3.2% (2/62), and culture in 0% of the patients. No rifampicin resistance was detected. CECT chest revealed findings suggestive of PTB in 38.7% (24/62) of cases.
Overall, 38.7% (24/62) of EPTB patients were diagnosed with concomitant subclinical PTB based on imaging and/or microbiological findings. Among all the diagnostic tools used, CT scan had the highest diagnostic yield. Subclinical PTB was more common among males, smokers, alcohol users, and individuals belonging to lower socio-economic strata.
Therefore, this emphasises the importance of early diagnosis, effective diagnostic & treatment protocols, strict guidelines implementation and appropriate screening practices to reduced the impact of pulmonary tuberculosis in an already existing pool of patients, especially in resource limited setup and population.

TBS-EP446 Evaluation of the second-generation Fujifilm SILVAMP TB-LAM assay for TB diagnosis in Nigerian adults

N. Tytarenko,[1] J.S. Bimba,[2] D. Vulcano,[1]
P. Comella-del-Barrio,[3] O. Osazuwa,[4] J. Creswell,[5]
J. Domínguez,[6] [1]Germans Trias i Pujol Research Institute (IGTP), Badalona, Spain, [2]Zankli Research Centre and Department of Community Medicine, Bingham University, Karu, Nigeria, [3]Universitat Autònoma de Barcelona, Barcelona, Spain, [4]Zankli Research Centre and Department of Community Medicine, Bingham University, Abuja, Nigeria, [5]Innovations & Grants at Stop TB Partnership, Geneva, Switzerland, [6]Germans Trias i Pujol Research Institute (IGTP); CIBER Enfermedades Respiratorias, CIBERES; Department of Genetics and Microbiology, Universitat Autònoma de Barcelona, Badalona, Barcelona, Spain
e-mail: ntytarenko@igtp.cat

Background: TB remains a major global health threat, with diagnostic challenges in low- and middle-income countries. The Fujifilm SILVAMP TB LAM (FujiLAM) assay was developed as a rapid urine-based test for TB diagnosis, but manufacturing inconsistencies in the first generation (v.1) led to the creation of FujiLAM (v.2).
This study evaluates the diagnostic performance and consistency of FujiLAM (v.2) compared to FujiLAM (v.1) in Nigerian adults with presumed TB.
Methods: We retrospectively analysed 178 urine samples from adults with presumed TB at district hospitals in Abuja, Nigeria. Reference standard used was culture and Xpert MTB/RIF. Sensitivity, specificity, and concordance with the reference standard were calculated for both FujiLAM versions, stratified by HIV status.
Results: FujiLAM (v.2) showed an overall sensitivity of 58.3% and specificity of 97.3%, while FujiLAM (v.1) yielded a sensitivity of 52.9% and specificity of 99.0%. These results indicated no significant difference in diagnostic accuracy, confirmed by McNemar's test (TB-positive samples: χ^2=0, p=1.0, 95% CI: 0.013–0.987; TB-negative samples: χ^2=0.333, p=0.56, 95% CI: 0.008–0.906).
For participants living with HIV, FujiLAM (v.1) detected TB in 5/7 and correctly classified 49/51 TB-negative samples. FujiLAM (v.2) detected 4/7 and 55/56, respectively. For those without HIV coinfection, FujiLAM (v.1) detected 9/17 and 96/97, and FujiLAM (v.2) detected 10/17 TB-positive and 94/97 TB-negative samples.
FujiLAM (v.2) showed improved test validity, with fewer invalid results (1 vs. 6). Concordance with the bac-

teriological reference standard remained high (92.1%, κ=0.623), and overall agreement was 97.1%, showing consistent results between both FujiLAM versions.
Conclusions: The second-generation FujiLAM assay showed diagnostic accuracy similar to FujiLAM (v.1). FujiLAM continues to be a promising, non-invasive tool for TB detection in people living with and without HIV. Further large-scale studies are recommended using multiple lots.

TBS-EP449 Novel mutations in genes associated with bedaquiline and linezolid resistance in drug- naiive *Mycobacterium tuberculosis* isolates

M. Varma-Basil,[1] C. Sharma,[1] D. Vashisth,[1] K. Chaudhary,[1] N. Gautam,[1] M. Pandey,[1] A. Singh,[1] [1]Vallabhbhai Patel Chest Institute, University of Delhi, Delhi, India
e-mail: sharma.chikanshi1209@gmail.com

Since Bedaquiline (BDQ) and Linezolid (LZD) have been introduced recently for treatment of multidrug resistant tuberculosis (MDR-TB), it is crucial to monitor emerging resistance patterns in regional *Mycobacterium tuberculosis* isolates.
Sputum samples were collected from 365 pulmonary tuberculosis patients including 103 new patients, 143 multidrug resistant TB (MDR-TB) patients not receiving BDQ/LZD, and 119 MDR-TB patients on BDQ and/or LZD therapy.
Minimum inhibitory concentrations (MICs) were determined using the microplate alamar blue assay (MABA). Samples were cultured on Löwenstein-Jensen (LJ) medium. A total of 89 *M. tuberculosis* strains were isolated: 41 from new smear-positive patients, 33 from MDR-TB patients, and 15 from patients on BDQ/LZD therapy.
All isolates were confirmed as *M. tuberculosis* using an in-house duplex PCR, and whole-genome sequencing was performed. Sequence data were analyzed using PhyResSE.
Novel insertions in the *Rv0678* gene were detected in three BDQ-exposed isolates with MICs >0.25 μg/ml. A canonical *Rv0678* mutation (Gly66Glu) associated with BDQ resistance was found in one isolate not previously exposed to BDQ but with a high MIC (1 μg/ml). Two new smear-positive isolates harbored *Rv0678* mutations (Ser-2Thr and Gly11Ser), although their BDQ MICs were not elevated. No non-synonymous mutations were found in *atpE* or *pepQ*. No isolate showed high MICs to LZD. No *rrl* mutations were detected. The canonical *rplC* mutation Cys154Arg was observed in one isolate exposed to LZD. The *rplC* mutation Thr102Ile was seen in one isolate not exposed to LZD; and Ile105Val in two isolates. A non-synonymous *rplD* mutation (Arg79His) was observed in one isolate not exposed to LZD.
This study highlights the emergence of novel mutations in BDQ and LZD resistance-associated genes, including in isolates without prior drug exposure, warranting further investigation. These findings underscore the importance of ongoing genomic surveillance to detect emerging resistance in *M. tuberculosis*.

TBS-EP452 Measuring cellular responses against respiratory pathogens can help to guide prophylaxis in immunocompromised patients

G. Safont,[1,2,3] D. Smalchuk,[1,3,4] D. Gaete,[5] R. Ugena-García,[6] J. Valera,[1,7] R. Preyer,[8] I. Latorre,[1,2,3] J. Domínguez,[1,2,3] [1]Institut d'Investigació Germans Trias i Pujol, Badalona, Spain, [2]CIBER de Enfermedades Respiratorias, Badalona, Spain, [3]Universitat Autònoma de Barcelona, Cerdanyola del Vallès, Spain, [4]Odesa I. I. Mechnykov National University, Odesa, Ukraine, [5]Universidad de la Frontera, Temuco, Chile, [6]Rheumathology Department from Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [7]Preventive Medicine Department from Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [8]Genome Identification Diagnostics GmbH (GenID), Straßberg, Germany
e-mail: ilatorre@igtp.cat

The potential of some respiratory pathogens to cause future pandemics underscores the need for robust preparedness, particularly to protect immunocompromised individuals who are at high risk of severe outcomes. Monoclonal antibody (mAb) prophylaxis has been seen to be beneficial during the COVID-19 pandemic for patients most prone to worse outcomes, but was only recommended for those patients without a specific humoral response to vaccination. Evaluating cellular immunity could give a better overview of the immune status to guide prophylaxis decisions in respiratory infections than serology alone.
Blood was collected from 130 mAb immunocompromised prophylaxis candidates grouped by serology status against SARS-CoV-2: positive (≥260 BAU/mL, n=90) and negative (<260 BAU/mL, n=40). Peripheral blood mononuclear cells (PBMCs) were isolated and stimulated overnight with a SARS-CoV-2 Spike pool. Cellular responses (IFN-γ, IL-2, IL-21, and IL-5) were measured using a FluoroSpot (CoV-iSpot, GenID, Germany) and quantified with an automatic reader.
Participants with negative serology showed a lower frequency (40% vs 60%) and intensity of SARS-CoV-2-specific responses (p=0.059 for IFN-γ, p=0.004 for IL-2, p=0.032 for IL-21, and 0.069 for IL-5), as well as lower polyfunctionality (p=0.0124) compared to those with positive serology. The multiparametric analysis showed a lower probability of IFN-γ response in participants with negative serology, no previous COVID-19, and under corticoid treatment compared to positive serology, previous COVID-19, and no corticoid treatment (3-13% and 68-88%, respectively).

These findings demonstrate that, in immunosuppressed patients, the absence of a humoral response does not signify a lack of cellular response. However, negative serology patients exhibit weaker and less polyfunctional cellular responses. Clinical factors such as previous infection and corticoid use significantly impair cellular responses, increasing susceptibility to severe respiratory infection. Therefore, assessing specific cellular immunity can guide clinicians in prioritizing mAb prophylaxis against respiratory pathogens.

TBS-EP455 Radiological features of pulmonary nontuberculous mycobacterial disease depending on the species of the pathogen

R. Khachetlov,[1] R. Ladyu,[1] M. Romanova,[1] A. Abramchenko,[1] A. Gayda,[1] A. Samoilova,[1] I. Vasileva,[1] A. Kazakov,[1] [1]Federal State Budgetary Institution "National Medical Research Center for Phthisiopulmonology and Infectious Diseases", Ministry of Health of the Russian Federation, Moscow, Russian Federation
e-mail: nsovca@yandex.ru

Background: More than 170 species of nontuberculous mycobacteria (NTM) have been described to date, with approximately 60 implicated in pulmonary disease. In addition to microbiological confirmation, radiological evaluation is a key tool for determining the need for therapy and monitoring disease progression.
Objective: To investigate radiological patterns of pulmonary NTM disease depending on the NTM species involved.
Materials and Methods: A retrospective analysis was conducted on 134 patients with confirmed pulmonary NTM disease from 50 regions of the Russian Federation, diagnosed at the National Medical Research Center for Phthisiopulmonology and Infectious Diseases in 2023–2025. Inclusion criteria: patients with NTM species identification by molecular-genetic or culture-based methods (sputum [×2], bronchoalveolar lavage, or surgical samples) using MALDI-TOF mass spectrometry, and available chest CT data prior to treatment initiation. Radiological features assessed included disease extent, cavitary lesions, bronchiectasis, and nodular dissemination.
Four NTM species were identified: *Mycobacterium avium* (n=77; 57.5%), *M. chimaera* (n=32; 23.9%), *M. kansasii* (n=17; 12.7%), and *M. abscessus* (n=8; 5.9%).
Results: Bilateral pulmonary involvement was common across all species: *M. avium* – 89.6%, *M. chimaera* – 96.9%, *M. abscessus* – 87.5%, and *M. kansasii* – 64.7% ($p>0.05$). Cavitary lesions were most frequently observed in *M. kansasii* cases (82.3%), while less frequent in *M. avium* (33.8%), *M. chimaera* (37.5%), and *M. abscessus* (25%) ($p<0.05$). Conversely, nodular dissemination was significantly less common in *M. kansasii* (41.1%) compared to other species: *M. avium* – 89.6%, *M. chimaera* – 84.4%, *M. abscessus* – 100% ($p<0.05$). Bronchiectasis was also less frequent in *M. kansasii* cases (23.6%) vs *M. avium* (62.3%), *M. chimaera* (68.8%), and *M. abscessus* (75%) ($p<0.05$).
Conclusion: Pulmonary NTM disease caused by *M. avium*, *M. chimaera*, and *M. abscessus* is typically characterized by bilateral nodular dissemination and bronchiectasis. In contrast, *M. kansasii* infection more frequently presents with cavitary lung disease and fewer bronchiectatic or disseminated changes.

TBS-EP458 Estimating the effect of implementing novel diagnostics in adults and children on pediatric TB indicators in KwaZulu-Natal, South Africa

M. Fajans,[1] S. Chang,[2] M.G.C.d. Enriquez,[2] D. Klein,[2] S. Naidoo,[3] D. Wilson,[4,5] Y. Naidoo,[5] A. Shapiro,[1] P. Drain,[1] [1]University of Washington, Seattle, United States of America, [2]Institute for Disease Modeling, Seattle, United States of America, [3]KwaZulu-Natal Department of Health, Pietermaritzburg, South Africa, [4]Umkhuseli Innovation and Research Management, Pietermaritzburg, South Africa, [5]University of KwaZulu-Natal, Pietermaritzburg, South Africa
e-mail: mfajans@uw.edu

Few modeling studies have evaluated effects of implementing oral swabs, newer generation urine LAM testing or computer aided detection for chest X-rays (CAD-CXR) in both adults and children. More information is needed to understand the impact of a missed diagnosis in adults on ongoing household transmission to pediatric contacts. Using simulated TB transmission modeling, our objective is to estimate the effect of implementing novel diagnostics in both adults and children in a South African district municipality on pediatric TB incidence, mortality, TB Preventive Therapy (TPT) initiation.
We will use TBSim v0.40, an agent-based stochastic TB transmission model, to simulate TB transmission within a simulated population representing uMgungundlovu district in KwaZulu-Natal, South Africa. We will simulate district transmission between January 2016 and December 2055, using a bi-weekly time step. We will apply age specific probabilities for risk of transmission between disease states using literature values, accounting for HIV and BCG status. We will use a combination of household and random networks to model agent interactions. Agents initiate health-seeking behavior once entering an active disease state, and initiate the diagnostic cascade if screened positive. We will simulate 13 separate diagnostic scenarios with varying diagnostic performance (Figure 1).
If test positive, the agent is initiated on treatment, with treatment success probability based on reported district success rate. Household members are then screened,

tested, or initiated on TPT if eligible. We will use a base population of 1,111,872 agents, an initial TB prevalence of 852 cases per 100,000 population, 272,666 household units with average size 3.7 individuals, and age structure which reflects 2016 census data.

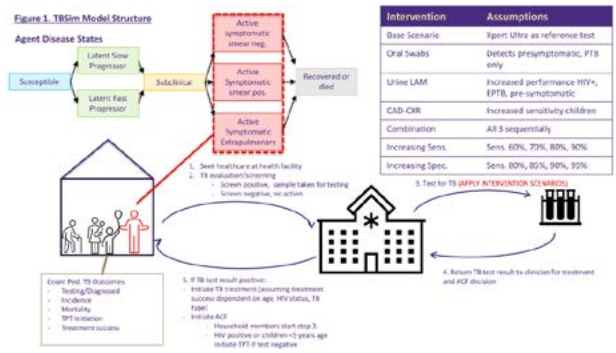

Figure 1.

For each simulated year, we will calculate pediatric TB incidence, TB related mortality, number of children tested/diagnosed, and number of children initiated on TPT. We will calibrate model estimates using annual district level pediatric incidence between 2016 and 2023.

TBS-EP461 The iron-vitamin D axis in tuberculosis: Hepcidin modulation as a target for precision host-directed therapy

S.P. Purwanto,[1,2] [1]East Java Provincial Health Office, Communicable Disease, Surabaya, Indonesia, [2]Prince of Songkla University, Epidemiology, Hat Yai, Thailand
e-mail: satiti.palupi@yahoo.co.id

Objective: Iron deficiency anemia (IDA, ~53%) and vitamin D deficiency (VDD, >70%) commonly co-occur in tuberculosis (TB), worsening treatment outcomes and mortality. Inflammatory hepcidin elevation restricts iron from *Mycobacterium tuberculosis* (Mtb), yet induces anemia of inflammation (AI). Vitamin D transcriptionally suppresses hepcidin (HAMP), offering a dual-acting immunometabolic intervention point.
Methods: We conducted a structured analysis of 72 studies including:
• Preclinical models (β2m-KO mice, C3HeB/FeJ granulomas)
• 12 clinical RCTs (vitamin D and iron supplementation)
• Spatial transcriptomic datasets from granulomatous lesions
• AI-driven cytokine network meta-analysis
• Machine learning (clustering, regression) to model micronutrient thresholds predictive of TB outcomes.
Key Findings:
1. Vitamin D suppressed *hepcidin* expression (↓32%, p<0.01) and upregulated ferroportin, enhancing macrophage iron efflux (↑1.8-fold, *p*=0.003).
2. Combined lactoferrin + vitamin D reduced *Mtb* burden 1.5-log (p<0.001) in iron-overloaded macrophages.
3. ML identified serum 25D >50 nmol/L + hepcidin <13.2 nmol/L as predictive of reduced TB progression (aHR=0.38; 95% CI 0.22–0.66) in high-anemia cohorts.
4. VDR TaqI 'tt' genotype carriers showed accelerated sputum conversion with vitamin D (aHR=1.7; 95% CI 1.2–2.4).

Conclusions & Vision: Modulating the vitamin D-hepcidin-ferroportin axis concurrently restricts *Mtb* iron access and ameliorates AI. We propose:
• **Precision trials**: Genetically stratified vitamin D supplementation (VDR/DBP screening)
• **HDT development**: Clinical evaluation of lactoferrin + vitamin D analogs
• **Policy integration**: Adoption of 25D/hepcidin thresholds in high-anemia settings.

TBS-EP464 Research on patients with NTM lung disease accompanied by anxiety or depression and related risk factors

X. Shi,[1] W. Sha,[1] X. Pan,[2] [1]Tongji University Shanghai Pulmonary Hospital, Shang Hai, China, [2]Shanghai Mental Health Center Affiliated to Shanghai Jiao Tong University School of Medicine, Shang Hai, China
e-mail: yisheng_tanxi@sina.com

Objective: To explore the relationship between nontuberculous mycobacterial (NTM) lung disease and anxiety and depression, as well as the related risk factors for NTM lung disease accompanied by anxiety and depression.
Methods: A total of 314 patients with NTM lung disease who visited Shanghai Pulmonary Hospital from October 2019 to October 2021 were designated as the study group, while 308 patients with pulmonary tuberculosis were designated as the control group. The Self-Rating Anxiety Scale (SAS) and Self-Rating Depression Scale (SDS) were used to assess the anxiety and depression symptoms of the patients. The prevalence rates of anxiety and depression, demographic characteristics, living environment, pet ownership, smoking, drinking, tuberculosis history, recurrent bronchiectasis history, physical complications, fever, cough, chest pain, and anemia were compared between the two groups.
Results: The prevalence of anxiety in patients with NTM lung disease was 21.3%, and the prevalence of depression was 29.6%. Multivariate logistic regression analysis revealed that autoimmune diseases (aOR, 7.48; 95% CI, 1.12-50.05) and chest pain (aOR, 2.35; 95% CI, 1.10-4.99) were risk factors for anxiety in patients with NTM lung disease. Being married (aOR, 4.84; 95% CI, 1.17-19.95), living in a dark and damp environment (aOR, 5.92; 95% CI, 1.62-31.65), chest pain (aOR, 2.29; 95% CI, 1.16-4.52),

and anemia (aOR, 2.31; 95% CI, 1.21-4.43) were risk factors for depression in patients with NTM lung disease. The AUC of the ROC curves were 0.755 and 0.702, respectively.

Conclusion: Patients with NTM lung disease are at a higher risk of developing anxiety or depression. There are differences in demographic and clinical characteristics between NTM lung disease and pulmonary tuberculosis patients. Autoimmune diseases and chest pain are related to anxiety in patients with NTM lung disease, while chest pain and anemia are related to depression in patients with NTM lung disease.

TBS-EP467 Reasons for refusal of TB preventive treatment uptake by eligible contacts of TB patients in high TB burden settings

S. Faisal,[1] K. Farough,[1] A. Rab,[2] A. Abbas,[3] R. Farrukh,[1] H. Mahmood,[4] [1]Greenstar Social Marketing, TB Program, Islamabad, Pakistan, [2]Greenstar Social Marketing, Health Services, Karachi, Pakistan, [3]Greenstar Social Marketing, TB Program, Lahore, Pakistan, [4]Integral Global, Islamabad, Pakistan e-mail: sobiahina@gmail.com

Background: One fourth of the global population is infected with tuberculosis (TB). UNHLM sets the target to provide TB preventive treatment (TPT) to 30 million infected people from 2023-27. Contrary to high commitment, only 3.2 percent of eligible household (HH) contacts started TPT in Pakistan during 2023(GTB Report 2024). Reaching TB contacts, is a programmatic challenge in resource limited and high TB burden countries. This situation gets worse when contacts refuse to take TPT despite of free services. This paper analyses the reasons for refusal of TPT uptake.

Methodology: A cross-sectional descriptive study was conducted involving HH contacts (who refused to take TPT) of bacteriologically confirmed TB patients diagnosed between November 2024 to February 2025 in Lahore, Rawalpindi and Peshawar. Among these, 429 individuals responded to surveyors. Data was collected through pre-tested structured questionnaire and analysed using SPSS version 26.

Results: Mean age of respondents was 39.83 years (SD 14.03), males 283 (66%) and females 146 (34%). Most of the respondents were parents (33%) followed by siblings (24%) and others. Reasons for refusal were, limited perception of susceptibility and severity among 186 (43%) contacts while barriers to health seeking included fear of TPT drugs & side-effects among 105 (24%), stigma among 74 (17%) and operational challenges among 64 (15%). The reasons of refusal were significantly associated with relation of respondent with TB patient (0.010) and the income status (0.017). Age was also significantly related with reasons of refusal; procedural reasons were more among older people and medicine fear were commoner among younger people. Lack of trust in TPT was significantly higher among uneducated (p=0.015) and people in low-income group (0.041).

Indicators	Sub-indicators	n	
	Total	429	
Sex	Male	283	66%
Age	Mean	39.83	SD±14.03
Education	No formal education	55	13%
Income (per month)	No income source	155	36%
Reasons for refusal	Lack of trust in the need for TPT	186	43%
	Fear of TPT drugs and their side effects	105	24%
	Stigma	74	17%
	Operational challenges	64	15%

Conclusion: Impercipient understanding of infected community about the TB infection and treatment requirement is the major barrier for TPT and may be addressed through advocacy and communication with relevant stakeholders.

TBS-EP470 Isolation of non-tuberculous mycobacteria (NTm) from household water of patients with NTM pulmonary disease

X. Shi,[1] W. Sha,[1] [1]Tongji University Shanghai Pulmonary Hospital, Shang Hai, China e-mail: shfksw@163.com

Background: Evidence collected over the past few decades has confirmed that NTM is a normal resident of an area, including various environments including soil and water sources. There is some evidence that susceptible individuals maybe infected from drinking water in their own homes.Understanding the link between household water sources and NTM pulmonary disease is crucial for developing targeted interventions and reducing the burden of this increasingly prevalent disease.

Design/Methods: To examine the prevalence of mycobacteria in household water, 500 mL water samples and swabs were collected from all taps of 19 patients' homes. The amplification of mycobacterial 16SrRNA with bacteriological identification was as a protocol to discriminate mycobacterial isolations from non- mycobacterial isolations. The 570bp 16SrRNA amplicon was sequenced and used to define mycobacterial species.

Results: The mycobacteria isolated from clinical samples from 19 patients included M. intracellulare, M. avium, M. abscessus, and M. kansasii. NTM isolated from household water of patients included M. avium (1 case), M. abscessus (2 cases), M. kansasii (8 cases), M. gordonae (1 case), M. gilvum (1 case), M. fortuitum (1 case), M. porcinum (1 case). M. abscessus, M. kansasii, and M. avium caus-

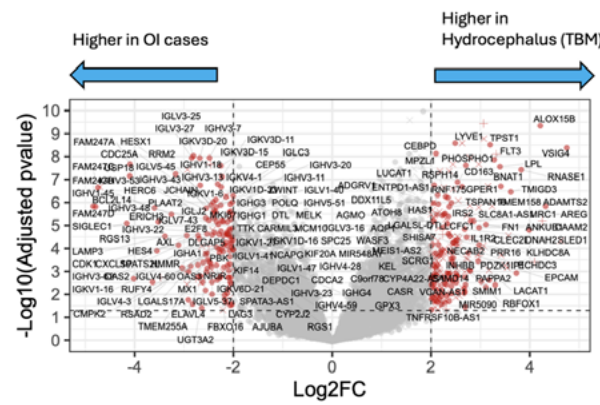
ing human disease were isolated from household water. Though M. intracellulare was the predominant species isolated from patients with NTM pulmonary disease, it wasn't found in household water. In addition,
our results revealed that NTM preferentially colonize in biofilm/sediment (75% of positive growths were from tap swab samples), indicating the significance of finding specific NTM species in household water in relation to the patients'conditions, or the lack of correlation between M. intracellulare in patients and its absence in household water.
Conclusions: The isolation of pathogenic NTM species from household water underscores the critical role of water hygiene in preventing NTM pulmonary disease and highlights the need for targeted public health strategies.

TBS-EP476 Substantial derangement in transcriptomic pathways seen in children with tuberculous meningitis and hydrocephalus

K. Madon,[1] C. Dunican,[1] N. Chegou,[2] R. Solomons,[3] J. Seddon,[1,3] M. Kaforou,[1] [1]Department of Infectious Disease, Imperial College London, London, United Kingdom of Great Britain and Northern Ireland, [2]South African Medical Research Council Centre for Tuberculosis Research, Biomedical Research Institute, Division of Immunology, Faculty of Medicine and Health Sciences, Stellenbosch University, Cape Town, South Africa, [3]Department of Paediatrics and Child Health, Stellenbosch University, Cape Town, South Africa
e-mail: k.madon@imperial.ac.uk

Background: Tuberculosis Meningitis (TBM) is the most severe form of tuberculosis (TB) disease. Even with early diagnosis and treatment the fatality rate in children is 20%, with 50% of survivors left with permanent neurological disabilities. Prognosis is worsened by complications from infarctions and hydrocephalus. Limited knowledge about the pathogenesis mechanisms of TBM infarction and hydrocephalus in children has hampered the identification of new therapeutics resulting in this high mortality rate.
Methods: Gene expression (RNA-seq, whole blood) data were analysed from a retrospective cohort of 27 children recruited from South Africa, 18 children with TBM, and 9 symptomatic controls. The gene expression was compared between these two groups as well as the subgroups of children with TBM with and without hydrocephalus and infarctions.
Results: Preliminary results showed 2367 differentially expressed genes (DEGs) between children with TBM and symptomatic controls. 4568 DEGs were found when comparing just the hydrocephalus subgroup to symptomatic controls (Figure 1).
Subsequent GO biological process analysis of both these genes sets revealed them to be largely related to B-cell mediated immunity and complement activation. When comparing the hydrocephalus subgroup to the non-hydrocephalus group, 79 DEGs involved in neutrophil activation and degranulation were found. No DEGs were found when comparing the infarction and non-infarction subgroups.

Figure 1: Volcano plot demonstrating differentially expressed genes between children with tuberculous meningitis and hydrocephalus and symptomatic controls



Discussion: Children with TBM and hydrocephalus appear to have substantial differences in the underlying biological pathways compared to symptomatic controls. This could have implications for understanding of the biological mechanisms responsible for TBM complications that worsen prognosis in children.

TBS-EP479 Adherence to isoniazid preventive therapy and its associated factors among HIV patients receiving treatment in five districts in Ghana

M.P. Kwabla,[1] A.S. Muntawakil,[1,2] M.A. Hamidu,[1,3] A. Appiah-Agyei,[1,4] M. Djan,[1,5] M. Muhammed,[1,6] G. Kye-Duodu,[1] F. Baiden,[1] [1]Department of Epidemiology and Biostatistics, Fred N. Binka School of Public Health, University of Health and Allied Sciences, Ho, Ghana, Hohoe, Ghana, [2]Nkoranza South Municipal Health Directorate, Nkoranza, Ghana, [3]Akwapim South Municipal Health Directorate, Aburi, Ghana, [4]Assin Foso Municipal Health Directorate, Assin Foso, Ghana, [5]Tarkwa Nsuaem Municipal Health Directorate, Tarkwa, Ghana, [6]Sekyere Afram Plains District Health Directorate, Drobonso, Ghana
e-mail: mkwabla@uhas.edu.gh

Background: Isoniazid Preventive Therapy (IPT) is an essential intervention for reducing the risk of tuberculosis (TB) infection among individuals living with HIV. Despite its proven benefits, adherence rates remain suboptimal in many settings. We assessed adherence to isoniazid preventive therapy and identified its associated factors among HIV patients receiving treatment in five districts in Ghana.

Methods: We used ART clinic records to randomly select HIV-positive adults who have been on IPT for at least one month for inclusion in the study. The contact information of the selected participants was used to trace them to their homes for interviews, while those who were due for ART visits at the time of the study were interviewed at the health facilities. Descriptive statistics provided summaries of adherence rates, while logistic regression helped identify associated factors of IPT adherence. STATA 17 software was used for the analysis.
Results: In the 1,265 HIV-positive adults studied, the mean age was 45 years (±22.5), with females being in the majority, 784 (62%). Seven hundred (66.1%) adhered to their IPT regimen, 956 (74.8%) correctly identified IPT's role in preventing TB in HIV patients, and 62.9% had a good level of knowledge of IPT. Barriers to adherence included side effects (389; 30.8%), difficulty in taking IPT alongside ART (358; 28.3%), long clinic waiting times (204; 16.1%), medication stockouts (262; 20.7%), and transport costs (305; 24.1%).
Being older than 50 years [AOR=0.58 (CI: 0.4–0.9), p=0.007], having had basic education [AOR=0.45 (CI: 0.3–0.7), p<0.001], being self-employed [AOR=0.74 (CI: 0.6–1.00), p=0.049], and level of IPT knowledge [AOR=2.17 (CI: 1.6–2.9), p<0.001] were significantly associated with IPT adherence.
Conclusion: IPT adherence was suboptimal when compared to the national target of 90%. Addressing medication stockouts and enhancing patient education could improve adherence.

TBS-EP482 Prospective prediction of TBAJ-876-PaL phase 2 clinical outcomes in NC-009 trial via a multi-model framework

E. Yang,[1] N. de Castro,[1] R.C. van Wijk,[1] E. Nuermberger,[2] R.M. Savic,[1] [1]University of California, San Francisco, San Francisco, United States of America, [2]Johns Hopkins University School of Medicine, Baltimore, United States of America
e-mail: eunsol.yang@ucsf.edu

Successful preclinical-to-clinical translation can accelerate development of safer, more effective tuberculosis regimens. Here, we leveraged a multimodal model-based framework to prospectively predict clinical outcomes of the promising diarylquinoline TBAJ-876, in combination with pretomanid and linezolid (TBAJ-876-PaL), in Phase 2 NC-009 trial (NCT06058299), ahead of trial read-outs. Analyses followed a pre-specified plan (v1.0, 2025-03-11), locked prior to availability of trial results.
We integrated translational tools incorporating TBAJ-876 preclinical and Phase 1 data with real-world patient phenotype evidence from clinical data on bedaquiline (B)-Pa-backbone regimens used as a proxy for TBAJ-876-PaL.
First, we quantified mouse exposure-response relationship by modeling individual contributions of TBAJ-876 and its active metabolite, TBAJ-876-M3, to bacterial colony-forming unit (CFU) decline.
Second, to align bacterial burden measures between preclinical and clinical settings, we utilized time-to-positivity (TTP)-CFU paired data across eight trials to convert baseline TTP from NC-009 to CFU for simulations.
Third, we predicted clinical responses to 25, 50, and 100 mg of TBAJ-876 with PaL by using mouse exposure-response, informed by clinical pharmacokinetic model, species-specific protein binding adjustments, and trial design.
Finally, to consider clinical features not reflected in translational models, we applied one-week delay for participants with bilateral cavitation and/or older age, based on phenotype-specific culture conversion profiles from previous trials. BPaL clinical outcomes were predicted similarly.
Predictions indicated clear dose-response for TBAJ-876-PaL, measured by time to stable culture conversion through 2 months, with a slow onset of dose-dependent separation becoming apparent only in the second month of treatment. TBAJ-876 at 100 mg with PaL was predicted to outperform BPaL.
Our framework integrated available data and knowledge to enhance reliability of clinical translation and enabled prospective prediction of TBAJ-876-PaL outcomes in NC-009 trial. Once validated, this approach will offer a leading model to inform dose selection and treatment optimization before trials, advancing development of novel tuberculosis regimens.

TBS-EP485 Implementation of TPT with shorter regimens: Experience from Bangladesh

R.J. Khan,[1] A. Rahman,[2] N. Uddin,[3] Z. Nasreen,[4] Z. Kabir,[4] J. Chakaya,[5] [1]National Tuberculosis Control Program Bangladesh, Ministry of Health & Welfare, Dhaka, Bangladesh, [2]Shaheed Ahsanullah Master 250 beded General Hospital, Directorate General of Health Services, Dhaka, Bangladesh, [3]Directorate General of Health Services, Ministry of Health & Family Welfare, Dhaka, Bangladesh, [4]Directorate General of Health Services, Dhaka, Bangladesh, [5]Liverpool School of Tropical Medicine., Nirobi, Kenya
e-mail: rifat.jahan1491@gmail.com

Bangladesh is one among the 30 high TB burden countries. The National TB Control Programme in Bangladesh has achieved a TB treatment coverage and treatment success rate at 82% and 95% respectively.
However, TB chemo-prevention had lagged behind with low coverage and low treatment completion rates among TPT eligible people. NTP Bangladesh set out to scale up

TPT implementation across the country to redress this programmatic constraint. Eros scaled up in 64 districts in 2022 covering throughout the country. From 2021 we initiated efforts to scale up TPT among eligible persons across the country. Using ACF and TB -IPC as entry points for TPT. We targeted House hold contacts of Pulmonary bacteriologically Confirm TB cases of all age group including children under five, PLHIV, people living with diabetes and other TB vulnerable populations for TB screening.

To enhance coverage of TB screening for the identified TB at risk populations NTP developed and implemented interventions for community engagement and behavior change and communication. People screening negative for TB were offered TPT using WHO recommended shorter regimens and supported to complete treatment.

The table below shows the results of the interventions that the National TB Control program Bangladesh implemented to scale up TPT.

Year	TPT NSP Eligible	PF target- N (% of NSP eligible)	Achievement -N (% of PF target)
2022	703931	133855 (19.01%)	153938 (115%)
2023	729553	149152 (20.44%)	165625 (111%)
2024	749208	168011 (22.42%)	177972 (105%)

We achieved a TT completion rate more than 96.00%. TPT was generally safe with no grade 3/4 adverse events observed.

Conclusion: While TPT implementation among healthy individual is very challenging, concerted efforts with multiple supportive interventions can lead to a successful implementation of this programmatic tool. This intervention can support efforts to decrease TB incidence in Bangladesh.

TBS-EP488 Empowering National TB Control Program through artificial intelligence-enhanced portable X-ray deployment in Bangladesh

R.J. Khan,[1] A. Rahman,[2] M. Rosenmoller,[3] N. Uddin,[2] Z. Kabir,[4] Z. Nasreen,[2] [1]National Tuberculosis Control Program Bangladesh, Dhaka, Bangladesh, [2]Directorate General of Health Services, Dhaka, Bangladesh, [3]DELFT IMAGING, Hertogenbosch, Netherlands, [4]Directorate General of Health Services, Ministry of Health & Family Welfare, Dhaka, Bangladesh
e-mail: rifat.jahan1491@gmail.com

Background: Tuberculosis remains a leading public health concern in Bangladesh. Despite national efforts, early detection and comprehensive screening remain challenging, especially in remote and underserved areas. In response, NTP of Bangladesh, in collaboration with SR and Delft Imaging, has been leveraging AI-enabled portable X-ray technologies to scale up and decentralize TB screening.

Objective: This initiative aims to evaluate the implementation and operational outcomes of AI-powered portable X-ray units across 26 strategically selected districts, improving TB case finding through technological innovation.

Methods: Since January 2023, portable X-ray units integrated with AI-based diagnostic support tools (e.g.,Delft Light, Delft CAD4TB, Qure.ai software) have been deployed in high-risk and hard-to-reach areas, including eight districts in Rajshahi and Rangpur, 3 hill tracts of Chattogram, and selected urban and rural districts across Sylhet, Barishal, Narsingdi, and Dhaka. Both Delft and Fuji X-ray machines have been equipped with AI software licenses. AI algorithms automatically analyze chest radiographs to detect TB-like abnormalities, supporting frontline health workers in triaging presumptive TB cases.

Results: From Jan-Dec 2024, the system has facilitated extensive community-level screening, contributing to a rising quarterly trend in TB detection. This digital innovation ensures efficient diagnosis where skilled radiologists are not available. Challenges such as equipment failure, lack of technologists, and energy constraints were mitigated through rapid maintenance, solar backup systems, and logistics support. As of now, 24 AI-equipped X-ray units are in active operation, strategic MoU between NTP with SR has been extended through 2026 to scale up these efforts.

Conclusion: Integration of Artificial Intelligence into TB screening workflows via portable X-rays marks transformative step in achieving early detection at scale. This model of decentralized, technology-driven case finding demonstrates significant promise in high TB burden settings. It underscores the potential of AI not just as a diagnostic aid but as a catalyst for broader health system innovation.

TBS-EP494 Ten years of tuberculosis treatment outcomes in North Africa: A systematic review and meta-analysis

M. Belkhir,[1] [1]University of Tripoli, Tripoli, Libya
e-mail: Montahabelkhir2002@icloud.com

Background: Tuberculosis (TB) continues to pose a significant public health challenge across North Africa, with treatment outcomes varying widely between countries. Despite global progress in TB control, the region experiences persistent difficulties including inconsistent cure rates, suboptimal treatment adherence, and increasing rates of drug-resistant TB. These issues are further compounded by political instability and limited healthcare resources in some areas.

This study aims to systematically review and analyze TB treatment outcomes across North African countries including Libya, Tunisia, Algeria, Morocco, Egypt, and Sudan, identify regional disparities and factors influencing treatment success. Outcomes of interest include cure rates, treatment completion, failure, default, and mortality.

Methods: This systematic review is being conducted following PRISMA guidelines. Studies are being identified through comprehensive searches of PubMed, Scopus, and Web of Science, targeting publications from January 2015 to May 2025. Eligible studies report treatment outcomes for TB patients in the specified countries. Data extraction and quality assessment are currently underway.

A meta-analysis using a random-effects model will be performed to estimate pooled treatment outcomes, and subgroup analyses will explore differences by country, TB type (e.g., drug-sensitive vs. drug-resistant), and exposure to conflict or instability.

Preliminary Observations: Early screening suggests significant disparities in TB treatment success across the region. Drug-resistant TB cases and populations in conflict-affected areas appear to face worse outcomes, indicating structural barriers to effective care and follow-up.

Conclusions: This ongoing research will provide a comprehensive overview of TB treatment outcomes across North Africa and identify key gaps in current national programs. Findings are expected to support evidence-based policymaking and inform regional strategies for improving TB control. Final results and recommendations will be presented at the conference in November 2025.

Keywords: Tuberculosis, North Africa, Treatment outcomes, Systematic review, Meta-analysis, Drug resistance

TBS-EP497 Impact of alternative latent-infection progression rates on modelled tuberculosis transmission

H. Cui,[1] Z. Wang,[1] Y. Xing,[1] L. Qin,[1] K. Ouyang,[1] T. Li,[2] Y. Zhao,[2] Z. Jia,[1] [1]Department of Global Health, School of Public Health, Peking University, Beijing, China, [2]Chinese Center for Disease Control and Prevention, Beijing, China
e-mail: wangzhq@bjmu.edu.cn

Background Uncertainty in the speed with which people with latent Mycobacterium tuberculosis infection progress to active disease is a major driver of variance in global burden projections.

Methods We developed an integrated transmission framework linking natural-history, drug-resistance, diagnostic and post-TB disease sub-models. The slow-progression rate (γ_s= 0.000594 per year) was fixed, while two published fast-progression (γ_f) hypotheses were compared: 0.0826 per year (Scenario A) and 0.955 per year (Scenario B). Model was calibrated to total TB incidence, deaths and rifampicin-resistant TB (RR-TB) incidence of China published by WHO.

Results Scenario A reproduced historical trends (R^2= 0.95 for total TB incidence, 0.99 for incident RR-TB incidence, 0.82 for TB deaths). Scenario B fitted less well for total TB incidence (0.58) and deaths (0.58) but comparably for RR-TB incidence (0.96).

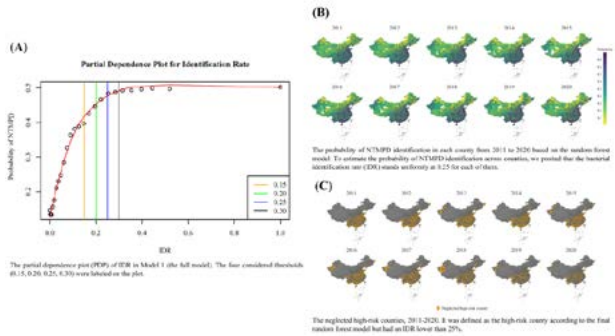
The posterior mean force of infection (λ) in 2023 was 2.35 per year (95 % credible interval [CrI] 1.16~3.58) under Scenario A versus 6.03 per year (95 % CrI 3.89~16.98) under Scenario B.

Conclusion Even apparently well-fitting TB models can diverge markedly when latent-to-active progression is weakly constrained. Generating empirical data on latent infection progression rates should therefore be prioritized to strengthen the evidence base supporting the End TB Strategy.

TBS-EP500 Eco-climate and socioeconomic determinants of non-tuberculous mycobacterial pulmonary diseases among notified TB cases in China: Observational and modelling study

H. Cui,[1] T. Li,[2] Y. Xing,[1] J. Zhang,[1] Y. Zhao,[2] Z. Jia,[1]
[1]Department of Global Health, School of Public Health, Peking University, Beijing, China, [2]Chinese Center for Disease Control and Prevention, Beijing, China
e-mail: litao1@chinacdc.cn

Objectives: To determine the prevalence of non-tuberculous mycobacterial pulmonary disease (NTMPD) in patients presumed to have pulmonary tuberculosis in China, and to assess the influence of ecological, climatic, and socioeconomic factors on the identification of NTMPD using random forest models.
Design: Observational study and modelling analysis.
Methods: The spatiotemporal distribution of NTMPD among registered TB cases in China from 2011 to 2020 was analyzed. Joinpoint regression models were used to explore temporal trends in NTMPD prevalence and their spatial heterogeneity. A random forest model was applied to assess the effects of ecological, climatic, and socioeconomic factors on NTMPD identification.
Data sources: National TB Information Management System (TBIMS).
Results: NTMPD cases were concentrated in the eastern and southeastern coastal areas of China. An overall decline in the NTMPD prevalence was observed (AAPC = -1.64%, 95% CI: -2.76% to -0.51%), though with notable spatial heterogeneity. The random forest analysis identified annual average temperature, GDP, and water coverage area as key predictors of NTMPD identification. A total of 573 counties still remained classified within the neglected high-risk category in 2020.



Conclusion: Despite the overall decrease in NTMPD identification in China, spatial heterogeneity and under-identification in high-risk counties highlight the need for improved bacterial identification and targeted public health interventions.

TBS-EP503 Trends in tuberculosis detection using GeneXpert in a rural Ghanaian district: A six-year retrospective analysis (2019–2024)

E. Hanu,[1] R. Wurapa,[2] [1]University of Health and Allied Sciences, F.N. Binka School of Public Health, Hohoe, Ghana, [2]Ghana Health Service, Nkonya, Ghana
e-mail: medeyram@gmail.com

Background: The GeneXpert MTB/RIF assay has improved tuberculosis (TB) diagnosis globally, but only few rural settings in West Africa have published data on long-term diagnostic trends. This study presents a six-year retrospective analysis of TB testing using GeneXpert in Biakoye District, Ghana, assessing test volume, MTB positivity rates, and rifampicin resistance detection from 2019 to 2024.
Methods: We conducted a retrospective review of GeneXpert test records from the Biakoye District TB program for the period January 2019 to April 2024. Data extracted included the number of tests conducted, MTB-positive results, and rifampicin resistance status. Smear microscopy data were unavailable. Descriptive analysis was used to assess trends over time.
Results: A total of 3,243 GeneXpert tests were conducted during the review period. Annual test volume ranged from 35 in 2020 (likely reflecting COVID-19 disruptions) to 1,220 in 2024, indicating improved programmatic scale-up. MTB positivity rates varied by year: 13.0% (2019), 100% (2020, n=35), 8.5% (2021), 13.6% (2022), 19.1% (2023), and 5.8% (2024), with an average positivity rate of 13.3%. Across all six years, no rifampicin resistance was detected. The highest number of confirmed TB cases (n=98) occurred in 2023.
Conclusion: We found increasing diagnostic coverage and fluctuating positivity rates for TB in a rural Ghanaian district using GeneXpert. The absence of rifampicin resistance detection over the study period may reflect low prevalence or limited detection capacity. The steep rise in 2024 testing volume highlights improved surveillance capacity.
Further studies to explore demographic patterns and confirm rifampicin susceptibility through complementary methods are recommended. Strengthening laboratory capacity and ensuring continuous GeneXpert access will be key to sustaining diagnostic gains in similar settings.
Keywords: Tuberculosis, GeneXpert, rifampicin resistance, rural Ghana, diagnostic trends, molecular diagnostics, TB surveillance

TBS-EP506 Fate of TB treatment among the patients who remained bacteriologically positive after two months of anti-TB drugs

S. Faisal,[1] K. Farough,[1] A. Shabbir,[2] G. Haider,[1] A. Rab,[3]
[1]Greenstar Social Marketing, TB Program, Islamabad, Pakistan, [2]National TB Control Program, Islamabad, Pakistan, [3]Greenstar Social Marketing, Health Services, Karachi, Pakistan
e-mail: sobiahina@gmail.com

Tuberculosis is the leading cause of mortality worldwide. Pakistan is the 5th high burden country with 686,000 annual incident cases. Although the treatment success rate of Pakistan is higher than global average, still 21,904 TB patients could not complete the treatment successfully during 2023. This paper evaluated the factors associated with unsuccessful treatment outcome of TB disease with special focus on those who remained sputum smear microscopy (SSM) positive after 2 months of treatment.

Methodology: This retrospective cross-sectional study evaluated the data of TB patients who started treatment at public private mix settings of 28 districts of Pakistan from July 2021 till March 2024.

The study included data of patients who had pulmonary TB, TB bacilli was confirmed on SSM or Gene Xpert, had valid results of 2 months follow-up (FU) SSM and the treatment outcome was declared. The study excluded patients whose information was missing, outcome was not declared or there was change in regimen.

Results: During the study period 11,228 patients started TB treatment with mean age 39.09 (SD± 18.66), and male to female ratio was 53:47. First FU SSM was positive among 319 patients (2.8%).

FU positivity was significantly higher among; male (3.2%) (P=0.012), treated after loss to FU (11.1%) and failure (6.3%) ($p < 0.001$), higher bacterial load at the beginning of treatment ($p < 0.001$) and with increase in age (p=0.020). FU SSM positivity was significantly associated with unsuccessful treatment outcome, i.e 9.7% vs 1.6% among FU SSM positive and negative patients ($p < 0.001$). Failure rate was 6.3% and 0.4% and death rate was 2.5% and 0.7% among the FU SSM positive and negative respectively ($p < 0.001$).

Indicators	Sub-indicators	Follow-up Positive n (%)	Follow-up Negative n (%)	P Value
Total Patients		319(2.8%)	10909(97.2%)	
Sex	Female	129(2.4%)	5193(97.6%)	0.012
History of Treatment	New	283(2.8%)	9848(97.2%)	<0.001
	Treatment after failure	2(6.3%)	30(93.8%)	
	Treatment after loss to follow-up	9(11.1%)	72(88.9%)	
Grading of SSM	Scanty	11(1.8%)	596(98.2%)	<0.001
	1+	76(2.2%)	3426(97.8%)	
	2+	63(2.9%)	2139(97.1%)	
	3+	141(5.7%)	2318(94.3%)	

Conclusion: Follow-up positivity is associated with social and clinical determinants and a strong predictor of treatment outcome and must be accounted for during treatment.

TBS-EP509 Physiotherapy management in tuberculosis patients with co-existing HIV infection: Challenges in immunocompromised care

E. Nakanwagi,[1] G. Wangolo,[2] [1]Uganda Allied Health and Management Sciences, Mulago, Kampala, Uganda, [2]Makerere University, Kampala, Uganda
e-mail: elizabethnakanwagi99@gmail.com

Background: The co-infection of tuberculosis (TB) and human immunodeficiency virus (HIV) presents a significant public health challenge, particularly low-resource settings where the burden of both diseases is high. Patients with TB-HIV co-infection experience physical impairments, including respiratory distress, debilitating fatigue, various musculoskeletal complications. Despite the critical role of physiotherapy in alleviating these conditions, its implementation in the care of immunocompromised patients remains inadequately explored.

This study aimed to examine the challenges and strategies in physiotherapy management of TB-HIV co-infected patients and to evaluate the effectiveness of current rehabilitation practices

Methods: A mixed-methods cross-sectional design was utilized, incorporating structured questionnaires administered to a sample of 25 TB-HIV co-infected patients and in-depth interviews conducted with 12 physiotherapists from selected healthcare facilities. Quantitively data was analyzed using descriptive statistics to identity prevalent symptoms and interventions, while qualitative responses were subjected to thematic analysis to uncover underlying challenges and strategies in physiotherapy practice.

Results: The findings revealed that a significant majority of patients reported experiencing fatigue (88%), shortness of breath (76%), and muscle weakness (64%). Physiotherapy interventions employed included pulmonary rehabilitation (68%) and strength training (56%).

However, physiotherapists identified several key challenges in their practice, including limited access to resources, difficulties in infection control, insufficient training in managing co-infected patients, and patient non- adherence attributed to fatigued and psychosocial distress.

Conclusion: Physiotherapy emerges as a crucial yet underutilized component of comprehensive care for TB-HIV co-infected patients. To enhance the effectiveness of physiotherapy interventions, it is essential to address barriers such as resource limitations, training gaps, and psychosocial challenges faced by patients. This can be achieved through the implementation of integrated, pa-

tient-centered approaches and robust policy-level support improving the overall management of immunocompromised individuals.

TBS-EP512 Can simple blood tests predict heart disease in patients with pulmonary tuberculosis? - The TB-HEART Study

M. Scopazzini,[1,2] A.S.V. Shah,[1] H. Ayles,[2,3] K. Shanaube,[4] A. Schaap,[2] E. Majonga,[1] D. Zenner,[5] L. Sigande,[2] B. Nyondo,[2]
[1]London School of Hygiene and Tropical Medicine, Department of Non-Communicable Diseases Epidemiology, Faculty of Epidemiology and Population Health, London, United Kingdom of Great Britain and Northern Ireland, [2]Zambart, Department of Clinical Research, Lusaka, Zambia, [3]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom of Great Britain and Northern Ireland, [4]Zambart, Lusaka, Zambia, [5]Queen Mary University of London, Wolfson Institute of Population Health, London, United Kingdom of Great Britain and Northern Ireland
e-mail: marcello.scopazzini1@lshtm.ac.uk

Background: Recent data suggest pulmonary tuberculosis (PTB) is associated with increased CVD morbidity, but mechanisms are poorly understood. In the TB-HEART study, we aimed to determine the burden of cardiac pathology in patients with PTB and explore the predictive value of cardiac and inflammatory biomarkers.
Methods: In a cross-sectional study design, we consecutively recruited outpatients with bacteriologically proven PTB in Lusaka, Zambia. All patients underwent detailed cardiovascular assessment including two-dimensional echocardiography, and blood draws to quantify myocardial injury (high-sensitivity troponin I [hs-cTnI]), myocardial remodelling (N-terminal pro-B-type natriuretic peptide [NT-pro-BNP]), and inflammation (C-reactive protein [CRP]).
The primary outcome was echocardiographic evidence of any cardiac pathology (pericardial effusion, at least mild left ventricular systolic dysfunction (LVSD) and/or evidence of constrictive physiology). We then quantified the distribution of hs-cTnI, NT-pro-BNP, and CRP and their association with prevalent cardiac pathology.
Results: Between November 1st 2023 and October 15th 2024, we recruited 252 participants with pulmonary TB [mean age 35.4 ± 11.1 years; 75.4% (n=190) = male; 28.9% (n=73) living with HIV (LWHIV)], of whom 240 completed echocardiography. Of these, 100/240 (41.7%) had evidence of cardiac pathology.
There was a statistically significant association between cardiac pathology and CRP [OR 1.63 (1.24-2.13) p<0.001 for each log-normal increase in value] and NT-pro-BNP [OR 1.53 (1.23-1.92) p<0.001 for each log-normal increase in value]. Mean hs-cTnI was not associated with cardiac pathology, nor were sex, BMI or HIV status. After adjusting for age and sex, CRP [OR 1.44 (1.08-1.92, p=0.01 for each log-normal increase in value] and NT-pro-BNP [OR 1.40 (1.09-1.80) p=0.007 for each log-normal increase in value] remained strongly associated with cardiac pathology.
Conclusions: Cardiac pathology was present in almost half our participants and was strongly associated with biomarkers of inflammation and myocardial remodelling. This may indicate a novel pathophysiological mechanism of disease linking TB and CVD.

	All participants n = 240	Participants without cardiac pathology 58.3%, n = 140	Participants with cardiac pathology 41.7%, n = 100	ORs (95% CI) for the association with cardiac pathology	p value*
Living with HIV, % (n)	29.6% (71)	28.6% (40)	31% (31)	0.84 (0.49-1.91)	0.93
BMI >18.5 kg/m²	52.1% (125)	55.7% (78)	47% (47)	1	
BMI <18.5 kg/m²	47.9% (115)	44.3% (62)	53% (53)	1.01 (0.57-1.81)	0.95
CRP, in g/dl (mean ±SD)	83 (±SD 68.3)	70.8 (±SD 61.1)	101 (±74.1)		
Lognormal distribution, in g/dl	3.96 (±1.12)	3.76 (±1.18)	4.29 (±0.92)	1.44** (1.08-1.92)	0.01
NT-pro-BNP, in pg/ml (mean ±SD)	276 (±SD 701)	183 (±SD 469.6)	407 (±SD 921)		
Lognormal distribution, in pg/ml	4.63 (± 1.30)	4.36 (±1.18)	5.02 (± 1.34)	1.40** (1.09-10.80)	0.007
hs-cTnI, in ng/ml (mean ±SD)	5.09 (±SD 0.83)	5.07 (±SD 0.57)	5.12 (± 1.1)		
Lognormal distribution, in ng/ml	1.62 (0.09)	1.62 (0.07)	1.62 (0.11)	1.34 (0.06-26.79)	0.85

*Table 1 - Age-and sex-adjusted odds ratios for the estimated associations between any cardiac pathology (presence of pericardial effusion, at least mild left ventricular systolic dysfunction, and/or constrictive physiology) and relevant indicators among 240/252 participants who underwent echocardiography. For CRP, the model contains 238 individuals with available blood test results, and for NT-pro-BNP and hs-cTnI, this is 240 individuals. **Log-transformed values for CRP, NT-pro-BNP and Troponin were used - the associated odds ratio are for each doubling of the biomarker value. Legend: *p values were derived from the Wald test.*

TBS-EP515 Threat beyond TB: Rising menace of NTM infections and the urgent need for accurate diagnosis

J. Turuk,[1] S. Pati,[1] S. Panda,[1] S. Rout,[1]
[1]ICMR-Regional Medical Research Centre, Bhubaneswar, Odisha, India, Bhubaneswar, India
e-mail: drjyotirmayeeturuk@gmail.com

Background: Incidence of non-tuberculous mycobacterial (NTM) infections is on rise globally and poses significant diagnostic and treatment challenges for tuberculosis. Most of them are resistant to anti-tubercular drugs and due to overlapping clinical manifestations with *M. tuberculosis*, NTM infections are often misdiagnosed as drug-resistant TB. NTM susceptibility to drugs varies from species to species and there is no specific regimen for treatment. In India, the true prevalence of NTM infections is unclear, with reported rates ranging from 2% to 10%. Therefore, accurate and rapid diagnosis of NTM is essential for appropriate antimicrobial therapy.
Methods: The study researchers in our lab have been investigating the incidence of the disease, standardizing various molecular methods for the identification of NTM isolates, and standardizing the drug susceptibility assay for clinical isolates.
Results: This five-year study (2019–2024) analysed 828 clinical samples for non-tuberculous mycobacteria (NTM) infections, finding an 8.1% incidence r. The majority of NTM cases were detected in males (65.7%) and adults aged 21–50. Higher positivity rates are found in pulmonary samples in comparison to extrapulmonary samples. The most frequently isolated species was *Mycobacterium intracellulare*, followed by *M. abscessus* and *M. fortuitum*. The present study confirmed regional variation in NTM species distribution, with higher cases found in coastal districts of Odisha, India.
Drug susceptibility testing (DST) showed species-specific resistance . *M. intracellulare* and *M. scrofulaceum* are found to be susceptible to amikacin and clarithromycin, while *M. fortuitum* and *M. abscessus* are resistant to the majority drugs.
Conclusion: The findings emphasize the need for species-level identification and precise antimicrobial treatment . Taking way forward the researchers are now comparing different molecular methods such as line probe assay, PRA hsp65 assay and next generation sequencing methods, to identify NTM species to find the most cost-effective method in resource constraint settings.

TBS-EP518 Genomic insights into *Mycobacterium tuberculosis* lineages and antimicrobial resistance profiles in three Canadian provinces

R. Singh,[1] C. Duncan,[2] E. Rea,[3] M. Richard-Greenblatt,[4] M. Sharma,[5] R. Long,[6] V. Hoeppner,[7] W. Wobeser,[8]
[1]Vaccine and Infectious Disease Organization, University of Saskatchewan, Saskatoon, Saskatchewan, Canada, [2]Ontario Public Health Laboratory, Toronto, Ontario, Canada, [3]Toronto Public Health, Toronto, Ontario, Canada, [4]The Hospital for Sick Children, Toronto, Ontario, Canada, [5]Public Health Agency of Canada, Winnipeg, Manitoba, Canada, [6]University of Alberta, Alberta, Canada, [7]University of Saskatchewan, Saskatoon, Saskatchewan, Canada, [8]Queen's University, Kingston, Ontario, Canada
e-mail: res498@mail.usask.ca

Tuberculosis (TB), caused by *Mycobacterium tuberculosis* (*Mtb*), remains a leading global health threat. Distinguishing reinfection from novel infection in recurrent TB is crucial for effective control, requiring high-resolution data. We employed Whole Genome Sequencing (WGS) on 153 *Mtb* sputum isolates from TB patients in Alberta, Saskatchewan, and Ontario, Canada.
Our analysis characterized genomic diversity, antimicrobial resistance (AMR) profiles, lineage identification, resistance mutation detection, and SNP-based analysis to infer evolutionary links. We observed diverse *Mtb* lineages, with Lineage 4 (Euro-American) predominating (n=74), followed by Lineage 3 (n=34), Lineage 2 (n=28), and Lineage 1 (n=15). The s-type was the most prevalent genotype within Lineage 4. One pair was classified as *M. orygis*. AMR was detected in 60 isolates, with high prevalence of isoniazid resistance (n=22), primarily associated with *katG* S315T and *fabG1* promoter mutations. Resistance-conferring mutations were also identified for streptomycin (n=20), rifampicin (n=9), ethambutol (n=5), ethionamide (n=2), and pyrazinamide (n=2). Eight isolates demonstrated co-resistance to both rifampicin and isoniazid.
When evaluating the relationship between lineage and resistance, most resistant isolates were associated with Lineage 1 (n=12), showing resistance to 24 drugs. This was followed by Lineage 2 (n=8), which exhibited resistance to 18 drugs; Lineage 4 (n=7), resistant to 14 drugs; and Lineage 3 (n=2), resistant to 4 drugs. The wet lab verified resistance in 29 isolates. Of the 29 cases, 16 were males over 24 years old, and 13 were females over 28. All occurred in individuals born abroad. This dataset shows that TB transmission is shaped by lineage distribution, drug resistance, and demographics.
In the future, SNP data and clinical records will be integrated to differentiate relapse from reinfection. The prevalence of Lineage 4 and multidrug-resistant strains highlights ongoing TB control challenges, emphasizing the vital role of WGS in real-time surveillance and public health strategies.

TBS-EP521 Transcriptomic profiles from animal hosts following infection with Mycobacterium bovis: A systematic review

E. Adams,[1] E. Suez,[2] H. Azami,[3] F. Quinn,[3]
L.C.M. Salvador,[4] [1]University of Georgia, Department of Infectious Diseases, Athens, United States of America, [2]University of Georgia/Institute of Bioinformatics, Department of Infectious Diseases, Athens, United States of America, [3]University of Georgia/Department of Infectious Diseases, Department of Infectious Diseases, Athens, United States of America, [4]University of Arizona/School of Animal and Comparative Biomedical Sciences, Tucson, United States of America
e-mail: lilianasalvador@arizona.edu

Introduction: Animal tuberculosis (aTB), caused primarily by *Mycobacterium bovis* (*M. bovis*), is a chronic zoonotic disease that affects a wide range of domestic and wild species. Understanding host–pathogen interactions at the molecular level is essential for developing improved control measures and diagnostic tools.

To better understand host responses to *M. bovis* infection, we conducted a systematic review of transcriptomic studies in infected animals.

Methods: This review followed the PRISMA guidelines. We searched PubMed, Web of Science, and BIOSIS databases for studies published between January 2007 and March 2024. Eligible studies involved natural or experimental *M. bovis* infection in any host species, followed by transcriptomic profiling using RNA-seq, microarray, or qRT-PCR. Reviews, meta-analyses, case reports, vaccine efficacy studies, and studies using BCG-only infection were excluded.

Results: The search identified 704 records; 263 remained after duplicate removal and 45 for eligibility. After screening and full-text evaluation, 22 studies met inclusion criteria. Early-stage infections (<48 hours post-infection) revealed upregulation of pathways associated with innate immunity, inflammation, endocytosis, and cell signaling (Table 1).

At mid-stage (~2 weeks post-infection), both pro- and anti-inflammatory cytokine responses were observed alongside adaptive immune activation. Late-stage responses (>4 weeks post-infection) predominantly involved adaptive immunity and tissue pathology.

Across studies, differentially expressed genes were largely driven by intracellular bacterial activity. However, no single gene was consistently expressed under comparable conditions across all studies.

Conclusion: Host transcriptomic responses to *M. bovis* infection vary across infection stages and study conditions.

However, metallopeptidase activity and anti-apoptotic gene expression emerged as recurring features and may represent potential biomarkers of *M. bovis* infection. Further research is needed to validate these targets.

Pathway	Differentially Expressed Genes
Innate Immunity & Inflammation	Upregulated: IL-18, IL-7, CSF3, CCL20, CSF2, NOS2, IL-1β, IL-23A, IL-6, CCL4, CXCL2, TNF-α, CCL8, CXCL11, IFN-γ, NFκB, IL-8, IL-12, FASLG, BCL2, IL-10, DDX58, OAS2, CASP8, CASP7, CXCL10, OAS1, PTX3, IL-17A, CCL5, IL-15, CCL1, CASP10
	Downregulated: CCL4, IL-8, IL-12, IL-6, FASLG, BCL2, IFN-γ, TNF-α, DFFA, AIFM1, CXCL6, IL-2, CSF2, IL-10, CCL3, PPBP, SPP1
Endocytosis and Trafficking	Upregulated: ANKRD17, ANTXR2, EHD4, KIF3A, EHD1, CLEC4E, LAMP3, MAPT, ATG5
	Downregulated: MAPT, AP1, SLC1A3, RAB42, SLC40A1, SLC546A3, SLC2A5, IGF2R, AP3B1, AP4M1, GGA1, ATPV0D2, ATP6V0A1, TAP2, SORT1, AP1B1
Cell Signaling	Upregulated: STAT1, C3AR1, CD244, GPNMB, EDN1, TLR2, TLR3, TRAF6, TRAF3, TICAM1, TICAM2, TAB2, TLR4, CD14, CXCR4, CCR5, CCR3, STAT2, TLR5, TLR10, CD40, ADRB3, CD80
	Downregulated: EDN1, ADORA3, S1PR1, VSTM2L, MYD88, PIK3IP1, GABBR2, TLR9, CCR3, TLR8, CCR1, CD14, CD38, CD55, CD36, FZD4, PTAFR, THBD, CCR1, PECAM1

Table 1: Major differentially expressed genes with known functions less than 48 hours post infection.

TBS-EP524 Assessment of awareness and knowledge of butchers on bovine tuberculosis in the Volta region of Ghana

I. Saliu,[1] [1]University of Health and Allied Sciences, Hohoe, Ghana
e-mail: sualaiddris@gmail.com

Background: Bovine tuberculosis (bTB) is a chronic infectious disease caused by Mycobacterium bovis, responsible for 143,000 new human cases and 12,300 deaths globally. Bovine tuberculosis poses significant risks to human health through the consumption of contaminated meat. Butchers, being in direct contact with animal carcasses, are at high risk of exposure.

This study aimed to assess the Awareness and knowledge of butchers in the Volta Region, Ghana, to identify gaps and challenges in disease management.

Methods: A cross-sectional study was conducted among 127 butchers in the seven districts in the Volta Region. Data were collected through interviews focusing on their awareness of bTB, knowledge of bTB, educational background, age, marital status, years of experience, and place of residence. The relationship between Knowledge of butchers and demographic characteristics was determined at a 5% significance level ($P < 0.05$)

Results: Out of 127 butchers interviewed, 71.6% had heard of bTB, mostly through work experience (96.7%), while only a minority cited formal education or media as sources of information.

Knowledge assessment revealed that 73.6% of butchers demonstrated good knowledge of bTB. Statistical analysis revealed that the district of residence was the main predictor of knowledge, with lower knowledge levels observed in Hohoe (33.3%) and Ketu South (50%), compared to Ho Municipal.

Other factors, such as educational level, years of experience, and marital status, were not significantly associated with knowledge in multivariate analysis.
Conclusion: The findings highlight overall awareness and knowledge of bTB among butchers are encouraging, however, reliance on informal workplace-based learning may limit the depth and accuracy of information, and also significant geographic disparities among butchers on knowledge of bTB is a major concern. Targeted education and training interventions are recommended to address these gaps and enhance bTB prevention and control in the meat industry.

TBS-EP527 Effectiveness of BPaL/BPaLM in central area of Taiwan

Y.-W. Huang,[1] W.-C. Huang,[2] W.-T. Yang,[3] C.-H. Shih,[4] C.-Y. Lin,[1] W.-W. Chen,[1] [1]Chang-Hua Hospital, Ministry of Health and Welfare, Changhua, Taiwan, [2]Taichung Veterans General Hospital, Taichung, Taiwan, [3]Taichung Hospital, Ministry of Health and Welfare, Taichung, Taiwan, [4]Nantou Hospital, Ministry of Health and Welfare, Nantou, Taiwan
e-mail: sweefa818@gmail.com

Background: All-oral treatment regimens that are more effective, shorter in duration, and have a more tolerable side effects, the six-month regimens all-oral BPaL (bedaquiline, pretomanid, and linezolid) and BPaLM (BPaL, and moxifloxacin), were recommended by the World Health Organization (WHO) in 2020 and 2022.
We aim to assess the treatment outcomes and adverse drug reactions of short-term regimens to drug-resistant tuberculosis (DR-TB) patients.
Method: A cohort of patients diagnosed with rifampicin-resistant or multidrug-resistant tuberculosis (RR/MDR-TB), exhibiting additional fluoroquinolone resistance, intolerance, or documented failure of prior second-line TB therapy, was treated with BPaL or BPaLM regimens between March 2021 and May 2025. Treatment outcomes and associated adverse events were systematically assessed.
Result: A total of 51 patients were included, 35 (94.6%) patients had successful treatment outcome, 14 patients ongoing treatment, and 2 (5.4%) patients died. The most common side-effects included 8 (21.6%) patients experienced gastrointestinal intolerance. As for the neurologic AEs, 1 (2.7%) patient had peripheral neuropathy with numbness in feet. Four (10.8%) patients developed Grade 3 anemia, 2 (5.4%) patients with QTcF prolongation was observed, and one patient 1 (2.7%) experienced elevated AST/ALT.
Conclusion: According to available data on tuberculosis treatment outcomes in Taiwan from 2007 to 2012—prior to the introduction of the BPaL regimen—among 692 patients diagnosed with MDR-TB treated with traditional regimen, 570 (82.4%) achieved successful treatment outcomes, 84 (12.1%) died, 18 (2.6%) treatment failure, and 20 (2.9%) were lost to follow-up.

AE	AE Patient (CTCAE Grade)	Action Required	SAE Patient (CTCAE Grade)	Action required
Gastrointestinal intolerance (nausea, vomiting, loss of appetite)	8 (Grade 2)	Supportive treatment	0	
Anemia	0		4 (Grade 3)	Reduced dosage of Linezolid (300 mg/day) EPO injection blood transfusion
Cardiac abnormalities (QTc prolongation)	2 (Grade 2)	Monitoring	0	
Liver toxicity (AST/ALT elevation)	0		1 (Grade 3)	Held medication for 2 weeks
Peripheral neuropathy	1 (Grade 2)	Stop Linezolid	0	

In patients treated with the BPaL/BPaLM regimen, when compared with the traditional regimen, the treatment rate(94.6%) is higher, death rate(5.4%) is lower and no treatment failure nor lose to follow-up. Although BPaL/BPaLM regimens may be associated with various adverse events, they can be effectively managed through proper monitoring, dose modifications, and supportive care.

TBS-EP530 Ibuprofen and acetylsalicylic acid as adjunctive to anti-tuberculosis treatment: Phase II clinical trial

C. Vilaplana,[1] Z. Waja,[2] N. Tukvadze,[3,4] T. Moloantoa,[5] L. Arias,[6] N. Gogichadze,[6,7] S. Vashakidze,[3,8] N. Martinson,[2,9] SMA-TB RCT team [1]Germans Trias i Pujol Research Institute & Hospital, Badalona, Spain, [2]Perinatal HIV Research Unit (PHRU), University of the Witwatersrand, Johannesburg, South Africa, [3]National Center for TB and Lung Diseases Georgia, Tbilisi, Georgia, [4]Swiss Tropical and Public Health Institute (SwissTPH), Allschwil, Switzerland, [5]Perinatal HIV Research Unit (PHRU), University of the Witwatersrand, Matlosana, South Africa, [6]Germans Trias i Pujol Research Institute, Badalona, Spain, [7]Universitat Autònoma de Barcelona, Bellaterra, Spain, [8]University of Georgia, Tbilisi, Georgia, [9]Johns Hopkins University Center for TB Research, Baltimore, United States of America
e-mail: cvilaplana@igtp.cat

We hypothesized that host-directed therapies (HDT) with anti-inflammatory effects could shorten tuberculosis (TB) treatment and improve outcomes when added to standard TB therapy. As part of the SMA-TB EU-funded project (GA847762), we conducted a Phase 2b randomized, double-blind, placebo-controlled trial (NCT04575519) to evaluate the efficacy and safety of two widely available, affordable, and well-tolerated non-steroidal anti-in-

flammatory drugs (NSAIDs) -acetylsalicylic acid (ASA) and ibuprofen (IBU)- as adjuncts to standard-of-care TB treatment in adults with pulmonary TB.
Between 2021 and early 2022, we screened 426 individuals and enrolled 221; 203 (179 drug-susceptible TB [DS-TB], 24 multidrug-resistant TB [MDR-TB]) were included in the final analysis. Participants were recruited at two South African sites (Soweto & Matlosana; n = 140) and one Georgian site (Tbilisi; n = 63). They were randomized in equal proportions to receive placebo (n = 67), ASA (n = 68), or IBU (n = 68) in addition to standard TB therapy. The trial was prematurely halted due to the COVID-19 pandemic and budget limitations.
Neither ASA nor IBU significantly reduced time to a 67 % reduction in a clinical TB score nor time to stable sputum culture conversion (primary endpoints). However, both drugs positively affected several secondary measures of treatment response, although effects varied across the cohort. In subgroup analyses, IBU conferred both short- and long-term clinical benefits in MDR-TB patients, and ASA promoted sustained cavity resolution in DS-TB. Both NSAIDs significantly decreased systemic inflammatory biomarkers during administration. Serious adverse event rates were comparable across all arms.
In conclusion, ASA and IBU did not improve primary clinical outcomes overall but demonstrated subgroup-specific benefits and anti-inflammatory activity. These findings support further investigation of personalized HDT strategies in TB. Alternative dosing regimens and other investigational anti-inflammatory agents warrant evaluation as potential HDT options to optimize patient-specific treatment.

TBS-EP533 Pathobionts and antimicrobial resistance in symptomatic people with and without tuberculosis

S. Moodley,[1] Z. Nkwanyana,[1] A. Okunola,[1] C. Kinnear,[2] N. Carstens,[2] C. Maus,[3] K. Broadbent,[3] R. Schlaberg,[3] R.M. Warren,[1] J. Metcalfe,[4] C.C. Marsh,[1] G. Theron,[1]
[1]Stellenbosch University, Cape Town, South Africa, [2]South African Medical Research Council Genomics Centre, Cape Town, South Africa, [3]Illumina,, San Diego, CA, United States of America, [4]University of California, San Francisco, CA, United States of America
e-mail: suventha@sun.ac.za

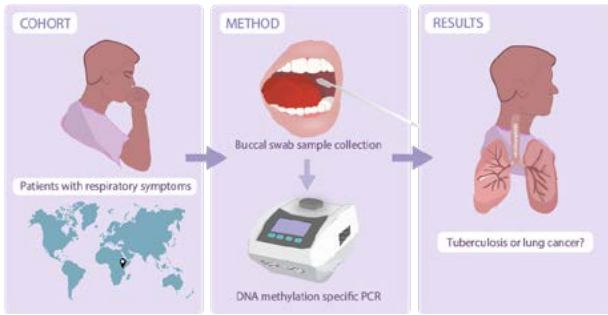
Tens of millions of symptomatic people are tested for tuberculosis (TB) annually yet a minority have TB. Most people without TB (non-TBs) have no further testing, leaving the underlying aetiologies unknown and missed opportunities to better integrate testing for other diseases within TB care cascades. These people, as well as those with TB, may have polymicrobial infections and antimicrobial resistance (AMR), another major public health issue.
We used the research Use Only Respiratory Pathogen ID/AMR panel (Illumina) to profile microbes and AMR markers in sputum of people cross-sectionally investigated for TB pre-treatment.
We found differences between non-TBs (n=238) and TBs (n=82). When TB groups were compared in people without HIV, non-TBs were *Rothia mucuilaginosa*- and *Moraxella catarrhalis*-enriched and TBs *Gemella Haemolysans-enriched. Rothia mucuilaginosa and Gemella Haemolysans* are normal flora but may be associated with disease in certain settings and *Moraxella catarrhalis* is frequently associated with respiratory disease.
Among non-TBs, the top three most abundant pathobionts were *Actinomyces graevenitz*ii, *Fusobacterium nucleatum* and *Ureaplasma murealyticum*, these are microbes frequently associated with disease. Non-TBs had a higher proportion of *s*ulfonamide AMR markers than TBs, whereas TBs had higher proportions of Lincosamide, Macrolide, Fluoroquinolone, Aminoglycoside, Isoniazid, Ethambutol, Para-Aminosalicylic Acid markers than Non-TBs.
This is study is one of the first to landscape potential pathogens in people without TB presenting to TB care in a high burden setting and identify alternative potential causes of their symptoms. This can inform diagnostic algorithms development and future studies on clinical significance.

TBS-EP536 Validation of a DNA methylation signature of active tuberculosis in the buccal mucosa using methylation-specific PCR

I. Öhrnberg,[1] L. Karlsson,[1] S. Sayyab,[1] A. Rahman,[1] J. Paues,[1] N. Kiprotich,[2] R. Tonui,[3] M. Lerm,[1] [1]Department of Biomedical and Clinical Sciences, Faculty of Medicine and Health Sciences, Linköping University, Linköping, Sweden, [2]Biochemistry and Clinical Chemistry, Moi University, Eldoret, Kenya, [3]Department of Pathology, Moi University, Eldoret, Kenya
e-mail: isabelle.ohrnberg@liu.se

Tuberculosis (TB) has a high mortality if left untreated but is curable with antibiotics. Distinguishing TB from lung cancer (LC) remains a significant clinical challenge, particularly in resource-limited settings. This pilot study investigates the potential of methylation-specific polymerase chain reaction (MSP) as a diagnostic tool to identify TB patients and distinguish them from patients with LC.
In a previous study (Öhrnberg *et al.* 2024), we collected buccal swab samples from patients with pulmonary TB (n=51) and healthy controls (n=10) and mapped their DNA methylation (DNAm) patterns using the Illumina Infinium Methylation EPIC 850 K platform. A DNAm profile distinct from healthy controls was discovered in the buccal mucosa of the TB patients.

We developed a machine learning model to predict symptom scores using the identified DNAm TB profile. The model was trained and evaluated on a validation cohort and two additional independent cohorts, achieving high performance. Further analysis of the model coefficients identified nine CpG sites as strong predictors.
Among these, three sites (CpG 1, CpG 2, and CpG 3) demonstrated the most significant differences in beta-values between TB patients and controls, indicating their potential diagnostic relevance. To validate our findings, we are conducting a MSP-based study in Eldoret, Kenya, where we are evaluating the methylation levels of the top three CpG sites in buccal swab samples collected from patients with active TB and LC patients. TB patients (n=8) and LC patients (n=6) were recruited for an initial analysis.

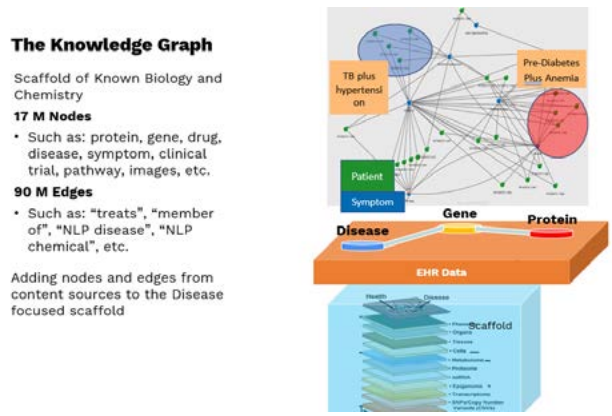


The machine learning model showed moderate accuracy in predicting symptom scores in both the TB and LC patients, based on DNAm in their buccal mucosa. Further analyses will explore the performance of the MSP model to distinguish TB and LC patients. The findings of this study have potential for further development of DNAm-based diagnostic tools for TB and LC.

TBS-EP539 The Tuberculosis Knowledge and Analytics Platform: TB Nexus Analytics

N. Rath,[1] K. Elliston,[1] R. Belvins,[2] Z. Temesgen,[3] P. Rice,[4] K. Elliston,[5] J. Menon,[1] [1]Open Source Pharma Foundation, Bangalore, India, [2]Ingentium, Boston, United States of America, [3]Mayo Clinic, Rochester, MN, United States of America, [4]Axiomedix, Upper Warren, United Kingdom of Great Britain and Northern Ireland, [5]Axiomedix, Boston, United States of America
e-mail: nibedita.rath@ospfound.org

The Tuberculosis Knowledge and Analytics Platform (TB Nexus Analytics) is a cutting-edge tool designed to revolutionize TB research and treatment. At its heart is the Tuberculosis Knowledge Base and Knowledge Graph (TB KBKG), a beta version that's already operational. This innovative "Google Maps for TB" harnesses AI and NLP to compile and organize data from global scientific literature and databases like Drug Bank, CHEMBL, PubChem, STRING, STITCH, KEGG, and more. It provides researchers with an intuitive visual interface to quickly cross-reference information on genes, pathways, and drug targets. It offers researchers a visual interface to quickly cross-reference information regarding genes, pathways, and drug targets, accelerating TB drug discovery by integrating diverse and up-to-date data sources to uncover new insights.
We conducted a workshop at NIRT, offering hands-on training to scientists and showcasing the platform's capabilities.
Central to this platform is the TB Data Commons, which gathers clinical, genomic, and other TB-specific data from different sources. This federated repository will empower researchers to uncover TB biomarkers through comprehensive investigations.
Unlike existing pharmaceutical Data Lakes and Analytics tools, which are often general, TB Nexus Analytics will exclusively target tuberculosis. This tool will analyze omics data, essential for understanding interactions between the TB pathogen and host, crucial for identifying biomarkers necessary for early diagnosis and monitoring. Additionally, the platform seamlessly interfaces with OSPF's TBKBKG. Linking new biomarkers and therapeutic targets will explore novel treatment strategies and enhance predictive modelling.



The TB Nexus Analytics is an innovative tool that has the power to bring together data analytics and scientific knowledge to enhance TB research and treatment. By integrating LLM and fostering collaboration among global researchers, it aims to significantly improve TB diagnosis, identify vital biomarkers, and advance targeted treatment strategies, playing a pivotal role in the fight against TB.

TBS-EP562 Effect of combined inspiratory and expiratory muscle training in pulmonary rehabilitation of active and post tuberculosis

S.T. Nakisanze,[1]
[1]Masaka Regional Referral Hospital, Masaka, Uganda
e-mail: tabithanakisanze99@gmail.com

Background: Pulmonary tuberculosis (TB) frequently results in lasting respiratory impairments such as reduced lung function, decreased exercise tolerance, respiratory muscle weakness, and decreased quality of life even after successful treatment. Inspiratory Muscle Training (IMT) and Expiratory Muscle Training (EMT) are emerging as essential pulmonary rehabilitative interventions.
This study evaluates the role of IMT and EMT individually and in combination in enhancing pulmonary function, exercise capacity, and quality of life in individuals with active or post pulmonary TB.
Methods: A cohort of 18 participants was randomly assigned into three groups (n=6 each). Group 1 received IMT, Group 2 received EMT, and Group 3 received combined IMT and EMT. All groups underwent 20-minute training sessions three times a week for eight weeks (24 sessions total). Assessments were conducted at baseline, mid-point, and post-intervention.
Primary outcomes included respiratory muscle strength, measured via Maximal Inspiratory Pressure (MIP) and Maximal Expiratory Pressure (MEP) as well as pulmonary function parameters (tidal volume, Forced Vital Capacity (FVC), exercise endurance, and health-related quality of life.
Results: All groups showed statistically significant improvements ($p < 0.05$) across measured outcomes. Group 1 (IMT) had notable gains in inspiratory strength and lung volumes, while Group 2 (EMT) showed marked improvements in expiratory muscle strength.
However, Group 3 (combined IMT and EMT) exhibited the most significant enhancements in all parameters, including MIP, MEP, FVC, exercise endurance, and quality-of-life scores.
Conclusion: Combined Inspiratory and Expiratory Muscle Training yields superior rehabilitative outcomes in TB and post-TB populations. This integrated approach effectively addresses both restrictive and obstructive lung patterns, making it a valuable adjunct to pulmonary rehabilitation protocols aimed at improving lung functional capacity and overall well-being.

TBS-EP565 Establishment of a model for early warning of onset in population exposed to *Mycobacterium tuberculosis*

H. An,[1] J. Du,[1] Y. Li,[2] L. Mao,[1] R. Nie,[3] Y. Su,[1] R. Wang,[1] E. Dong,[1] Y. Nie,[1] W. Zhao,[1] [1]The Eighth Medical Center of PLA General Hospital, Senior Department of Tuberculosis, Beijing, China, [2]Beijing Jiaotong University, School of Automation and Intelligence, Beijing, China, [3]91827 Troop of the Chinese People's Liberation Army, Health Service Company (PLA), Weihai, China
e-mail: dujingli2006@sohu.com

Background: Tuberculosis (TB) develops gradually, and traditional screening fail to detect early *Mycobacterium tuberculosis* (MTB) infections. Early detection in exposed groups is essential for timely intervention.
Design/Methods: We screened 178 close contacts of an active tuberculosis (ATB) case initially and after 3 months using serum exosome-derived TB biomarkers (LAM and LprG), serum proteomics, interferon-gamma release assays (IGRAs), and the tuberculin skin test (TST). Computed tomography (CT) scans and artificial intelligence (AI) tracking technology identified lesion features. A sophisticated deep learning model was developed utilizing a multimodal neural network architecture that integrates convolutional neural networks (CNNs) for the analysis of CT images, alongside fully connected layers for processing structured clinical and biomarker data.
This model was designed with the objective of predicting the onset risk of TB as an early warning system for populations exposed to MTB. The model underwent iterative optimization using data from the cohort.
Results: Out of 178 people, 14 initially had positive serum exosome-derived TB biomarkers despite negative results of CT, TST, and IGRAs. After three months, 10 of these 14 tested positive on TST/IGRAs, indicating that serum exosome-derived TB biomarkers can detect MTB infection earlier than TST/IGRAs. Enhancements in a deep learning model, based on all screening indicators, improved its predictive performance for MTB exposure population of infection onset. The model demonstrated strong generalization and stability through cross-validation and proved effective in early warning and clinical application in an actual MTB-exposed cohort.
Conclusions: Serum exosome-derived TB biomarkers offer a new method for early MTB infection detection. By combining these biomarkers with established tests like IGRAs and TST, and using AI-enhanced CT lesion monitoring within a deep learning framework, a high-performance early warning model can be developed. This model could significantly improve the accuracy and effectiveness of TB screening in at-risk populations.

TBS-EP568 Nutritional status of tuberculosis patients and its associated factors in four districts in Ghana

M.P. Kwabla,[1] E.J. Addo,[1,2] N. Martey,[3,4] Y.R. Doku,[3,5] S. Nyame,[3,6] G. Kye-Duodu,[1] G.K. Amenuvegbe,[1] F. Baiden,[1] [1]Department of Epidemiology and Biostatistics, Fred N. Binka School of Public Health, University of Health and Allied Sciences, Ho, Ghana, Hohoe, Ghana, [2]Jasikan Municipal Health Directorate, Jasikang, Ghana, [3]Department of Family and Community Health, Fred N. Binka School of Public Health, University of Health and Allied Sciences, Ho, Ghana, Hohoe, Ghana, [4]Ho Municipal Health Directorate, Ho, Ghana, [5]Hohoe Municipal Health Directorate, Hohoe, Ghana, [6]Kpando Municipal Health Directorate, Kpando, Ghana
e-mail: mkwabla@uhas.edu.gh

Background: Malnutrition is a significant concern in tuberculosis (TB) patients, with a bidirectional relationship between the two conditions. While malnutrition increases the risk of developing active TB by 6 to 10 times, TB also leads to malnutrition. TB patients who are malnourished have delayed recovery and higher mortality rates compared to well-nourished individuals. Hence, WHO recommends addressing malnutrition in TB management to improve treatment outcomes and reduce mortality rates. This study assessed the nutritional status of pulmonary TB patients and its associated factors in four districts in Ghana.
Methods: We reviewed records of TB patients who were registered between January 2021 and August 2024 from four districts and used their contact information to trace them for interviews using a structured questionnaire. We conducted face-to-face and telephone interviews. We extracted data on weight and height from available health and civic records to compute body mass index (BMI). Logistic regression analysis was used to determine the relationship between variables.
Results: Of 607 TB patients surveyed, 253 (41.7%) were aged 49+, 387 (63.8%) were males and 309 (50.9%) were low-income earners. The study found 206 (33.9%) patients to be underweight, 304 (50.1%) malnourished based on BMI indices while 272 (44.8 %) and 310 (51.1%) experienced weight loss and food insecurity respectively. A total of 281 (46.3%) indicated having consumed balanced diets while 228 (37.6%) had received moderate level of support during treatment. One-third of patients 183 (33.8%) had good knowledge of nutrition. Significant predictors of malnutrition included residence in Jasikan (aOR=4.19, p<0.001) or Kpando (aOR=3.72, p<0.001), male gender (aOR=2.02, p=0.003), being unemployed (aOR=2.4, p=0.02), having had tertiary education aOR=0.4, p=0.02), and limited healthcare access (aOR=0.4, p=0.003).
Conclusion: More than half of TB patients were malnourished. There is the need to integrate nutrition assessment and support systems into TB management in the study districts.

TBS-EP571 Maternal and infant outcomes in acute hematogenous disseminated pulmonary tuberculosis during pregnancy

J. Du,[1] H. An,[1] [1]The Eighth Medical Center of PLA General Hospital, Senior Department of Tuberculosis, Beijing, China
e-mail: anhuiru74@sina.com

Background: The outcomes of acute hematogenous disseminated pulmonary tuberculosis (HDTB) in pregnancy are not well understood. Our study aims to investigate the clinical features and outcomes for pregnant women with acute HDTB, examine the link between these features and the prognosis for both mothers and infants, and share insights to enhance diagnosis and treatment.
Design/Methods: We analyzed the clinical data of 65 pregnant women with acute HDTB admitted to three Chinese hospitals between January 2013 and December 2022, focusing on clinical characteristics, treatment outcomes, and their interrelationships.
Results: In this study of 65 pregnancies with acute HDTB, 72.3% (47/65) followed *in vitro* fertilization embryo transfer (IVF-ET), and 63.1% (41/65) were associated with tuberculous meningitis. Common clinical symptoms included fever (98.5%), cough (63.1%), vaginal bleeding (46.2%), and headache (63.1%). Cranial enhanced MRI detected tuberculous meningitis in 83.3% (40/48) of cases, compared to 65.2% (30/46) via lumbar puncture. The positive rate for interferon-gamma release assays (IGRAs) was 81.7% (49/60). Adverse pregnancy outcomes included 44.6% (29/65) spontaneous abortions, 24 induced abortions, 12 deliveries (including twins), and 4 stillbirths (30.8%). Among live births, 61.5% (8/13) were low birth weight, 38.5% (5/13) had congenital tuberculosis (with 3 fatalities and 1 mobility disorder), and 7.69% (1/13) had congenital heart disease. Fisher's analysis revealed that adverse fetal outcomes were significantly more common in acute HDTB pregnancies with vaginal bleeding (100%) compared to those without (76.92%), and in cases with reduced amniotic fluid (100%) compared to those without (71.43%), with both differences being statistically significant (P<0.05).
Conclusions: Out of 65 pregnant acute HDTB patients, 47 (72.3%) underwent IVF-ET. Adverse pregnancy outcomes are common, and ultrasound monitoring of amniotic fluid can assess fetal health. Vaginal bleeding and reduced amniotic fluid may indicate potential fetal issues.

TBS-EP577 Development of a loop-mediated Isothermal amplification (LAMP) assay for the detection of pepQ gene in Mycobacterium tuberculosis

J.M. Bislumbre,[1] J.M. Cuales,[1] J.M.L. Majaducon,[1] M.K.J.R. Mendoza,[1] C. Pangilinan,[1] R. Basilio,[2] M. Kato-Maeda,[3] R. Destura,[1] [1]National Training Center for Biosafety and Biosecurity, National Institutes of Health, University of the Philippines, Manila, Philippines, Manila, Philippines, [2]Research Institute for Tropical Medicine, Muntinlupa City, Metro Manila, Philippines, [3]University of California San Francisco, San Francisco, California, United States of America
e-mail: jtbislumbre@up.edu.ph

Bedaquiline is one of the components of the Bedaquiline-Pretomanid-Linezolid (BPaL) treatment regimen recommended for treating multidrug-resistant tuberculosis (MDR-TB), which was rolled out in the Philippines in 2021. As of writing, there have been no studies conducted on the epidemiology of bedaquiline resistance in the country due to the lack of low cost methods to identify drug resistant tuberculosis.

We aimed to develop a loop-mediated isothermal amplification (LAMP) assay to detect the presence of the pepQ gene specific to *Mycobacterium tuberculosis*, wherein mutations are associated with bedaquiline resistance. This assay may be used as a diagnostic assay for the presence of *Mycobacterium tuberculosis* in clinical samples. One LAMP primer set targeting pepQ was specifically designed to include one single nucleotide polymorphism (SNP) associated with bedaquiline resistance. This set was evaluated in silico then subsequently optimized with a synthetic gene fragment as a positive control.

External primers (F3 and B3) were validated using quantitative PCR using dilutions of the synthetic positive control (10^8 - 10^0 DNA copies/uL). Optimization steps involved variations of the reaction temperature (63°C-65°C), incubation time (30, 40, 50 and 60 minutes), Bst polymerase type (Bst 1 and Bst 2), and total reaction volume (25 uL and 12.5 uL).

Using Bst 1, optimized conditions were found to be 63°C for both 50 and 60 minutes of incubation with an analytical sensitivity of 10^5 DNA copies/uL. For clinical diagnosis, this analytical sensitivity must be improved. To address this, Bst 2 was used to investigate the possible variations in the optimized conditions from Bst 1.

Preliminary testing showed an optimized incubation temperature from 63°C-65°C. The succeeding optimization steps are yet to be conducted. This assay, as a preliminary step, may further be applied in downstream applications which might be able to detect the specific mutations for bedaquiline resistance.

TBS-EP580 Factors that impact the expansion of coverage for preventive treatment of TB in the Kyrgyz Republic

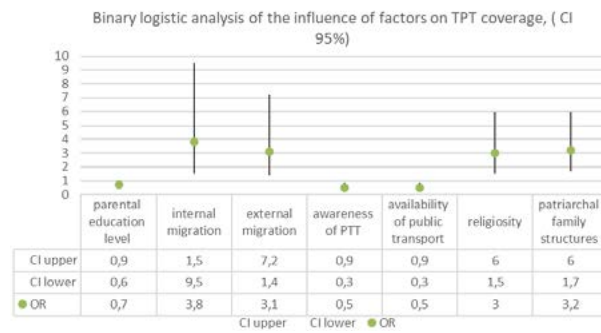
D. Madybaeva,[1] N. Shumskaia,[1] L. Zhirnova,[1]
[1]Public Foundation "Den Sooluk Nuru", Bishkek, Kyrgyzstan
e-mail: dinara.madybaeva@yale.edu

Background: TB preventive treatment, including chemoprophylaxis for people at risk of TB, is a key component of the fight against the spread of this disease. In Kyrgyzstan, in 2019–2022, the average number of contacts of patients with bacteriologically confirmed pulmonary TB and screened for TB was 3.2–3.5 people per index case, of which children account for 35–37%.

Methodology: This cross-sectional study aimed to identify factors influencing TB preventive treatment coverage. Data were collected using quantitative and qualitative methods across all regions. Respondents—parents of child contacts—were selected randomly. Descriptive statistics, Pearson's chi-square test, and binary logistic regression were used for analysis in SPSS v22.0.

Results: A total of 289 respondents participated, covering all regions. Key barriers to tuberculosis preventive therapy coverage included migration status (OR = 3.8; CI = 1.5–9.5), religiosity (OR = 3.0; CI = 1.5–6.0), patriarchal family structure (OR = 3.2; CI = 1.7–6.0), and lack of information (OR = 4.3; CI = 1.6–11.9). Protective factors that reduced the likelihood of refusal or interruption of treatment included parental education (OR = 0.7; CI = 0.6–0.9), awareness of TPT (OR = 0.5; CI = 0.3–0.9), and access to public transport (OR = 0.5; CI = 0.3–0.9). Complex diagnostic and testing procedures further complicated the timely initiation of chemoprophylaxis.

There are no clear mechanisms and criteria for regular analysis of data on the cascade of contact care and preventive treatment of children. Automation and digitalization of accounting processes are recommended to improve monitoring and reporting.



Conclusion: Barriers to TB preventive treatment in Kyrgyzstan are multifactorial, including social, logistical, and informational challenges. Improving access to care, simplifying diagnostic pathways, enhancing public awareness, offering psychosocial support, and increasing program funding are essential to expanding TPT coverage and strengthening TB prevention efforts.

TBS-EP583 Clinical features of pulmonary tuberculosis and nanostructural characteristics of multidrug-resistant Mycobacterium tuberculosis strains

N. Yatskevich,[1] A. Astashonok,[2] A. Ivanova,[1]
N. Poleshchuk,[2] A. Skrahina,[1] [1]Republican Scientific and Practical Centre for Pulmonology and Tuberculosis, Minsk, Belarus, [2]Republican Center for Hygiene, Epidemiology and Public Health, Minsk, Belarus
e-mail: yahoravanatallia@mail.ru

Background: The development of effective short regimens for tuberculosis (TB) treatment is an urgent task. However, no rapid methods are currently available to assess the biological activity of Mycobacterium tuberculosis for the purpose of determining optimal treatment duration.
Aim. To analyse clinical and instrumental features of the infectious process course in pulmonary tuberculosis (TB) and to characterise of *M.tuberculosis* with multidrug resistance/resistance to rifampicin (MDR/RR), pre-extensively drug resistance (pre-XDR) architectonics and morphogenesis.
Materials and methods: 40 MDR/RR-TB, pre-XDR-TB patients (30 men (75%), 10 women (25%) aged 34 to 61 years) were enrolled in the study (Table). The results of diagnostic material microbiological examination, clinical, chest X-ray examination of included patients were analysed. The architectonics and morphogenesis of *M.tuberculosis* were studied.
Results: Median time [IQR] to culture conversion in patients with favourable treatment outcome (FTO) was 54.0 [28.0;84.0], with unfavourable treatment outcome (UTO)-123.0 [87.0;231.3] days (p=0.0001). Significant differences in mycolic acid layer thickness were found when transferring from mycobacilli (12 [10;12] nm) to rounded morphovars (30 [30;40] nm, p=0.003). Mycobacteria surface stiffness coefficient was significantly higher in patients with UTO than in patients with FTO (Me-58.3 [48.2;72.1] pN/μm vs. Me-7 [5;7.4] pN/μm) (Figure). The surface stiffness coefficient of the *M. tuberculosis (H37Rv)* strain susceptible to anti-TB drugs was 5–7 pN/μm.

Table. Baseline characteristics of patients

Total enrolled	Group 1, n (%) * 22 (100)	Group 2, n (%) * 18 (100)	P-value**
Male	15 (68.2)	15 (83.3)	>0.05
Age, mean (range)	48.2 (+-9.1)	47.8 (+-9.1)	>0.05
Mean BMI mean (range)	22.1 (+-4.9)	20.5 (+-3.4)	>0.05
Sputum smear positive at baseline	11 (50.0)	13 (72.2)	>0.05
pre-XDR-TB at baseline	11 (50.0)	7 (38.9)	>0.05
HIV-positive	2 (9.1)	3 (16.7)	>0.05
HCV-positive	3 (13.6)	6 (33.3)	>0.05
Alcohol abuse in anamnesis	8 (36.4)	9 (50.0)	>0.05
Diabetes mellitus	4 (18.2)	2 (11.1)	>0.05
Cavity	**8 (36.4)**	**13 (72.2)**	**0.024**

*Figures are presented as number (percentage), if not indicated otherwise
**χ^2 used for calculation of the difference between groups

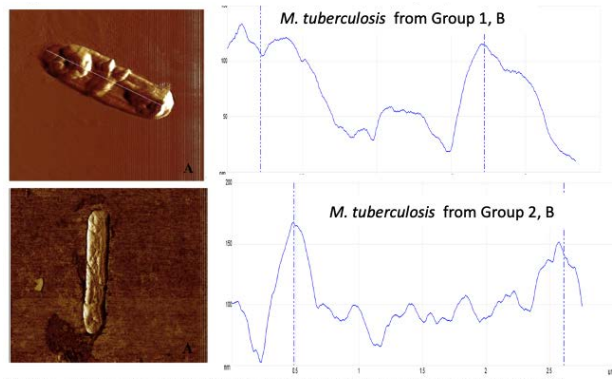


Figure. Surface topography of the rod-shaped form of *M.tuberculosis* (A) and analysis of cross-sectional microprofiles of the bacterial structure (B)

Conclusion: Among bacillary mycobacteria morphovars there is a shift of mechanically rigid zones to the middle of the bacterial structure. Changes in the architectonics of mycolic acids, the appearance of forms with a rigid envelope may correlate with the virulence of mycobacteria and the clinical course of tuberculosis.

TBS-EP586 Long term impact of pulmonary TB on health-related functioning and well-being in four African countries

N. Jinga,[1] K. Hirasen,[1] M. Rassool,[2] S. Charalambous,[3] D. Evans,[1] [1]Health Economics and Epidemiology Research Office, University of the Witwatersrand, Johannesburg, South Africa, [2]Clinical HIV Research Unit (CHRU), Wits Health Consortium (WHC), Health Science Research Office (HSRO), Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [3]The Aurum Institute, Johannesburg, South Africa
e-mail: khirasen@heroza.org

Introduction: Pulmonary TB continues to negatively affect the health-related quality of life (HRQoL) of survivors, even after treatment completion.
Objective: To describe health-related functioning and well-being in TB survivors 4-7 years after completing TB treatment.
Methods: A cross-sectional study conducted at four African countries—The Gambia, Mozambique, Tanzania, and South Africa. The study included adults (≥18 years) who had completed treatment for pulmonary TB between and 04/2018 and 07/2020. Data were collected using three validated instruments: Medical Outcomes heath survey (SF-12), Kessler Psychological Distress Scale (K10), and Sheehan Disability Scale.
We report mean scores for the Mental Component Summary (MCS), Physical Component Summary (PCS) scores from the SF-12, proportion experiencing mild (20-24), moderate (25-29) or severe (≥30) psychological distress.

Results: A total of 470 patients were included, 64% were male (301/470), with a mean age of 41.4 years (SD 11.8). Average MCS and PCS scores were similar for the 6–7 years (56.6 ± 8.1 and 51.4 ± 8.4) and the 4-5 years (55.5 ± 8.2 and 51.7 ± 8.5) group, respectively. The two most concerning findings were that 15-20% of TB survivors continue to experience severe psychological distress (≥30), and 28-36% still consider the financial burden of TB on their households to be severe. However, some social consequences of TB, such as its impact on work, family, and social life, appear to have fully resolved.

		4- and 5-years after TB treatment completion (n=353)	6- and 7-years after TB treatment completion (n=162)
Employment	Employed – n (%)	253 (89.7)	122 (88.4)
	Unemployed – n (%)	29 (10.3)	16 (11.6)
Changed jobs in the last 6 months?	Yes – n (%)	15 (6.0)	5 (4.2)
If employed, hours worked per week	Mean (SD)	49.6 (22.4)	49.6 (22.4)
Days unproductive in the last week	Mean (SD)	1(0.0)	1(0.0)
Long-term financial impact of TB	None/little	142 (50.4)	53 (39.3)
	Moderate	59 (20.9)	33 (24.4)
	Severe/very severe	81 (28.7)	49 (36.3)
Health-related quality of life (SF-36)			
Physical Component Summary	PCS – Mean (SD)	51.7 (8.5)	51.4 (8.4)
Poor physical functioning*	≤50 – n (%)	83 (23.5)	36 (22.2)
Mental Component Summary	MCS – Mean (SD)	55.5 (8.2)	56.6 (8.1)
Poor mental functioning*	≤50 – n (%)	64 (18.1)	22 (13.6)
Psychological distress	<20 normal	258 (73.1)	124 (76.5)
	20-24 mild distress	19 (5.4)	10 (6.2)
	25-29 moderate distress	4 (1.1)	3 (1.9)
	≥30 severe distress	72 (20.4)	25 (15.4)
Long-term impact of TB on work/ school	Mild (0-3)	251 (96.2)	124 (93.9)
	Moderate (4-6)	6 (2.3)	5 (3.8)
	Markedly (7-10)	4 (1.5)	3 (2.3)
Long-term impact of TB on family life	Mild (0-3)	277 (98.6)	133 (96.4)
	Moderate (4-6)	2 (0.7)	4 (2.9)
	Markedly (7-10)	2 (0.7)	1 (0.7)

Conclusions: Health-related functioning is generally lowest at the start of TB treatment, improves throughout treatment, but shows limited recovery after its completion. In this and other work, we find that a subset of TB survivors experiences a decline in HRQoL, particularly in mental health, around 30 months after completing TB treatment. Further research is needed to assess whether poor mental health and financial strain reported 4-7 years post-treatment are directly linked to TB.

TBS-EP589 Enrichment of *M. tuberculosis* in patient sputa using a limiting dilution assay

D. Liebenberg,[1] B. Kana,[1] [1]University of the Witwatersrand, Johannesburg, South Africa
e-mail: dale.liebenberg@wits.ac.za

The limiting dilution most probable number (MPN) assay is a method of detecting the presence of differentially culturable tubercle bacteria (DCTB) in patient sputum. These DCTB can grow in liquid media, with and without culture filtrate (CF) supplementation, but not on solid media.

In a preliminary study, 16S sequencing was performed on 20 patient samples recovered following the completion of MPN assays, from the plate wells representing both supplementation with and without CF. Additionally, 3 of the corresponding original patient sputum samples were also sequenced and analysed.

Mycobacterium tuberculosis was detected in all the 40 isolates, with 75% of the isolates being drastically enriched for *M. tuberculosis* (>82% of identified sequence reads per isolate). For all but 2 of the samples, there was minimal difference in the level of *M. tuberculosis* enrichment between the CF supplemented/not supplemented isolates. The predominate species identified in the supplemented isolates of these two samples were *Paenibacillus polymyxa* and *Bacillus subtilis*. The remaining samples, with a minimal *M. tuberculosis* presence, were dominated by *Ralstonia pickettii*, *Rhodococcus hoagie*, *Methylobacterium radiotolerans* and *Afipia genosp*.

Analysis of the three sputum samples revealed trace or undetectable levels of *M. tuberculosis*, however both of the corresponding MPN isolates for each sample was completely dominated by *M. tuberculosis*. While samples from both HIV positive and negative persons could be enriched with *M. tuberculosis*, the 10 isolates (25%) for which this was not the case were all from HIV negative persons.

This investigation shows that, in most cases, the MPN assay can be used to enrich patient sputum samples for the detection of *M. tuberculosis*, which is a valuable capability when trying to detect low levels of bacteria in patient samples.

TBS-EP592 Bridging diagnostic gaps of drug-resistant pulmonary tuberculosis with clinical diagnosis in a low-and middle-income state, Southwest, Nigeria: A secondary data analysis

E. Irek,[1] A. Isinkaye,[2] A. Orojo,[3] [1]Afe Babalola University Multi-System Hospital, Ekiti, Nigeria, [2]Federal Teaching Hospital, Ido, Ekiti, Nigeria, [3]Tuberculosis Leprosy and Buruli Control Programme, Primary Health Care Development, Ekiti, Nigeria
e-mail: dj1irek@yahoo.com

Introduction: Drug-resistant tuberculosis (DR-TB) poses a significant challenge to global TB control efforts, particularly in low- and middle-income countries where diagnostic resources are limited thereby widening treatment gap. This has increased morbidity and mortality due to TB in Sub-Saharan Africa. We sought to evaluate the role of clinical diagnosis in identifying DR-TB in pulmonary TB cases missed by the sputum GeneXpert MTB/RIF assay in Ekiti State, Nigeria.
Methods: A secondary data analysis was conducted using the 2024 National Tuberculosis, Leprosy and Buruli Ulcer Control Programme (NTBLCP) register in Ekiti State. Data on demographics, diagnostic methods, and resistance patterns were extracted and analyzed using descriptive statistics.
Results: Among 28 DR-TB cases identified, GeneXpert MTB/RIF assay detected only 53.6% (15/28), missing 46.4% (13/28), which were subsequently identified through clinical suspicion followed by Line Probe Assay+/- culture. MDR-TB accounted for 46.4% (13/28), rifampicin mono-resistance for 39.3% (11/28), and isoniazid mono-resistance for 14.3% (4/28). Two cases of pre-XDR TB were observed among people living with HIV, both of whom had false-negative GeneXpert results. The average diagnostic delay from GeneXpert testing to LPA-based diagnosis was 16 days.

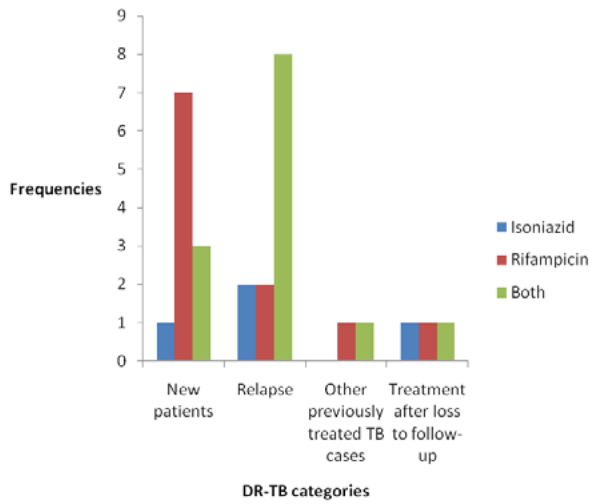

Figure 1: Distribution of the categories of DR-TB patients with drug-resistance patterns using LPA in Ekiti State, Nigeria, 2024

Conclusion: Clinical evaluation is critical in bridging diagnostic gaps created by false-negative GeneXpert results, ensuring timely identification and treatment of DR-TB.

TBS-EP595 Diagnostic potential of hematological counts and ratios in pediatric tuberculosis: A five-year retrospective study

S. Mäsiarová,[1] M. Krivošová,[2] P. Kunč,[3] J. Fábry,[4] I. Porvazník,[5] I. Solovič,[5] J. Mokrý,[1] M. Dohál,[2]

e-mail: masiarova18@uniba.sk

The diagnosis of tuberculosis (TB) in children remains a challenge due to the often nonspecific clinical presentation and the difficulty in obtaining reliable biological samples. In recent years, attention has shifted toward the potential of basic hematological parameters and their derived ratios as supportive diagnostic tools. Indicators such as platelet count (PLT), leukocyte count (LEU), erythrocytes (ERY), haemoglobin, mean platelet volume (MPV), and ratios like neutrophil-to-lymphocyte (NLR), monocyte-to-lymphocyte (MLR), and platelet-to-lymphocyte (PLR) have shown promise in differentiating between various forms of TB and in assessing disease severity.
This retrospective study evaluated 446 pediatric patients hospitalized between 2020 and 2024 at the Clinic of Children's Tuberculosis and Respiratory Diseases. The study population included 217 children with active TB (including 26 with disseminated forms), 60 with latent TB, 18 with mycobacteriosis, and 125 controls. The control group consisted of symptomatic patients without confirmed TB and individuals who had contact with TB-positive persons. The average age of patients with active TB was 7.1 ± 5.1 years.
Using multivariable linear regression adjusted for age, sex, and comorbid inflammatory conditions, we found that the following hematological markers were significantly different in children with active TB compared to controls: platelet count ($p = 0.022$), lymphocyte count ($p = 0.044$), PLR ($p = 0.010$), and NLR ($p = 0.001$). These findings underline the diagnostic value of simple, routinely avail-

able blood parameters in pediatric TB and highlight their potential role in clinical decision-making, especially in resource-limited settings.

This project was supported by the grants APVV-18-0084, APVV-22-0342, VEGA-1/0093/22, VEGA/1/0049/25, and by the EU NextGenerationEU through the Recovery and Resilience Plan for Slovakia under the project No. 09I03-03-V02-00036.

TBS-EP598 Polystyrene particles alter mycobacterial lipidic cell wall composition

I. Romero-Andrada,[1,2] N. Traba,[2] J. Domínguez,[1,2,3] E. Julián,[2] A. Lacoma,[1,2,3] [1]Institut d'Investigació Germans Trias i Pujol, Badalona, Spain, [2]Universitat Autònoma de Barcelona, Barcelona, Spain, [3]CIBER de Enfermedades Respiratorias, Instituto de Salud Carlos III, Madrid, Spain
e-mail: iromero@igtp.cat

Introduction: The genus Mycobacterium comprises both pathogenic and non-pathogenic species, characterized by their highly hydrophobic cell wall enriched with diverse lipids. Micronanoplastics, as pervasive environmental pollutants, have shown to affect microbial communities and pose a risk to human health[1].

In this study, we examine the effects of nano-sized polystyrene (PS) particles on the mycobacterial phenotype, with a focus on changes in the composition of their lipid-rich cell wall.

Materials and methods: *Mycobacterium smegmatis* mc^2 155, a non-pathogenic fast-growing model for *Mycobacterium tuberculosis*, was cultured in Tryptic Soy Broth (TSB) medium or Middlebrook 7H9 medium supplemented with albumin-dextrose-catalase (ADC). Cultures were exposed to 100 µg/mL PS and incubated at 170 rpm and 37ºC for 72 hours. Bacterial biomass was harvested, followed by total lipid extraction through filtration and decantation. Lipid profiles were monitored by using thin-layer chromatography (TLC) with different elution systems of different polarity.

Results: *M. smegmatis* growth was influenced by both, culture media and PS exposure. While higher bacterial growth was observed in TSB compared to 7H9 in the absence of PS; the presence of PS triggered an increased bacterial growth in TSB but reduced it in 7H9 medium.

Additionally, PS exposure altered lipid expression: the presence of some polar lipids was reduced in TSB, while both apolar and polar lipids, including glycopeptidolipids and phosphatidylinositol mannosides, showed decreased expression in 7H9.

Conclusions: Both the culture medium and PS exposure affect the lipid composition of *M. smegmatis* cell wall. Notably, PS presence tends to decrease expression of diverse key cell wall lipids, suggesting an impact on host-mycobacteria interaction.

TBS-EP601 Population pharmacokinetics of isoniazid in TB patients: Accounting for age, sex, weight, diabetes, and HIV

F. Ridolfi,[1] J. Pasipanodya,[1] B. Hachey,[1] C. Staats,[1] M. Cordeiro-Santos,[2,3] A. Kritski,[4] M. Figueiredo,[1] B. Andrade,[5,6,7,8,9] V. Rolla,[10] T. Sterling,[1] G. Amorim,[11] Regional Prospective Observational Research in Tuberculosis (RePORT)-Brazil consortium [1]Vanderbilt University Medical Center, Department of Medicine, Division of Infectious Diseases, Nashville, United States of America, [2]Fundação Medicina Tropical Dr. Heitor Vieira Dourado, Manaus, Brazil, [3]Universidade do Estado do Amazonas, Manaus, Brazil, [4]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [5]Instituto Gonçalo Moniz, Fundação Oswaldo Cruz, Salvador, Brazil, [6]Multinational Organization Network Sponsoring Translational and Epidemiological Research (MONSTER) Initiative, Salvador, Brazil, [7]Faculdade de Tecnologia e Ciências (UniFTC), Curso de Medicina, Salvador, Brazil, [8]Universidade Salvador (UNIFACS), Laureate Universities, Salvador, Brazil, [9]Escola Bahiana de Medicina e Saúde Pública (EBMSP), Salvador, Brazil, [10]Instituto Nacional de Infectologia Evandro Chagas, Fiocruz, Rio de Janeiro, Brazil, [11]Vanderbilt University Medical Center, Department of Biostatistics, Nashville, United States of America
e-mail: felipe.ridolfi@vumc.org

Background: We previously found that individuals with tuberculosis (TB) and poorly controlled diabetes mellitus (DM) had a lower risk of adverse drug reactions, presumably because of low drug concentrations. To investigate this, we developed a compartmental population pharmacokinetics (PopPK) model for isoniazid (INH) concentrations.

Methods: We included culture-confirmed, drug-susceptible, pulmonary TB participants from the RePORT-Brazil observational cohort, sparsely sampled during month 1; they received standard TB treatment. We developed a one-compartment PopPK model, with absorption rate constant (ka), clearance (Cl), and volume of distribution (Vd) parameters.

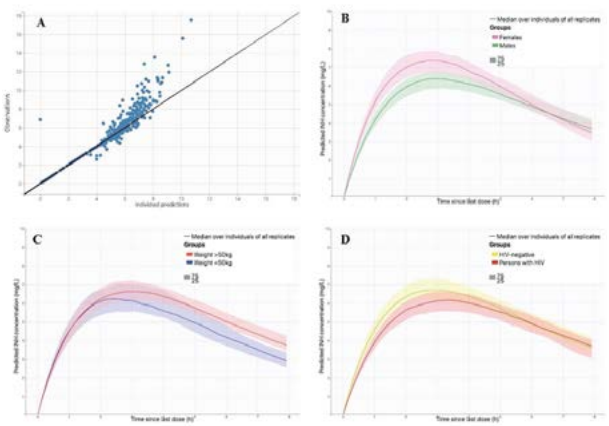
Random effects captured inter-individual variability. Age, sex, weight, body mass index (BMI), DM-, and HIV-status at baseline were analyzed. INH concentration was quantified by liquid chromatography-mass spectrometry (SCIEX6500 Qtrap, Redwood City, CA). Time since last dose (in hours) was self-reported, and samples below quantification levels were excluded. Stochastic approxi-

mation of the expectation maximization (SAEM) algorithm in Monolix® was used for model parameter estimation, and Simulx®, for simulations.

Results: There were 333 study participants. The final PopPK model with best fit estimated ka of 0.59, Cl of 6.12L/h, and Vd of 5.62L, and included age, sex, weight, and HIV status, but not DM. Persons with HIV had significantly lower absorption rate compared to HIV-seronegative individuals (-0.12, 95% Confidence Interval (CI) -0.23;-0.004, p=0.04), females had lower Vd compared to males (Vd -3.9 95%CI -6.75;-1.05, p<0.001), age was associated with decreased Vd (-0.039, 95%CI -0.07;-0.0077, p=0.01), while weight, with increased Vd (0.35, 95%CI 0.2; 0.51, p<0.001) (Figure 1).

The inter-individual variability was considerable, with omega values for ka (0.33, Coefficient of Variation (CV)= 55%), Vd (2.85, CV= 51%), and Cl (1.36, CV=22%).

Figure 1. Model performance and simulations of INH concentration stratified by sex, weight, and HIV-status.



Legend. (**A**) Model performance. Observations vs. individual predictions of INH plasma concentrations from the PopPK model. Simulated predicted concentrations stratified by sex (**B**), weight (**C**), and HIV-status (**D**). The stratified concentrations by age are not displayed.

Conclusions: This PopPK model captured variability in INH absorption, distribution, and clearance among patients with pulmonary TB in Brazil. Age, sex, weight, and HIV-status influenced INH concentrations, but DM did not.

TBS-EP603 Single-cell transcriptomic profiling identifies immune signatures in latent Mycobacterium tuberculosis infection and active tuberculosis

J. Tian,[1] M. Gao,[1] Z. Zhou,[1] W. Wang,[1]
[1]Fudan University, Shanghai, China
e-mail: 23111020039@m.fudan.edu.cn

Background: Latent Mycobacterium tuberculosis (*Mtb*) infection (LTBI) results in varied outcomes owing to different host immune responses. However, the immune mechanisms underlying the progression from LTBI to active tuberculosis (ATB) remain poorly understood in humans.

Methods: We employed single-cell RNA sequencing to profile immune cell populations in peripheral blood from healthy controls (HC), LTBI, and ATB. We performed unsupervised clustering based on gene expression profiles using Seurat.

We conducted enrichment analyses on differentially expressed genes of CD8+ T cells across different groups to identify functional changes they mediate. Mfuzz was utilized to classify genes into distinct groups according to expression similarity to examine dynamic expression changes at various infection stages. SCENIC was employed to predict transcription factor activity and regulatory networks in different CD8+ T cell subsets.

Findings: Cluster analysis delineated 10 cell subsets. Analysis of CD8+T cells revealed that genes highly expressed in LTBI were predominantly enriched in the regulation of innate immune response, particularly natural killer cell-mediated immunity and cytotoxicity.

Analysis of this pathway highlighted KLRC2, which was upregulated in CD8+T cells in LTBI compared to HC and ATB patients. In the CD8+T cell subset with elevated KLRC2 expression, transcription factors such as EOEMS, IRF2, and IKZF2 exhibited high activity.

We hypothesize these cells possess potent cytotoxic functions and memory cell characteristics, persisting in the bloodstream to maintain the latent state following Mtb infection.

Interpretation: We propose that the frequency of CD3+ CD8+ KLRC2+ T cells in peripheral blood may serve as a novel biomarker to distinguish LTBI from HC and ATB. These cells contribute to maintaining the latent infection state, and their loss may correlate with the transition from latent infection to active.

This study enhances our understanding of the immune landscape across different *Mtb* infection states and may inform future prophylactic treatment strategies.

TBS-EP606 Latent tuberculosis infection retains cytotoxic molecule expression and functionality lost during active disease

C. Peña Bates,[1] J. Flores Gonzalez,[2] N. Alvarado Peña,[2] M.A. Salazar,[2] N. Gutierrez,[3] E. Albores Mendez,[3] L. Chavez Galan,[2] L. Ramon Luing,[2] [1]Universidad Nacional Autónoma de México, CDMX, Mexico, [2]Instituto Nacional de Enfermedades Respiratorias, CDMX, Mexico, [3]Escuela Militar de Graduados de Sanidad, Universidad del Ejército y Fuerza Aérea Mexicanos, CDMX, Mexico
e-mail: krlox.peba@hotmail.com

Introduction: Latent tuberculosis infection (LTBI) remains a major global health concern. Studies using murine models have shown that $CD8^+$ T cells are essential for preventing LTBI reactivation. In contrast, active tuberculosis (TBA) is associated with reduced frequency and functionality of these cells. This study aimed to evaluate the capacity of cytotoxic molecule production (transcriptional/protein levels) by cells from individuals with LTBI or TBA, both at baseline and following exposure to *Mycobacterium bovis* BCG.
Methods: Peripheral blood mononuclear cells (PBMCs) and plasma were obtained from patients with TBA (n=80), QuantiFERON-positive contacts (LTBI, n=20), and QuantiFERON-negative contacts (n=20). Expression of *GZMA*, *GZMB*, *PRF1*, and *GNLY* (by qPCR) and soluble levels of granzyme A/B, perforin, granulysin, sFas, sFasL, and cytokines associated with cytotoxicity (TNF, IFN-g, IL-2, IL-4, IL-6, IL-10, IL-17) (by flow cytometry) were assayed. A subset of PBMCs from LTBI (n=5) and TBA (n=10) individuals was cultured with BCG to assess functional responses.
Results: Compared to TBA, PBMCs from LTBI individuals exhibited significantly higher transcriptional levels of *GZMA*, *GZMB*, *PRF1*, and *GNLY* ($p<0.0001$). Similarly, soluble protein levels of cytotoxic molecules (granzymes, perforin, granulysin, sFas, sFasL) and related cytokines were elevated in LTBI. Upon BCG stimulation, LTBI PBMCs maintained high levels of cytotoxic molecules, whereas TBA PBMCs failed to mount a comparable response ($p<0.05$).
Conclusion: Individuals with LTBI, but not those with TBA, preserve the ability to produce cytotoxic molecules in response to mycobacterial stimulation.
This suggests that LTBI is associated with an active and functional cytotoxic immune response, potentially contributing to the containment of *Mycobacterium tuberculosis* infection.

TBS-EP609 Harnessing AI for rapid, consistent, and efficient scientific writing: Large language models for TB trial protocol generation

B.H. Aldana,[1] P. Phillips JP,[1] [1]University of California, San Francisco, San Francisco, United States of America
e-mail: brian.aldana@ucsf.edu

Background: Developing tuberculosis (TB) clinical trial protocols demands specialized expertise and considerable resources. While general-purpose large language models (LLMs) may reduce manual workload, they typically lack TB-specific training and raise privacy concerns when used with sensitive documents. Recent innovations such as low-rank adaptation (LoRA) and retrieval-augmented generation (RAG) address these limitations by enhancing domain-specific accuracy. Recent advances in efficiency further allow private, offline deployment on modest hardware. Using semantic similarity and qualitative evaluation, we developed a robust, fine-tuned LLM augmented with RAG that reliably drafted key sections of TB clinical trial protocols.
Objectives/Methods: Using a computer with a single graphics processing unit, we developed a LoRA- and RAG-enhanced text generation pipeline and evaluated its performance when drafting TB clinical trial protocol sections.
We compared three models:
1. Mistral-7B;
2. Mistral-7B enhanced with LoRA and fine-tuned on 13 phase III TB protocols (2014–2024); and;
3. A RAG-augmented, LoRA-enhanced Mistral-7B model incorporating five TB guideline documents as external context.
Model outputs were generated in response to prompts targeting efficacy objectives, treatment-stopping rules, and inclusion/exclusion criteria. These outputs were then evaluated for their accuracy, relevance, and semantic similarity to human-generated content.
Results: TB-specific fine-tuning substantially improved the factual accuracy, plausibility, and semantic alignment of LLM-generated protocol sections. Notably, Model 3 outperformed the other models on both familiar and novel tasks, including the generation of inclusion/exclusion criteria for a drug absent from the training set and retrieval corpus.

Model	Prompt (Condensed)*	Output (Condensed)*
Model 1 Mistral 7B	Draft a concise primary efficacy objective for a Phase 3 clinical trial evaluating a 4-month BPaLM (bedaquiline, pretomanid, linezolid, and moxifloxacin) regimen for MDR TB.	"...to evaluate the proportion of participants who achieve a favorable outcome at 6 months following a 4-month regimen of..."
Model 2 Mistral + LoRA		"... to evaluate the efficacy of a 4-month regimen in achieving favorable treatment outcome in adult patients with..."
Model 3 Mistral + LoRA + RAG		"...to evaluate the efficacy of a 4-month regimen in achieving bacteriological cure at 26 weeks post-treatment initiation..."
Model 1	List 3 specific conditions or events in which participants should discontinue treatment or study drug. These criteria should reflect typical SAEs or lab abnormalities observed with investigational TB medications.	"...liver enzymes (ALT, AST) more than 5x the ULN then they must permanently discontinue treatment due to the risk of liver failure"
Model 2		"...if they develop severe neurotoxicity, such as peripheral neuropathy, optic neuritis, or encephelopathy."
Model 3		"...discontinuation of investigational drug due to severe adverse events: -severe hepatotoxicity, -severe nephrotoxicity..."
Model 1	List 2 inclusion and 2 exclusion criteria for a Phase 3 clinical trial evaluating quarbodepistat in combination with bedaquiline and delaminid in the treatment of MDR-TB.	"...intolerance to any of the study drugs or their excipients or a history of SAEs to similar drugs (quinolones or macrolides)"
Model 2		"Pregnant or breastfeeding women, or women of childbearing potential not using effective contraception."
Model 3		"Participants with a history of significant cardiac disease or QTc prolongation."

*Condensed outputs are a representative sample of prompt or output text, with full text being available in the write-up.
**For the full model, language was slightly tweaked to include the phrase "treatment discontinuation"

Conclusion: Domain-adapted LLMs offer a practical solution for accelerating the development of TB clinical trial protocols. Our pipeline showed strong potential for drafting key sections offline and, therefore, for maintaining the privacy of our data. This work demonstrates how LLMs can be safely applied in global health contexts.

TBS-EP612 New tuberculosis diagnostic technologies enable decentralized participant-driven active case detection vaccine efficacy trials with asymptomatic TB endpoints

M. Ruhwald,[1] G. Churchyard,[2] R. Houben,[3] R. White,[4] A. Garcia-Basterio,[5] [1]Novo Nordisk Foundation Initiative for Vaccine and Immunity, Copenhagen, Denmark, [2]Aurum Institute, Johannesburg, South Africa, [3]LSTHM, London, United Kingdom of Great Britain and Northern Ireland, [4]LSHTM, London, United Kingdom of Great Britain and Northern Ireland, [5]IS Global, Barcelona, Spain
e-mail: mru@nividevelopment.dk

Tuberculosis (TB) vaccine efficacy trials traditionally rely on symptomatic, microbiologically confirmed TB disease endpoints. These require large cohorts and long follow-up, making trials costly and complex. However, a recent shift in WHO guidelines recognizes TB as a continuum of disease, with *asymptomatic TB* (aTB) - bacteriologically confirmed TB without reported symptoms - emerging as a biologically active and epidemiologically important phase. The characteristics of aTB are uncertain, but aTB may be twice as prevalent as symptomatic TB and may contribute to transmission and morbidity. Including aTB as a trial endpoint could accelerate vaccine development by enabling earlier detection of vaccine effects in smaller, shorter, and more cost-effective trials.

This paper proposes a decentralized, participant-driven trial model leveraging recent diagnostic innovations to detect both symptomatic TB (sTB) and aTB. We examine how emerging technologies such as tongue swab-based molecular tests, cfDNA assays, portable chest X-ray with CAD, and digital tools like cough apps and wearables, may support sensitive, repeatable, and non-invasive screening beyond traditional trial settings (figure).

Incorporating aTB as a composite primary or secondary endpoint - combined with decentralized testing and digital data collection - may radically reduce reliance on symptom-driven screening and enhance representation of vaccine impact across the full TB disease spectrum. Challenges include validating tests for low-burden disease, managing intermittent bacterial shedding, and producing regulatory-grade evidence. Nonetheless, advancements in test sensitivity, usability, and decentralized trial infrastructure support the feasibility of consistently detecting aTB. Repeated testing and digital integration also facilitate real-time efficacy and safety monitoring.

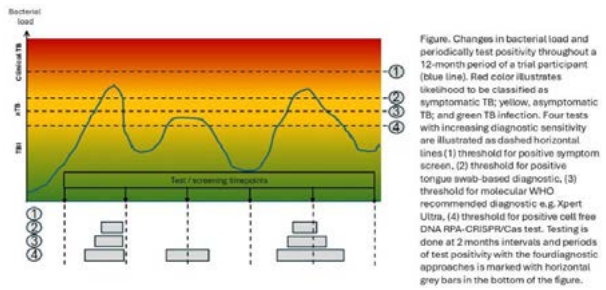


Figure. Changes in bacterial load and periodically test positivity throughout a 12-month period of a trial participant (blue line). Red color illustrates likelihood to be classified as symptomatic TB; yellow, asymptomatic TB; and green TB infection. Four tests with increasing diagnostic sensitivity are illustrated as dashed horizontal lines (1) threshold for positive symptom screen, (2) threshold for positive tongue swab-based diagnostic, (3) threshold for molecular WHO recommended diagnostic e.g. Xpert Ultra, (4) threshold for positive cell free DNA RPA-CRISPR/Cas test. Testing is done at 2 months intervals and periods of test positivity with the fourdiagnostic approaches is marked with horizontal grey bars in the bottom of the figure.

We outline a roadmap for integrating these innovations into TB vaccine trials, emphasizing research priorities such as better characterising aTB, diagnostic validation in early TB, usability of self-collection tools, and development of digitally triggered composite endpoints to enable faster, scalable, and more representative TB vaccine evaluations.

TBS-EP614 Predictive modeling of tuberculosis prevalence among medical workers in the Vinnytsia Region, Ukraine: Insights from 2007–2029

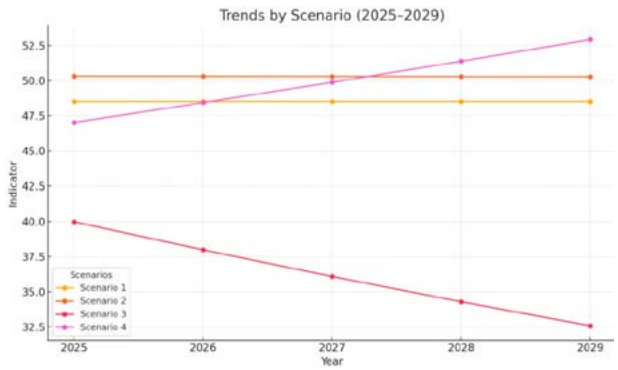
A. Bogomolov,[1] O. Lytvynyuk,[1] M. Tkhorovskiy,[1] S. Zaikov,[2] [1]National Pirogov Memorial Medical University, Vinnytsya, Ukraine, [2]Shupyk National Healthcare University of Ukraine, Kyiv, Ukraine
e-mail: bogomolov@vnmu.edu.ua

The aim of our study was a detailed predictive analysis of tuberculosis (TB) prevalence trends among medical workers in the Vinnytsia region of Ukraine over the next five years (2025–2029), utilizing historical incidence data spanning 2007–2023.

With linear regression and scenario-based modeling, four distinct scenarios were developed to model future trends: (1) maintenance of current trends reflecting recent disruptions, (2) reversion to pre-COVID-19 patterns observed from 2007–2019, (3) an optimistic scenario assuming improved healthcare interventions and military conflict resolution, and (4) a pessimistic scenario accounting for potential worsening due to ongoing war and healthcare challenges.

Historical data reveal a volatile incidence among medical workers, with a peak of 58.4 per 100,000 in 2010, a sharp decline to 21 in 2022, and a rebound to 44.3 in 2023, while the general population showed relative stability, ranging from 47.3 to 65.6 per 100,000, with a 2023 rate of 53. Projections indicate that under the current trend scenario, medical worker incidence stabilizes at approximately 48.5 per 100,000, while general population rates may decline to 42.0 by 2029. The optimistic scenario, driven by enhanced TB screening, treatment access, and support from initiatives like WHO programs, predicts a significant reduction to 32.57 for medical workers and 44.15 for

the population. In contrast, the pessimistic scenario, influenced by disrupted healthcare services and increased exposure risks, forecasts an increase to 52.91 and 59.66, respectively. These models highlight the critical role of external factors, such as the ongoing war, in shaping TB dynamics in the Vinnytsia region.



In conclusion we suggest that sustained public health investments, including mobile clinics and training for medical personnel, are essential to curb rising prevalence, particularly under adverse conditions.

TBS-EP616 Knowledge of tuberculosis prevention and control among public service vehicle operators in the South Rift Valley, Kenya

C. Sambu,[1,2,3] T. Koech,[3] J. Koskey,[4] [1]Riftvalley Technical Training Institute, Health sciences, Eldoret, Kenya, [2]Great Lakes University of Kisumu, TICH, Kisumu, Kenya, [3]Kapkatet County Referral Hospital, Nutrition, Kericho, Kenya, [4]University of Kabianga, Kericho, Kenya
e-mail: cheruiyotsambu@yahoo.com

Public service vehicles (PSVs) in the South Rift Valley, Kenya, present a unique and concerning environment for potential pulmonary tuberculosis (PTB) transmission. The confined spaces, often characterized by poor ventilation and close passenger proximity, create conditions conducive to airborne spread. Recognizing the crucial role PSV operators play in mitigating this risk, this study aimed to evaluate the baseline knowledge of PTB prevention and control measures among PSV operators in the South Rift Valley, Kenya.

Descriptive cross-sectional study was conducted, employing systematic sampling to recruit 120 drivers and 80 conductors in Kericho county and Bomet county. Data was collected using a pre-tested, interviewer-administered, semi-structured questionnaire. Adequate knowledge was defined as correctly answering ≥50% of knowledge-based questions. Statistical analysis was performed using SPSS version 22 and included chi-square ($\chi 2$) tests to assess associations, with statistical significance set at $p<0.05$.

Ethical approval was obtained, and informed consent was secured from all participants. The mean age (±SD) was 35.4 (±5.5) years for drivers and 26.7 (±4.8) years for conductors. The majority (86%, n=172) of participants had attained secondary education.

Overall, 68% demonstrated adequate PTB knowledge. Drivers exhibited significantly higher knowledge levels compared to conductors ($\chi 2 = 6.25$, $p = 0.012$). Education level was significantly associated with knowledge ($\chi 2 = 12.8$, $p = 0.001$).

Notably, half (50%, n=40) of conductors demonstrated adequate PTB knowledge. A significant proportion (87.5%, n=49) of those with primary level education demonstrated inadequate PTB knowledge. While overall PTB knowledge was moderate, a statistically significant knowledge gap exists among conductors, indicating a critical vulnerability within this population.

Considering the high PTB burden in Kenya (WHO, 2023) and the inherent transmission risks within PSVs (Ministry of Transport, Kenya, 2022), targeted interventions are essential to improve knowledge and control PTB transmission. This study underscores the urgent need to protect public health.

TBS-EP617 Analysis of mixed-strain Mycobacterium tuberculosis infections reveals lineage- and clinical-specific patterns

A. Gabrielian,[1] M. Harris,[1] B. Jeffrey,[1] M. Galac,[1] M. Peyton,[1] G. Rosenfeld,[1] K. Wollenberg,[1] D. Hurt,[1] A. Rosenthal,[1] [1]National Institute of Allergy and Infectious Diseases, OCICB, Rockville, United States of America
e-mail: gabr@niaid.nih.gov

Persisting tuberculosis (TB), especially drug-resistant forms, remains a global health challenge. Mixed-strain infections (MSIs), in which drug-sensitive and drug-resistant Mycobacterium tuberculosis clones co-exist, can undermine diagnostics, impede therapy, and drive chronic or latent disease.

Leveraging the TB Portals multi-domain database—linking full-genome sequencing of 9 667 isolates from Eastern Europe and Central Asia to patient-centric clinical, socioeconomic, and radiological data—we applied QuantTB to identify 521 MSIs (5.4 %): 481 two-strain, 39 three-strain, and one four-strain events.

MSIs were underrepresented among newly diagnosed cases yet enriched in patients with relapse, treatment failure, or chronic TB definitions. Clinically, MSIs showed higher sputum smear grades (≥ 2+), a male predominance, and elevated rates of treatment failure and loss to follow-up; in Outcomes, cure and mortality rates matched expectations. Resistance profiles revealed over-representation of MDR and XDR TB and under-representation of fully drug-sensitive infections.

Two-strain MSIs were driven by Lineage 2 (Beijing) and key Euro-American subclades, while three-strain events comprised almost exclusively Lineage 4.3 (Latin American–Mediterranean) and 4.1 (Haarlem), reflecting their high intra-sublineage diversity and balanced within-host fitness. Beijing strains, by contrast, frequently outgrow minor partners.

Although MSIs are a minority of sequenced cases, they disproportionately correlate with high bacillary burdens, drug resistance, and adverse outcomes. These lineage-specific co-infection dynamics underscore the need for lineage-aware surveillance, enhanced mixed-strain detection, and tailored treatment strategies—particularly for patients with relapse or treatment failure—to prevent amplification and transmission of complex MSIs in high-burden settings.

TBS-EP618 Is transmission the primary route to bedaquiline resistance? A context specific framework for transmission threshold estimation

A. Kjaersgaard,[1,2] C. Kim,[1,2] T. Ntshiqa,[3,4] S. Charalambous,[3,4] C.F. McQuaid,[1,2] L. Goscé,[1,2] R.G. White,[1,2] T.D. McHugh,[5] R.M.G.J. Houben,[1,2] G.M. Knight,[1,2,6] WellModTB Study Group [1]London School of Hygiene and Tropical Medicine, Department of Infectious Disease Epidemiology, London, United Kingdom of Great Britain and Northern Ireland, [2]TB Modelling Group, London School of Hygiene and Tropical Medicine, London, United Kingdom of Great Britain and Northern Ireland, [3]The Aurum Institute, Johannesburg, South Africa, [4]University of Witwatersrand, School of Public Health, Johannesburg, South Africa, [5]Center for Clinical Microbiology, University College London, London, United Kingdom of Great Britain and Northern Ireland, [6]AMR Centre, London School of Hygiene and Tropical Medicine, London, United Kingdom of Great Britain and Northern Ireland
e-mail: abel.kjaersgaard@lshtm.ac.uk

Infection with Mycobacterium tuberculosis strains that are resistant to bedaquiline (BDQ) threaten TB control. Such resistant infections can arise in three ways: spontaneous emergence without any drug exposure, acquisition during treatment or transmission. To determine interventions for control, it is vital to estimate the relative contribution of each of these three mechanisms to resistance burden. While it is likely that eventually the majority of BDQ resistant (BDQR) infections will be due to transmission, as is the case for MDR-TB, determining the point at which the predominant mechanism switches from spontaneous emergence and acquisition to transmission is vital to informing intervention policy.

To estimate the contributions of each mechanism, we developed a novel static threshold model which asks whether spontaneous mutation and acquisition alone can explain the current prevalence of BDQR in MDR/RR-TB patients. The model establishes a threshold above which transmission must be invoked to explain the observed BDQR prevalence. The model incorporates prior treatment levels and uncertainty in acquisition and mutation rate estimates.

Preliminary analysis suggests that transmission may become the dominant mechanism once BDQ is being used to treat more than 50% of MDR/RR-TB patients and BDQR prevalence in MDR/RR-TB is above 2.15%. From the limited prevalence data available from South Africa and Mozambique, it seems transmission may already be the dominant mechanism in both countries. Our Mozambique analysis shows that in early BDQ rollout, it can appear that the contribution of transmission reduces, but this is due to the increased contribution of the acquisition mechanism.

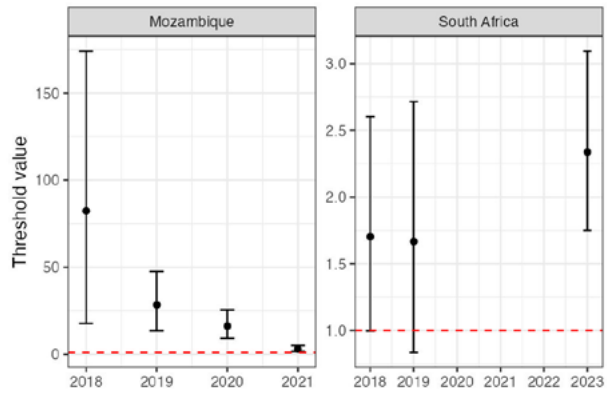


Figure 1: Threshold values by year in Mozambique and South Africa. Points are mean estimates; errorbars are 95% CIs. Threshold values >1 (red, dashed line) indicate transmission. Note, axes differ.

Our threshold analysis may enable new insights into BDQR spread whilst also providing a framework for context specific analysis. Preliminary modelling suggests that even at low resistance prevalence levels in MDR/RR-TB, BDQR is mostly transmitted, highlighting the need for early diagnosis, high coverage of BDQ drug susceptibility testing and effective BDQR treatment.

TBS-EP620 Utility of antibody responses in the diagnosis of tuberculosis in rural Papua New Guinea

C. Rush,[1] S. McIntyre,[1] J. Warner,[1] H. Vanderven,[1] [1]College of Medicine and Dentistry and Australian Institute of Tropical Health and Medicine, James Cook University, Townsville, Australia
e-mail: catherine.rush@jcu.edu.au

Background: TB is endemic in Papua New Guinea (PNG) and diagnosis is challenging, due to limited access to healthcare resources. Recent studies suggest that *Mycobacterium tuberculosis* (Mtb) antibodies may have diag-

nostic utility. The objectives of this study were:
1. To determine whether Mtb antibody levels differ between interferon gamma (IFN-γ) release assay (IGRA) positive and negative individuals;
2. To investigate whether Mtb antibodies are useful biomarkers to differentiate TB disease states.
Methods: Plasma was collected from adult participants at the Balimo District Hospital, Balimo, PNG. Initially, participants with known IGRA status were divided into IGRA+ and IGRA- groups. ESAT6- and CFP10-specific isotype, subclass and Fc gamma receptor (FcγR) binding antibodies were measured using bead-based multiplex assays.
The study cohort was also divided by TB disease state into TB negative, laboratory confirmed TB, clinical TB, and LTBI groups and plasma were tested for antibody isotype, subclass and FcγR binding to Mtb antigens ESAT6, CFP10, PstS1, HspX, MPT32, MPT64 and Ag85B.
Results and Conclusions: There was no significant difference in anti-ESAT6 or anti-CFP10 antibodies between IGRA+ and IGRA- individuals for any isotype, subclass, or FcγR binding. A weak positive correlation between anti-CFP10 IgG1 and IFN-γ release was the only significant correlation between Mtb-specific humoral and cellular immunity.
Across the TB groups, anti-PstS1 total IgG, anti-PstS1 IgG1 and anti-MPT32 IgG1 were elevated in the laboratory confirmed TB group compared to the TB negative group. Interestingly, anti-HspX IgA1 was elevated in the clinical TB group, but not the laboratory confirmed TB group, relative to the TB negative group.
There were no significant differences in Mtb-specific antibody levels across the three TB disease states and high intragroup variability was observed across all groups including the TB negative group. These findings underscore the necessity for further research on Mtb-specific antibody responses in TB-endemic communities.

TBS-EP622 Evaluation of the consistency between phenotypic MIC and genomic mutations in the detection of Bedaquiline and Clofazimine cross-resistance in *Mycobacterium tuberculosis* isolates from the Philippines

S. Yoshida,[1] A. Akio,[1] A. Osugi,[1] R. Basilio,[2] J. Bascuña,[2] M. Kato-Maeda,[3] S. Mitarai,[1] K. Tsuyuguchi,[4] [1]Research Institute of Tuberculosis, Japan Anti-Tuberculosis Association, Kiyose, Tokyo, Japan, [2]National Tuberculosis Reference Laboratory-Research Institute for Tropical Medicine, Muntinlupa City, Philippines, [3]University of California, San Francisco, San Francisco, United States of America, [4]NHO Kinki-chuo Chest Medical Center, Sakai, Japan
e-mail: yoshida_shiomi@jata.or.jp

Background: Bedaquiline (BDQ) and Clofazimine (CFZ) are increasingly chosen for drug-resistant tuberculosis (TB) treatment. However, given their critical therapeutic roles, cross-resistance between these drugs have emerged as major concerns. As BDQ and/or CFZ-containing regimens increase, is important to support clinical decision with an improved genetic BDQ resistance information.
Purpose: This study was aimed to phenotypically and genotypically assess BDQ and CFZ resistance in *Mycobacterium tuberculosis* (MTB) isolates from DR-TB patients in the Philippines.
Methods: DR-TB clinical isolates (n=188) were isolated from 188 Philippines' patients. MIC for MTB was established in accordance with the guidelines by the CLSI M24-A2. Drug resistance mutations related to BDQ and repurposed CFZ were detected using the online tool TB Profiler, which could also report lineage information about the strains.
Results: Only 5 (2.7 %) isolate was resistant to BDQ, based on the CLSI breakpoint of 0.5 μg/mL. The three isolates with MIC at 1 to BDQ were all resistant to CFZ; these isolates' MIC with 4. Out of three cross-resistant between BDQ and CFZ isolates, only one isolate had mutation in mmpR5_c.198dupG, and was identified as lineage 1.
Discussion and Conclusion: Our study found that only one BDQ-resistant isolates had duplication mutations in *Rv0678*, however, other four isolates were resistant to BDQ (MIC range from 0.5 to 1) harboured no mutation in all known resistance-associated genes. This demonstrated that the mutation of Rv0678 has low specificity in predicting BDQ and/or CFZ resistance.
Although previous reports indicate that the duplication mutation at base pair 198 of *Rv0678* is rare, our results suggest that isolates harboring this mutation may reflect the level of protein inactivation. The reasons for the differences between the phenotypic and genomic resistance of our study could be due to missed low-frequency resistance mutations, mutations in novel resistance genes, or erroneous phenotypic DST results.

TBS-EP624 Gastrointestinal parasites and their association with TB immune responses in Rural Papua New Guinea

C. Rush,[1] J. Scott,[1] W. Melrose,[2] D. Pelowa,[3] J. Warner,[1]
[1]College of Medicine and Dentistry and Australian Institute of Tropical Health and Medicine, James Cook University, Townsville, Australia, [2]College of Medicine and Dentistry, James Cook University, Townsville, Australia, [3]Balimo District Hospital, Balimo, Papua New Guinea
e-mail: jeffrey.warner@jcu.edu.au

Background: Tuberculosis remains a major public health threat in Papua New Guinea (PNG), particularly in remote and resource-limited regions such as Balimo, Western Province. The burden of TB in PNG is compounded by the high prevalence of parasitic infections, including soil-transmitted helminths (STH) and intestinal protozoa, which are known to modulate host immune responses. Although substantial evidence suggests that parasitic co-infections can influence immunity to *Mycobacterium tuberculosis* (Mtb), the extent to which these interactions impact TB pathogenesis and clinical outcomes remains unclear and context dependent.
This study aimed to investigate the immunological effects of co-endemic parasitic infections in a TB-endemic community.
Methods: Blood, sputum, and stool samples, along with demographic and clinical information, were collected from participants categorized into three groups: individuals with active pulmonary TB, those with latent TB infection, and TB-naïve community members. Stool analysis identified individuals with confirmed STH or protozoan infections, including both pathogenic and commensal species. Peripheral blood samples were analysed for innate and adaptive immune markers, including T cell subsets and cytokine profiles. TB-specific immune responses were further evaluated using interferon gamma release assays (IGRA) and the TAM-TB flow cytometry assay.
Results: Our results revealed a high prevalence of CCR3+ eosinophils in individuals with active STH infections and those seropositive for *Strongyloides stercoralis*, indicating ongoing immune modulation.
Additionally, many community members exhibited impaired CD4+ and CD8+ T cell function, which could compromise protective immunity against Mtb, potentially leading to increased TB susceptibility, diagnostic delays, and poorer treatment outcomes.
Conclusions: These findings emphasise the need for integrated disease control strategies that address co-infections and their immunological consequences. A better understanding of parasite–TB interactions is essential for optimizing TB vaccination, diagnostics, and treatment approaches, particularly in co-endemic settings.
This study underscores the importance of interdisciplinary research linking infectious disease ecology, immunology, and public health policy.

TBS-EP626 Accelerating tuberculosis prevention: Assessing novel TB preventive treatments in a preclinical infection model

A. Lupien,[1,2,3,4] F. McIntosh,[3] I. Roe,[3] F. Gafar,[4,5,6] M. Behr,[1,2,3,4] D. Menzies,[4,7,8,9] [1]McGill University (Department of Medicine), Montreal, Canada, [2]McGill University (Department of Microbiology and Immunology), Montreal, Canada, [3]Research Institute of the McGill University Health Centre (Infectious Diseases and Immunity in Global Health Program), Montreal, Canada, [4]McGill International TB Center, Montreal, Canada, [5]McGill University (Respiratory Epidemiology and Clinical Research Unit, Centre for Outcomes Research and Evaluation), Montreal, Canada, [6]Universitas Padjadjaran (Department of Biomedical Sciences, Faculty of Medicine), Bandung, Indonesia, [7]Research Institute of the McGill University Health Centre (Respiratory Epidemiology and Clinical Research Unit, Centre for Outcomes Research and Evaluation), Montreal, Canada, [8]McGill University (Department of Epidemiology, Biostatistics and Occupational Health), Montreal, Canada, [9]Montreal Chest Institute (McGill University Health Centre), Montreal, Canada
e-mail: andreanne.lupien@mcgill.ca

Tuberculosis (TB) caused over 1.25 million deaths globally in 2023. Following infection with *Mycobacterium tuberculosis* (M.tb), active disease can develop in up to 20% of infected patients, often after several months or years following infection. During this period, treatments can be administered to limit disease progression, known as tuberculosis preventive therapy (TPT). However, current TPTs are lengthy (up to 9 months) and can produce serious side effects due to anti-TB drug toxicity, leading to limited administration among infected individuals. Therefore, we need effective therapeutic options with fewer side effects and shorter durations.
Large-scale clinical trials evaluating TPT efficacy are costly and time-consuming. To streamline the development of new TPTs, we established a murine model of M.tb infection to evaluate short-course treatments (≤2 months) with minimal toxicity and relapse rates comparable to the standard 4-month rifampicin regimen (4R10), as part of the SSTaRLeT adaptive clinical trial.
We validated the model by comparing 4R10 with a 2-month high-dose rifampicin regimen (2R20). At 2 months post-treatment with R20, only 1 of 5 mice had detectable lung bacteria.
We also assessed relapse rates following treatment durations of 4, 6, and 8 weeks with 2R20, finding outcomes similar to 4R10 following 2 months of treatment with R20 (40% vs. 47% relapse for 4R10 and 2R20, respectively), supporting the potential of shorter regimens.
We also evaluated the efficacy and optimal duration of the HP regimen (daily administration of isoniazid and rifapentine) and a novel LvP regimen (daily administration of levofloxacin and rifapentine). Levofloxacin offers a favourable toxicity profile and potential efficacy against drug-resistant strains.

To further refine these two TPTs, we are conducting pharmacokinetic steady-state studies to optimize the dosing of both regimens. This model enables rational preclinical testing of TPT, avoiding arbitrary drug repurposing and accelerating the path toward effective, shorter-duration regimens.

TBS-EP628 The computer-aided detection software using chest X-ray images in TB screening may have the potential to identify early TB patients in China

W. Liu,[1] [1]Jiangxi JF Healthcare Technology Co., Ltd., Nanchang, China
e-mail: whhzliuwei@163.com

Pulmonary tuberculosis (PTB) remains a global public health challenge, with 10.8 million new cases reported in 2023. Early diagnosis is crucial for controlling its spread, yet traditional sputum-based tests face limitations in turnaround time and resource availability. Artificial intelligence (AI)-based computer-aided detection (CAD) systems, leveraging deep learning, offer a promising solution for automated PTB detection. In a latest meta-analysis including five software solutions for chest X-ray has shown sensitivity and specificity as follows: JF CXR-1, 86.0% and 80.0%; qXR, 90.0% and 64.0%; Lunit INSIGHT CXR, 90.0% and 63.0%; CAD4TB, 91.0% and 60.0%; InferRead DR Chest, 89.0% and 59.0%, of which JF CXR-1 and InferRead DR Chest are from China.
Another interesting research focusing on aged ≥65 years old in Jiangshan County, Quzhou City, China also used JF CXR-1 v2 for detecting chest X-ray images and to estimate its potential capacity for identifying PTB cases. A total of 49,919 subjects participated in the 2020 examinations. Of these, 40,741 and 39,185 completed the follow-up surveys in 2021 and 2022, respectively. The pooled prevalence of suspected PTB reported by radiologists was 1.21% (1579/129,776), compared with 12.43% (16,129/129,776) reported by CAD. Of 101 bacteriologically confirmed PTB cases notified over three years, radiologists and CAD reported 45.54% (46/101) and 83.16% (84/101) as suspected cases, respectively. Among subjects with abnormal CAD (CAD score>0.35), the majority of the notified confirmed PTB patients (63/84) had their CAD scores >75% quantiles (as>0.75). With 3 years` results, their CAD scores exhibited dynamic changes along with disease progression or treatment with median scores peaking in the year of diagnosis. This intriguing finding suggests that CAD for CXR reading assisted radiologists in PTB screening by reducing workload and improving case finding. The CAD primary score may have the potential to identify high-risk individuals and early PTB patients.

TBS-EP630 Comparing LAM to other sputum-based biomarkers in NC-009 trial

J. Timm,[1] J. Nedelman,[1] M. Betteridge,[1] M. Olugbosi,[2] M. Beumont,[1] E. Sun,[1] [1]TB Alliance, Research and Development, New York, United States of America, [2]TB Alliance, Research and Development, Johannesburg, South Africa
e-mail: juliano.timm@tballiance.org

New mycobacterial markers are needed to shorten and improve outcome predictability of TB drug trials, which still rely on sputum culture, a resource-intensive procedure with results taking up to 8 weeks. PATHFAST TB LAM Ag assay (LAM), a semi-automated chemiluminescent enzyme immunoassay that quantifies mycobacterial lipoarabinomannan in sputum within 1 hour, appears as a promising alternative, but has been only evaluated in patients treated for up to 2 weeks.
We compared LAM with other sputum-based biomarkers, namely acid-fast bacilli smear microscopy (AFB), Xpert threshold cycle (Ct) and MGIT time-to-positivity (TTP) in NC-009, an ongoing randomized, controlled, phase 2 study evaluating 3 doses of the next-generation diarylquinoline TBAJ-876 in combination with pretomanid and linezolid (876PaL) for 8 weeks, followed by isoniazid-rifampicin for 15- and 26-week total treatment durations.
Comparator arms are 26-week BPaL and standard-of-care HRZE/HR. LAM, AFB, Ct and TTP levels were obtained from 2 sputum samples at baseline and during treatment (day 15, and weeks 4, 8, 15 and 26), as well as in select recurrence cases, for a subcohort of 159 South African participants.
All assays were performed using the same starting material, decontaminated sputum samples. LAM was quantified in a PATHFAST instrument; AFB, Ct and TTP levels were derived using standard procedures. Quantitative readouts for LAM, Ct and TTP, and semi-quantitative AFB were used to determine the dynamics of each test throughout drug treatment and in pairwise correlation analyses.
LAM performance (sensitivity/specificity/negative predictive value/positive predictive value) was assessed by classifying sputum samples into negative (below cutoff) versus positive and using MGIT as a reference. LAM results at each visit were also examined as predictors of stable culture conversion. In general, LAM data paralleled TTP data beyond 2 weeks of treatment.

TBS-EP632 Low complexity-manual nucleic acid amplification tests for detection of pulmonary tuberculosis in adolescents and adults with presumptive tuberculosis: A systematic-review and meta-analysis of diagnostic accuracy

V.A. Srinivasalu,[1] L.R. Inbaraj,[1] J. Daniel,[2] M.K. Sathyanarayanan,[1] A. Bhaskar,[1] K. Scandrett,[3] A. Korobitsyn,[4] N. Ismail,[4] Y. Takwoingi,[3] [1]Indian Council of Medical Research - National Institute for Research in Tuberculosis, Chennai, India, [2]Christian Medical College, Vellore, India, [3]University of Birmingham, Birmingham, United Kingdom of Great Britain and Northern Ireland, [4]World Health Organization, Geneva, Switzerland
e-mail: vickysurgeon@gmail.com

Background: Early detection and treatment of tuberculosis (TB) is crucial for global TB elimination. LC-mNAATs such as TB-LAMP (loop-mediated isothermal amplification) are World Health Organization (WHO) recommended rapid diagnostics (mWRDs) shown to have comparable performance to low complexity automated NAATs for pulmonary TB. Our review aimed to synthesize evidence for LC-mNAATs for detection of pulmonary TB (PTB) to inform an update of the 2024 WHO consolidated guideline on diagnosis of TB.
Design/Methods: We searched CENTRAL, MEDLINE, EMBASE and other electronic databases using specific search terms. We also performed hand searches and bibliography mining. A WHO public call for data contributed additional studies. We included studies that evaluated design locked marketed LC-mNAATs against microbiological or composite reference standards in adolescents and adults (>10 years) with presumptive PTB. We independently in pairs screened titles/abstracts and full texts, extracted data, and performed quality assessment of included studies. Certainty of evidence was assessed using the GRADE approach.
Results: We screened 1138 titles and abstracts and included 27 studies from 151 full texts. The studies generally had low risk of bias and applicability concern (Figure 1A). From 26 studies (18297 participants, Figure 1B), summary sensitivity (95% CI) and specificity (95% CI) on respiratory specimens for detection of PTB were 84.1% (78.3 to 88.6) and 96.1% (94.2 to 97.4), high certainty of evidence. Among PLHIV, summary sensitivity was 77.1% (60.8 to 87.9) and summary specificity was 95.9% (84.9 to 99.0) (8 studies, 2991 participants). Summary sensitivity and specificity were 95.9% (92.2 to 97.9) and 43.7% (26.8 to 62.2) among smear positive individuals (16 studies, 1568 participants).
Conclusion: TB-LAMP has satisfactory performance for detecting PTB in adolescents and adults. Though the inability to detect rifampicin resistance is a limitation, TB-LAMP could be a potential alternative for smear microscopy and other mWRDs that necessitate complex infrastructure.

Figure 1A. Risk of bias and applicability summary. **Figure 1B.** Forest plot of LC-mNAATs for detection of PTB: respiratory specimens and microbiological reference standard.

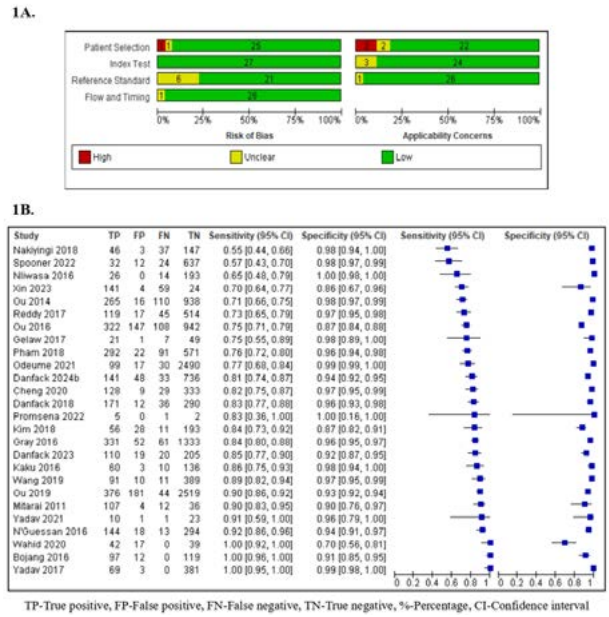

Figure 1A. Risk of bias and applicability summary. Figure 1B. Forest plot of LC-mNAATs for detection of PTB: respiratory specimens and microbiological reference standard.

TBS-EP634 Impact of TB preventive therapy at grassroots level in community setting in Pune, India

G. Narke,[1] B. Hodgar,[2] L. Gophane,[3] A. Dadewar,[4] [1]Pimpri-Chinchwad Municipal Corporation, Pune, India, [2]Pimpri-Chinchwad Municipal Corporation, Pimpri Chinchwad, India, [3]Pimpri-Chinchwad Municipal Corporation, Pimpri Chinchwad, Pune, India, [4]Pimpri-Chinchwad Municipal Corporation, Pimpriii Chinchwad, India
e-mail: drgovindanarke@gmail.com

Background: Tuberculosis (TB) remains a significant public health issue in India. Preventing TB among high-risk populations, particularly household contacts (HHCs) of TB patients, is essential to achieving elimination goals. This study evaluates the impact of community-based TB Preventive Therapy (TPT) implementation through active contact tracing, regular follow-up, and upfront molecular testing.
Methods: A total of 310 TB index cases were notified over one year. Contact tracing was conducted for all, identifying 834 household contacts. Among them, 821 (98%) were screened for TB symptoms across multiple visits. 23 symptomatic individuals were identified and 22 tested using NAAT, resulting in the diagnosis of 2 active TB cases. Asymptomatic and eligible contacts were initiated on a 3HP TPT regimen. Follow-up was conducted for one year to assess treatment completion and TB incidence.

Results: The implementation outcomes are summarized below:

Sr. No.	Indicator	Value
1	TB Index Cases	310
2	Household Contacts Traced	834
3	Contacts Screened for Symptoms	821 (98%)
4	Symptomatic Contacts Identified	23
5	TB Cases Diagnosed After NAAT	2
6	Contacts Started on TPT (3HP)	466 (99.8%)
7	TPT Completion (Among Initiated)	451 (96.8%)
8	TB Cases After TPT Completion (1-Year)	3

Conclusion: The high rate of screening, treatment initiation, and completion demonstrates that TPT delivery at the grassroots level is highly feasible and impactful. The very low incidence of TB among those who completed TPT highlights its effectiveness in preventing disease. This model can serve as a scalable strategy to support TB elimination efforts across similar community settings.

TBS-EP636 Innovative AI tool for TB diagnosis based on metabolomic detection in urine

A. Moran-Canella,[1] J.L. Izquierdo-Garcia,[2] I. Rodriguez,[2] J. Dominguez,[1] [1]Fundació Institut d'Investigació en Ciències de la Salut Germans Trias i Pujol (IGTP), Barcelona, Spain, [2]Universidad Complutense de Madrid (UCM), Madrid, Spain
e-mail: jadominguez@igtp.cat

Tuberculosis (TB) persists as a global threat for public health and remains one of the most threatening and underdiagnosed curable infectious diseases. Current diagnostic methods present limitations, and there is an urgent need to develop a rapid, accurate and accessible diagnostic tool to improve TB control and reduce disease burden. We present an innovative solution based on urinary metabolomic detection powered by artificial intelligence (AI) and benchtop nuclear magnetic resonance (NMR) spectroscopy.

Previous clinical evidence within our research group showed significant changes in the concentration of eight metabolites in the urine of TB patients compared to healthy individuals.

In 1H NMR spectroscopy, every metabolite produces a unique pattern of peaks resulting from oscillations of its hydrogen nuclei in a magnetic field. The concentration of each metabolite is directly proportional to the area of its peaks. The complexity of NMR spectra lies in several factors: variations in peak width, positional shifting of peak clusters due to pH variability in urine the sample, white noise, and contamination of the sample.

Neural network (NN) models play a big role in analyzing complex NMR spectra and accurately quantifying metabolite concentrations. NNs were trained with thousands of synthetized NMR spectra to address the lack of training samples. The simulations included all features listed above to accurately replicate real cases.

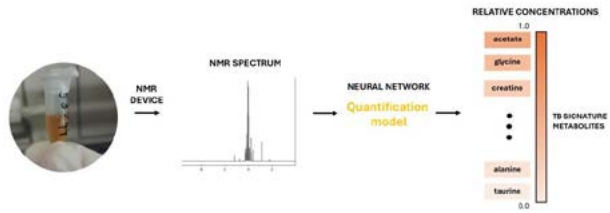

Figure 1.

NNs are later fine-tuned with real annotated NMR spectra. The models are able to capture subtle NMR information that traditional techniques fail to identify. Our test *(Figure 1)* allows an automatic and quick identification and quantification of dominant metabolites within urine samples that will subsequently provide accurate TB diagnosis. Clinical studies performed in Europe, Haiti and Nigeria have proved the metabolomic signature to be a global diagnostic method and will increase the NN models' robustness across different clinical settings.

TBS-EP641 Detection of LAM in exhaled breath condensate for tuberculosis diagnosis and treatment monitoring using different immunoassays

J. Nigou,[1] N. Gogichadze,[2] N. Tukvadze,[3] S. Nicolas,[1] Z. Waja,[4] S. Vashakidze,[5] N. Martinson,[4] C. Vilaplana,[2] SMA-TB RCT team [1]Institute of Pharmacology and Structural Biology, CNRS / Université de Toulouse, Toulouse, France, [2]Germans Trias i Pujol Research Institute & Hospital, Badalona, Spain, [3]National Center for TB and Lung Diseases Georgia, Swiss TPH, Tbilisi, Georgia, [4]Perinatal HIV Research Unit (PHRU), University of the Witwatersrand, Johannesburg, South Africa, [5]National Center for TB and Lung Diseases Georgia, University of Georgia, Tbilisi, Georgia
e-mail: jerome.nigou@ipbs.fr

Exhaled breath condensate (EBC), the liquid phase of the exhaled air sampled by cooling, appears as a promising sample to facilitate clinical diagnosis of TB across patient populations and monitor treatment efficacy. Yet, its relevance and usefulness in the management of TB has to be validated in large cohorts. We previously reported that Lipoarabinomannan (LAM), a mycobacterial cell envelope lipoglycan and established TB biomarker in urine, was present in large amount in EBC from TB patients collected in the frame of a pilot study in Colombia (PMID: 36517492).

We took advantage of the SMA-TB EU-funded project (GA847762) Phase II clinical trial (NCT04575519), conducted to evaluate ibuprofen and acetylsalicylic acid as anti-inflammatory adjunctive to anti-tuberculosis treat-

ment, to nest a clinical study and collect EBC samples from the enrolled patients. Samples were collected at baseline (from n=217 patients) and along the course of treatment (from n=86 patients; 5 time-points). In addition, as this sample is known to show important inter- and intra-subject variability, samples were collected at 4 different times of the same day for a limited number of patients. Here, we report the quantification of LAM in EBC samples collected in the frame of SMA-TB in South Africa and Georgia, using 3 different techniques based on an immunoassay: a home-made laboratory Dot-Blot, a lateral flow test from LIONEX GmbH, and the PATH-FAST™ analyzer.

TBS-EP644 Treatment outcomes of tuberculosis among artisanal and small-scale miners in Zimbabwe: A follow-up observational study using secondary data

D. Moyo,[1,2] R. Ncube,[3] F. Kavenga,[4] F. Moyo,[5] G. Madziva,[6] N. Chiboyiwa,[7] O. Muzvidziwa,[8] B. Chigaraza,[5] M. Ncube,[5] C. Timire,[9] T. Muperi,[8] K. Mutungamiri,[10,11]
[1]National University of Science and Technology, Bulawayo, Zimbabwe, [2]Baines Occupational Health Services, Bulawayozimba, Zimbabwe, [3]The Union Zimbabwe Trust, Harare, Zimbabwe, [4]Ministry of Health and Childcare, Harare, Zimbabwe, [5]Baines Occupational Health Services, Bulawayo, Zimbabwe, [6]Baines Occupational Health Services, Harare, Zimbabwe, [7]Ministry of Health and Childcare Zimbabwe, Bulawayo, Zimbabwe, [8]Baines Occupational Health Services, Gweru, Zimbabwe, [9]Ministry of Health and Child care, Harare, Zimbabwe, [10]Jointed Hands Welfare Organization, Gweru, Zimbabwe, [11]Jointed Hands Welfare Organization, Gweruzimb, Zimbabwe
e-mail: moyod@mweb.co.zw

In Zimbabwe, artisanal and small-scale miners (ASMs) are a key vulnerable group with high risk for tuberculosis (TB), HIV, and silicosis. The main purpose of this study was to investigate treatment outcomes of TB among ASMs. We conducted a follow-up observational study using secondary data. We analyzed data from 208 ASMs treated for TB at two occupational health clinics. We found a high treatment success rate of 87%, comparable to the national average for drug-sensitive TB. Unsuccessful outcomes were due to death (5%) and loss to follow-up (7%). Over a quarter of ASMs had unknown HIV status. Our study is the first to document treatment outcomes of TB among ASMs in Zimbabwe. Encouragingly, this study demonstrates the possibility of achieving good TB treatment outcomes even among highly mobile populations like ASMs. Further research is needed to analyze leakages across the whole TB patient pathway among ASMs. Additionally, addressing the high rate of unknown HIV statuses among ASMs is crucial to further improve overall TB treatment outcomes in this population.

TBS-EP647 Enhancing lung health through physiotherapy for overall well-being

E. Nakanwagi,[1] G. Wangolo,[2] [1]Uganda Institute of Allied Health and Management Sciences, Mulago, Kampala, Uganda, [2]Makerere University, Kampala, Uganda
e-mail: elizabethnakanwagi99@gmail.com

Background: Lung health is essential for overall well-being, yet respiratory conditions such as tuberculosis, chronic obstructive pulmonary disease (COPD), asthma, and post-COVID-19 complications continue to affect millions worldwide. Physiotherapy has emerged as a vital intervention in improving pulmonary function, reducing respiratory distress, and enhancing quality of life.
This study explores the role of physiotherapy in promoting lung health and its impact on overall well-being.
Methods: A systematic review of existing literature and clinical studies was conducted to evaluate the effectiveness of physiotherapy techniques, including breathing exercises, airway clearance techniques, pulmonary rehabilitation, and physical conditioning. Data from patient records, clinical trials, and meta-analyses were analyzed to assess improvements in lung function, oxygen saturation levels, and patient-reported outcomes.
Statistical analysis was performed using a random-effects model to assess mean differences in lung function parameters such as forced expiratory volume (FEV1), peak expiratory flow rate (PEFR), and oxygen saturation. A significance level of $p < 0.05$ was used to determine statistical relevance.
Results: The findings indicate that physiotherapy interventions significantly improve pulmonary function parameters, with a mean increase in FEV1 by 12% ($p = 0.002$) and PEFR by 15% ($p = 0.004$), enhance exercise tolerance, and reduce respiratory symptoms in chronic lung conditions patients. Patients who underwent structured physiotherapy programs reported better lung capacity, improved oxygen exchange levels ($p = 0.007$), and reduced episodes of breathlessness. physiotherapy contributed to overall well-being by improving mobility, reducing fatigue, and enhancing mental health.
Conclusion: Physiotherapy is a crucial component in lung health management, offering non-invasive and effective interventions for patients. Introducing physiotherapy into standard care could lead improved respiratory function, increased physical activity, and better quality of life. Future research should focus on optimizing physiotherapy protocols and expanding access to pulmonary rehabilitation programs.

TBS-EP650 Rational use of antibiotics and antimicrobial resistance in pulmonary infections

M. Durdyyeva,[1] B. Hojagulyyev,[1] [1]Myrat Garryyev State Medical University in Turkmenistan, Ashgabat, Turkmenistan
e-mail: dmyakhri@yandex.com

Antimicrobial resistance (AMR) is a major global health threat, despite the annual increase in newly developed antibacterial agents. The WHO Global Strategy for Containment of Antimicrobial Resistance emphasizes the need to preserve the effectiveness of essential medicines such as antibiotics for current and future generation. Resistance in microorganisms leads to prolonged hospital stays, increased healthcare costs, and higher mortality rates. This study aimed to assess the prevalence, structure, and rational use of antibiotics in patients with respiratory tract diseases in Turkmenistan.

Medical records of 269 patients with upper and lower non-specific respiratory infections were reviewed. Most patients were aged 41–60 years (68.5%), and 51.3% were female. Clinical diagnoses included community-acquired pneumonia (47.3%), chronic obstructive pulmonary disease (18.2%), and chronic bronchitis (34.5%).

Bacteriological examination showed Staphylococcus aureus in 28.6%, Streptococcus spp. in 15.2%, Pseudomonas aeruginosa in 4.8%, Streptococcus pneumoniae in 25.1%, mixed flora in 20.0%, and Candida spp. in 6.3%. Cephalosporins (39.8%) were the most prescribed antibiotics, followed by fluoroquinolones (17.8%), penicillins (13.4%), aminoglycosides (13.0%), tetracyclines (5.6%), macrolides (4.1%), antifungals (4.8%), and carbapenems (1.5%). Antimicrobial resistance was detected in 61.3% of patients. The most frequent resistances were to cephalosporins (35.2%), penicillins (21.6%), aminoglycosides (12.0%), macrolides (8.0%), fluoroquinolones (7.8%), tetracyclines (5.6%), carbapenems (3.4%), antifungals (1.8%), and sulfonamides (4.6%).

Contributing factors to AMR included empirical antibiotic prescribing without microbiological testing, short treatment durations, and premature discontinuation of therapy. Effective AMR prevention strategies must include stewardship programs, guideline-based prescribing, and increased awareness among healthcare providers.

TBS-EP653 Tissue-specific immune phenotyping reveals divergent responses to BCG vaccination and *Mycobacterium tuberculosis* challenge

S. Díaz-Fernández,[1] J. Puñet-Ortiz,[2] J. Díaz,[3] P. Soldevilla,[1] C. Peña,[4] J.B. Torrelles,[5] J. Domínguez,[1] I. Latorre,[1] [1]Institut d'Investigació Germans Trias i Pujol. CIBER Enfermedades Respiratorias, CIBERES, Instituto de Salud Carlos III. Departament de Genètica i Microbiologia, Universitat Autònoma de Barcelona, Badalona, Spain, [2]Plataforma de Citometría, Institut d'Investigació Germans Trias i Pujol, Badalona, Spain, [3]Centre de Medicina Comparativa i Bioimatge de Catalunya (CMCiB), Institut d'Investigació Germans Trias i Pujol, Badalona, Spain, [4]Integrative Immunology Lab. Instituto Nacional de Enfermedades Respiratorias. CDMX, México. Institut d'Investigació Germans Trias i Pujol, Badalona, Spain, [5]Population Health and Host Pathogen Interactions Programs, International Center for the Advancement of Research & Education (I•CARE), Texas Biomedical Research Institute, San Antonio, Texas, United States of America
e-mail: ilatorre@igtp.cat

Aim: To identify tissue-residency profiles playing a relevant role in *Mycobacterium tuberculosis* (*Mtb*) immunity in a mouse model of tuberculosis (TB): in the absence of vaccination, after naïve BCG-vaccination, or with a vaccination strategy based on the exposure of naïve BCG to human alveolar lining fluid (ALF-BCG) to evaluate the influence of the lung environment on immune responses.
Methods: C57BL/6 mice were infected by aerosolization (Glas-Col chamber) with *Mtb* $H_{37}R_v$. Infected mice were divided into 3 groups: unvaccinated, naïve BCG or ALF-BCG-vaccinated. Mice received subcutaneous vaccination 4 weeks prior infection; and sacrificed 6 weeks post-infection. At necropsy, blood and lungs were extracted, and cells were obtained after erythrocyte lysis and Percoll density-gradient centrifugation, respectively. Cells were stimulated overnight with specific mycobacteria antigens (ESAT-6/CFP-10 or PPD) and stained for surface and intracellular markers specific to T-, B- and NK-cells. Samples were acquired using Cytek Aurora and analysed with OMIQ for unsupervised high-dimensional analyses.
Results: Tissue-resident memory CD4 and CD8 T-cells ($CD69^+CD103^+$) were enriched in the parenchyma of unvaccinated infected mice. Naïve BCG-vaccination resulted in several changes in lung and blood immune cell populations: (i) lung exhibited a terminally differentiated CD8 T-cell response ($KLRG\text{-}1^+CX3CR1^+$) with decreased IL-17a and increased activated B-cells ($CD44^+$I-A/I-$E^+CD1d^+CD69^+$); while (ii) the blood showed a shift towards pro-inflammatory CD4/CD8 Th17 responses and mature $CD11b^+CD27^-$ NK-cells (expressing $CD44^+KLRG1^+CD62\text{-}L^+$). ALF-BCG-vaccination enhanced certain naïve BCG-driven immune responses, mainly the abundance of activated B-cell clusters in lung, and specific memory T-cells in blood.

Conclusions: Following *Mtb* infection, lung immune cells display specific tissue-residency phenotypes. Moreover, immune mechanisms driven by BCG have diverse local and systemic effects, being cell profiles remarkably different depending on the tissue of origin. ALF-BCG-vaccination drove enhanced specific B and T-cell immune subsets *vs.* naïve BCG.

TBS-EP656 Risk of human tuberculosis associated with exposure to livestock in rural Ballabgarh, Haryana: A Case-Control Study

R. Kumar,[1] H.R. Salve,[1] P. Misra,[1] M. Papanna,[2] R. Kumar,[3] N. Jindal,[3] [1]All India Institute of Medical Sciences, New Delhi, Centre for Community Medicine, New Delhi, India, [2]Huck Institutes of the Life Sciences, The Pennsylvania State University, Pennsylvania, United States of America, [3]Lala Lajpat Rai University of Vety & Animal Sciences (LUVAS), Hisar, India
e-mail: dr.rakesh3105@gmail.com

Background: There is very limited data on contribution of zoonotic TB in overall burden of tuberculosis in India. This study was conducted to estimate the risk of tuberculosis among individuals exposed to livestock in rural Ballabgarh, Haryana.
Methods: An unmatched case control study was conducted between October 2022- March 2023 in a rural area of the Ballabgarh block in Haryana, India. Patients of all ages and sexes with microbiologically confirmed tuberculosis were enrolled as cases. Outpatient attendees of the facilities in the study area who resided in the same area as cases and among whom tuberculosis was ruled out by chest x-ray, and sputum examination by smear microscopy and molecular methods were enrolled as controls. Case to control ratio was 1:3. Information on demographics, livestock ownership and exposure to cattle and raw milk consumption were elicited through structured questionnaire. The livestock at the case and control household were screened using Interferon Gamma Release Assay (IGRA) test. Multivariable logistic regression was done to assess the association between exposure and tuberculosis.
Results: 65 cases and 205 controls were enrolled in the study. The mean age of cases was 39.9 years (SD-18.3) and that of controls was 41.3 years (SD-14.4). 26 (41.3%) of the household with cases and 89 (43.4%) of the household with controls had livestock. 18% (39/219) of the livestock were positive by IGRA; 20% (31/157) buffalos, 11.8% (6/51) cattle and 18.1% (2/11) goats. Contact with livestock (aOR- 0.6; 95% CI- 0.3-1.2) and consumption of raw milk (aOR-0.5;95% CI- 0.2-1.4) were not associated with risk of tuberculosis. There was no increased risk of bovine tuberculosis among livestock in households with cases as compared to controls (cOR for buffalo- 0.95, 95% CI- 0.41-2.20; cOR for cattle: 0.74, 95% CI- 0.12-4.50)
Conclusion: Exposure to livestock was not associated with increased risk of tuberculosis.

Exposures	Case (n=63) n (%)	Control (n=205) n (%)	Crude Odds ratio (95% CI)	Adjusted Odds (95% CI)	P value
Age (Years)					
<=40	32 (50.8)	109 (53.2)	Ref		
=>41	31 (49.2)	96 (46.8)	1.1 (0.6-1.9)	1.1 (0.6-2.0)	0.723
Sex (Male)	54 (66.7)	85 (41.5)	2.8 (1.6-5.1)	3.1 (1.7-5.7)	0.000
Owning livestock	26 (41.3)	89 (43.4)	0.9 (0.5-1.6)	-	
Owning cattle (cow/bull)	10 (15.9)	39 (19.2)	0.8 (0.4 -1.7)	-	
Owning buffalo	19 (30.2)	66 (32.2)	0.9 (0.5-1.7)		
Owning goats & sheep	1 (1.6)	5 (2.4)	0.6 (0.1-5.6)	-	
Contact with livestock	15 (23.8)	75 (36.6)	0.5 (0.3-1.0)	0.6 (0.3-1.2)	0.157
Consumption of raw milk	5 (7.9)	26 (12.7)	0.6 (0.2-1.6)	0.5 (0.2-1.4)	0.176

TBS-EP659 Navigating funding challenges to end tuberculosis in Bangladesh: A call for sustained commitment and domestic investment

M.S. Alam,[1] P. Daru,[1] P.K. Modak,[1] M.M.-U.A. Rubel,[1] J. Faruque,[1] L. Stevens,[2] C. Mergenthaler,[3] R. Baten,[4] N.A. Saki,[5] S. Rahman,[6] M. Rahman,[7] S. Hossain,[8] [1]Independent Public Health Consultant, Dhaka, Bangladesh, [2]Independent Public Health Consultant, Weymouth, United Kingdom of Great Britain and Northern Ireland, [3]KIT Institute, Amsterdam, Netherlands, [4]Morgan State University, Baltimore, United States of America, [5]World Health Organization (WHO), Dhaka, Bangladesh, [6]Individual Consultancy, Dhaka, Bangladesh, [7]Delft Imaging, Dhaka, Bangladesh, [8]Individual Public Health Consultant, Dhaka, Bangladesh
e-mail: shamsher367@gmail.com

Tuberculosis (TB) remains a persistent public health challenge in Bangladesh, with an estimated 379,000 cases reported in 2023—reflecting a 7.4% increase from 2015 and a modest 1.1% rise from 2022. Despite the disease being preventable and curable, Bangladesh continues to face significant hurdles, especially with the growing threat of multidrug-resistant TB (MDR-TB), which poses both a health and security risk. Systemic challenges—including inadequate funding, limited domestic financial commitment, and uneven access to quality diagnostic and treatment services—have hampered TB control efforts.
These challenges have been exacerbated by the global funding crisis triggered by the U.S. STOP order on January 27, 2025, which led to major funding withdrawals by international donors, severely impacting TB programs worldwide, including Bangladesh.
Bangladesh's National TB Control Program has demonstrated consistent efforts in scaling up TB detection and treatment, contributing to the global success of saving an

estimated 79 million lives since 2000. In 2023, the country secured US$ 92 million for TB programming—an improvement in domestic contribution to 38% compared to 3.7% in 2015. However, the national TB budget stood at US$ 365 million in 2023, with a staggering 81% unfunded. This critical gap threatens the sustainability of existing interventions and the ability to scale up essential services, particularly for MDR-TB.

While the TB incidence appears stable, the progress is fragile. The increasing share of domestic funding signals progress, yet it remains insufficient to meet the growing programmatic needs. The reliance on unpredictable external funding underscores the vulnerability of TB responses in Bangladesh.

To achieve the 2030 TB elimination target under the Sustainable Development Goals, Bangladesh must prioritize increased domestic resource mobilization, integrate TB services within primary healthcare, and ensure sustained policy and financial commitments. Strengthening health systems and investing in MDR-TB prevention and treatment are vital to maintaining progress.

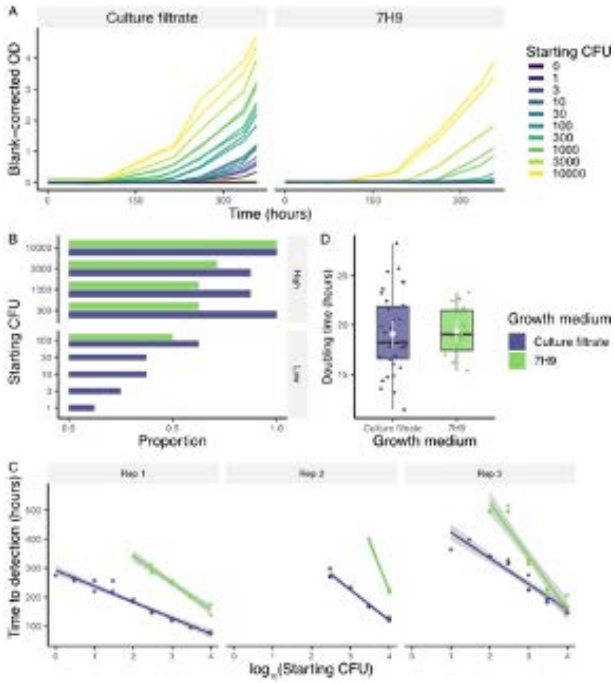
TBS-EP662 Density-dependent enhancement of *Mycobacterium tuberculosis* growth by culture filtrate

R. Dinkele,[1,2] D. Ralefeta,[1,2] A. Moosa,[1,2] D. Warner,[1,2] S. Gessner,[1,2] [1]Molecular Mycobacteriology Research Unit, University of Cape Town, Cape Town, South Africa, [2]Institute of Infectious Disease and Molecular Medicine, University of Cape Town, Cape Town, South Africa
e-mail: ryan.dinkele@uct.ac.za

The culturing of *Mycobacterium tuberculosis* (*Mtb*) remains a critical research and diagnostic tool. However, growing *Mtb* from paucibacillary inocula, particularly clinical samples, is challenging. Culture filtrate (CF) supplementation of standard growth media (7H9) has been proposed to enhance *Mtb* culturability by restoring growth in a subpopulation known as differentially culturable tubercule bacilli (DCTB). While efforts have been made to identify the active components of CF, limited data describe how CF supplementation influences culturability from extremely low-density inocula.

We performed a half-logarithmic (~3.16-fold) dilution series of *Mtb* H37Ra from 10,000–0 CFU, culturing each inoculum in either 7H9 or CF. Growth was monitored using optical density measurements, and growth outcomes (growth/no-growth), time to detection (TTD), and maximal growth rate were calculated for each sample.

Inocula of ≥300 CFU were 33 times more likely to grow compared to inocula of ≤100 CFU, accounting for growth media. CF supplementation increased the odds of growth fivefold and reduced the TTD by an average of 294 hours compared to 7H9, without affecting the maximal growth rate. However, this effect was not consistent at all inoculum densities. The difference in TTD between CF and 7H9 reduced by 58 hours for every $\log_{10}$-increase in inoculum density, becoming negligible at ~60,000 CFU/mL.



While CF enhanced the probability of *Mtb* growth, this effect was most pronounced at low inoculum densities. Given the proposition that DCTB comprise a subset of the population that would have been diluted out in these low-density samples, and considering the inverse relationship between CF efficacy and inoculum density, we propose that CF promotes growth only in low-density inocula, rather than by specifically resuscitating DCTB. These findings suggest that other mechanisms, such as quorum sensing, might have an important role in growth initiation in *Mtb*.

TBS-EP665 Detection of first-line and second-line Drug-Resistance mediating mutations in *Mycobacterium tuberculosis* with DNA extracted with different extraction methods directly from sputum using Next-Generation Sequencing

V. Allerheiligen,[1] L. Wolf,[1] M. Eckart,[1] V. Falvo,[2] A. Salahoru,[2] W. Carbone,[2] [1]Hain Lifescience a Bruker company, Nehren, Germany, [2]ELITechGroup a Bruker company, Turin, Italy
e-mail: vera.allerheiligen@bruker.com

Mycobacterium tuberculosis complex (MTBC) is a group of highly transmissible bacterial pathogens that cause significant worldwide morbidity and mortality, particularly among HIV-infected patients. Annually, MTBC is responsible for approximately 1.3 million deaths. The emergence of multi-drug-resistant (MDR) strains within the MTBC has significantly reduced treatment options. Current methods for detecting drug resistance in MTBC can be time-consuming, often requiring up to two months to yield results.

Next-generation sequencing (NGS) has provided valuable insights into the genetic diversity of MTBC, which are crucial for understanding the evolution and transmission of the disease. NGS has also facilitated the identification of drug-resistant strains, enabling rapid and accurate tailoring of treatment. Seven genes have been used for tuberculosis (TB) first-line and second-line drug resistance analysis: rpoB (Rifampicin), katG and inhA (Isoniazid), rrs (Amikacin), rrs and eis (Capreomycin), and gyrA and gyrB (Levofloxacin, Moxifloxacin).

NGS was performed using DNA from manual extraction (FluoroLyse, Hain Lifescience) or automated extraction (GXT fleXT, Hain Lifescience and InGenius, ELITech Group) from NALC-NAOH decontaminated native sputum. Multiplex PCR targeting the seven resistance genes was employed for targeted NGS using Oxford Nanopore and Illumina technologies. Library preparation incorporated eight distinct barcodes on a single flow cell. Variant calling and annotation were performed using TB-Profiler. Concurrently, extracted DNA was analysed with FluoroType MTBDR VER 2.0 and LiquidArray MTB-XDR VER 1.0 as references. Analytical sensitivity and sequencing quality were evaluated, demonstrating promising results.

TBS-EP668 Frequency and co-resistance of bedaquiline, clofazimine, delamanid, and pretomanid in MDR-TB isolates at a North Indian reference laboratory

R. Ratnam,[1] P. Jain,[1] A. Jain,[1] M. Singh,[1] R.A.S. Kushwaha,[1] U. Singh,[1] V.P. Singh,[1]
[1]King George's Medical University, Lucknow, India
e-mail: rashmi19micro@gmail.com

Background: The emergence of multidrug-resistant (MDR-TB) and extensively drug-resistant tuberculosis (XDR-TB) has spurred use of novel and repurposed agents—bedaquiline (BDQ), clofazimine (CFZ), delamanid (DLM), and pretomanid (Pa). Primary phenotypic resistance to these drugs, however, may undermine treatment efficacy.

Objective: To determine the frequency of phenotypic resistance to BDQ, CFZ, DLM, and Pa, and to assess co-resistance patterns among MDR-TB isolates from treatment-naïve and follow-up pulmonary tuberculosis patients in North India.

Methods: A total of 70 MDR-TB isolates (55 treatment-naïve; 15 persistently culture-positive ≥4 months after treatment initiation) were tested at the Intermediate Reference Laboratory for Tuberculosis, Department of Microbiology, King George's Medical University, Lucknow, India (NABL-accredited). Liquid culture drug susceptibility testing was performed on the Becton Dickinson BACTEC MGIT 960 system using WHO-recommended critical concentrations: BDQ 1 μg/mL; CFZ 1 μg/mL; DLM 0.06 μg/mL; Pa 0.5 μg/mL (low) and 2 μg/mL (high). Proportions of resistant isolates were calculated with 95% Wilson confidence intervals (CI).

Results: Among treatment-naïve isolates, BDQ resistance was detected in 10/55 (18.2%, 95% CI 10.2–30.3%); of these, 7/10 (70.0%, 95% CI 39.7–89.2%) also exhibited CFZ resistance. Low-level Pa resistance occurred in 3/55 (5.5%, 95% CI 1.9–14.9%); no DLM resistance was observed. Two isolates (2/55; 3.6%, 95% CI 1.0–12.3%) displayed pan-resistance to BDQ, CFZ, Pa, fluoroquinolones, linezolid, and pyrazinamide.

In follow-up samples, BDQ resistance appeared in 6/15 (40.0%, 95% CI 19.8–64.3%), with CFZ co-resistance in 4/6 (66.7%, 95% CI 30.0–90.3%). Low-level Pa resistance was noted in 2/15 (13.3%, 95% CI 3.7–37.9%); no DLM or high-level Pa resistance was seen.

Conclusions: Primary phenotypic resistance to bedaquiline was detected in nearly one-fifth of treatment-naïve MDR-TB isolates and commonly accompanied by clofazimine cross-resistance. Continued surveillance and routine susceptibility testing for these new and repurposed agents are essential to optimize MDR-TB treatment regimens.

TBS-EP671 In-vitro evaluation of indigenous device - K8 Spider Enteric Capsule for Adsorption and Transfer of *MTB Bacilli* for routine diagnosis

S. Raja,[1] N. Yash,[2] S.M. Rudresh,[1] R. Narang,[1]
[1]AIIMS BIBINAGAR, Hyderabad, India, [2]MGIMS, Wardha Maharastra, India
e-mail: rahuldevnarang@gmail.com

Background: Paucibacillary TB represents a significant diagnostic challenge, particularly in immunocompromised patients like HIV and those with extra-pulmonary disease.
K8 Spider Enteric Capsule: Biocompatible gelatin capsule (size2) filled with autoclaved highly absorbent braids of hand-spun cotton yarn (Khadi) which is smooth, non-traumatic and non–toxic. K8 spider named due to the pattern of unfurling resembling a spider web.
Intra-capsular assembly was connected with extra-capsular string (sterilised surgical silk) through tight knot passing through pinhole which will be tapped to the cheek.
In-vitro Experiment with *MTB* H37Rv strain: Concentration of 10^4 -10^7 of H37Rv strain of *MTB suspensions* were made. 0.1ml of each conc. transferred to 30ml distilled water (30-30,000 bacilli/ml). K-8 spider kept for 1 hour and transferred to 5ml PBS, kept for 30 mins. Centrifuged at 3000 rpm,15 mins; sediment was subjected to: MGIT, LJ culture and AFB smear.
Observation: Growth observed in all except 10^4 and it was confirmed as *MTB*
Inference: K-8 spider's showing adherence to *MTB* and successful release on centrifugation (300 bacilli/ml)
In-vitro Experiment with *Known MTB Positive Sputum Sample*: 3 ml of two normal saline samples adjusted to pH of 3 & 5. K-8 spider enteric capsule added and kept for 15 mins. 1 ml of *MTB* positive sputum sample (3+ grade) added into each tube and kept for 60 mins.
K-8 spider transferred to 5 ml PBS and decontaminated. Centrifuged and sediment was subjected to LJ slants, AFB smear; Blood agar for decontamination.
Observation: Capsule dissolved in 15 mins in pH-3; 25 mins in pH-5. Growth observed in both conditions.
Inference: K-8 spider found no variability in the results due to acidic pH.
Conclusion: K-8 spider enteric capsule effectively picked up mycobacteria and has the potential to be used as a sample collection/concentration method for effective diagnosis in sputum scarce children and HIV/AIDS subjects.

TBS-EP674 Breaking resource barriers: Development of portable AIMLAM for active TB diagnosis in the HIV- population

Z. Ru,[1] L. Liu,[1] Y. Deng,[1] S. Wang,[1] J. Lou,[1] X. Yang,[1]
[1]Leide Biosciences Co., LDT, Guangzhou, China
e-mail: yangx@leidebio.com

Urine lipoarabinomannan (LAM) testing is a promising biomarker for the development of rapid tuberculosis (TB) diagnostic assays. However, due to the very low concentration of LAM in urine samples from HIV-negative individuals, its application has traditionally been limited to HIV-positive populations. Chemiluminescent immunoassays (CLIA) offer higher sensitivity but require expensive instruments, limiting their accessibility in resource-limited settings.
To address this challenge, we developed AIMLAM—a fluorescence lateral flow immunoassay (FLF) integrated with a novel Rapid Urine Processor (RUP)—designed to deliver near-CLIA sensitivity in a portable, cost-effective format.

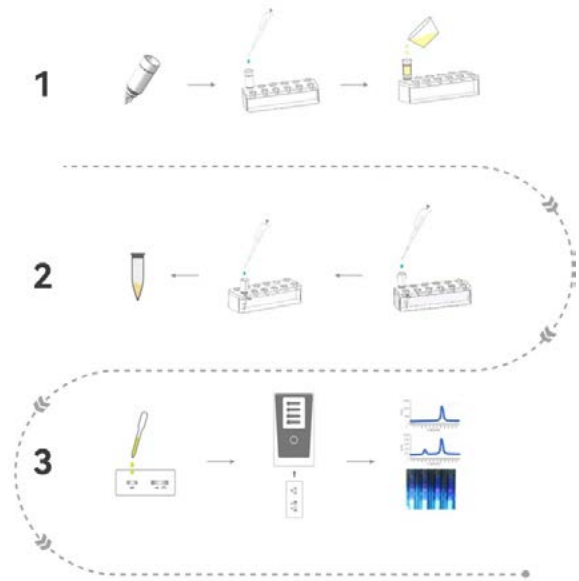


Fig 1: Operational Workflow for AIMLAM Fluorescent Lateral Flow Assay
The workflow comprises three main stages:
1. Device Preparation: Active the RUP2 device for 3 minutes, followed by a brief wash.
2. Urine Concentration: Add the urine sample to the RUP2 device and incubate for 20 minutes. Perform washing and elution steps to obtain the concentrated sample.
3. Detection: Apply the concentrated sample to the test card and incubate for 20 minutes, then test by fluorescence detector.

The AIMLAM assay involves two simple steps: urine processing using the RUP device, followed by fluorescence detection using a portable analyzer. A 6 mL urine sample is concentrated 20-fold prior to signal detection, and the

total assay time is approximately one hour. The study cohort included 77 TB patients (CRS+), 53 non-TB patients (CRS−), and 117 healthy controls. The overall sensitivity and specificity of AIMLAM were 50.6% and 94.7%, respectively. In microbiologically confirmed (MRS+) TB cases, AIMLAM achieved a sensitivity of 60.8%.
The 20× urine concentration using the RUP device significantly enhanced sensitivity without compromising specificity. The AIMLAM-FLF assay can be easily adapted for use in resource-constrained settings. Its strong diagnostic performance, ease of use, and affordability make it a promising tool for expanding access to TB diagnosis and supporting global TB control efforts.

TBS-EP677 Exhaled breath condensate: A new window on aerobiology of *Mycobacterium tuberculosis*

B. Patterson,[1] R. Seldon,[1] A. McKerry,[1] Z. Hoosen,[1] J. Kutschenreuter,[2] M.-C. Loader,[2] D. Warner,[3] R. Wood,[1]
[1]Aerobiology and TB Research Unit, Desmond Tutu Health Foundation, Cape Town, South Africa, [2]Institute for Infection and Immunity, City St George's, University of London, London, United Kingdom of Great Britain and Northern Ireland, [3]Institute of Infectious Disease and Molecular Medicine, Faculty of Health Sciences, University of Cape Town, Cape Town, South Africa
e-mail: b.patterson1@nhs.net

Introduction: Aerosolised Mycobacterium tuberculosis (Mtb) has been detected across the tuberculosis (TB) disease spectrum and in randomly selected individuals in high-burden settings using a Respiratory Aerosol Sampling Chamber (RASC) with identification via DMN-trehalose staining and fluorescence microscopy. These findings have major epidemiological implications and require validation in other settings. This study presents a simplified exhaled breath condensate (EBC) device and assesses its potential to replicate RASC findings using an array of Mtb bacillus and host disease assays.
Method: The EBC sampler uses a copper cooling block with thermoelectric pads in which sits a glass tube for sample collection. A stainless-steel mouthpiece, secured by a 3D-printed holder, connects to a one-way valve and exit HEPA filter. This design maximises capture of the particle content of EBC and limits contamination with all participant-contact components disposable. Two patient groups were sampled with EBC pellets stained with DMN-trehalose to detect viable Mtb, and genomic detection used droplet digital PCR (ddPCR) for RD9. Supernatant samples were analysed for matrix metalloproteinases (MMP-1 and MMP-9) by DuoSet ELISA assay.
Results: Among the first TB patient group all confirmed by Xpert on sputum (n=10), 5 of 8 evaluable samples (62.5%) were positive by DMN-trehalose staining, and 4 of 10 (40%) by ddPCR. For the second group (n=15) including symptomatic (n=10: 5 Xpert+ and 5 Xpert-) and asymptomatic (n=5: Xpert-) community cases, positive LF-LAM (n=3) strongly correlated with high concentration of MMP-9 (n=3) (p=0.03). Table shows results for cases with either positive LF-LAM or high concentration MMP-9 only.

Patient	Presentation	Xpert status	EBC LF-LAM	EBC MMP-9	EBC MMP-1	Clinical Phenotype
1	Symptomatic	Positive	Positive (2+)	Detected	Not detected	Pulmonary TB case
2	Symptomatic	Negative	Positive (1+)	Detected	Not detected	Pulmonary TB case
3	Asymptomatic	Negative	Positive (1+)	Not detected	Not detected	?Subclinical TB/Mtb colonisation
4	Asymptomatic	Negative	Negative	Detected	Not detected	Alternative lung pathology

Conclusion: This pilot study demonstrates that a simple, deployable EBC device can detect viable and genomic Mtb, as well as LF-LAM and host-produced MMP-9 – critical for lung tissue destruction and granuloma formation. These findings support the feasibility of using a bespoke EBC device to study TB transmission in various epidemiological contexts.

TBS-EP680 Assessment of a simplified and portable IGRA-TB platform based on fluorescence immunoassay for the diagnosis of *Mycobacterium tuberculosis* Infection

J. Valera,[1] H. Samson,[2] J.N. Ekwu,[2] P. Madrid,[3] J.W. Dyaji,[2] I. Latorre,[4] J.S. Bimba,[5] J. Domínguez,[4] [1]Preventive Medicine Department from Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [2]Zankli Research Centre, Bingham University, Karu, Nigeria, [3]Institut d'Investigació Germans Trias i Pujol, Badalona, Spain, [4]Institut d'Investigació Germans Trias i Pujol. CIBER Enfermedades Respiratorias, CIBERES, Instituto de Salud Carlos III. Departament de Genètica i Microbiologia, Universitat Autònoma de Barcelona, Badalona, Spain, [5]Zankli Research Centre, Bingham University. Department of Community Medicine, Bingham University, Karu, Nigeria
e-mail: jadominguez@igtp.cat

Objective: To evaluate whether a simplified and portable fluorescence immunoassay (FIA)-based IGRA-TB platform for the detection of interferon-gamma (IFN-γ) released in response to *Mycobacterium tuberculosis*-specific antigens can serve as an alternative to ELISA-based IGRAs, particularly in high TB burden setting such as Nigeria.
Methods: We prospectively selected two group of patients. Group 1. 50 TB disease patients with microbiologic confirmation by culture and/or PCR. These patients were included in the Asokoro Hospital (a secondary health facility in Nigeria). Tests were performed at the Zankli Research Center. Group 2. Healthy individuals (n=108), younger than 50 years old, with no signs or symptoms of active TB, and no known exposure to a pulmonary TB case. Determinations were performed at Institut

d'Investigació Germans Trias i Pujol (Badalona, Spain). For the FIA (Ichroma and AFIAS IGRA-TB; Boditech), 3 mL of blood was collected in three different stimulation tubes (nil, TB antigen, and mitogen).
After incubation of the tubes at 37°C during 16-24h, plasma was collected for assays development. IFN-γ released in the sample forms an antigen-antibody complex in the cartridge leading to fluorescence intensity signal.
Results: Among the 108 healthy individuals, 105 (97.2%) were classified as negative and 3 (2.8%) as positive across both diagnostic methods. Regarding the 50 samples collected from TB disease cases, 24 (48.0%) were positive for FI-AFIAS, 20 (40.0%) were negative, and 6 (12.0%) were indeterminate. For FI-Ichroma, 24 (48.0%) were positive, 25 (50.0%) were negative, and only 1 (2.0%) was indeterminate.
Conclusions: The FIA-based IGRA-TB platforms demonstrated high specificity and moderate sensitivity (48%) for detecting active TB. This simplified and portable system requires minimal laboratory infrastructure and hands-on time, making it suitable for point-of-care screening in decentralized settings.
These preliminary results should be consolidated in contact tracing studies to assess their performance compared with other IGRAs available.

TBS-EP683 Diagnostic Utility of Fluorescein Diacetate (FDA) Staining for Rapid Tuberculosis Detection: A Comparative Study Against Automated Liquid Culture

R. Ratnam,[1] P. Jain,[1] U. Singh,[1] M. Singh,[1] A. Jain,[1] V.P. Singh,[1]
[1]King George's Medical University, Lucknow, India
e-mail: rashmi19micro@gmail.com

Background: Rapid and reliable detection of *Mycobacterium tuberculosis* (MTB) is critical for effective tuberculosis (TB) control, especially in high-burden settings. This study evaluates the diagnostic performance of Fluorescein Diacetate (FDA) staining against the gold-standard liquid culture (LC) method.
Methods: This cross-sectional study was conducted at the Intermediate Reference Laboratory, Department of Microbiology, King George's Medical University, Lucknow, India, accredited by NABL and NTEP. A total of 109 sputum samples (>3 mL) from patients referred for TB diagnosis (n=67) or follow-up monitoring (n=42) between January–February 2025 were analyzed. All samples underwent auramine staining, automated liquid culture (MGIT 960), and FDA staining. Culture contamination cases were excluded. Diagnostic performance metrics for FDA were calculated using LC as the reference.
Results: Among diagnostic samples, 29 were auramine-positive. FDA correctly identified 16 culture-positive cases (TP), misidentified 5 culture-negative (FP), and missed 3 culture-positive (FN); 2 were true negatives (TN). In auramine-negative diagnostic samples (n=38), FDA failed to detect 3 culture-positive (FN), while 34 were TN.
Among follow-up cases, FDA accurately detected 4 culture-positive cases among 6 auramine-positive samples and 1 additional case in auramine-negative samples. Combined across all groups (excluding contaminated), FDA demonstrated:

- **True Positives (TP)**: 24
- **False Positives (FP)**: 5
- **False Negatives (FN)**: 7
- **True Negatives (TN)**: 72

From these, calculated performance values were:

- **Sensitivity**: 77.4%
- **Specificity**: 93.5%
- **Positive Predictive Value (PPV)**: 82.8%
- **Negative Predictive Value (NPV)**: 91.1%
- **Accuracy**: 88.9%

Conclusion: FDA staining offers a rapid, cost-effective alternative to culture with high specificity and acceptable sensitivity for MTB detection. Its implementation in resource-limited settings may improve timely initiation of TB treatment

TBS-EP686 Gross and histopathology of pulmonary tuberculosis in Asian elephants (*Elephas maximus*)

D. Abraham,[1] P. Deepa,[2] T.V. Anilkumar,[3] [1]Department of Forests and Wildlife, Government of Kerala, Palakkad Kerala, India, [2]Kerala Veterinary and Animal Sciences University, Pookode Kerala, India, [3]Sree Chitra Tirunal Institute for Medical Sciences & Technology, Thiruvananthapuram, Kerala, India
e-mail: dr_da@hotmail.com

Pulmonary tuberculosis caused by the *Mycobacterium tuberculosis* complex (MTC) pathogens in mammals is characterised by granulomatous reaction consisting of different types of cells like foamy macrophages, epithelioid macrophages, and Langhan's giant cells with a peripheral rim of lymphocytes and a fibrous capsule. A few granulocytes and plasma cells may also be present in these granulomas with a central core of necrosis and mineralisation.
Minor variations in the proportion of these components are recorded in the lesions caused by various species of MTC pathogens in different mammalian hosts. Most reported cases of tuberculosis in Asian elephants (*Elephas maximus*) are caused by the human strains of *Mycobacterium tuberculosis* and have shown involvement of lungs and associated lymph nodes.
This report gives a pictorial description of the important types of lesions and cells observed in the granulomas in lung nodules, collected during post-mortem examinations of six Asian elephants. Grossly, the affected lobes of lungs revealed circumscribed lesions of varying sizes with

56, 84, 112, 140 and 168 during first-line anti-TB treatment. Mycobacterial species were isolated by culture and characterised by microscopy, *rpoB*, spoligotyping, drug susceptibility testing against isoniazid (INH) and rifampicin (RIF).

One hundred and fourty-five newly diagnosed patients comprising 104 suffering from only TB and 41 co-morbid with diabetes (TBDM). Of these, 21 cases maintained viable mycobacterial [(*Mycobacterium tuberculosis*: 16 (Lineage, L 2: 2 and L4: 14), *Mycobacterium africanum* (3 (L5: 1 and L6: 2) and 2 unidentified strains)] culture at the end of day 56 of treatment. Out of these, 7 (7/41:17%) were TBDM and 14 (14/104;13%) were TB cases (p=0.432). Four of the cases' isolates were found to be resistant to INH (2 TBDM, 2 TB) at diagnosis. Isolates from 13 cases that were susceptible at diagnosis evolved to be resistant during treatment; 9 from 4 TBDM and 5 TB cases became INH resistant, 3 from TB cases became RIF resistant and 1 TB case became multidrug resistant-TB. The remaining 4 cases remained susceptible (1 TBDM) at day 56 (p=0.72).

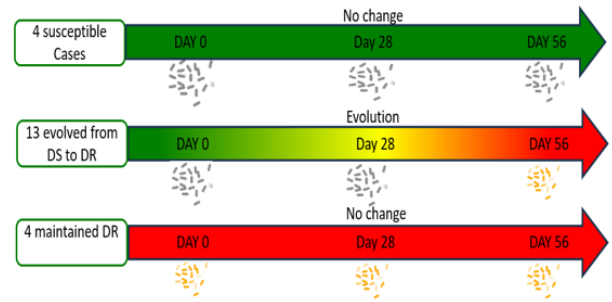

Fig 1. Evolution of drug resistance in TB patients.

We observed that drug resistance occurred on day 56 in 52.9% of the drug-resistant cases. All cases were counselled and those whose regimen needed to be changed were done according to national guidelines. Our findings highlight the need to closely monitor patients during anti-TB treatment to detect and manage drug resistant strains promptly to optimize patient care and adhere to national guidelines for regimen adjustments. The serial isolates are being sequenced to understand the underlying molecular mechanism.

TBS-EP695 Post TB morbidity - What is the optimal management of TB IRIS? Proposal for a clinical trial

K. Singh,[1,2] J. Denholm,[1,2] [1]The University of Melbourne, Melbourne, Australia, [2]The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia
e-mail: kasha.singh@unimelb.edu.au

TB treatment is almost always microbiologically successful. New drugs provide expanded treatment options improving outcomes for those with drug intolerance or resistance. Challenges in delayed diagnosis and post-TB morbidity persist and contribute significantly to the burden of disease attributable to TB globally. Pulmonary impairment due to scarring is the best characterised contributor to post-TB morbidity. However immune reconstitution inflammatory syndrome (IRIS) affecting lymph nodes and lungs is also a problem.

IRIS is well-recognised in people living with HIV, however also affects those without hIV infection. It is characterised by lymph node enlargement which may be painful and may lead to skin breakdown with sinus formation, although marked clinical heterogeneity is seen. Clinical manifestations can be uncomfortable and disfiguring and can therefore cause significant distress/morbidity. The optimal management of TB IRIS is unknown.

We propose a study to investigate whether surgery may lead to improved outcomes in lymph node TB IRIS. We propose that patients with lymph node TB IRIS, occurring following successful treatment for TB are randomised to best medical therapy or surgical review. Surgical consultation may lead to operative management.

Primary outcome measures for the study will be patient reported outcome measures („PROMS") at 26 weeks post-randomisation. Secondary outcomes include change in characteristics of the lesion (size, discharge, pain scores). Outcomes will be assessed monthly (at 4, 8, 12, 16, 20 and 26 weeks).

To our knowledge this is the first randomised study to investigate treatment of TB-IRIS.

TBS-EP698 Preliminary diagnostic performance of novel LAM antibodies in CSF of HIV negative Vietnamese children with TB meningitis: A SURE substudy

J. Huynh,[1,2] K. Scott,[3] N.T.H. Nguyen,[4] T.H. Trinh,[5] R. Basu-Roy,[6,7] T.T.T. Nguyen,[1,2] G.E. Thwaites,[1,2] H. Ramachandraiah,[8] [1]Oxford University Clinical Research Unit, Ho Chi Minh City, Viet Nam, [2]Oxford University, Oxford, United Kingdom of Great Britain and Northern Ireland, [3]Meso Scale Diagnostics, Maryland, United States of America, [4]Pham Ngoc Thach Hospital, Ho Chi Minh City, Viet Nam, [5]Children's Hospital 2, Ho Chi Minh City, Viet Nam, [6]Blizard Institute, London, United Kingdom of Great Britain and Northern Ireland, [7]MRCCTU at UCL, London, United Kingdom of Great Britain and Northern Ireland, [8]FIND, Geneva, Switzerland
e-mail: jhuynh@oucru.org

Background: Early diagnosis of tuberculous meningitis (TBM) improves outcomes however point-of-care(POC) testing is lacking. Commercialised POC testing for TB measures lipoarabinomannan (LAM) in urine. It is unknown whether LAM concentrations in CSF are below the detection limit of these assays. We determined the concentration and performance of LAM antibodies in CSF of children with TBM and non-TBM.

Methods: Nested within a randomised controlled trial of short-intensified therapy for children with TBM (SURE ISRCTN40829906), a case-control substudy was conducted at Pham Ngoc Thach Hospital and Children's Hospital 2 in Ho Chi Minh City, Vietnam. Pre-treatment CSF was tested using Ziehl Neelsen(ZN) stain, Xpert Ultra, and MGIT. Cryopreserved CSF was tested for LAM using anti-LAM capture antibodies; S4-20(FujiLAM), FIND-28, and BTM-1 covering a range of epitopes, and A194 as the detection antibody. LAM immunoassays employed a multiplexed sandwich format and electrochemiluminescence detection (U-PLEX LAM, Meso Scale Diagnostics, LLC). Performance was assessed in those with microbiologically confirmed ('definite') TBM and non-TBM.

Results: We selected samples from 20 children with definite TBM and 10 non-TBM children on this reference laboratory platform. 18/20 studied were ZN smear positive, 11 Ultra positive, and 8 culture positive. The analytical limit of detection for LAM was 24.4 pg/ml for all antibody pairs. The sensitivity and specificity of CSF S4-20 was 30% (95% CI 2-54%) and 90% (95% CI 56-99%) respectively, whereas in urine it was 65% (95% CI 41-85%) and 80% (95% CI 44-97%).

The sensitivity and specificity of CSF FIND-28 was 25% (95% CI 9-49%) and 100% (95% CI 69-100%) respectively; and for CSF BTM-1 it was 70% (95% CI 45-88%) and 70% (95% CI 35-93%).

Conclusion: S4-20 showed higher sensitivity in urine than CSF. BTM-1 had higher sensitivity in CSF which warrants further investigation as a potential point-of-care test for childhood TBM.

TBS-EP707 Ecological epidemiology insights into the risk of tuberculosis infection among captive Asian elephants

D. Abraham,[1] P. Deepa,[2] K.P. Venugopal,[3] [1]Department of Forests and Wildlife, Government of Kerala, Palakkad, Kerala, India, [2]Kerala Veterinary and Animal Sciences University, Pookode, Wayanad, Kerala, India, [3]Government Medical College Hospital Kottayam, Kottayam, Kerala, India
e-mail: dr_da@hotmail.com

We assessed the tuberculosis infection risk among captive Asian elephants in southern India using an ecological approach. Over a five-year-period, a total of 60 dead captive elephants were selectively included in the study. For the evaluations, a matched case-control study design with equal number of cases and controls was used.

Evaluations were conducted between 30 tuberculosis-confirmed animals and 30 disease-free animals. We examined the two potential risk factors for tuberculosis infection in elephants: the risk of transmission from diseased elephants and the risk of transmission from diseased mahouts.

Up to ten contact-elephants and ten contact-mahouts were listed for each of the 30 cases and controls. The disease statuses of the contact-elephants and contact-mahouts were determined from archived and current health records.

The individual averages, followed by the group averages of the contact positivity rates, were subsequently calculated for both the case and control groups. The group averages of the elephant and mahout contact positivity rates were then compared between the positive and negative groups.

The final prediction estimates individual probability of TB based on observed symptoms and covariates using the parameter estimates of the BLCA model.
Predicted TB probabilities for different parameter combinations ranged from 0.04% to 35.6% in training data and 0.04% to 33.4% in validation data. When evaluated against a confirmatory reference standard, the final dynamic prediction rule achieved an AUC of 0.81 on internal data and 0.79 on external validation data, and was at least 0.70 on each of the 18 different datasets. With a threshold at 0.57%, optimized for balanced accuracy, a sensitivity of 75% with a specificity of 73% in the training data and 71% in the validation data could be reached.

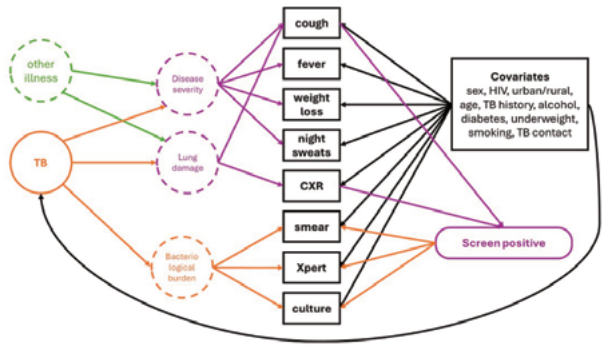

Figure 1. Schematic structure of the BLCA model for TB prediction. Squares denote observed information, circles unobserved, with TB status itself explicitly modelled and the dashed circles not modelled but used to define the dependencies between the observed tests. The presence of a screening variable for inclusion for bacteriological testing induced additional dependency. Orange arrows have impact on true TB positives only, green on the TB negatives only, while purple arrows have impact on both TB positives and negatives.

The BLCA algorithm addresses analytical challenges given the absence of a gold standard. While not recommended as a stand-alone tool for guiding treatment decisions, the model shows promise as a TB triage tool that, when combined with imaging results in an easy-to-use app format, can better identify patients who need confirmatory bacteriological testing.

TBS-EP731 The potential number of false-positive and false-negative TB diagnoses in low- and middle-income countries: A bayesian analysis of routine reporting data

N. Menzies,[1] A. van Lieshout Titan,[1,2] P. Dodd,[3] T. Cohen,[4]
[1]Harvard TH Chan School of Public Health, Boston, United States of America, [2]Delft Institute of Applied Mathematics, TU Delft, Delft, Netherlands, [3]School of Medicine and Population Health, University of Sheffield, Sheffield, United Kingdom of Great Britain and Northern Ireland, [4]Yale School of Public Health, New Haven, United States of America
e-mail: nmenzies@hsph.harvard.edu

Background: Commonly-used tuberculosis diagnostics have imperfect sensitivity, and many individuals are diagnosed clinically. However, clinical diagnosis has poor sensitivity and specificity. We investigated the implications for tuberculosis diagnostic outcomes in low- and middle-income countries.
Methods: We extracted tuberculosis notifications for 2023 by country, type of diagnosis (bacteriologically-confirmed vs. clinically-diagnosed), rapid diagnostic test (RDT) use, and HIV status.
We combined these data with published evidence on sensitivity and specificity at each step of diagnosis, to assess algorithm performance and estimate total false-positive and false-negative diagnoses. We also projected the impact of achieving 100% RDT use, compared to current coverage.
Findings: We estimated results for 111 countries with 6.8 million total tuberculosis notifications in 2023. Assuming 25% tuberculosis prevalence among individuals evaluated for tuberculosis, average algorithm sensitivity and specificity were 81.3% (95% uncertainty interval: 76.7-85.3) and 89.8% (87.7-91.6) respectively.

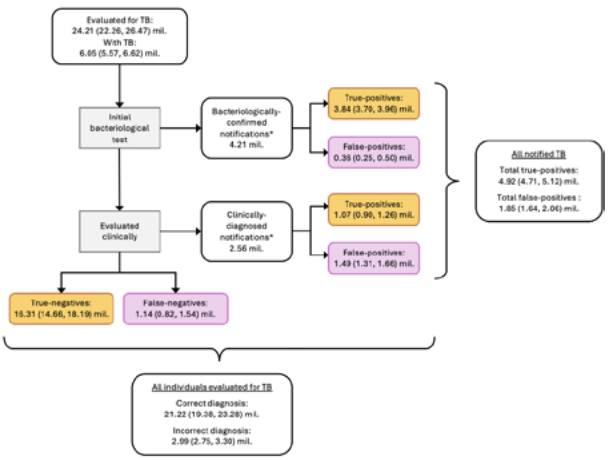

Figure. Estimated global number of individuals receiving true-positive, true negative, false-positive, and false-positive diagnoses, among individuals evaluated for TB disease in 2023.
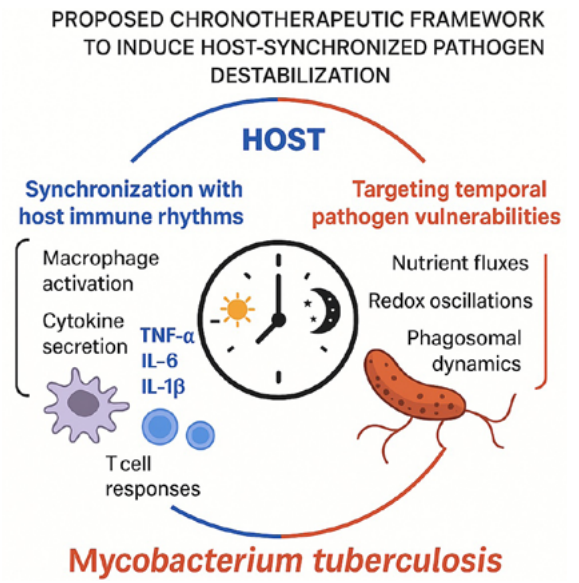
Assumes 25% initial TB prevalence. Parentheses indicate 95% uncertainty intervals.



Conclusion: Chronotherapy introduces a time-based, host-synchronized paradigm for TB treatment. By precisely targeting circadian-aligned immune function and leveraging predictable Mtb vulnerabilities, this approach may shorten treatment duration, improve efficacy, and reduce resistance. This framework supports future chrono-HDT trials and opens a new frontier in personalized, temporal TB medicine.

Keywords: tuberculosis, chronotherapy, circadian rhythm, host-directed therapy, macrophage, Mtb metabolism, temporal immunity

TBS-EP743 Neutrophil, lymphocyte and monocyte ratios in children with active and latent tuberculosis

L. Gorbach,[1] [1]State Institution "Republican Scientific and Practical Center "Mother and Child" of the Ministry of Health of the Republic of Belarus, Minsk, Belarus
e-mail: larisa-horbach@yandex.ru

Introduction: An estimated global total of 10.8 million people fell ill with tuberculosis (TB) in 2023, including 1.3 million children under 14 years of age. The neutrophil-to-lymphocyte-ratio (NLR), monocyte-to-lymphocyte-ratio (MLR) reflects essential components of the cell-mediated inflammatory response. The aim of the study was to research NLR and MLR in the blood of children with active and latent TB.

Methods: The first group included 26 children with pulmonary TB, the second group - 88 children with latent TB. The blood cell counts in children were studied before the start of treatment.

Results: Both groups didn't differ in mean age and gender. The average age of children in the first group was 5,1± 2,3 years, in the second group - 5,7± 3,4 years. The
